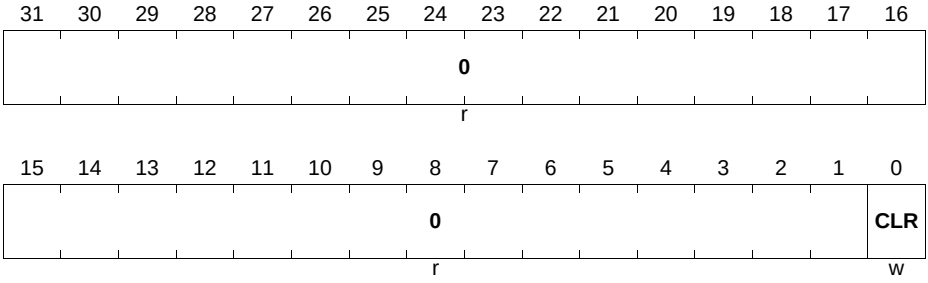
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bit (<>_KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (EC_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

18 Asynchronous/Synchronous Interface (ASCLIN)

The main purpose of the ASCLIN module is to provide asynchronous serial communication with external devices using only data-in, data-out signals.

The focus of the module is set to fast and flexible communication: either fast point-to-point or master-to-many slaves communication using the LIN protocol.

Additionally, the module supports the synchronous SPI communication.

Figure 18-1 shows an overview of the ASCLIN module.

Note: The RX, TX, RTS, CTS, SCLKO, SLSO signal names are prefixed with "A" in order to achieve unique names on chip level, distinct from signal names of other communication modules.

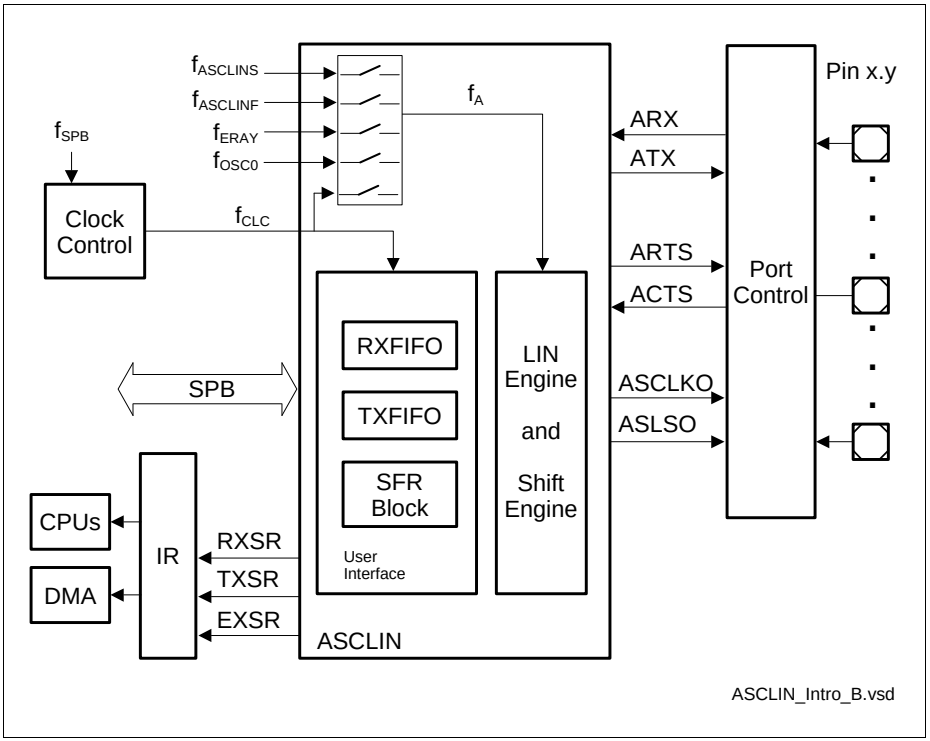


Figure 18-1 Block Diagram of the ASCLIN module.

>> **Registers Overview**

>> **BPI_FPI Module Registers**

18.1 Feature List

This section describes the features of the ASCLIN module.

General Features

- 16 bytes TxFIFO
- 16 bytes RxFIFO
- Pack / unpack capabilities of the Tx and Rx FIFO
- Interrupt generation
  - On a configurable transmit FIFO level
  - On a configurable receive FIFO level
  - On an error condition (frame, parity, overrun error)
  - On various module internal events (end of ASC/SPI frame, LIN events)
- Interrrupt signals capable of triggering either a CPU or a DMA
- Programmable oversampling of 4 to 16 times per bit
- Programmable sampling point position
- Programmable digital glitch filter and median filter for incoming bit stream
- Shift direction LSB first
- Internal loop-back mode

Standard ASC Features

- Full-duplex asynchronous operating modes
  - 7-bit, 8-bit or 9-bit (or up to 16-bit) data frames, LSB first
  - Parity-bit generation/checking
  - One or two stop bits
  - Max baud rate f_A / 16 (6.25 MBaud @ 100 MHz f_A module clock)
  - Min. baud rate f_A / 268 435 456 (0.37 Baud @ 100 MHz f_A module clock)
- Optional RTS / CTS handshaking
- Support of
  - JASO D 903

Extended ASC Features

- Programmable oversampling of 4 to 16 times per bit
  - module capability of up to 4 times higher baud rates (f_A / 4) then the standard ASC
  - system considerations like pad type, incoming signal quality and accumulated PLL jitter can lead to constraints regarding the usable oversampling ratios (for example f_A / 8 = 200MHz / 8 = 25 MBaud)
- Programmable sampling point position

LIN Features

- Support of

  - LIN version 1.3
  - LIN version 2.0
  - LIN version 2.1 and
  - J2602
- Break detection
- Break injection
- Sync field generation
- Auto baud detection based on Sync Field measurement
- Optional Collision detection, required for LIN version 2.1
- LIN Watchdogs
  - Header time-out
  - Frame or Response time-out
- Stuck at zero/one monitoring
- Bus idle time monitoring
- Wake-Up
- Minimum CPU load in master mode
  - Single interrupt indicating the end of the frame
- Minimum CPU load in slave mode
  - Single interrupt at the end of the header reception
  - Single interrupt at the end of the response or end of frame
- Standard operation with one interrupt per transmitted or received byte supported

SPI Features

- SPI master modes (slave mode not supported):
  - Four-wire or three-wire (with / without slave select output signal)
- Up to 16-bit data width
- Full-duplex and half-duplex
  - Min. baud rate f_A / 268 435 456 MBaud (= 0.37 Baud @ 100 MHz f_A module clock)
  - Max. baud rate f_A / 4 MBaud (= 25 MBaud @ 100 MHz f_A module clock)
- Programmable leading and trailing delays

18.2 Overview

This section shows the essential sub blocks of the module when used as standard ASC, as LIN or as SPI master.

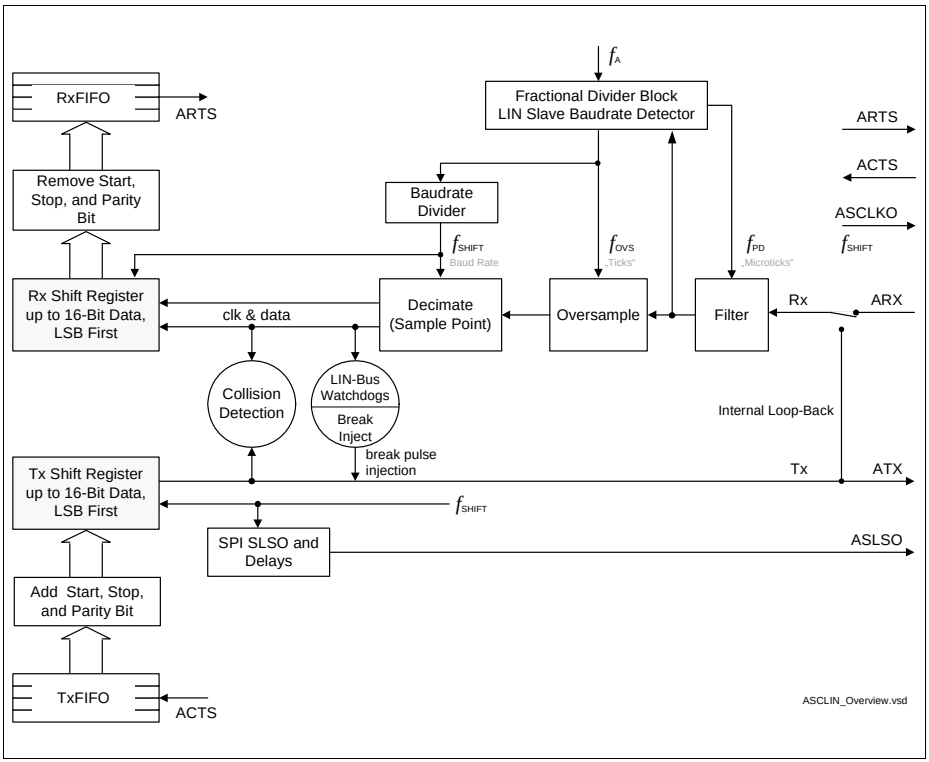

Figure 18-2 Architecture Overview

Note: Collision detection is mandatory only in the LIN specification V2.1.

Note: In LIN mode, both ARX and ATX signal must be connected to the LIN bus in order ASCLIN module to work properly.

18.3 External Signals

The ASCLIN module provides the following external signals:

- Serial clock output ASCLK
- Receive data input ARX (Master Receive MR input in SPI mode)
- Transmit data output ATX (Master Transmit MT output in SPI mode)
- Slave select signal output ASLSO
- Request to send handshake output ARTS
- Clear to send handshake input ACTS

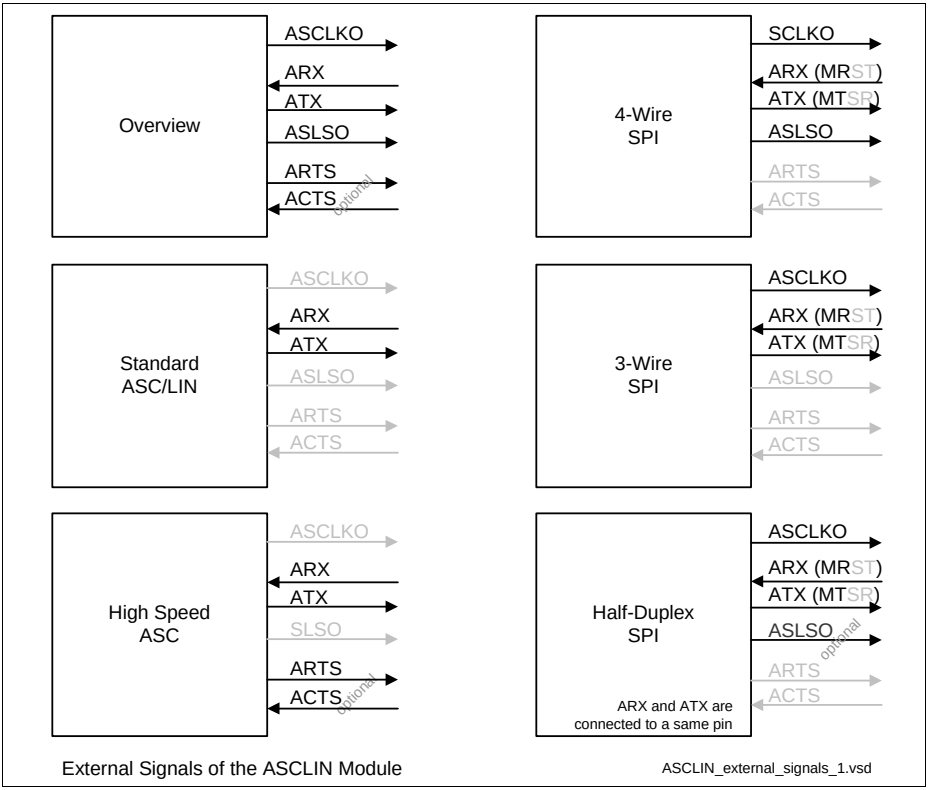

Figure 18-3 External Signals of the ASCLIN Module in Different Modes

18.4 User Interface

The user interface contains a Tx FIFO and an Rx FIFO.

They provide the following services: takes data packets with width optimal for the FPI[1] bus and packs them to serial frames, buffers the FPI bus data, manages handshaking. These features are designed to optimize the use of the module in LIN, high-speed ASC and SPI mode. They also optimize the use of the module in standard ASC mode.

18.4.1 TxFIFO Overview

The Tx FIFO has the ability to pack 16-bit writes from the FPI bus to two up-to-8-bit frames or one up-to-16-bit frame. It also has the ability to pack 32-bit writes from the FPI bus to four up-to-8-bit or two up-to-16-bit frames.

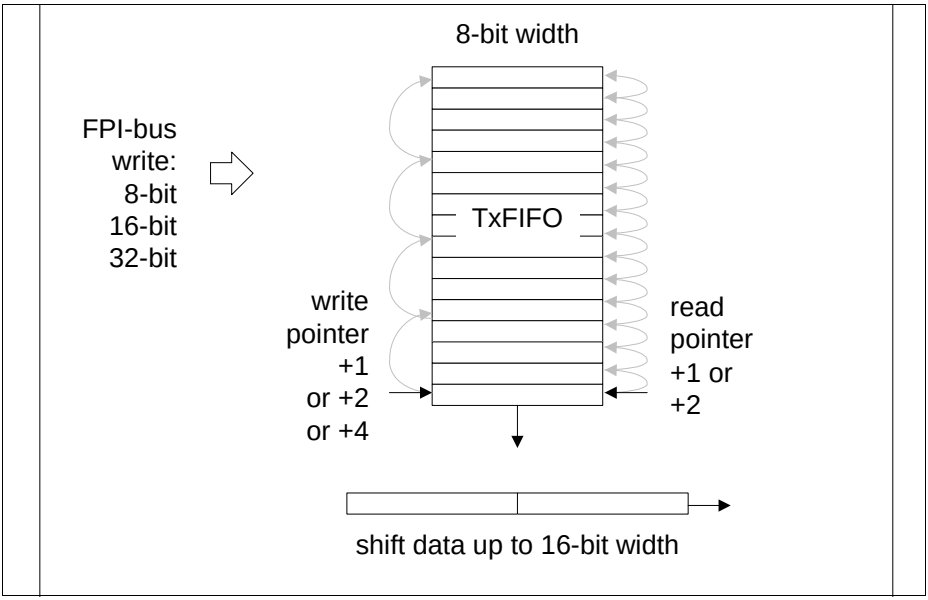

Figure 18-4 TXFIFO Overview

The number of bytes written to the TxFIFO is always defined with the **TXFIFOCON**.INW, does not depend on the SPB write width, and should be equal to it.

If the SPB write width is shorter than INW, then the missing part is padded with zeros.

If the SPB write width is longer then INW, then the excessive part is lost.

1) FPI is the protocol used on the System Peripheral Bus (SPB).

On the shift register side, the TxFIFO is always emptied by a number of bytes as needed for the data width field **DATCON**.DATLEN.

The **Table 18-1** describes all the possible write (fill) combinations. The bytes which will be filled into the TXFIFO are labeled as A, B, C, D and 0.

Table 18-1 Inlet Width versus SPB Write Width

TxFIFO Contents		SPB Bus Write Width		
		8-Bit A	**16-Bit BA**	**32-Bit DCBA**
Inlet Width INW	**8-Bit**	A	A	A
	16-Bit	0A	BA	BA
	32-Bit	000A	00BA	DCBA

18.4.2 Using the TxFIFO

The Tx FIFO has the ability to pack 16-bit writes from the FPI bus to two up-to-8-bit frames or one up-to-16-bit frame.

Note: Some (but not all) use-cases are described in the sections below. The software can always access the TXFIFO 8, 16 or 32 bit wide, according to its requirements.

18.4.2.1 Standard ASC Mode

The most standard usage of the ASC module is to transmit 7 or 8-bit values, and to fill the FIFO with 8-bit wide FPI-bus accesses. The FPI bus access is 8-bit wide, and there is only BS0 (Byte Select 0) signal active.

The transmit data is written to the address TXDATA. The Tx_Inlet_Width is 8-bit, and the Tx_Outlet_Width is 8-bit.

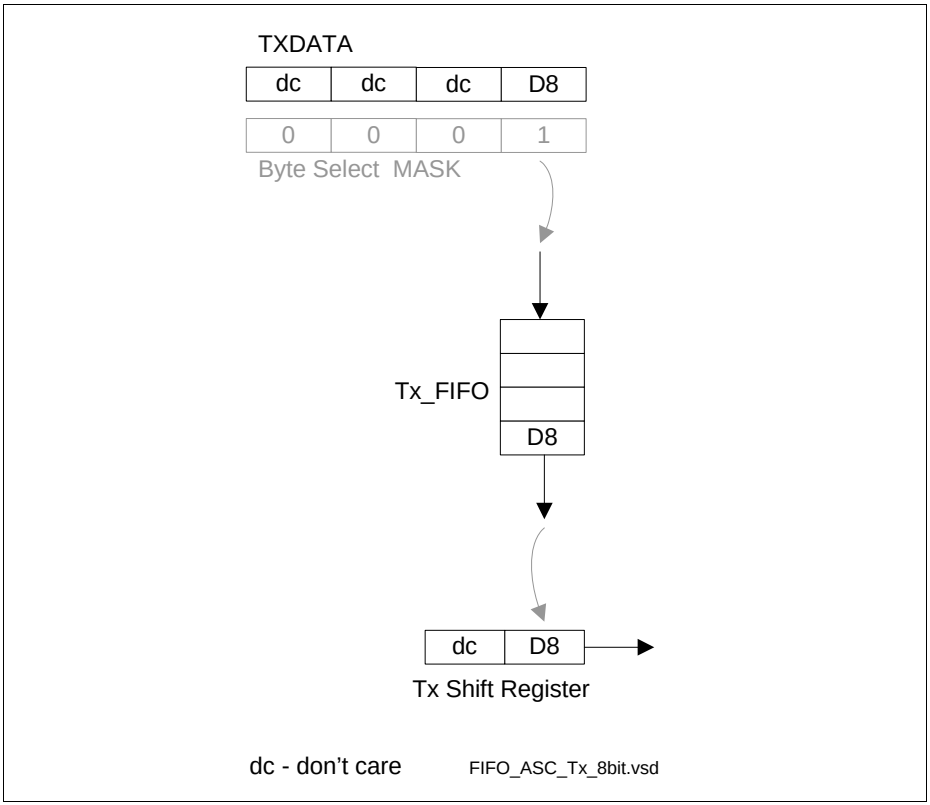

Figure 18-5 FIFO Operation in 7- or 8-Bit ASC Mode, with or without Parity

A less common mode of operation of the ASC module is to transmit 9-bit values, containing either 9-bit data or 8-bit data. The FPI bus access should be 16-bit wide, and there are BS0 and BS1 (Byte Select 0 and 1) signals active. The shift register is filled with two 8-bit values at the location read pointer and read pointer + 1.

The transmit data is written to the address TXDATA. The Tx_Inlet_Width is 16-bit, and the Tx_Outlet_Width is 16-bit.

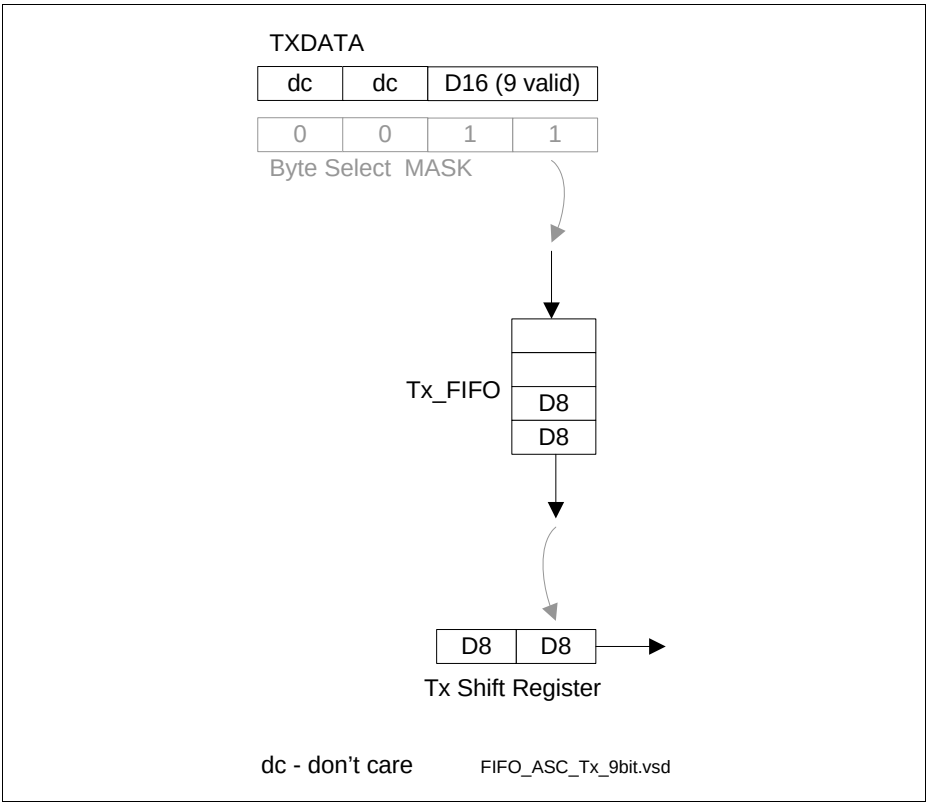

Figure 18-6 FIFO Operation in 9-Bit ASC Mode

18.4.2.2 High Speed ASC Mode

In order to reduce the FPI bus load by not using a 32-bit move for 7 or 8-bit values, one option is to fill the FIFO with 32-bit wide accesses containing four 8-bit wide values. All Byte Select signals BS[3:0] are active, and all four bytes are written in the TX FIFO in one cycle. At the same time, the write pointer of the TXFIFO jumps by the amount of four.

The transmit data is written to the address TXDATA. The Tx_Inlet_Width is 32-bit, and the Tx_Outlet_Width is 8-bit.

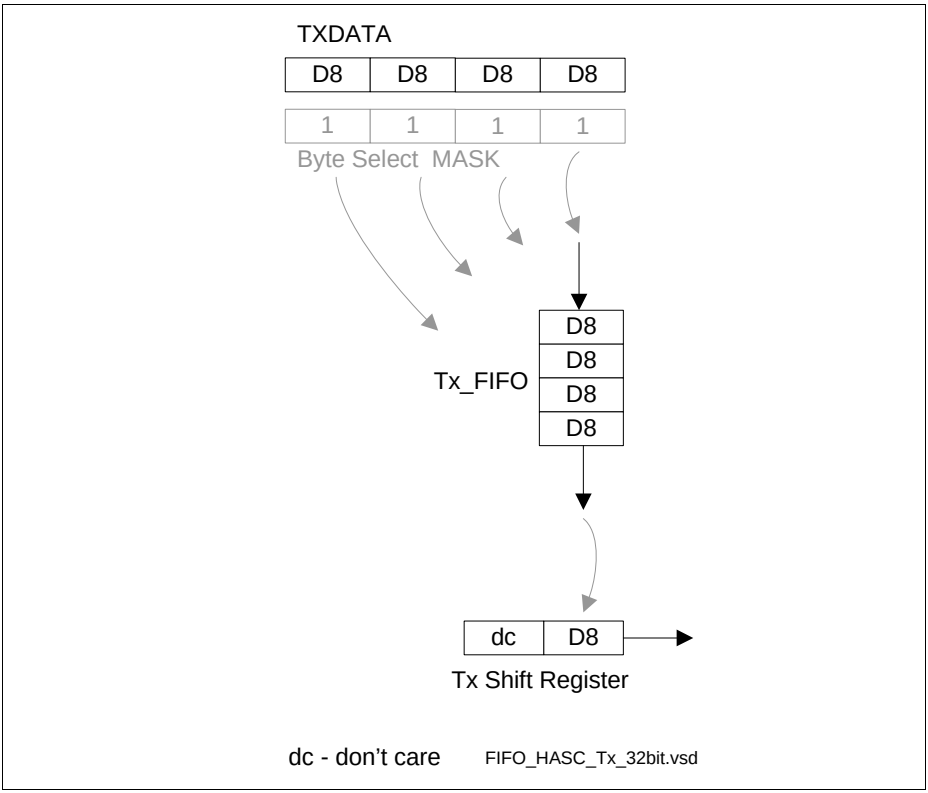

Figure 18-7 High-Speed Communication Scenario

18.4.2.3 LIN Mode

In LIN mode, several 8-bit frames are preceded by a low break pulse.

The generation of the break pulse is programmable with an 8 bit timer in units of bits, where the wide range of break pulses can be generated, for example in a range between 13 and 26 bits and beyond (up to 256 bits, but these lengths would violate the maximum LIN header length). The detection of the break pulse is programmable with an 8 bit timer in units of bits. Among others , the standard thresholds of 10 and 11 bit times can be set. .

The pulse is generated by an module internal timer. The transmit sequence consists of filling the stopped TXFIFO with the appropriate bytes, and then starting the break pulse, which activates the TxFIFO.

The transmit data is written to the address TXDDATA. The Tx_Inlet_Width can be 8-bit (or 16-bit, or 32-bit), and the Tx_Outlet_Width is 8-bit.

18.4.2.4 SPI Mode

SPI mode is used most often to send or receive data of 8 or 16-bits length, or some length in between. Therefore the reading out of the Tx FIFO must be 8 or 16-bit wide, and write could be 16-bit wide, or even 32-bit wide if two frames are packed in one FPI bus access.

The transmit data is written to the address TXDATA. The Tx_Inlet_Width is up to 32-bit, and the Tx_Outlet_Width is up to 16-bit.

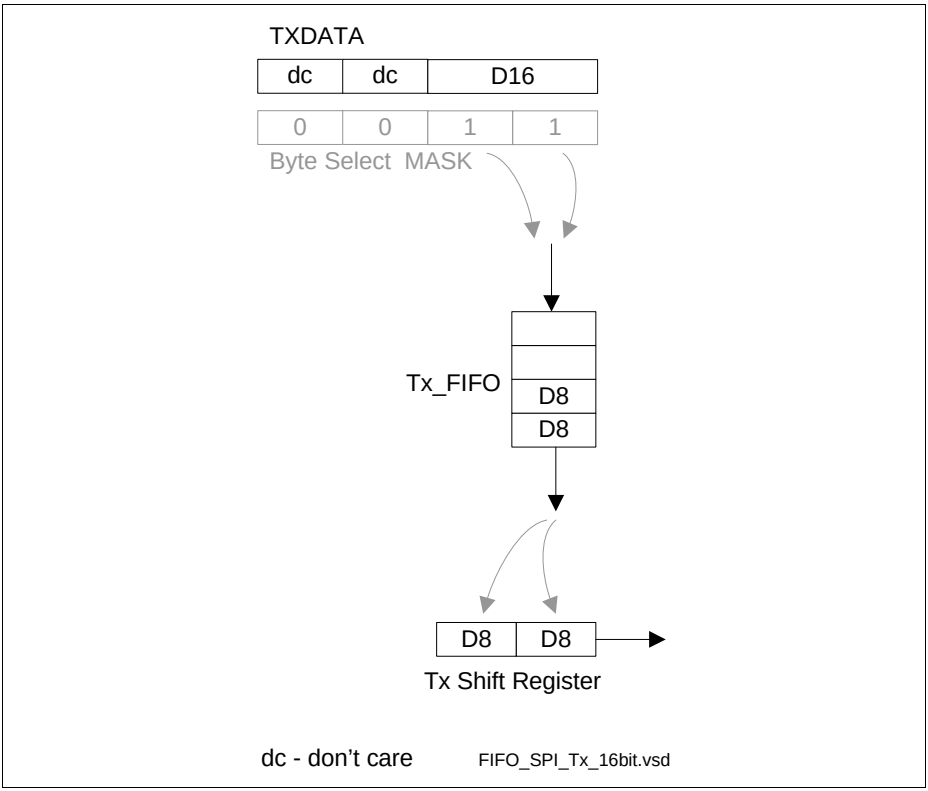

Figure 18-8 TXFIFO Operation in SPI Mode

18.4.3 RxFIFO Overview

The Rx FIFO has the ability to pack two up-to-8-bit frames or one up-to-16-bit frame to one 16-bit write to the FPI bus. It also has the ability to pack four up-to-8-bit 2-up-to-16-bit frames to one 32-bit write to the FPI bus.

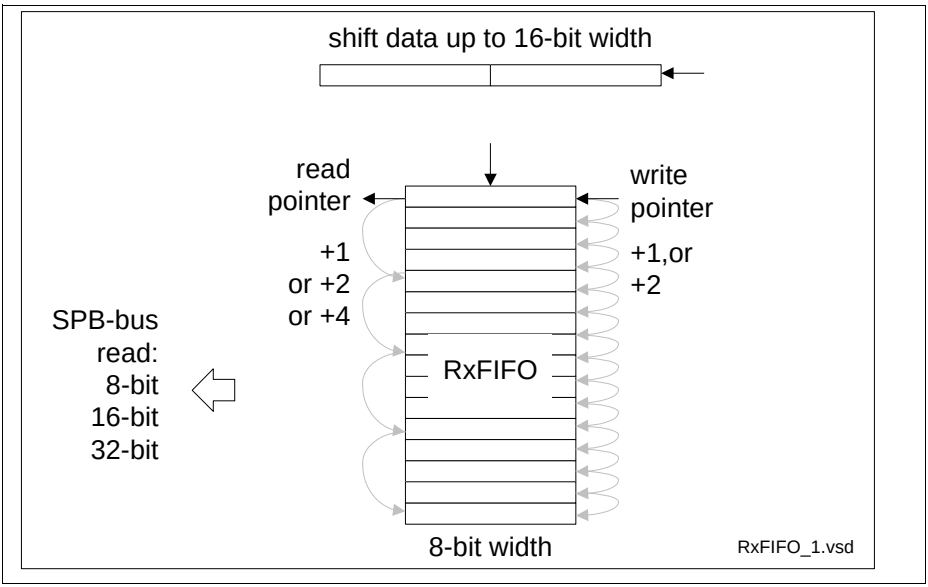

Figure 18-9 RXFIFO Overview

The number of bytes taken out of the RxFIFO is always **RXFIFOCON**.OUTW, does not depend on the SPB bus read width, which should be normally equal to OUTW.

If the SPB read width is shorter than the OUTW, then the missing part is filled with zeros.

If the SPB read width is longer then OUTW width, then the excessive part is lost.

On the shift register side, the RxFIFO is always filled with a number of bytes as needed for the data width field **DATCON**.DATLEN.

The **Table 18-2** describes all the possible combinations. The bytes in the RxFIFO are named A, B, C and D, A being the first one to take out. The padding byte is 0.

*Note: In case of an underflow, i.e. when a read access is performed to RXDATA and the number of bytes to be taken out of the FIFO as given by the setting of **RXFIFOCON**.OUTW exceeds the number of bytes that are actually stored in the FIFO, as indicated by **RXFIFOCON**.FILL, then the RXFIFO delivers the available data padded with zeros up to the read access width. However, the data remain in the FIFO and the filling level **RXFIFOCON**.FILL is not changed. To remove the data, the user software must flush the RXFIFO. The bit **FLAGS**.RFU is set.*

Table 18-2 Outlet Width versus SPB Read Width

SPB-Read Data, taken from the RxFIFO		SPB Bus Read Width		
		8-Bit	**16-Bit**	**32-Bit**
Outlet Width OUTW	**8-Bit**	A	A	A
	16-Bit	0A	BA	BA
	32-Bit	000A	00BA	DCBA

18.4.4 Using the RxFIFO

The Rx FIFO has the ability to pack two up-to-8-bit frames or one up-to-16-bit frame to one 16-bit write to the FPI bus.

18.4.4.1 Standard ASC Mode

The received data is read from the address RXDATA.

In case of data width of 7 or 8 bits, one read on this address delivers one byte and empties the FIFO for one element, if the Rx_Outlet_Width is 8-bit. The Rx_Inlet_Width is 8-bit.

In case of data width of 9 bits, one read on this address delivers two byte and empties the FIFO for two elements, if the Rx_Outlet_Width is 16-bit. The Rx_Inlet_Width is 16-bit.

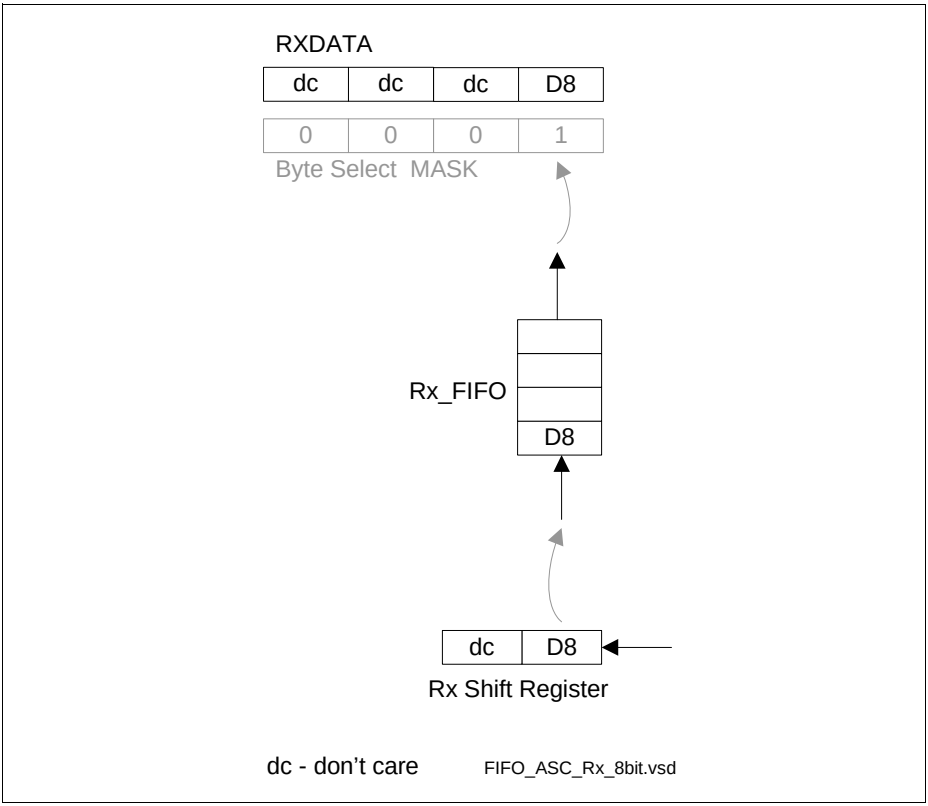

Figure 18-10 8-Bit ASC Reception

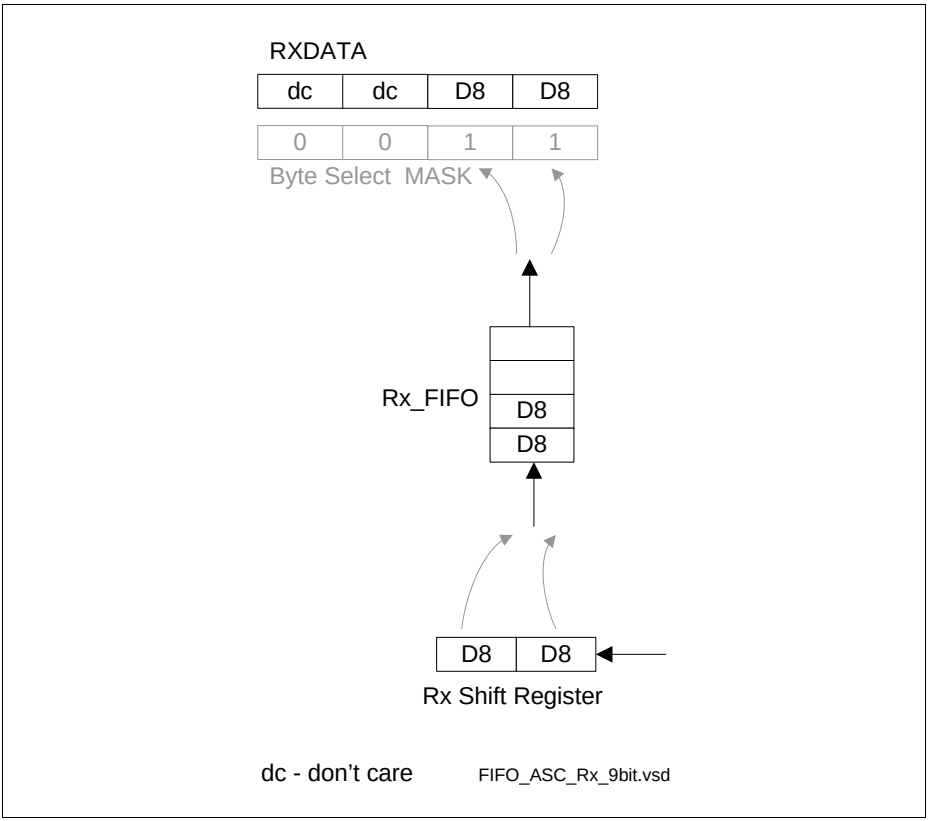

Figure 18-11 9-Bit ASC Reception

18.4.4.2 High Speed ASC Mode

The received data is read from the address RXDATA.

In case of data width of 7 or 8 bits, one read on this address can deliver (one or two or) four bytes and empties the FIFO by four elements, if the Rx_Outlet_Width is 32-bit. The Rx_Inlet_Width is 8-bit.

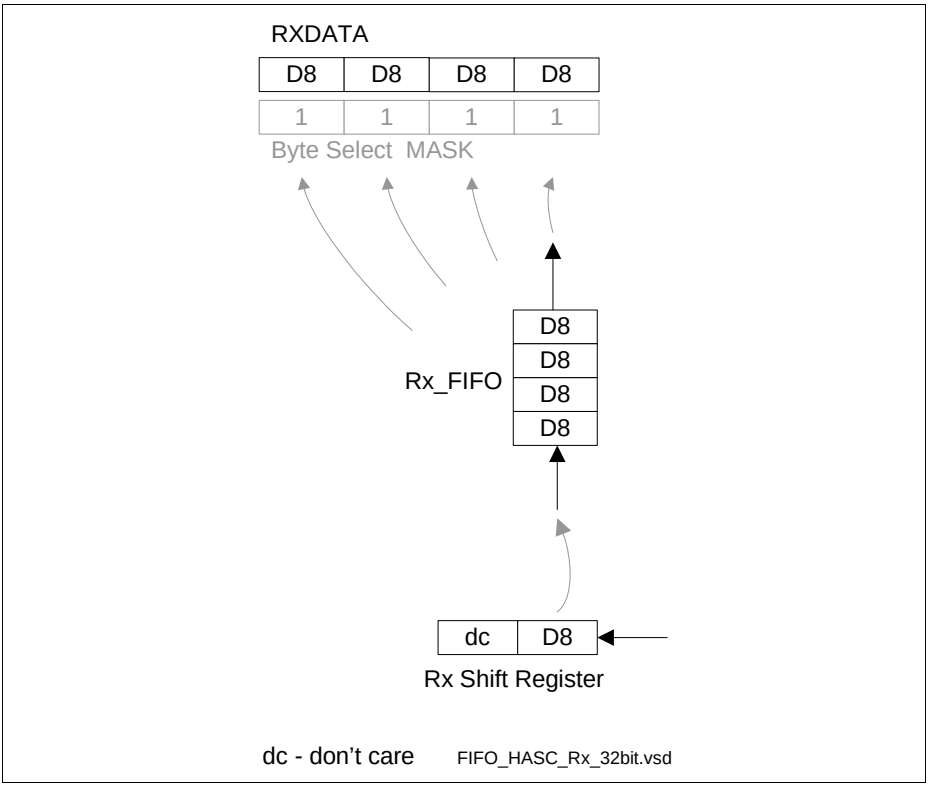

Figure 18-12 High Speed ASC Communication

18.4.4.3 LIN Mode

The received data is read from the address RXDATA.

The read data width is 8 bits (or 16 bit or 32 bit), one read on this address delivers one byte and empties the FIFO by one element, if the Rx_Outlet_Width is 8-bit. The Rx_Inlet_Width is 8-bit

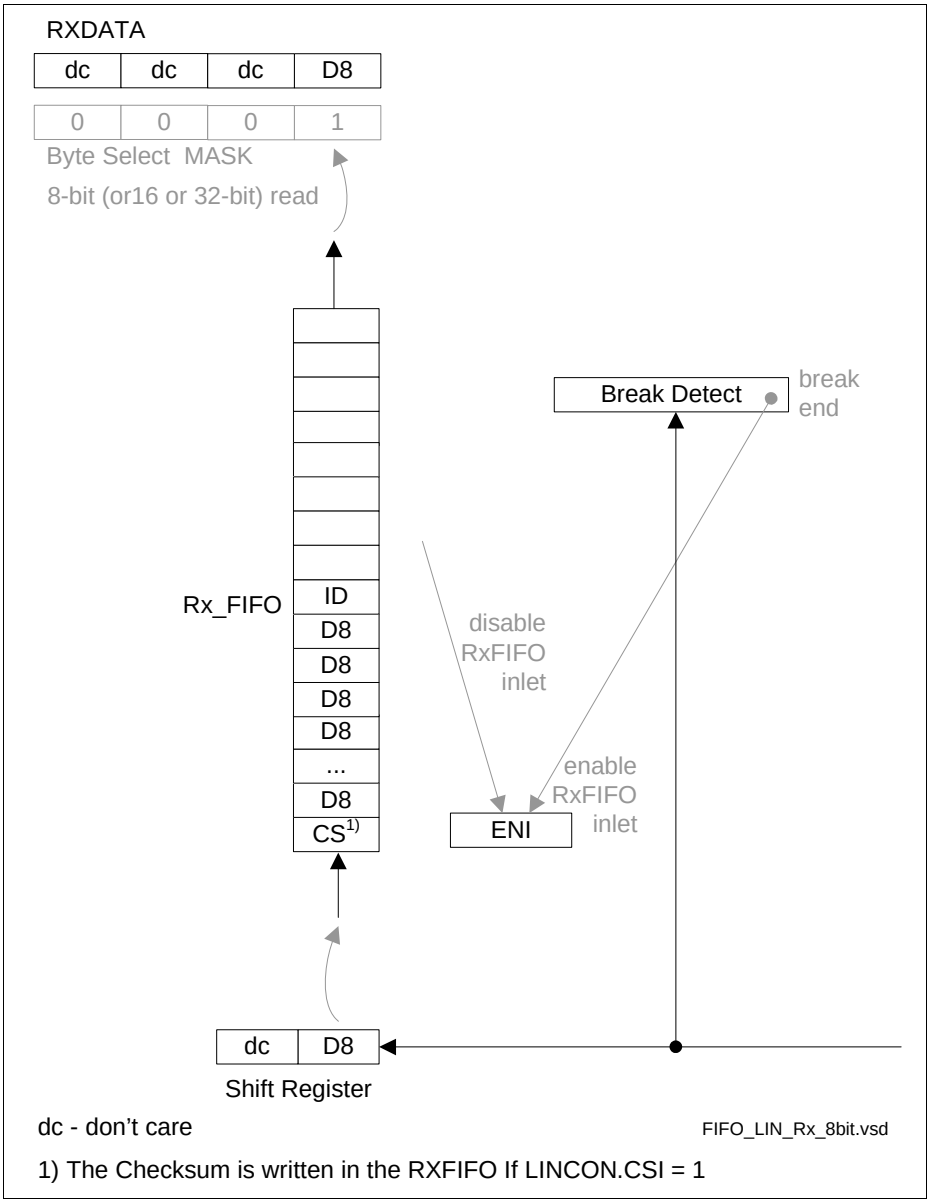

Figure 18-13 RXFIFO Operation in LIN Mode

18.4.4.4 SPI Mode

The received data is read from the address RXDATA.

In case of data width of 16 bits, one read on this address delivers two bytes and empties the FIFO by two elements, if the Rx_Outlet_Width is 16-bit. The Rx_Inlet_Width is 16-bit

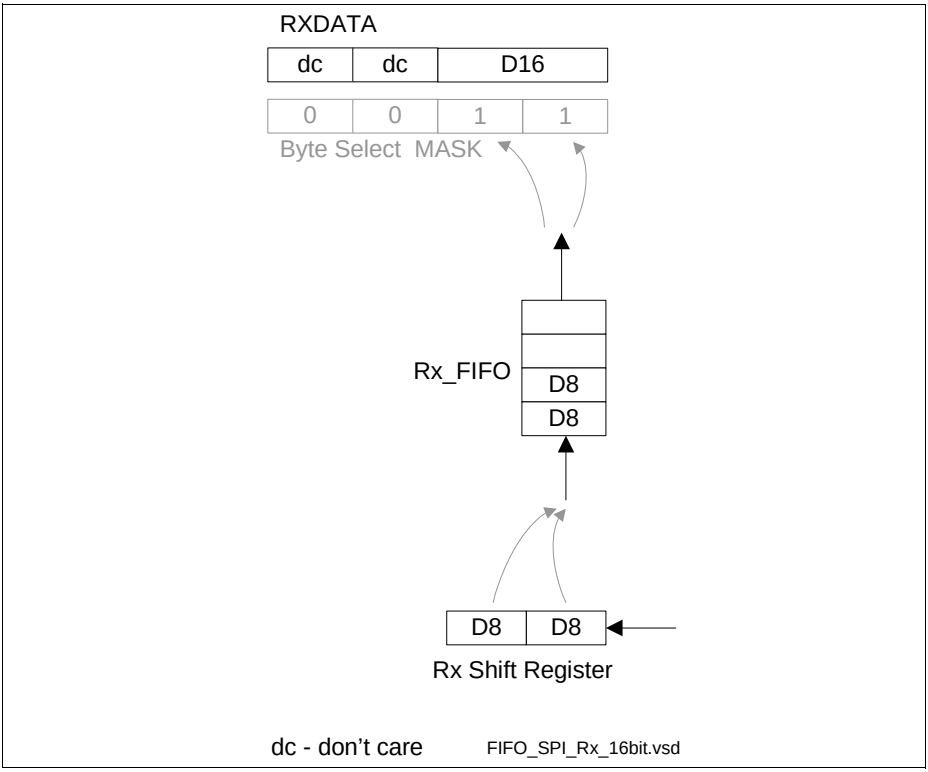

Figure 18-14 RXFIFO Operation in SPI Mode

18.4.5 RTS / CTS Handshaking

A receiver deactivates the RTS (Request to Send) output signal when the RXFIFO is almost full, in order to avoid its overload. When the the emptying of the RXFIFO starts, for example by a DMA, and the filling level falls below the threshold level, the RTS output is activated again. The threshold level is fixed to RXFIFO size minus four, in order to support byte, two bytes and four bytes DMA transfers.

The transmitter receives the RTS output of the receiver on its CTS input and accordingly pauses and resumes the transmission.

18.5 Clock System

The clock system generates all the clocks needed for the proper operation of the ASCLIN module: digital filter clock, oversampling clock, bit time and serial SPI clock.

The clock used for the clock system f_A is independent from the SPB bus clock and remains constant if the SPB bus clock changes, for example in power saving scenarios. The bit field **CSR**.CLKSEL selects the clock source for the f_A frequency, which can be synchronous or asynchronous, higher or lower than the SPB bus frequency.

18.5.1 Baud Rate Generation

Fractional Divider, n-divider and oversampling divider with configurable sample point.

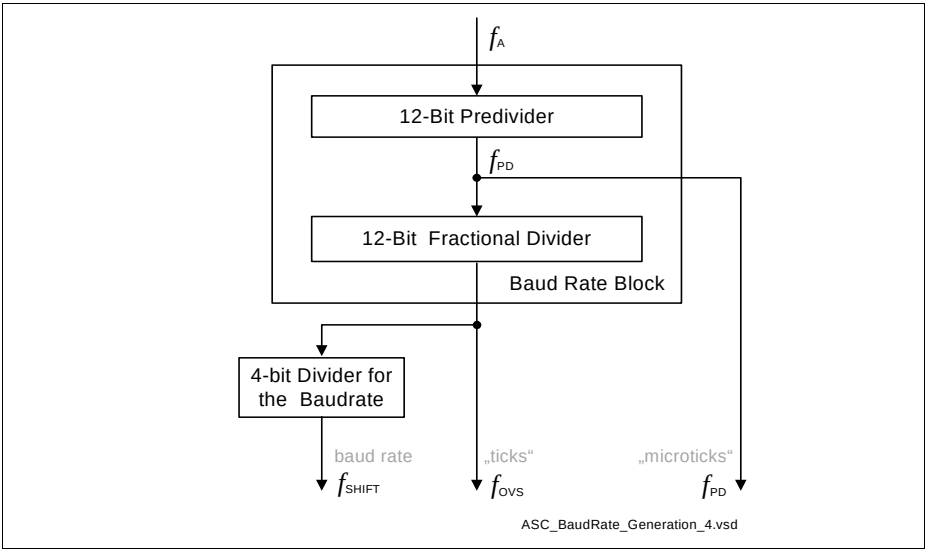

Figure 18-15 Baud Rate Generation

The following bit fields are available for configuring of the 28-bit baud rate divider chain:

- **BITCON**.PRESCALER - the division ratio of the predivider
- **BRG**.NUMERATOR - the nominator of the fractional divider
- **BRG**.DENOMINATOR - the denominator of the fractional divider
- **BITCON**.OVERSAMPLING - the division ratio of the baudrate post divider

The chain of the generated frequencies from f_A down to the f_{SHIFT} (the baudrate) is calculated as follows:

$f_{PD} = f_A$ / (**BITCON**.PRESCALER + 1)

$f_{OVS} = f_{PD}$ * **BRG**.NUMERATOR / **BRG**.DENOMINATOR,

$f_{SHIFT} = f_{OVS}$ / (**BITCON**.OVERSAMPLING + 1)

*Note: Fractional division requires that **BRG**.NUMERATOR is less or equal than the **BRG**.DENOMINATOR.*

The overall formula is given as follows:

(18.1)

$$BAUDRATE = \frac{f_A \times NUMERATOR}{(PRESCALER + 1) \times DENOMINATOR \times (OVERSAMPLING + 1)}$$

18.5.2 Bit Timing Properties

The ASCLIN module provides flexible programming of the bit oversampling, sampling point and input signal filtering properties.

The oversampling factor for the incoming bit-stream is configurable from 4 to 16 ticks (or time quanta) per bit.

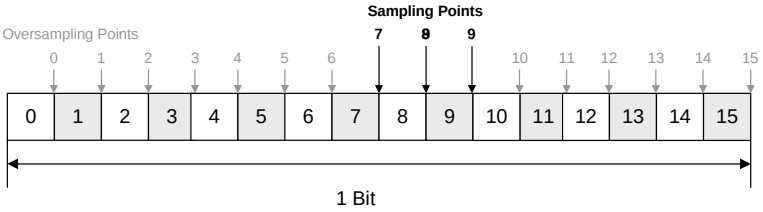
At the same time, using the oversampling frequency, a digital median filter can be enabled to filter the incoming bit stream. The filtering uses the standard majority out of three procedure. If the filter is disabled, then each bit is sampled only once.

The sampling point is also configurable and should be used in conjunction with the oversampling factor. One standard setting is 16x oversampling and using the samples 7, 8 and 9 for the data. Another possible setting could be 8x oversampling and using the samples 3, 4, and 5 for data.

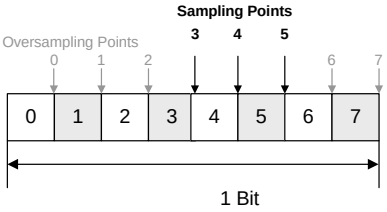
The following bitfields are available for configuring the bit properties:

- **BITCON**.PRESCALER - the twelve bit integer divider defining the microtick used by the fractional divider to generate the baud rate, and by the digital filter for the deglitching of the RX input signal.
- **BITCON**.SAMPLEPOINT - the bit field defining the sampling point position, and the duty cycle in the SPI mode.
- **BITCON**.SM - the bit enables the digital median filter (majority out of three): 1 or 3 samples per bit.
- **IOCR**.DEPTH - the bitfield defining the floating average filter depth: off or 1 to 63 microticks
- **BITCON**.OVERSAMPLING - the bitfield defining the number of ticks per bit, in the range of 4 to 16. This is a post-divider located after the fractional divider.

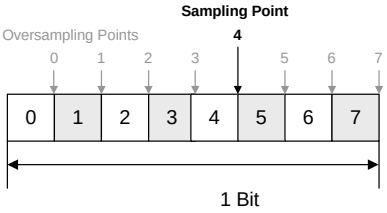
16x Oversampling, 3 sample points, relevant sample position 8



8x Oversampling, 3 sample points, relevant sample position 4



8x Oversampling, 1 sample point, relevant sample position 4



16x Oversampling, 1 sample point, relevant sample position 12

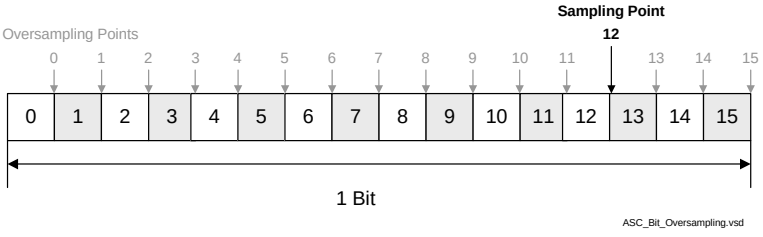


Figure 18-16 ASCLIN Bit Structure

Generally, the sampling point should be placed in the middle of the bit. This position is optimal in case the baud rate (the oscillator frequency) is not very precise and stable.

If the oscillator precision is very high, which is usually the case when two microcontrollers driven by quartz oscillators communicate, but the signal edges are very unsymmetrical, which is the case if open drain half-duplex connection is used, it can be of advantage to move the sample point somewhere in the second half of the bit. Open drain connection usually causes the “0” bits to be longer than the “1” bits. In such a case, optimizing the sampling point would mean placing it in the middle of the shorter “1” bit.

At the end, different combinations of oscillator precision, asymmetry of the edges, and loop-delays for collision detection result in different optimal positions of the sampling point.

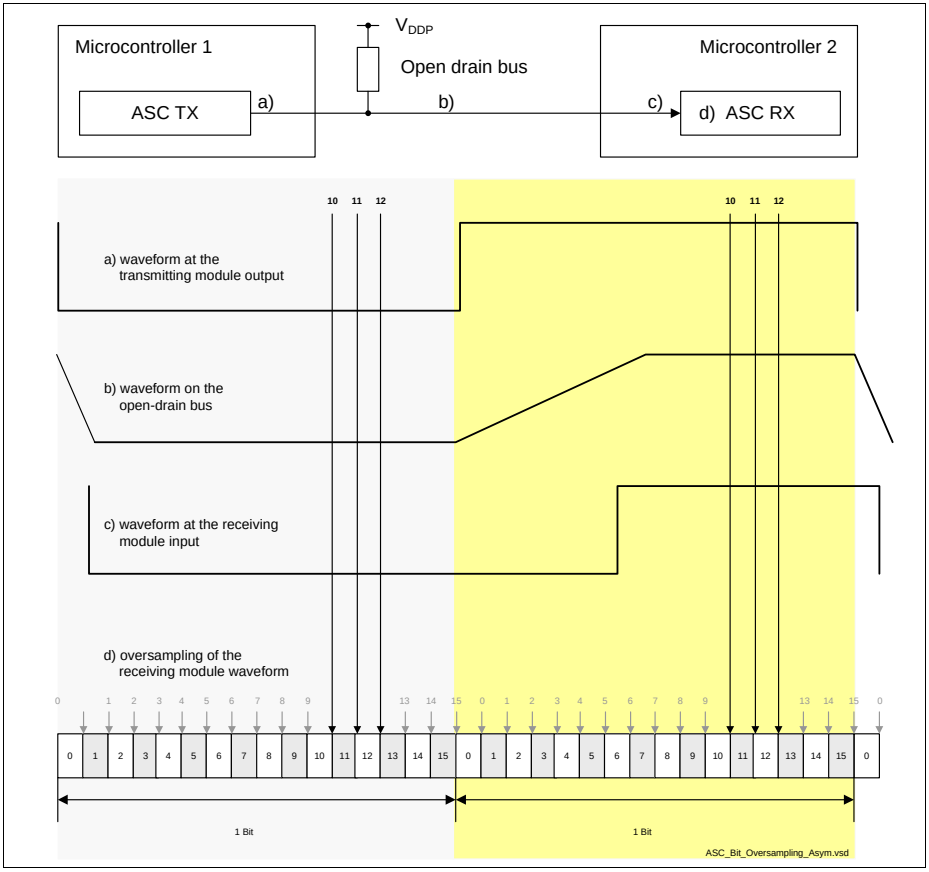

Figure 18-17 Bit Length Asymmetry and the Sampling Point

18.6 Data Frame Configuration

Applicable as transmitter and receiver, the parity scheme is configured in the bit fields **FRAMECON**.ODD, the data length in the bit fields **DATCON**.DATLEN and the stop bits in the bit fields **FRAMECON**.STOP.

18.7 Miscellaneous Configuration

Loop - back

18.8 Synchronous Mode

In synchronous mode the module supports the SPI setting of shift edge first, than the latch edge, see **Figure 18-18**. The module is set in synchronous mode by using the bit field **FRAMECON**.MODE.

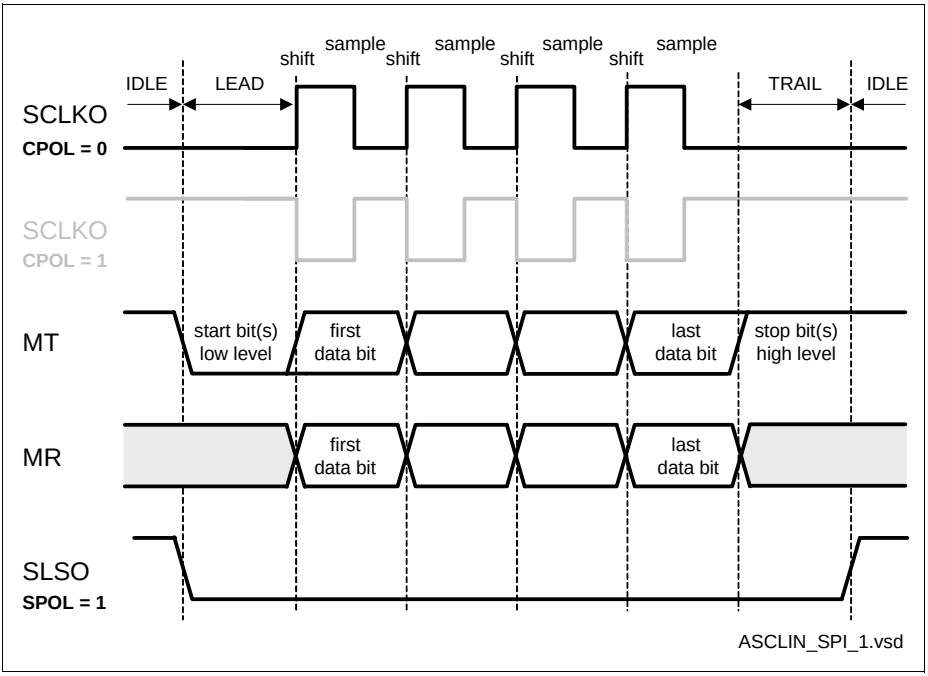

Figure 18-18 SPI Timing

18.8.1 Baud Rate and Clock Generation

The baud rate and clock generation in the synchronous mode uses generally the same counters and principles as in the asynchronous mode. It uses the same prescaler, fractional divider, and oversampling divider with configurable sample point. The only difference is that the shift clock is driven as output signal at the pin SCLKO. If a symmetrical shift clock is required, the oversampling ratio should be an even number, and the sampling point should be set to one half of the oversampling ratio (see the **BITCON** register).

The clock polarity is configured in the bit **IOCR**.CPOL.

18.8.2 Data Frame Configuration

The leading and trailing delays are configured in the bit fields **FRAMECON**.LEAD and **FRAMECON**.STOP. The IDLE phase duration is configured using the bit field **FRAMECON**.IDLE. The data length of 2 to 16 bit is defined in the bit field **DATCON**.DATLEN.

18.8.3 Slave Selects Configuration

The SPI master activates automatically the slave select output signal for each data word. The polarity of the slave select can be configured by using **IOCR**.SPOL

18.8.4 Miscellaneous Configuration

Loop - back

18.9 LIN Support

The ASCLIN module provides hardware support for the LIN protocol.

It supports all four elementary LIN transactions:

- TxH - Transmission of Header
- TxR - Transmission of Response
- RxH - Reception of Header
- RxR - Reception of Response

By supporting additionally the combinations of these elementary transactions, the module actually supports all LIN use cases: sending and receiving headers and responses as

- LIN master or
- LIN slave

A LIN master is engaged in three elementary transactions: TxH, TxR, RxR. It never engages in RxH, because a master never receives a header, it only transmits a header.

A LIN slave engages also in three elementary transactions: RxH, TxR, RxR. It never engages in TxH, because a slave never transmits a header, it only receives a header.

Each elementary transaction needs some hardware resources in order to be completed with minimum CPU intervention. Here is a list of tasks per transaction, supported by hardware, and the required hardware resources:

- TxH - Transmission of Header - master mode only
  - break generation: 8-bit bit-field defining the break length in units of bits
  - sync-field generation: hard coded 55H byte
  - ID transmission with interrupt generation
- TxR - Transmission of Response - master and slave mode
  - number of bytes parameter: bit-field of length 4
  - checksum generation: hardware engine, supporting classic and enhanced checksum, which can be enabled or disabled
- RxH - Reception of Header - slave mode only
  - optional auto-baud detection: fractional divider with programmable nominator and denominator
  - number of bytes parameter: bit-field of length 4
  - checksum detection: hardware that supports classic and enhanced checksum, which can be enabled or disabled; a checksum error is flagged, and an error interrupt can be triggered, if enabled
  - interrupt at end of header (necessary to set the number of bytes for the RxR phase)
  - timeout on overflow: 8-bit timer
  - break detection:8 bit timer with programmable threshold in units of bits
- RxR - Reception of Response - master and slave mode
  - number of bytes parameter: bit-field of length 4

– checksum: the received checksum is optionally delivered in the RXFIFO
– timeout on overflow: 8-bit timer

The break detection feature is always active.

Wake-up signal generation in both slave and master mode

For many LIN configuration parameters, the hardware of the ASCLIN module provides wider ranges than the LIN standard parameters. Therefore the application software shall take care that appropriate LIN standard values are used to configure the module. Such configuration parameters are:

- break length
- data width
- break threshold
- wake-up length
- header, frame and response timeout
- idle time

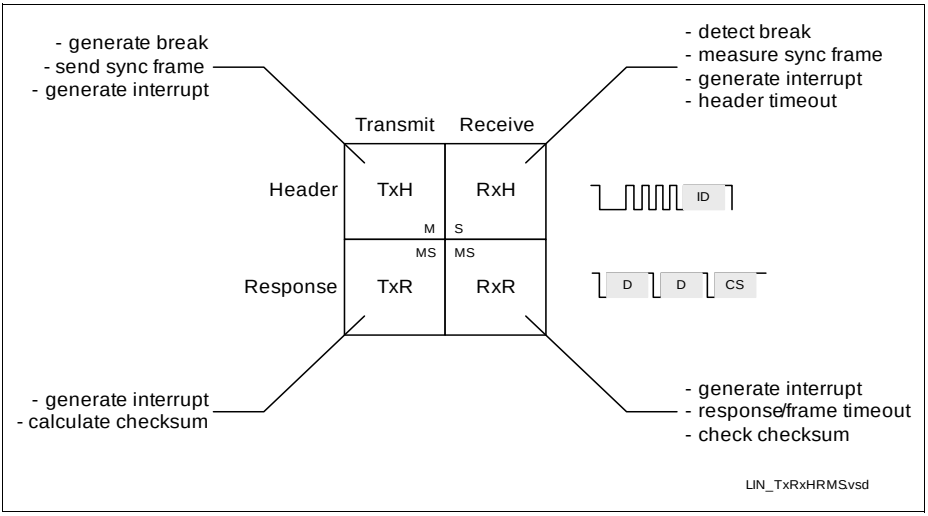

Figure 18-19 Overview of the elementary LIN transactions

18.9.1 LIN Watchdog

The LIN watchdog monitors the duration of the header, the frame or the response, and appearance of break pulses. It checks against the pre-defined time limits.
If the limits are violated, timeout interrupts are generated.

The LIN watchdog is necessary in slave mode.

The wake pulse generation is performed using the shift register and an appropriate data byte containing several consecutive zero bits. The wake pulse detection is done using falling edge detection.

For monitoring the bus for long idle or zero states flags for rising and falling edge are available. These flags can be polled with some appropriate time raster (in microseconds or miliseconds range).

The header timeout value is known at module initialization time and remains constant for all frames.

The frame or response timeout value depends on the length of the response (1 to 8 bytes) and must be set by software depending on the received ID, after the header has been received. The initial value of this timeout should be set by software to the maximum allowed by the timer, that is 256.

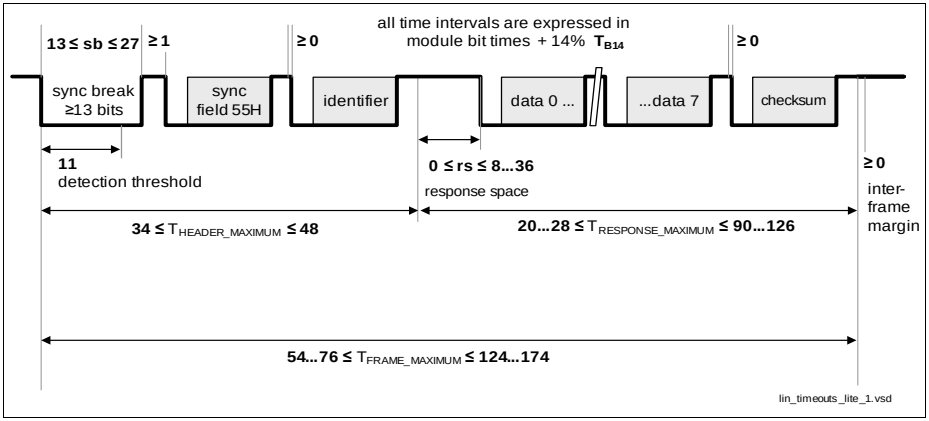

Figure 18-20 Duration of the Elements of a LIN Frame

The module provides timer blocks running in parallel, performing watchdog functions on specific timing requirements of the LIN protocol.

18.9.1.1 LIN Break, Wake, Stuck Handling

This subsection describes:

- the monitoring of the LIN Bus
- Break Pulse detection and generation and
- Wake Pulse detection and generation.

Monitoring the Bus

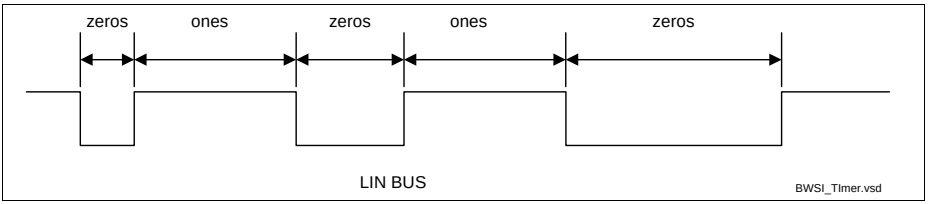

Figure 18-21 LIN Bus View as Sequence of Sequences of Zeros and Ones

Monitoring the bus for long idle periods (or stuck periods) is supported by providing the bit fields **FLAGS**.RED and **FLAGS**.FED. Polling these fields periodically within some time raster defined by the operating system or timer for example each 1ms or each 10 ms can be used for detecting very long inactive periods in the range, for example, of 150 ms to 10s. Additionally, an interrupt on edge can be enabled by using the corresponding enable bits in the **FLAGSENABLE** registers. Setting and clearing the flags can be done by software by using the **FLAGSSET** and **FLAGSCLEAR** register.

Note: The low break or wake up pulses do not cause a dummy byte to be transferred to the receive FIFO and do not cause a frame violation error interrupt. After the pulse the shift register goes into initial state and waits for the falling edge of the start bit of the next frame.

Break and Wake Pulse Detection

The detection of the break pulse, which is defined as low pulse with a minimum duration of 13 bit times, is performed using a threshold of either 10 or 11 bit times. The break detection threshold is set using the bitfield **LINBTIMER**.BREAK.

Detecting a break pulse anywhere in the frame resets the LIN state machine to the “Break Delimiter Detected” state BDD and the whole sequence inclusive the watchdog timeout counting starts from the beginning .

Note: Detecting a break pulse anywhere in the frame could result in setting the Frame Error Flag (FE)

Wake low-pulse detection is done by monitoring the bus for a falling edge in sleep mode. If an early wake-up shall be suppressed, the parameter **IOCR**.DEPTH (glich filter) may be used.

Break and Wake Pulse Generation

The generated break low-pulse duration is defined by the bit field **LINBTIMER**.BREAK in the range of 1 to 64 bits.

Wake low-pulse is nominal 5 bit times long, but can be set to any value between 1 and 9, by writing the appropriate character in the TXFIFO and requesting its transmission as the wake pulse by setting **FLAGS**.TWRQ.

Note: Injecting the low pulse disables the reception with the shift register, so that this low pulse is not detected or treated as a normal ASC frame.

18.9.1.2 LIN Header and Response Timers

The LIN header and response times can be monitored separately.

(>>**LINHTIMER**, **DATCON** description)

- Header duration measurement
  - In master mode starting point of the time measurement is falling edge of the break pulse.
  - In slave mode starting point of the time measurement is the moment of detecting that there is a break pulse going on, that is the moment of detection of a low pulse longer than either 10 or 11 bit times, as configured in the **LINBTIMER** register.
- Response duration measurement
  - In both master and slave modes the response duration measurement starts with the end of the header and ends with the end of the response. “End” means end of the last bit of the last byte (of the checksum byte).

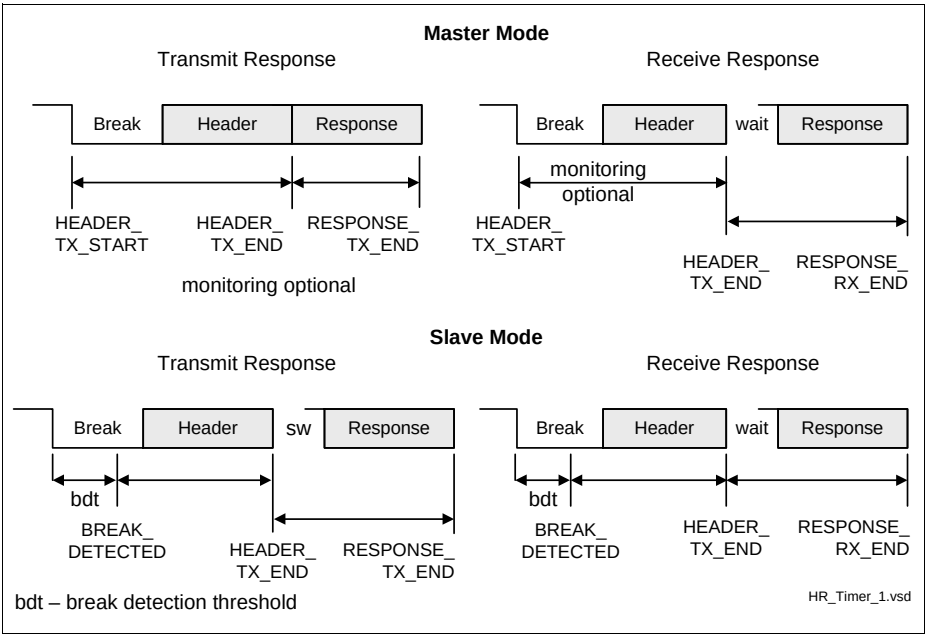

Figure 18-22 Duration Measurement of the Header and Response

Note: Transmitting master node can optionally monitor its own header or response timouts, in order to detect some error conditions, like TXFIFO not containing the ID or data to be transmitted. However, these error conditions can be detected also in other ways.

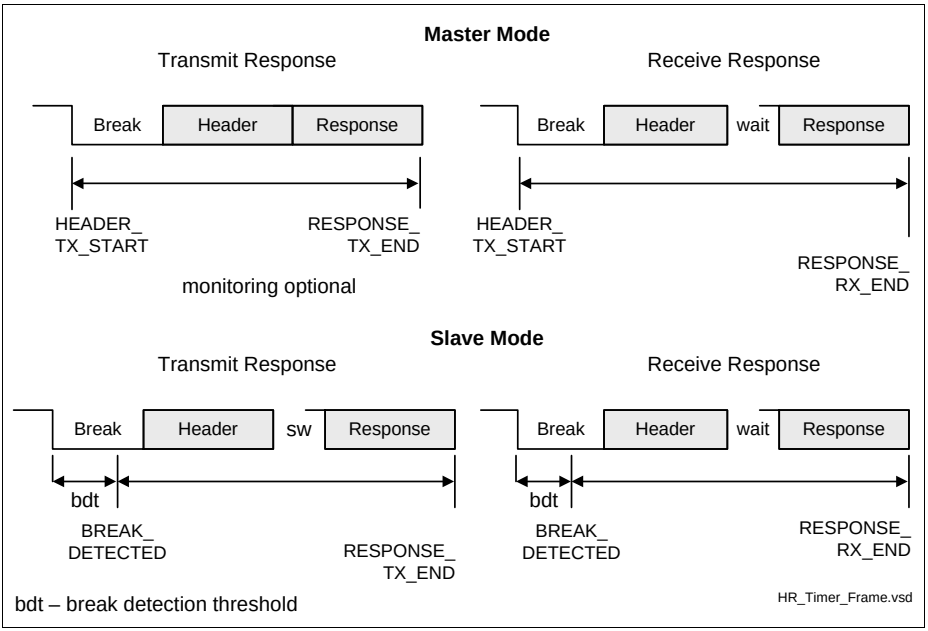

Figure 18-23 Duration Measurement of the Response or Frame

Acording to the setting of the bit **DATCON**.RM, the **DATCON**.RESPONSE bit field defines response or frame duration threshold.

18.9.2 LIN Master Sequences

The sequences described below are examples how the elementary LIN transactions can be executed. There exist other ways to do them, for example by using other events to control the protocol flow: fifo level events instead of end of header / response events. Some alternatives are indicated in the lists below with brackets.

Initialize the module in LIN master mode:

- deactivate the clock source : **CSR**.CLKSEL = 0 (off)
- wait or poll for **CSR**.CON = 0 (see also **Clock Reconfiguration**)
- enter the INIT mode : **FRAMECON**.MODE = INIT
- activate the clock source : set **CSR**.CLKSEL
- wait or poll for **CSR**.CON = 1
- deactivate the clock source : **CSR**.CLKSEL = 0 (off)
- wait or poll for **CSR**.CON = 0
- select the operation mode : **FRAMECON**.MODE = 3 (LIN)
- configure the master mode : **LINCON**.MS = 1
- configure the baud rate : **BRG**
- configure the bit timing : **BITCON**.PRESCALER and OVERSAMPLING
- configure the bit sampling : **IOCR**.DEPTH, **BITCON**.SM, SAMPLEPOINT
- configure the frame parameter : **FRAMECON**.PEN=0 (no parity), STOP = 1
- configure the break length : **LINBTIMER**.BREAK = 13 (typ)
- configure the delay parameter : **FRAMECON**.LEAD, **FRAMECON**.IDLE
- configure the checksum mode : **LINCON**.CSEN, **LINCON**.CSI
- activate the clock source : set **CSR**.CLKSEL
- wait or poll for **CSR**.CON = 1

Send only a header [master task]:

- configure the watchdog timer : **DATCON**.RESPONSE =256 (max)
- configure the RXFIFO : **RXFIFOCON**.ENI = 0 (or 1), OUTW, BUF=0, flush
- configure the TXFIFO : **TXFIFOCON**.ENO = 0, INW, flush
- clear the event flags : **FLAGSCLEAR**.THC, TRC, RRC, CEC, FEC, HTC, RTC, LPC, LC, TFOC/LC, RFOC/UC/LC
- enable the TX interrupt event : **FLAGSENABLE**.THE
- enable the EX interrupt events : **FLAGSENABLE**.HTE, CEE, (FEE, LPE)
- write into the TXFIFO : **TXDATA** = ID byte
- start the header transmission : **FLAGSSET**.THRQS = 1
- configure the TXFIFO : **TXFIFOCON**.ENO = 1

Note: If the software needs the sent ID in the RXFIFO, it should add the setting of ENI=1 to the sequence above - before triggering the header transmission. In such a case

after the header has been transmitted the ID byte will be available in the RXFIFO, but not the sync byte.

React to the interrupt(s) indicating the end of transmission (and reception) of the ID byte:

- check the error flags : **FLAGS**.HT, CE (FE, LP)
- read from the RXFIFO : **RXDATA**=received ID, if no error has been detected

Check the transmitted / received ID to determine with which response sequence: transmit, receive or ignore to continue (same procedure as in the slave mode).

Send a response to the latest header [slave task]:

- configure the response count : **DATCON**.DATLEN
- configure the watchdog timer : **DATCON**.RESPONSE
- configure the checksum mode: **DATCON**.CSM
- configure the RXFIFO : **RXFIFOCON**.ENI =0
- configure the TXFIFO : **TXFIFOCON**.ENO = 1
- clear the event flags : **FLAGSCLEAR**.TRC, TFOC/UC, CEC, RTC, BDC
- enable the TX interrupt event : **FLAGSENABLE**.TRE
- enable the EX interrupt events: **FLAGSENABLE**.TFOE, CEE (RTE), BDE
- write into the TXFIFO : **TXDATA** = data bytes D0, D1, ... (and optionally the checksum byte if the hardware checksum generation is disabled)
- start response transmission : **FLAGSSET**.TRRQS = 1
- the corresponding interrupts signal an error or the end of the response transmission

Receive a response to the latest header [slave task]:

- configure the response count : **DATCON**.DATLEN
- configure the watchdog timer : **DATCON**.RESPONSE
- configure the checksum mode: **DATCON**.CSM
- configure the RXFIFO : **RXFIFOCON**.ENI = 1
- clear the event flags : **FLAGSCLEAR**.RRC, RFOC/UC, FEC, LCC, RTC, FEDC, REDC, BDC
- enable the RX interrupt event : **FLAGSENABLE**.RRE
- enable the EX interrupt events: **FLAGSENABLE**.RFOE/UE, FEE, (LCE), RTE, BDE
- The corresponding interrupts signal that the whole response has been received (= end of the frame) or an error has occured.

Note: If checksum injection has been enabled, the received (custom) checksum is also written into the RXFIFO and should be taken into account.

- Fetch from the RXFIFO : **RXDATA** = received data, if no error occured

*Note: The hardware checksum check can be enabled using the bit **LINCON**.CSEN. The received checksum write to the RXFIFO can be enabled using the **LINCON**.CSI.*

Ignore the latest header [slave task]:

- configure the RXFIFO : **RXFIFOCON**.ENI = 0
- set the header only mode : **DATCON**.HO = 1
- clear the event flags : **FLAGSCLEAR**.FEDC, REDC, BDC

The LIN master always knows if the header is followed by a response transmission (by himself) or a response reception (by a slave) or the response transmission is from slave to slave, except in case of a slave that does not respond always, but driven by internal events.

In case of addresing an always responding slave, it is recommended first to configure the header and response (transmission or reception), and afterwards to start the header transmission and optionally, at the same time, the response transmission.

To start a transaction consisting of sending a header and sending or receiving a response, which makes one whole LIN frame [master node]:

- configure the response count : **DATCON**.DATLEN
- configure the watchdog timer : **DATCON**.RESPONSE
- configure the checksum mode : **DATCON**.CSM
- configure the RXFIFO : **RXFIFOCON**.BUF = 0, flush, ENI = 0
- configure the TXFIFO : **TXFIFOCON** flush, ENO = 0
- clear the interrupt event flags : **FLAGSCLEAR**.THC, TRC, RRC, CEC, FEC, HTC, RTC, LPC, LCC, TFOC/UC/LC, RFOC/UC/LC, FEDC, REDC, BDC
- send case
  - enable the TX interrupt event : **FLAGSENABLE**.TRE, (THE, HTE)
  - enable the EX interrupt events: **FLAGSENABLE**.TFOE, CEE, (FEE, RTE, LPE, BDE)
- receive case
  - enable the RX interrupt event: **FLAGSENABLE**.RRE. (THE, HTE)
  - enable the EX interrupt events: **FLAGSENABLE**.RFOE/UEE, CEE, FEE, RTE, (LCE, BDE)
- write into the TXFIFO : **TXDATA** = ID byte
- send case
  - write to TXFIFO : **TXDATA** = data bytes (and optionally checksum byte if the hardware checksum is disabled)
- start the header transmission : **FLAGSSET**.THRQS = 1
- configure the TXFIFO : **TXFIFOCON**.ENO = 1

Note: If the software needs the sent ID in the RXFIFO, it should add the setting of ENI=1 to the sequence above - before triggering the header transmission. In such a case after the header has been transmitted the ID byte will be available in the RXFIFO, but not the sync byte.

- send case
  - start transmit response : also set **FLAGSSET**.TRRQS = 1

- the corresponding interrupt signals an error or the end of the response transmission
- read from the RXFIFO : if no error detected, **RXDATA** = received ID
- receive case
  - fetch from the RXFIFO : if no error has been detected, **RXDATA** = received data bytes and optionally the checksum byte

18.9.3 LIN Slave Sequences

The sequences described below are examples how the elementary LIN transactions can be executed. There exist other ways to do them, for example by using other events to control the protocol flow: fifo level events instead of end of header / response events. Some alternatives are indicated in the lists below with brackets.

Initialize the module in slave mode:

- deactivate the clock source : **CSR**.CLKSEL = 0 (off)
- wait or poll for **CSR**.CON = 0 (see also **Clock Reconfiguration**)
- enter the INIT mode : **FRAMECON**.MODE = INIT
- activate the clock source : set **CSR**.CLKSEL
- wait or poll for **CSR**.CON = 1
- deactivate the clock source : **CSR**.CLKSEL = 0 (off)
- wait or poll for **CSR**.CON = 0
- select the operation mode : **FRAMECON**.MODE = 3 (LIN)
- configure the slave mode : **LINCON**.MS = 0
- configure the baud rate : **BRG**, autobaud detection enable, **BRD**.UPPER / LOWERLIMIT
- configure the bit timing : **BITCON**.PRESCALER and OVERSAMPLING
- configure the bit sampling : **IOCR**.DEPTH, **BITCON**.SM, SAMPLEPOINT
- configure the frame parameter : **FRAMECON**.PEN = 0 (no parity), STOP= 1
- configure the break length : **LINBTIMER**.BREAK = 11 (typ)
- configure the header timeout : **LINHTIMER**.HEADER
- configure the delay parameter : **FRAMECON**.IDLE
- configure the checksum mode : **LINCON**.CSEN, **LINCON**.CSI
- activate the clock source : set **CSR**.CLKSEL
- wait or poll for **CSR**.CON = 1

In slave mode, the module waits for a header from the master, that is, it waits for a break pulse followed by the sync byte and the ID.

Configure for header reception [slave task]:

- configure the watchdog timer : **DATCON**.RESPONSE =256 (max)
- configure the RXFIFO : **RXFIFOCON** bufmode = 0, flush, ENI = 0
- clear the interrupt flags : **FLAGSCLEAR**.RHC, TRC, RRC, FEC, HTC, RTC, BDC, LPC, LAC, LCC, TFOC/UC/LC, RFOC/UC/LC
- enable the RX interrupt event : **FLAGSENABLE**.RHE
- enable the EX interrupt event : **FLAGSENABLE**.HTE, CEE, FEE, LAE, LPE

React to the interrupt(s) generated after receiving the ID byte:

- check error flags : **FLAGS**.HT, FE, LA, LP
- read from the RXFIFO : if no error detected, **RXDATA** = received ID

Check the received ID to determine which response sequence (send, receive or ignore header) to use next.

The LIN slave does not know in advance if it will respond to the header with a transmission himself or it will receive a response by another slave. It looks up the received ID and decides if this ID is associated with a transmit or receive response or if it is don't care (it is for some other slave). This look-up and the subsequent configuration of the module must be performed by software within the allowed response time.

Send a response to the latest header [slave task]:

(same sequence as in master mode)

Receive a response to the latest header [slave task]:

(same sequence as in master mode)

Ignore the latest header (if the received ID contains an error or is not for this slave) [slave task]:

(same sequence as in master mode)

18.9.4 Using the ENI and HO Bits

Both the ENI (Enable Input) and HO (Header Only) bits affect the reception of the various byte types in the LIN frame.

The HO bit is normally used in cases where the response part of a frame should be ignored; the module waits for the next break signal. The ENI bit can be set by the user software, but is also set by the hardware in slave mode after the sync byte reception, in order to enable the transfer of the ID byte of the header in the RXFIFO.

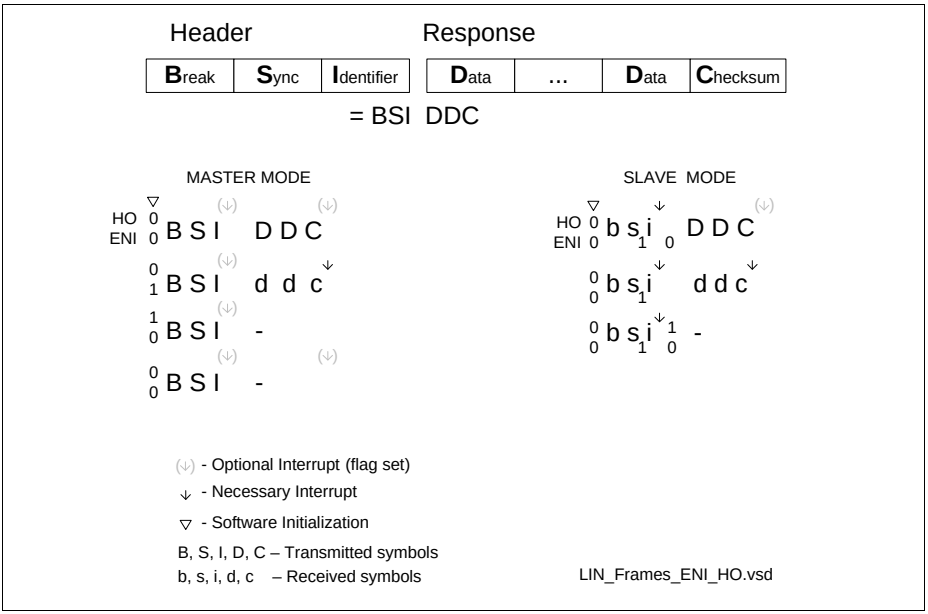

Figure 18-24 ENI and HO bits

18.9.5 LIN Error Recovery

This section describes the behavior of the module in case of errors detected during reception and during transmission of a LIN frame.

Recepton Related Errors

In case of an reception error, the receive state machine goes into the state for waiting for break, and the corresponding interrupt is triggered.

ID Parity error

Checksum error

Timeout error

Framing error

Baud Rate error

Transmission Related Errors

Collision error (LIN2.1 mandatory). If the collision detection mechanism is enabled **FLAGSENABLE**.CEN, the frame will be aborted and the transmiter state machine goes to the idle state.

18.9.6 LIN Sleep and LIN Wake-Up

Wake up low pulse in duration of 250us to 5ms can be generated by the module.

Wake up low pulse in duration longer than 150us wakes up a sleeping module.

A master node which has received a wake up pulse can start polling the slaves, that is it can start sending break pulses and headers, and sending or receiving corresponding responses.

A slave which has been woken up shall be capable of receiving LIN headers after a wake-up time of maximum 100ms. A slave issuing a wake-up pulse expects to receive a header within 150ms to 250ms after the end of the wake-up pulse. If the header does not come, the slave issues a wake up pulse again.

18.10 Auto Baud Rate Detection

Auto baud rate detection is active in slave mode during the reception of the sync field in the LIN header. It measures the longest time interval between two falling edges in the 55H sync field. The measured value is loaded in the denominator of the fractional divider and used afterwards for generating the baudrate for the reminder of this frame if the auto baud rate usage is enabled (**LINCON**.ABD = 1).

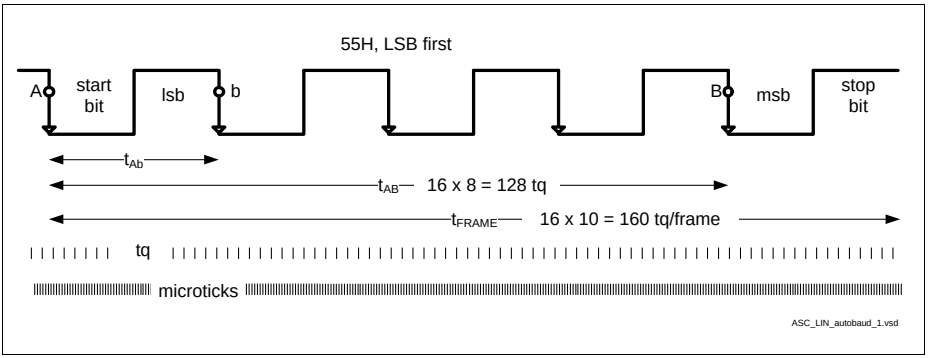

Figure 18-25 Measurement of the Sync field

The following bitfields are available for monitoring the autobaud detection:

- **BRD**.MEASURED - the measured time interval between the first and the fifth falling edge of the sync byte
- **BRD**.UPPERLIMIT - In case the LIN autobaud detection measures a baud rate 14% lower than the nominal one, that is measures a time interval longer than the UPPERLIMIT, a baud rate error event is triggered that, if enabled, generates an interrupt.
- **BRD**.LOWERLIMIT - In case the LIN autobaud detection measures a baud rate 14% higher than the nominal one, that is measures a time interval shorter than the LOWERLIMIT, a baud rate error event is triggered that, if enabled, generates an interrupt.

Auto Baud Rate Operation

The **BRD**.UPPERLIMIT defines the maximum allowed duration for 8 bits in microticks, and therefore the minimum allowed baud rate. In order to define 14% lower baud rate, 8-bit duration 16% longer than the nominal must be entered in the UPPERLIMIT bit field. This is due to the fact that BaudRate = 1 / BitTime, and UPPERLIMIT defines the time.

The **BRD**.LOWERLIMIT defines the minimum allowed duration for 8 bits in microticks, and therefore the maximum allowed baud rate. In order to define 14% higher baud rate, 8-bit duration 12% shorter than the nominal must be entered in the LOWERLIMIT bit

field. This is due to the fact that BaudRate = 1 / BitTime, and LOWERLIMIT defines the time.

If the autobaud is activated, the fractional divider uses a numerator value of 8 x (**BITCON**.OVERSAMPLING + 1) and ignores the bit field **BRG**.NUMERATOR. For the standard LIN protocol oversampling of 16 (**BITCON**.OVERSAMPLING = 15), the numerator value used internally is 128, ignoring the bit field **BRG**.NUMERATOR. Nevertheless, programming 128, or 8 x (OVERSAMPLING + 1) in **BRG**.NUMERATOR may increase the clarity of the software.

Regarding the denominator of the fractionial divider, defined in **BRG**.DENOMINATOR, its initial value is the nominal value and is set by the application software. During the operation of the module, the **BRD**.MEASURED value is automatically loaded into the **BRG**.DENOMINATOR, as long as it is within the limits.

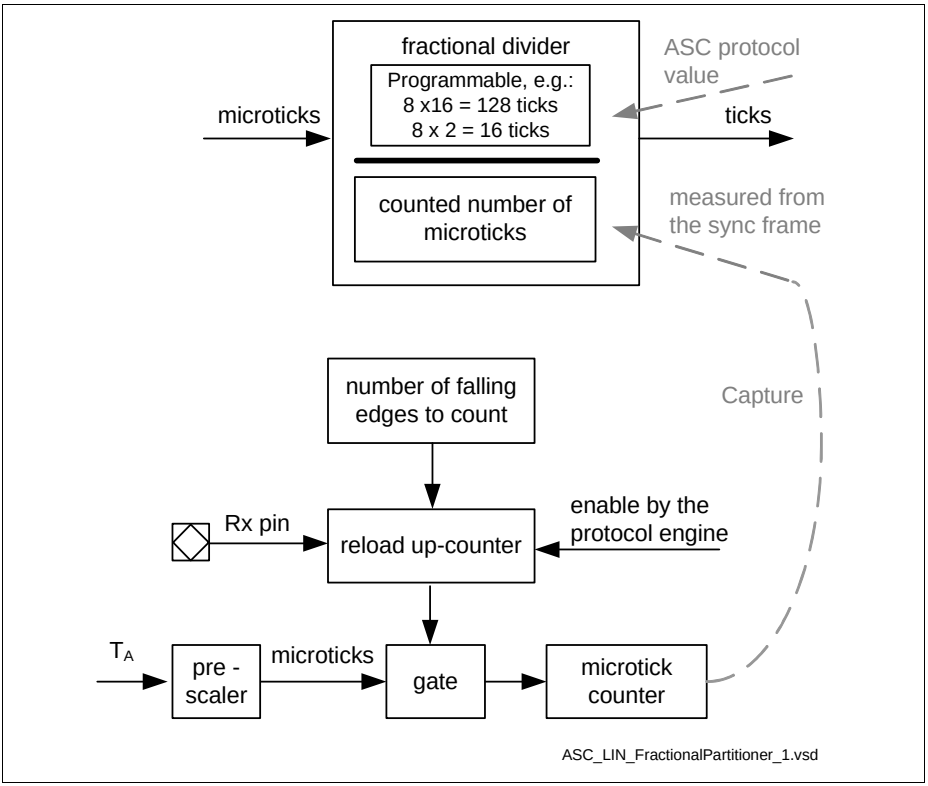

Figure 18-26 Overview of the LIN Auto Baud Detection Principle

Auto baud rate detection measures the time between the first and the fifth falling edge of the sync field in T_{SYS} units and loads this number in the denominator. The LIN protocol uses baud rates in a range between 2400 Baud to 19200 Baud.The expected time at 19.2 KBaud is 8 * 52.1 us = 416.8 us abd the expected denominaror value at T_{SYS} = 10ns is in the range of 417us / 10ns = 41 700.

The numerator operates internally with the quantums for 8 bits, 16 times oversampling for LIN protocol: 8*16=128. The bit field **BRG**.NUMERATOR is ignored.

18.11 Collision Detection

Collison detection monitors the consistency of transmitted and the echoed received bytes in LIN mode and half duplex SPI mode.

18.12 LIN Protocol Control

There is a central LIN protocol state machine. It is connected to the receiver and the transmitter shift registers, the Tx and Rx FIFOs, the checksum logic and the watchdog timers. The machine takes care of generating the sync byte of 55_H and the automatic handling of the checksum. Both the classic LIN V1.3 and the enhanced LIN V2.0 / V2.1 checksum are supported (>> **LINCON** register). The hardware checksum feature is switchable on and off, and the choice between using the classical and the enhanced checksum is done by software with the **DATCON**.CSM bit on a frame by frame basis. As can be seen in the **Figure 18-28**, for the LIN version 2.0 and 2.1, the enhanced checksum is calculated for the identifiers 0...59, and the classical checksum for the identifiers 60...63.

Additionally, the parity of the ID field is generated in master mode, and checked in slave mode. In slave mode, in case of a mismatch between the received and the calculated parity, an error interrupt is raised.

In receive case, if **LINCON**.CSI = 1, the received checksum byte is written to the RXFIFO after the last data byte.

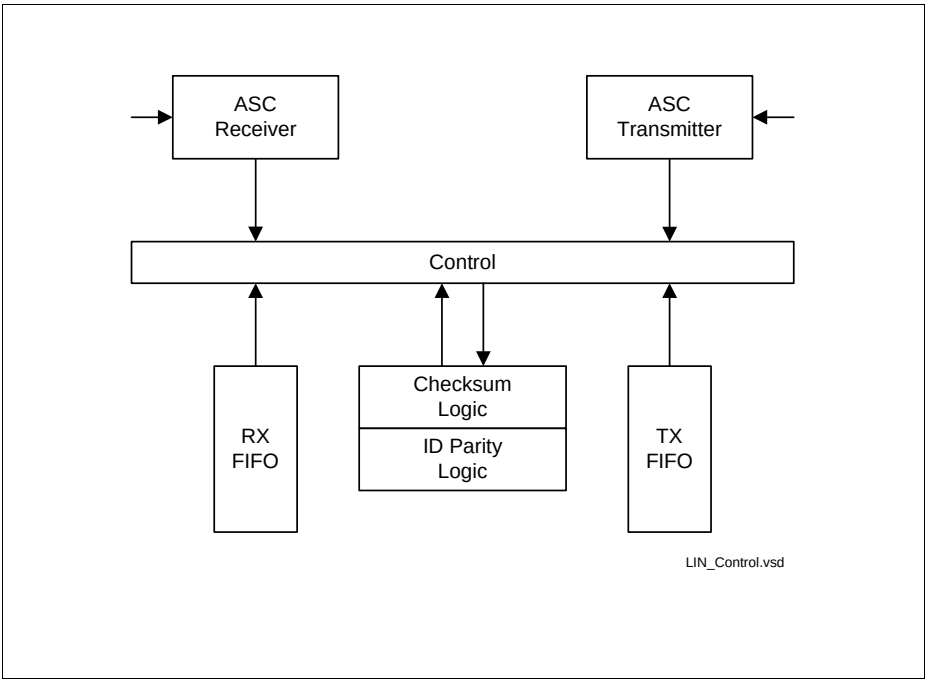

Figure 18-27 Block Diagram of the LIN Control Subsystem

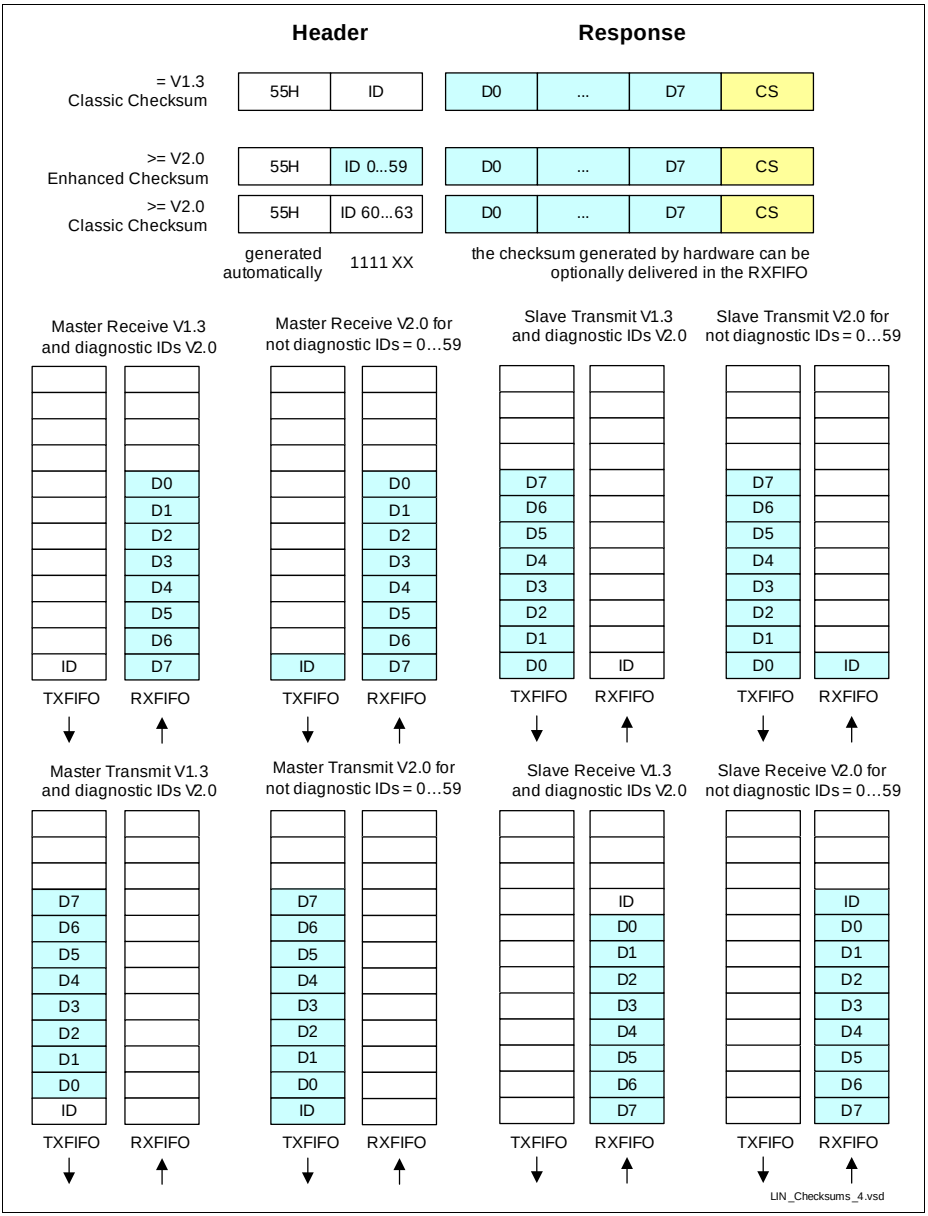

Figure 18-28 Coverage of the Checksum in Different Use Cases

18.13 Interrupts

The ASCLIN module generates three interrupts:

- TX - Transmit Interrupt
  - signals the TxFIFO level event (**FLAGS**.TFL)
- RX - Receive Interrupt
  - signals the RxFIFO level event (**FLAGS**.RFL)
- EX - Extended Error Interrupt
  - signals every error (**FLAGS**.PE, FE, CE, RFO, RFU, TFO) and
  - some additional events (**FLAGS**.FED, RED)

The LIN events related to transmission and reception of header and response are mapped to the corresponding transmit, receive and extended error interrupts

- TX:
  - transmission of the header in master mode completed (**FLAGS**.TH)
  - transmission of a response completed (**FLAGS**.TR)
- RX:
  - reception of the header in a slave mode completed (**FLAGS**.RH)
  - reception of the response completed (**FLAGS**.RR)
- EX:
  - LIN protocol (**FLAGS**. BD, TC) and
  - LIN error events (**FLAGS**.HT, RT, LP, LA, LC)

In order to determine which event is the source of a LIN interrupt, the **FLAGS** register must be polled.

Triggering a DMA

The interrupt signals are used also as DMA trigger signals. The interrupt signals are connected to the Interrupt Router Module, which routes the interrupts either to a CPU or to a DMA. There are no separate DMA triger signals.

Relationship between the Service Request Nodes and the Event Nodes

There are several events mapped to each service request node.

Each service request (interrupt) node contains an SRC (Service Request Control) register containing a sticky flag bit and the associated set, clear and enable bits. The SRC registers are located in the IR (Interrupt Router) module.

The service request flags in the SRC registers are set by hardware, and if the enable bit is set, will be cleared by hardware when the interrupt servicing starts.

One interrupt node may be triggered by more than one events. Each event which causes an interrupt also has a sticky flag bit and associated set, clear and enable bits. These bits are distributed in four registers: **FLAGS**, **FLAGSSET**, **FLAGSCLEAR**, and **FLAGSENABLE** located in the ASCLIN module. Each set of four bits associated to one event builds a virtual “event node”, see **Figure 18-29**.

The event flags are set by hardware and if enabled, trigger an interrupt. They are not cleared by hardware. They are cleared only by software in the corresponding interrupt service routine, which usually polls the flags to find the cause for the interrupts. The event flags can be also set by software for test purposes.

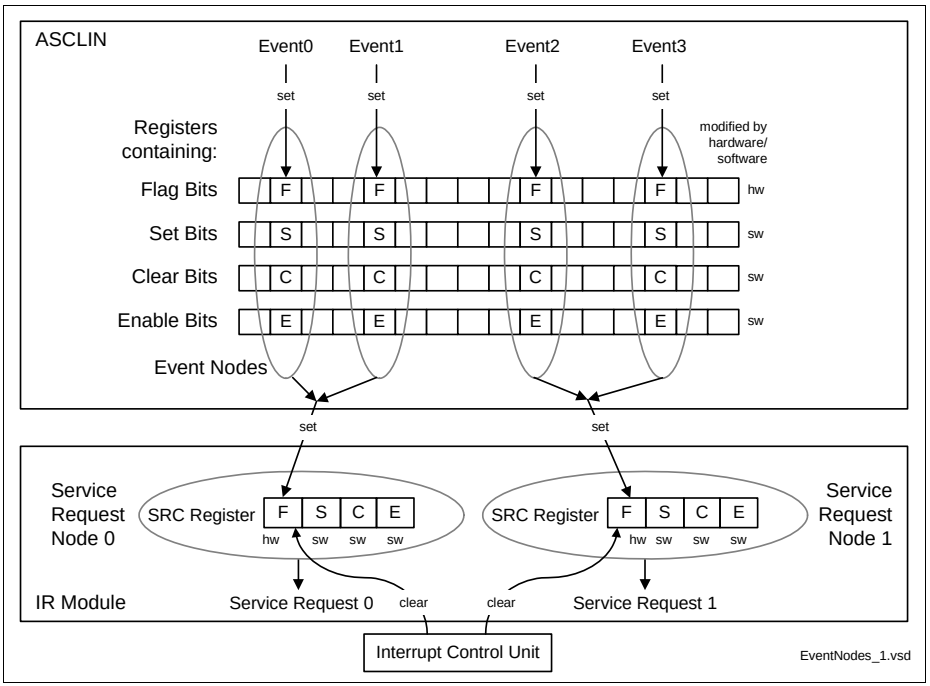

Figure 18-29 Relationship between Event Nodes and Service Request Nodes

Some flags do not generate interrupts and do not have enable bits. They are used either for issueing requests, which are subsequently acknowledged by hardware, or only for polling by software, see **Figure 18-30**.

Clearing an request / acknowledge flag by software is ignored (for example **FLAGS**.TRRQ, THRQ, TWRQ).

There are no pure polled only flags in the ASCLIN module, although by letting the enable bits disabled, all interrupt event flags can be used as polled only (for example idle and stuck monitoring by using **FLAGS**.FED, RED). Setting such bits per software in such a case is meaningless, except for test purposes.

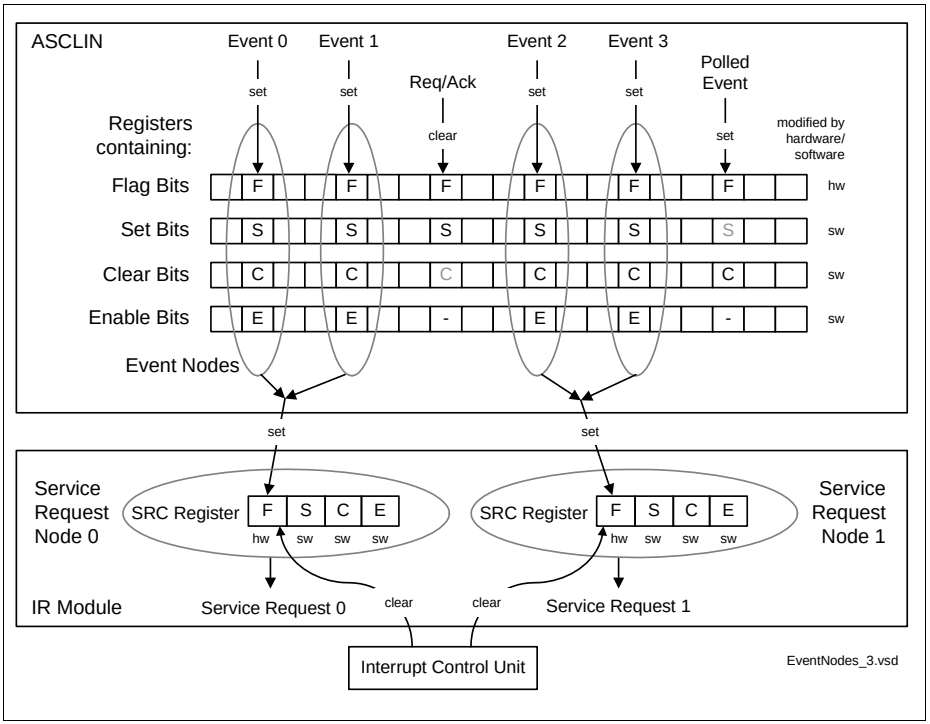

Figure 18-30 Acknowledge Flags and Polled Flags

18.14 Digital Glitch Filter

The digital glitch filter removes short glitches from the input data signal by using an increment / decrement counter with programmable threshold. On the other hand, the filter introduces a delay into the signal path, depending on the digital filter sampling frequency f_{PD} and the threshold programmed in the bit field **IOCR**.DEPTH.

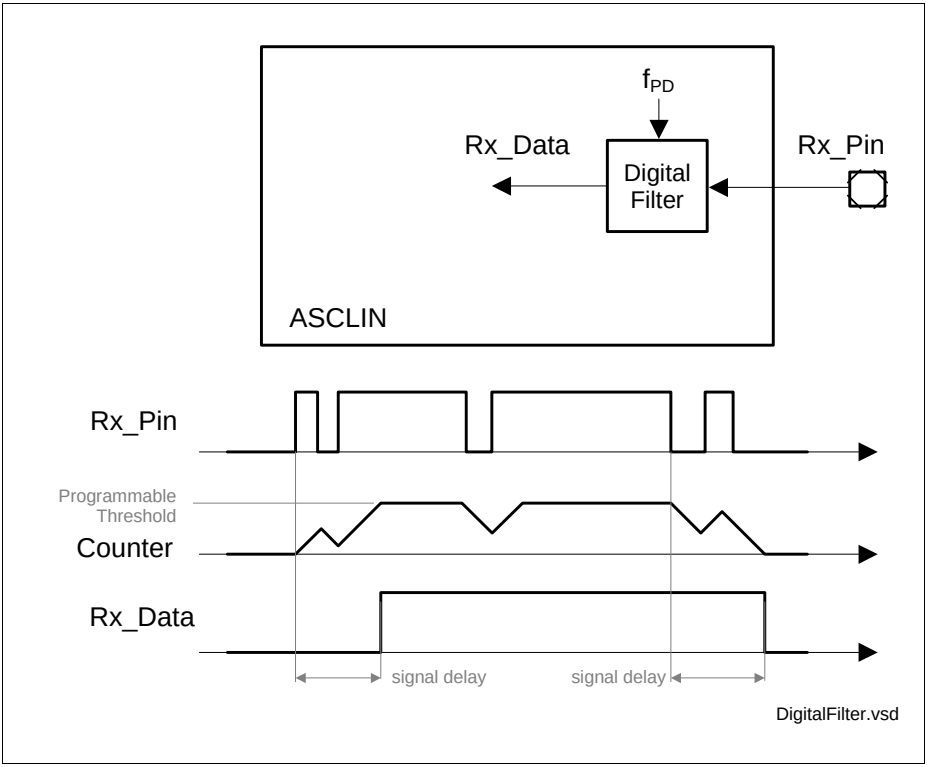

Figure 18-31 Digital Filter

18.15 Suspend, Sleep and Power-Off Behavior

Generally, the ASCLIN module transmits short data frames, not longer than 16 bits, mostly 8 bit long, sometimes with very low baud rates, down to few KBaud. In LIN mode, the data frames build LIN frames.

Simply freezing the module in the middle of an asynchronous ASC frame mostly results in an erroneous data at the receiver side, depending on the data content.

Freezing the module inside the LIN frame transmission, but between the transmission of single bytes results in a timeout error at the receiver side.

If the ASCLIN module gets a request for switching off the clock, it disables immediately all request lines towards the DMA in order to stop further DMA transfers.

In order to power down the module in a well defined way, the user software must take care that the power down request is issued when there is no ongoing single frame or LIN frame transfer and that both FIFOs are empty.

18.15.1 OCDS Suspend

OCDS soft suspend request suspends the module activity at the end of the current transaction. In ASC and SPI cases, this is the end of the current frame. In LIN case, this is the end of the current LIN frame (regular end of response, header timout, or response timeout).

OCDS hard suspend request, for debugging purposes, immediately freezes the ASCLIN module in the current state. The SPB clock feeding the kernel clock f_{CLC} is immediatly switched off. If f_{CLC} is selected for f_A (by using the **CSR**.CLKSEL bit field), the asynchronous clock f_A is also immediately switched off.

*Note: The asynchronous clock f_A remains switched on if a clock source other than f_{CLC} is selected for f_A (by using the **CSR**.CLKSEL bit field).*

Note: Reading and writing of registers is possible but will enable the kernel clock f_{CLC} for a few cycles. Attention: register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a ASCLIN kernel reset might not be sufficient to bring the system into a defined state.

18.15.2 Sleep Mode

Going into sleep mode implies that the ASCLIN module has finished all activities and that the TX and RX FIFOs are empty. It is the responsibility of the user software to issue a sleep request in a safe time interval, where no race conditions or pipeline effects between the ASCLIN module and the DMA can occur.

The ASCLIN module behaves in the same way as in case of disable request..

18.15.3 Disable Request (Power-Off)

Going into power off implies that the ASCLIN module has finished all activities and that the TX and RX FIFOs are empty. It is the responsibility of the user software to issue a power-off request in a safe time interval, where no race conditions or pipeline effects between the ASCLIN module and the DMA can occur. This is no issue if the power-off procedure is one-way, that is no continuation of operation without reinitialization of the module is expected.

The ASCLIN module sets immediately all outputs to inactive, stops reacting to inputs, the internal state machines go to initial state, the registers remain unchanged, and then the module acknowledges the request. All clocks to the module are switched off.

18.16 Reset Behavior

There are two sources of reset:

- BPI (Bus Peripheral Interface)
- Reset bit in the kernel register KRSTx0.RST and KRSTx1.RST.

Both sources reset the ASCLIN module. They execute an Application Reset, which resets all the registers except the OCS register. All output signals get the reset value.

The **OCS** register is reset by the Debug Reset.

18.17 Use Case Example ASC Interface

This section explains the core functionality of the ASCLIN interface with a code example. The example uses the ASC feature of the module to transmit and receive a data set via loop back mode (see also figure 21-2 (LINK!)). The following settings are used:

- Data length: 8 bit
- Baud rate: 9600 Bd
- One stop bit, parity bit checking, oversampling factor 16, sampling points 7,8 and 9
- Rx and Tx interrupt

Step description to initialize the ASC module with the settings from above:

(Line 1) reset ENDINIT to get access to ENDINIT protected register, here ASCLIN0_CLC. (see also ENDINIT protection chapter 8.9.3(LINK))

(Line 2) enable the control of the module in the clock control register CLC (LINK)

(Line 3) store CLC register in a dummy variable (has to be defined before). Read back to avoid pipeline effects.

(Line 4) set ENDINIT to lock the protected register again.

(Line 5) The clk source gets set in the clock selection register CSR (LINK). Before setting a source, no clk supply ([3:0]=0) must be set. Final clk selection in Line 20.

(Line 6) This line sets the loop back mode in the input and output control register IOCR (LINK). (see also figure 21-2 (LINK))

(Line 7) This line clears and enables the Tx FIFO and also defines the writing size of 1 byte per clk. The Tx FIFO filling level to trigger an interrupt gets set to 0 ([11:8] =0). The Tx FIFO triggers a Tx interrupt, if the Tx FIFO filling level falls to or below that defined level. The Tx interrupt get enabled in Line 14. (see also chapter 21.4.1 TxFIFO Overview (LINK) and TXFIFOCON (LINK) register)

(Line 8) This line installs the Rx FIFO identically like the Tx FIFO from the line above. (see also RXFIFOCON (LINK) and chapter 21.4.2 RxFIFO Overview (LINK))

(Line 9) The oversampling factor (here 16), the sample points (here 7,8 and 9) and the prescalar for the baudrate (here 10) gets configured in the bit configuration register BITCON (LINK). (see also section 21.5. Clock System (LINK))

(Line 10) One stop bit and initialize mode as basic operation mode (necessary before switching to another mode) are getting configured in the FRAMECON (LINK) register. The parity bit feature with parity type even gets also enabled.

(Line 11) The data length of 8 bits gets set in the DATCON (LINK) register.

(Line 12) the clk divider for the baud rate gets set to 48/3125 in the baud rate generation register BRG (LINK) (see also 21.5. Clock System (LINK))

*Note: assuming f_{clc} = 100 MHz and (defined in line 8) prescalar = 10, oversampling = 16: f_{shift} = (f_{clc}/prescalar * 48/3125) / oversampling =* ***9600 Bd***

(Line 13) Clear all interrupt flags in the FLAGSCLEAR (LINK) register. Before setting the respective interrupt flags in Line 14

(Line 14) enable the Tx and Rx interrupts in the FLAGSENABLE (LINK) register. The interrupts getting triggered by the FIFO's (see Line 6/7).

(Line 15) This line enables the Tx interrupt in the service request control register SRC_ASCLIN0TX (LINK) and sets the interrupt priority to ASC0TX_PRIO (1...255).

(Line 16) This line enables the Rx interrupt in the service request control register SRC_ASCLIN0RX (LINK) and sets the interrupt priority to ASC0RX_PRIO (1...255).

(Line 17 and 18) The interruptHandlerInstall function gets called (this function has to be written first, see interrupt handler example (LINK) for more details). This function installs the interrupt service routine (ISR) entry address in the interrupt vector array with the priority ASC0TX_PRIO respectively ASC0RX_PRIO.

(Line 19) setting operating mode finally to ASC (see also Line 9).

(Line 20) setting clk source finally to f_{clc} (see also Line 4).

Note: your Tx ISR function prototype would be: void ASC0_TX_ irq (void); here could be your ISR code;

Initialization of the ASC interface:

```
(1)  SCU_vResetENDINIT (0);     // enable ENDINIT register
(2)  ASCLIN0_CLC = 0x000;       // disable module control
(3)  dummy = ASCLIN0_CLC;       //read back
(4)  SCU_vSetENDINIT (0);       // lock ENDINIT register
(5)  ASCLIN0_CSR = 0;           // clk source, no clk
(6)  ASCLIN0_IOCR = 0x10000001;           // Loopback
(7)  ASCLIN0_TXFIFOCON = 0x00000043;      // init TXFIFO
(8)  ASCLIN0_RXFIFOCON = 0x00000043;      // init RXFIFO
(9)  ASCLIN0_BITCON = 0x830F0009;    // OS 16, SP 7,8,9, PS 10
(10) ASCLIN0_FRAMECON = 0x40000200;       // 1 Stop, Init Mode, P
(11) ASCLIN0_DATCON = 0x7;      //8 Data Bits
(12) ASCLIN0_BRG = 0x00300C35;       // divider for Baudrate
(13) ASCLIN0_FLAGSCLEAR = 0xFFFFFFFFF;    // Clear all Flags
(14) ASCLIN0_FLAGSENABLE = 0xF0000000;    // Enable TX/RX Int.

(15) SRC_ASCLIN0TX = (1 << 10) | ASC0TX_PRIO;

(16) SRC_ASCLIN0RX = (1 << 10) | ASC0RX_PRIO;
```

```
(17) interruptHandlerInstall (ASC0TX_PRIO, & ASC0_TX_irq);
(18) interruptHandlerInstall (ASC0RX_PRIO, & ASC0_RX_irq);

(19) ASCLIN0_FRAMECON |= 0x00010000;// Mode ASC
(20) ASCLIN0_CSR = 1;            //clk source CLC
```

Note: Before an interrupt is able to occur, the interrupt system has to be globally enabled. The Interrupt Control Register (ICR) holds the global interrupt enable bit (ICR.IE) which enables the CPU service request system. Most compiler support the attribute (or similar):
__enable();
to set this bit. (See also Architecture Manual for more details)

18.18 Kernel Registers

This section describes the kernel registers of the ASCLIN module. All ASCLIN kernel register names described in this section will be referenced in other parts of the TC27x User's Manual by the module name prefix "ASCLIN0_" for the ASCLIN0 interface and "ASCLIN1_" for the ASCLIN1 interface.

All registers in the ASCLIN address spaces are reset with the application reset (definition see SCU section "Reset Operation").

ASCLIN Kernel Register Overview

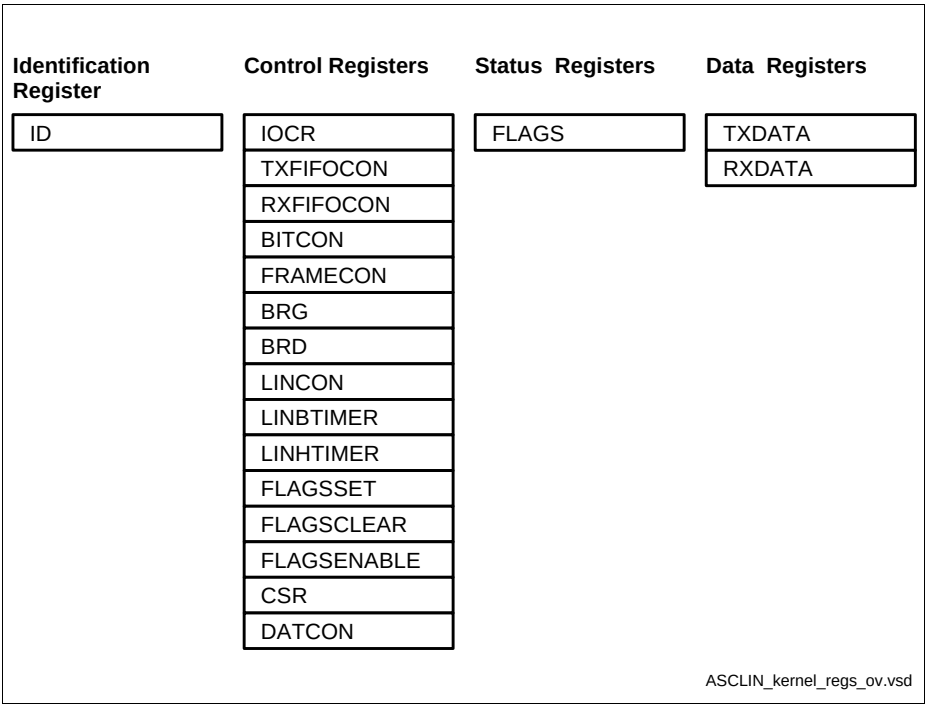

Figure 18-32 ASCLIN Kernel Registers

*Note: Absolute Register Address = Module Base Address (**Table 18-3**) + Offset Address (**Table 18-4**).*

Table 18-3 Registers Address Space

Module	Base Address	End Address	Note
ASCLIN0	$F0000600_H$	$F00006FF_H$	–
ASCLIN1	$F0000700_H$	$F00007FF_H$	–
ASCLIN2	$F0000800_H$	$F00008FF_H$	–
ASCLIN3	$F0000900_H$	$F00009FF_H$	–

Table 18-4 Registers Overview

Register Short Name	Register Long Name	Offset Address	Write [1] Access	Reset Value
IOCR	Input Output Control Register [2]	04_H	U, SV,P	X000 0000
ID	Module Identification Register	08_H	BE	00C1 C0XX
TXFIFOCON	TX FIFO Configuration Register	$0C_H$	U, SV,P	0000 0000
RXFIFOCON	RX FIFO Configuration Register	10_H	U, SV,P	0000 0000
BITCON	Bit Timing Configuration Reg. [2]	14_H	U, SV,P	0000 0000
FRAMECON	Frame Configuration Register [2]	18_H	U, SV,P	0000 0000
DATCON	Data Configuration Register	$1C_H$	U, SV,P	0000 0000
BRG	Baud Rate Generation Register [2]	20_H	U, SV,P	0000 0000
BRD	Baud Rate Detection Register [2]	24_H	U, SV,P	0000 0000

1) All registers have read access mode U, SV. Read access from reserved addresses delivers bus error (BE). All registers belong to application (class 3) reset except OCS, which belongs to debug (class 1) reset.
2) This register is writable only if **CSR**.CLKSEL=0.

List of Access Protection Abbreviations

U - User Mode

SV - Supervisor Mode

BE - Bus Error

nBE - no Bus Error

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

SE - Safety ENDINIT

18.18.1 Kernel Registers

IOCR

The Input and Output Control Register IOCRx determines several properties of the RX and TX signal path:

for the RX signal:

- the alternate input
- the filter depth

for the TX signal

- the trigger source

(>> **Table 18-4** register overview)

(>> **Baud Rate Generation**)

(>> **Bit Timing Properties**)

IOCR

Input and Output Control Register (04) **Reset Value: X000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						DEPTH						0	ALTI		
r						rw						r	rw		

Field	Bits	Type	Description
ALTI	[2:0]	rw	**Alternate Input Select** Selects the alternate input for the RX signal: 000_B Alternate Input 0 selected 001_B Alternate Input 1 selected $\cdots_B$ … 111_B Alternate Input 7 selected

Field	Bits	Type	Description
DEPTH	[9:4]	rw	**Digital Glitch Filter Depth** DEPTH determines the number of port input samples clocked with microticks that are taken into account for the calculation of the floating average. The higher the DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 000000_B off, default 000001_B 1 000010_B 2 000011_B 3 $\ldots_B$ … 111111_B 63
CTS	[17:16]	rw	**CTS Select** Selects the CTS input pin out of maximum four possible. 00_B 0 01_B 1 10_B 2 11_B 3
RCPOL	25	rw	**RTS CTS Polarity** RCPOL defines the active level or the RTS and CTS signals. Active means ready/clear to send. 0_B active high 1_B active low
CPOL	26	rw	**Clock Polarity in Synchronous Mode** CPOL defines the idle level of the clock signal if the module is set in the SPI mode. The idle level is the level outside the data transmission time intervals. Default is low level. 0_B Idle low 1_B Idle high
SPOL	27	rw	**Slave Polarity in Synchronous Mode** Defines the idle level of the SLSO signal, which is the level outside the data transmission, leading and trailing time intervals. 0_B Idle low 1_B Idle high

Field	Bits	Type	Description
LB	28	rw	**Loop Back Mode** Enables the in module connection of the transmit signal to receive signal. If Loop-back is enabled, the module can be run and tested without an external connection, in ASC and SPI modes. In LIN mode, loopback should not be used, because the module can be either master or slave. 0_B Disabled 1_B Enabled
CTSEN	29	rw	**Input Signal CTS Enable** Enables the sensitivity of the module to the external CTS signal. If disabled, the CTS signal is considered being permanently active. 0_B Disabled 1_B Enabled
RXM	30	rh	**Receive Monitor** Shows the status of the receive signal. 0_B Current signal is low. 1_B Current signal is high.
TXM	31	rh	**Transmit Monitor** Shows the status of the transmit signal. 0_B Current signal is low. 1_B Current signal is high.
0	3, [15:10], [24:18]	r	**Reserved** Read as 0; should be written with 0.

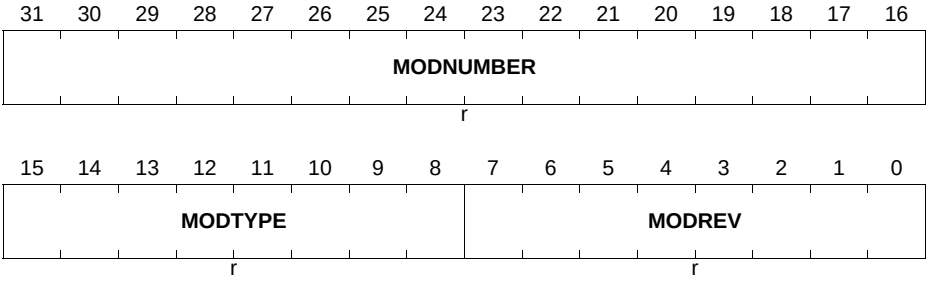
ID

The Module Identification Register ID contains read-only information about the module version.

(>> **Table 18-4** register overview)

ID

Module Identification Register (08$_H$) Reset Value: 00C1 C0XX$_H$



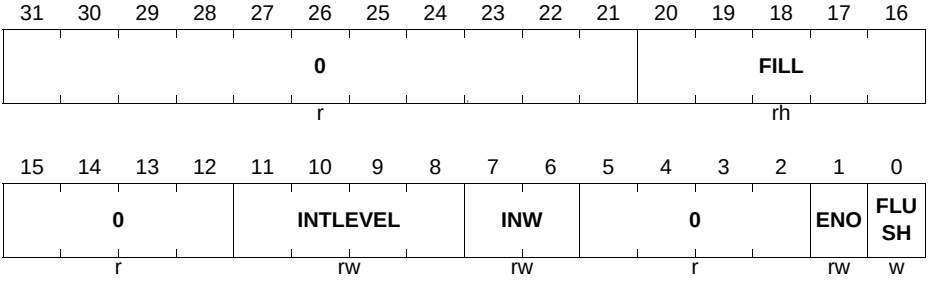
Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field is C0$_H$. It defines a 32-bit module.
MOD NUMBER	[31:16]	r	**Module Number Value** This bit field together with MODTYPE uniquely identifies a module.

TXFIFOCON

(>> **Table 18-4** register overview)

TXFIFOCON

TX FIFO Configuration Register ($0C_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
FLUSH	0	w	**Flush the transmit FIFO** Write of 1 brings the Tx FIFO in empty state. Write of 0 has no effect. 0_B No effect 1_B Empty the Tx FIFO
ENO	1	rw	**Transmit FIFO Outlet Enable** Enables the TxFIFO outlet. In SPI and ASC modes, data transmission starts immediately when the data is available, whereas in LIN case the transmission start is controlled by the protocol engine. 0_B Disabled. In LIN case, if the protocol engine tries to fetch data. 1_B Enabled. In LIN case, no data is moved to the shift register until it is fetched by the protocol engine.
INW	[7:6]	rw	**Transmit FIFO Inlet Width** Defines the number of bytes written to the Tx FIFO with one FPI bus write. 00_B 0 01_B 1 10_B 2 11_B 4

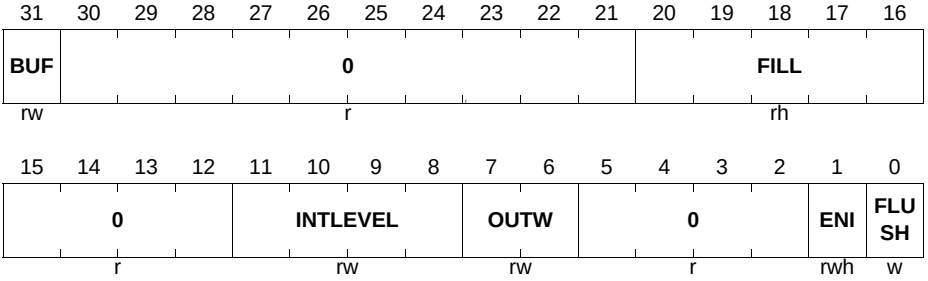
Field	Bits	Type	Description
INTLEVEL	[11:8]	rw	**FIFO Interrupt Level** Defines the filling level that triggers an re-fill interrupt or DMA access. An interrupt is generated when the filling level falls to INTLEVEL or below, each time when a data byte is taken out of the FIFO 0000_B 0 0001_B 1 0010_B 2 $...B$ ... 1111_B 15
FILL	[20:16]	rh	**FIFO Filling Level** Read only bit-field containing the current filling level of the FIFO. 00000_B 0 00001_B 1 $...B$ ... 10000_B 16 10001_B reserved 10010_B reserved 10011_B reserved 10100_B reserved 10101_B reserved 10110_B reserved 10111_B reserved 11000_B reserved 11001_B reserved 11010_B reserved 11011_B reserved 11100_B reserved 11101_B reserved 11110_B reserved 11111_B reserved
0	[5:2], [15:12], [31:21]	r	**Reserved**

RXFIFOCON

(>> **Table 18-4** register overview)

RXFIFOCON

RX FIFO Configuration Register (10_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
FLUSH	0	w	**Flush the receive FIFO** Write of 1 brings the Rx FIFO in empty state. Write of 0 has no effect. 0_B No effect 1_B Empty the Rx FIFO
ENI	1	rwh	**Receive FIFO Inlet Enable** Enables the receiver and the filling of the Rx FIFO through the shift register. In LIN slave mode, this bit is set by hardware after the correct reception of the sync byte. The software can clear this bit after reception of an foreign ID in order to suppress the reception of the following response. 0_B Disabled 1_B Enabled
OUTW	[7:6]	rw	**Receive FIFO Outlet Width** Defines the number of bytes read to the Rx FIFO with one FPI bus read. 00_B 0 01_B 1 10_B 2 11_B 4

Field	Bits	Type	Description
INTLEVEL	[11:8]	rw	**FIFO Interrupt Level** Defines the filling level that triggers a drain interrupt or DMA access. An interrupt is generated when the filling level rises to INTLEVEL or beyond, each time when a data byte is delivered to the FIFO. 0000_B 1 0001_B 2 $...B$ ... 1111_B 16
FILL	[20:16]	rh	**FIFO Filling Level** Read only bit-field containing the current filling level of the FIFO. 00000_B 0 00001_B 1 $...B$ ... 10000_B 16 10001_B reserved 10010_B reserved 10011_B reserved 10100_B reserved 10101_B reserved 10110_B reserved 10111_B reserved 11000_B reserved 11001_B reserved 11010_B reserved 11011_B reserved 11100_B reserved 11101_B reserved 11110_B reserved 11111_B reserved

Field	Bits	Type	Description
BUF	31	rw	**Receive Buffer Mode** If this bit is zero, then the RXFIFO behaves normally as described in the ITS If this bit is set, the RXFIFO behaves as simple 32-bit one stage RX buffer, which is overwritten with each new received data. The received bits appear in the RXDATA register on the lowest bit locations. The upper locations are padded with zeros. 0_B RXFIFO 1_B Single Stage RX Buffer
0	[5:2], [15:12], [30:21]	r	**Reserved**

BITCON

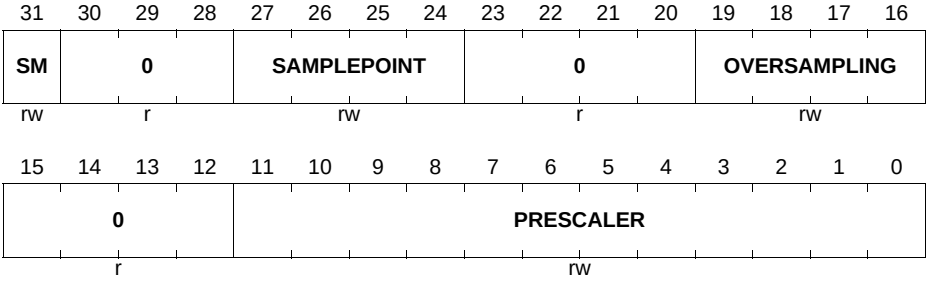
The BITCON Register defines the integer timer parameters in the baud rate generation block.

(>> **Table 18-4** register overview)

(>> **Baud Rate Generation**)

(>> **Bit Timing Properties**)

BITCON
Bit Configuration Register **(14_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
PRE SCALER	[11:0]	rw	**Prescaling of the Fractional Divider** Prescaler in the range of 1 to 4096. Used also as a microtick generator for the input digital filter.
OVER SAMPLING	[19:16]	rw	**Oversampling Factor** Defines the bit length in ticks in the range of 1 to 16. The lengths of 1 to 3 are not allowed. The position of the sampling points is shown in **Figure 18-16**. 0000_B 1 (not allowed) 0001_B 2 (not allowed) 0010_B 3 (not allowed) 0011_B 4 $\cdots_B$ ... 1111_B 16

Field	Bits	Type	Description
SAMPLE POINT	[27:24]	rw	**Sample Point Position** Programmable in the range of 0 to 15 according to the **Figure 18-16**. For example, if three sample points at position 7, 8, 9 are required, this bit field would contain 9. 0000_B 0 (not allowed) 0001_B 1 $...B$ ... 1111_B 15 In SPI mode, this bit field + 1 defines the length of the first SCLK half period in ticks. Values equal or higher then the OVERSAMPLING value are forbidden.
SM	31	rw	**Sample Mode** Number of samples per bit. 0_B 1 1_B 3
0	[15:12], [23:20], [30:28]	r	**Reserved**

FRAMECON

The parameters regarding the properties of the message frame of the ASC communication are controlled by the Frame Control Register FRAMECON.

(>> **Table 18-4** register overview)

FRAMECON
Frame Control Register **(18_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ODD	**PEN**	**CEN**	**MSB**	**0**										**MODE**	
rw	rw	rw	rw											rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	**LEAD**			**STOP**			**IDLE**			**0**					
r	rw			rw			rw			r					

Field	Bits	Type	Description
IDLE	[8:6]	rw	**Duration of the IDLE delay** Defines the duration of the IDLE delay in bit times. If more characters are available in the TXFIFO, this is the pause inserted between the characters. In the SPI mode, this is the idle time between the frames. In the ASC and LIN mode, this is the pause inserted between transmission of bytes. Idle also applies to the pause between the header and the response (response space). *Note: The collision detection runs in parallel to the idle delay and in LIN mode may extend the time between two bytes for one bit length. This effect may occure if the the round trip delay including the digital filter delay is longer than the idle delay.* 000_B 0 001_B 1 $\cdots_B$ ... 111_B 7
STOP	[11:9]	rw	**Number of Stop Bits** Defines the number of stop bits in ASC and LIN mode, or the trailing delay in SPI mode. In ASC mode, standard values are 1 and 2. In LIN mode, standard value is 1. In SPI mode there is no standard value. Nevertheless, all settings are possible in all modes. 000_B 0 (not allowed in ASC and LIN modes) 001_B 1 $\cdots_B$ ... 111_B 7
LEAD	[14:12]	rw	**Duration of the Leading Delay** Defines the leading delay in bit times in SPI mode. Has no meaning in the ASC mode. In LIN mode, this is a delay inserted between the end of the break and the start of the sync character. 000_B 0 (not allowed in LIN mode) 001_B 1 $\cdots_B$ ... 111_B 7

Field	Bits	Type	Description
MODE	[17:16]	rw	**Mode Selection** This bit field defines the basic operating mode of the module. In initialize mode, all outputs are at inactive level, an the module does not respond to the input signals. Changing the mode of the module must be done by switching first to initialize mode, and then to the other mode. The SCLK signal generated by the module is active only in the SPI mode. The CTS output generated by the module is active only in the ASC mode. 00_B Initialize mode 01_B ASC mode 10_B SPI mode 11_B LIN mode
MSB	28	rw	**Shift Direction** Defines the shift direction of the shift register. Relevant for the SPI mode. In ASC and LIN modes, should be set to zero. Parity bit is shifted out last independently of the shift direction. 0_B LSB first 1_B MSB first
CEN	29	rw	**Collision Detection Enable** Enables the collision detection mechanism. 0_B Disabled 1_B Enabled
PEN	30	rw	**Parity Enable** Enables the parity bit attached to the data bits. Parity bit can be used for ASC and SPI protocols. The standard LIN bytes do not use this parity bit. 0_B Disabled 1_B Enabled

Field	Bits	Type	Description
ODD	31	rw	**Parity Type** Defines the type of parity bit attached to the data bits. This setting is valid for all modes of operation (ASC, LIN, SPI). 0_B Even 1_B Odd
0	[5:0], 15, [27:18]	r	**Reserved** Read as 0; should be written with 0.

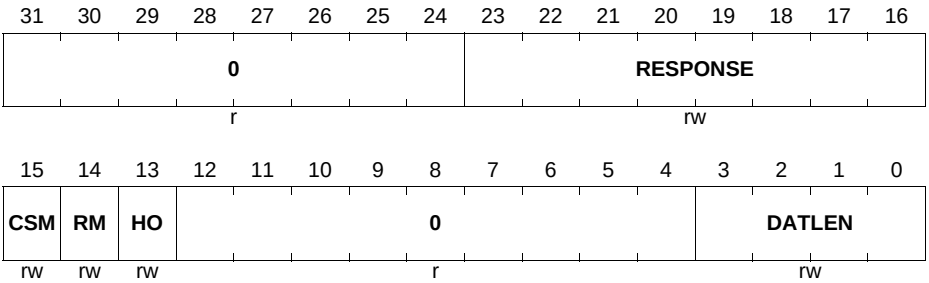
DATCON

DATCON register defines the number of bits in the ASC (affecting the LIN protocol, if used) and SPI frames, data length or the number of data bytes in a LIN response (if any) and the checksum mode. It additionly defines the time window for the LIN response.

In case the whole LIN response does not fit in this time window, an error interrupt is generated. The measurement starts at the end of the last bit of the header, and ends at the end of the last bit of the response.

(>> **Table 18-4**)

DATCON
Data Configuration Register **($1C_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RESPONSE	[23:16]	rw	**Response Timeout Threshold Value** Defines the timer limit in the range of 1 to 256 bit times.
HO	13	rw	**Header Only** Defines if the LIN frame shall consist of a header and response or of a header only. 0_B Header and response expected 1_B Header only expected, response ignored
RM	14	rw	**Response Mode** Defines if the RESPONSE bit field defines a LIN Response or LIN Frame timeout threshold. See **Figure 18-23**. 0_B Frame 1_B Response

Field	Bits	Type	Description
CSM	15	rw	**Checksum Mode** Defines if the classic or the enhanced checksum will be calculated by the checksum block. 0_B Classic 1_B Enhanced
DATLEN	[3:0]	rw	**Data Length** Defines the number of bits in a character. In the ASC mode, standard length is 7, 8, or 9 bits. In the SPI mode, there is no standard length. In ASC and SPI modes, any length from 2 to 16 bits is possible, although not standard for some protocols. In LIN mode, standard length is 8 bits per character. Therefore, this field defines the number of data bytes of the response. 0000_B 1 0001_B 2 0010_B 3 0011_B 4 $...{}_B$ ... 1111_B 16
0	[31:24], [12:4]	r	**Reserved**

BRG

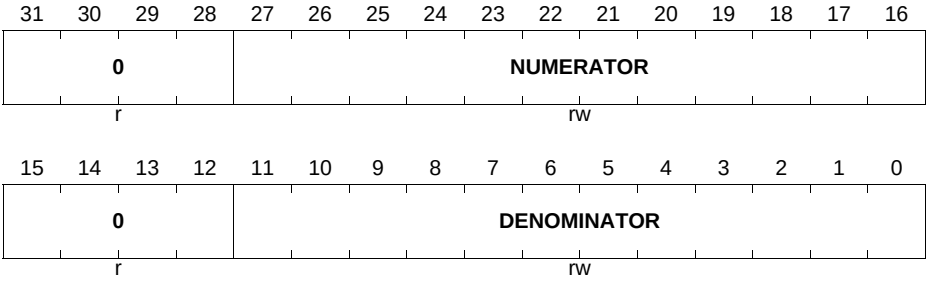
Configures the numerator and the denominator of the fractional divider in the baud rate generation block.

(>> **Table 18-4** register overview)

(>> **Baud Rate Generation**)

BRG

Baud Rate Generation Register (20_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
NUMERATOR	[27:16]	rw	**Numerator** Defines the numerator of the fractional divider in a range of 0 to 4095. Programmed by software. The setting of 0 is not allowed.
DENOMINATOR	[11:0]	rw	**Denominator** Programmed by software, in a range of 0 to 4095. The setting of 0 is not allowed If the module is used as ASC, SPI, LIN master and LIN slave without autobaud detection, this value determines the baud rate. In slave mode with autobaud detection, it contains the nominal value. For the value measured by the autobaud detection hardware, see the **BRD** register.
0	[15:12], [31:28]	r	**Reserved**

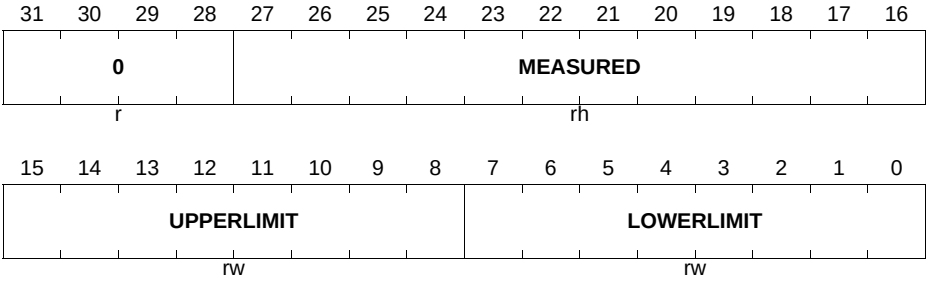
BRD

The BRD defines the properties specific for the automatic baud rate detection when the module operates as a LIN slave.

(>> **Table 18-4** register overview)

(>> **Auto Baud Rate Detection**)

BRD
Baud Rate Detection Register **(24_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
LOWER LIMIT	[7:0]	rw	**Lower Limit** This field defines the 8 most significant bits of the 12 bit compare value. The lower four bits are 1000_B. See **Auto Baud Rate Detection**.
UPPER LIMIT	[15:8]	rw	**Upper Limit** This field defines the 8 most significant bits of the 12 bit compare value. The lower four bits are 1000_B. See **Auto Baud Rate Detection**.
MEASURED	[27:16]	rh	**Measured Value of the Denominator** This bit field contains the measured value of the duration of 8-bits form the sync field of the LIN header in microtics. It is automatically loaded in the denominator of the fractional divider, in case of LIN slave operation with autobaud detection.
0	[31:28]	r	**Reserved**

LINCON

LINCON contains bits that control LIN specific features of the module.

(>> **Table 18-4** register overview)

(>> **LIN Protocol Control** chapter)

(>> **LIN Master Sequences**, **LIN Slave Sequences**)

LINCON
LIN Control Register **(28_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				ABD	MS	CSEN	0	CSI	0						
r				rw	rw	rw	r	rw	r						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															
r															

Field	Bits	Type	Description
CSI	23	rw	**Checksum Injection** Defines if the received checksum byte is written into the RXFIFO or not. See **LIN Protocol Control**. 0_B Not written 1_B Written
CSEN	25	rw	**Hardware Checksum Enable** Enables the hardware checksum generation and checking. 0_B Disabled 1_B Enabled
MS	26	rw	**Master Slave Mode** Configures if the module in LIN mode operates as master or as slave. 0_B Slave 1_B Master

Field	Bits	Type	Description
ABD	27	rw	**Autobaud Detection** Enables the autobaud detection feature in LIN slave mode. In all other operating modes of the module (LIN master, ASC, SPI) not effective. If the autobaud detection is disabled (the oscillator precision of the slave is sufficient), the measurement is still active and the **FLAGS**.LA will be set when the value is outside the **BRD**.LOWERLIMIT and .UPPERLIMIT range. Additionally the stop bit of the sync field is checked if correct. If not correct, a framing error is triggered. 0_B Disabled 1_B Enabled
0	24, [22:0], [31:28]	r	**Reserved** Read as 0; should be written with 0.

LINBTIMER

This register defines

- break detection limit if the module operates as LIN slave or
- length of the generated break pulse if the module operates as LIN master.

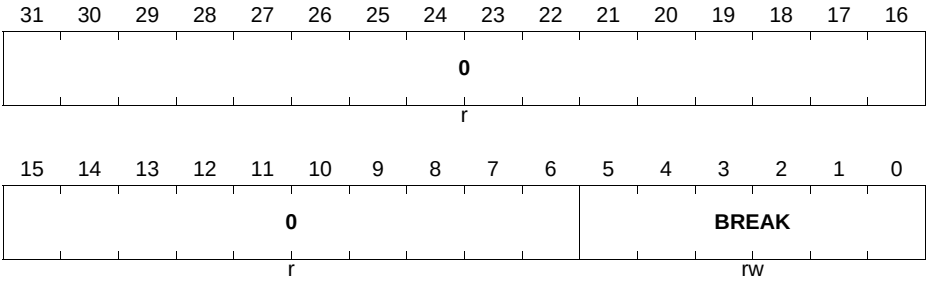
The break timer, if enabled, monitors the bus continuously.

(>> **Table 18-4** register overview)

(>> **LIN Break, Wake, Stuck Handling**)

(>> **LIN Master Sequences**, **LIN Slave Sequences**)

LINBTIMER
LIN Break Timer Register **($2C_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
BREAK	[5:0]	rw	**Break Pulse Generation and Detection** In LIN slave mode, this bit field defines the duration of the detection threshold for the break pulse. In LIN master mode, this bit field defines the duration of the transmitted break pulse. The time unit is bit time.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

LINHTIMER

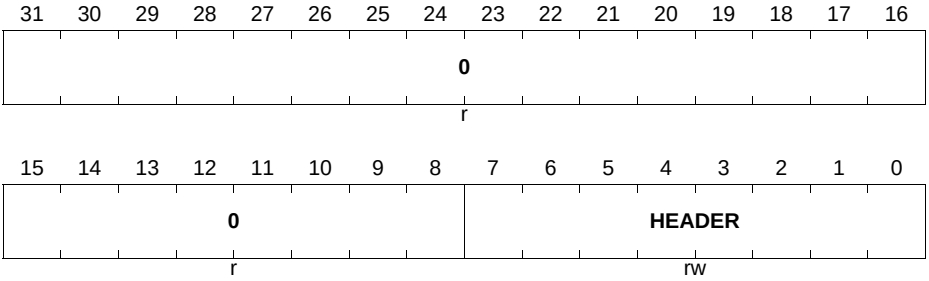
LINHTIMER register defines the time windows for the header of a LIN frame.

In master mode, the timer starts counting at the falling edge of the break pulse, and stops counting when the last bit of the header (including the stop bits) has been transmitted. If the predefined time in the HEADER bit field is violated, an error interrupt is generated (if enabled).

In slave mode, the timer starts counting when the break pulse has been detected, after a low time of 10 or 11 bit times, and stops counting when the last bit of the header has been received. If the predefined time in the HEADER bit field is violated, an error interrupt is generated (if enabled).

(>> **Table 18-4** register overview)

LINHTIMER
LIN Header Timer Register **(30_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
HEADER	[7:0]	rw	**Header Timeout Threshold Value** Defines the timer limit in the range of 1 to 256 bit times.
0	[31:8]	r	**Reserved** Read as 0; should be written with 0.

FLAGS

The FLAGS register contains all the flag bits of the ASCLIN module: the LIN phase flags (header and response transmit and receive), the overflow flags of the LIN timers, and the standard ASC error flags.

A corresponding interrupt triggering can be enabled using the **FLAGSENABLE** register.

(>> **Table 18-4** register overview)

(>> **LIN Master Sequences**, **LIN Slave Sequences**)

FLAGS
Flags Register **(34_H)** **Reset Value: $0000\ 0000_H$**

rh	rh	rh	r						rh	rh	r	rh	rh	rh	rh

Field	Bits	Type	Description
TH	0	rh	**Transmit Header End Flag** Signals the HEADER_TX_END event. Set by hardware, clear by software. If enabled, a transmit interrupt is triggered. 0_B No HEADER_TX_END event since the last clear by software 1_B New HEADER_TX_END event since the last clear by software
TR	1	rh	**Transmit Response End Flag** Signals that RESPONSE_TX_END event. Set by hardware, clear by software. If enabled, a transmit interrupt is triggered. 0_B No RESPONSE_TX_END event since the last clear by software 1_B New RESPONSE_TX_END event since the last clear by software

Field	Bits	Type	Description
RH	2	rh	**Receive Header End Flag** Signals that HEADER_RX_END event. Set by hardware, clear by software. If enabled, a receive interrupt is triggered. 0_B No HEADER_RX_END event since the last clear by software 1_B New HEADER_RX_END event since the last clear by software
RR	3	rh	**Receive Response End Flag** Signals that RESPONSE_RX_END event. Set by hardware, clear by software. If enabled, a receive interrupt is triggered. 0_B No RESPONSE_RX_END event since the last clear by software 1_B New RX_RESPOSE_END event since the last clear by software
FED	5	rh	**Falling Edge from Level 1 to Level 0 Detected** This bit is set by hardware when a falling edge is detected on the RX line. 0_B No falling edge detected 1_B Faling edge detected
RED	6	rh	**Rising Edge from Level 0 to Level 1 Detected** This bit is set by hardware when a rising edge is detected on the RX line. 0_B No rising edge detected 1_B Rising edge detected
TWRQ	13	rh	**Transmit Wake Request Flag** Signals that transmission of wake has been requested. No interrupt triggered. As soon as the wake pulse transmission starts, the bit is cleared by the hardware. 0_B No Transmit Wake Request pending 1_B Transmit Wake Request pending.
THRQ	14	rh	**Transmit Header Request Flag** Signals that transmission of header has been requested. No interrupt triggered. As soon as the header transmission starts, the bit is cleared by the hardware. 0_B No Transmit Header Request pending 1_B Transmit Header Request pending.

Field	Bits	Type	Description
TRRQ	15	rh	**Transmit Response Request Flag** Signals that transmission of response has been requested. No interrupt triggered. As soon as the response transmission starts, the bit is cleared by the hardware. 0_B No Transmit Response Request pending 1_B Transmit Response Request pending.
PE	16	rh	**Parity Error Flag** Signals parity error. If enabled, an error interrupt is triggered. Parity error occurs if the internally calculated parity bit is not equal to the received parity bit. 0_B Last message received error free 1_B Last message received with parity error
TC	17	rh	**Transmission Completed Flag** Signals an end of an ASC or SSC frame. This bit is set after the last stop bit transmission in ASC mode, or after the trailing delay in case of SPI mode. If enabled, an EX interrupt is triggered. Should be cleared by software. 0_B No end of frame event pending 1_B End of frame event pending
FE	18	rh	**Framing Error Flag** Signals framing error. If enabled, an error interrupt is triggered. Framing error occurs if “0” is received at a stop bit position. If autobaud detection is deactivated, then the sync field is checked for framing error. 0_B Last message received error free 1_B Last message received with error
HT	19	rh	**Header Timeout Flag** Signals violation of the header duration limit. If enabled, an error interrupt is triggered. 0_B No HEADER_OVERFLOW event since the last clear by software 1_B New HEADER_OVERFLOW event since the last clear by software

Field	Bits	Type	Description
RT	20	rh	**Response Timeout Flag** Signals violation of the response or frame duration limit as defined in **DATCON**.RM bit. If enabled, an error interrupt is triggered. 0_B No timout event since the last clear by software 1_B New timout event since the last clear by software
BD	21	rh	**Break Detected Flag** Signals a detection of a break pulse. If enabled, an error interrupt is triggered. Slave mode only. 0_B No BWS_OVERFLOW event since the last clear by software 1_B New BWS_OVERFLOW event since the last clear by software
LP	22	rh	**LIN Parity Error Flag** Signals parity error in the LIN identifier. If enabled, an error interrupt is triggered. Applies to LIN mode only. LIN parity error occurs if the internally calculated parity bits are not equal to the received parity bits. 0_B Last ID received error free 1_B Last ID received with parity error
LA	23	rh	**LIN Autobaud Detection Error Flag** Signals baudrate outside the range defined by **BRD**.LOWERLIMIT and **BRD**.UPPERLIMIT. 0_B No autobaud detection error 1_B Autobaud detection error
LC	24	rh	**LIN Checksum Error Flag** Signals checksum error when receiving response, if the internally calculated checksum is different than the received checksum. If enabled, an error interrupt is triggered. 0_B Last checksum error free 1_B Last checksum shows an error

Field	Bits	Type	Description
CE	25	rh	**Collision Detection Error Flag** When transmitting, signals if the transmitted data differs from the received data. If enabled, an error interrupt is triggered in case of a mismatch. Collision detection is mandatory only when supporting LIN version 2.1. 0_B No mismatch 1_B Mismatch detected
RFO	26	rh	**Receive FIFO Overflow Flag** Signals an overflow error. If enabled, an error interrupt is triggered. 0_B No overflow error pending 1_B Overflow error pending
RFU	27	rh	**Receive FIFO Underflow Flag** Signals an underflow error. If enabled, an error interrupt is triggered. See also **RxFIFO Overview**. 0_B No underflow error pending 1_B Underflow error pending
RFL	28	rh	**Receive FIFO Level Flag** An interrupt (if enabled) is generated when the RXFIFO filling level rises to INTLEVEL or above, each time when a data byte is delivered to the RXFIFO. This flag signals that the event from above occured. 0_B No receive interrupt pending 1_B Receive interrupt pending
TFO	30	rh	**Transmit FIFO Overflow Flag** Signals an overflow error. If enabled, an error interrupt is triggered. 0_B No overflow error pending 1_B Overflow error pending
TFL	31	rh	**Transmit FIFO Level Flag** A TXFIFO refill interrupt (if enabled) is generated when the filling level falls to INTLEVEL or below, each time when a data byte is taken out of the TXFIFO. This flag signals that the event from above occured. 0_B No transmit interrupt pending 1_B Transmit interrupt pending

Field	Bits	Type	Description
0	4, [12:7], 29	r	**Reserved** Read as 0; should be written with 0.

FLAGSSET

The FLAGSSET register contains the write only bits used to set the corresponding bits in the FLAGS register by software. Setting a flag bit triggers an interrupt, if the corresponding interrupt enable bit is set.

(>> **Table 18-4** register overview)

(>> **LIN Master Sequences**, **LIN Slave Sequences**)

(>> **FLAGS** register)

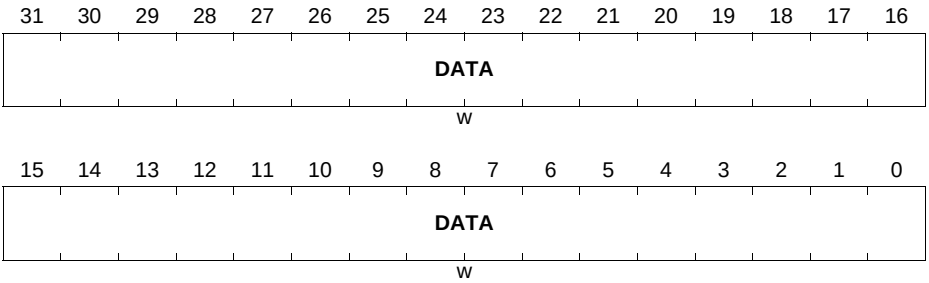
TFLE	31	rw	**Flag Enable Bit** This bit enables the interrupt for the flag at the corresponding position in the FLAGS register. 0_B Disabled 1_B Enabled
0	4, [15:7], 29	r	**Reserved** Read as 0; should be written with 0.

TXDATA

Writing data to this register enters the data to the TXFIFO.

(>> **Table 18-4**)

TXDATA
Transmit Data Register **(44_H)** **Reset Value: 0000 0000_H**



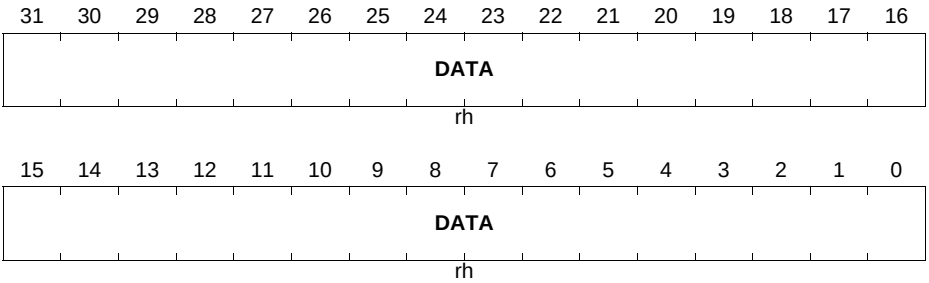
Field	Bits	Type	Description
DATA	[31:0]	w	**Data** Writing to this bit field writes the content to the TXFIFO, depending on the write width - 8, 16 or 32 bit. read from this register returns 0.

RXDATA

Reading data from this register takes data from the RXFIFO.

(>> **Table 18-4**)

RXDATA
Receive Data Register **(48_H)** **Reset Value: 0000 0000_H**



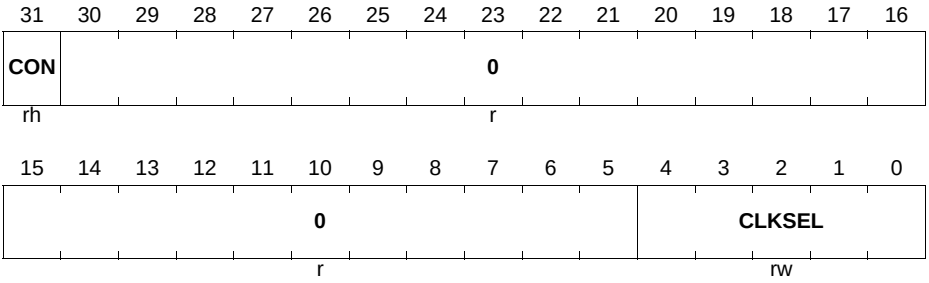
Field	Bits	Type	Description
DATA	[31:0]	rh	**Data** Reading from this bit field takes content from the RXFIFO, depending on the read width - 8, 16 or 32 bit. Write to this register has no effect.

CSR

This register is used to select the clock source for the baud rate generation, detection, timeouts and the SPI delays.

(>> **Table 18-4**)

CSR
Clock Selection Register **($4C_H$)** **Reset Value: $0000\ 0000_H$**



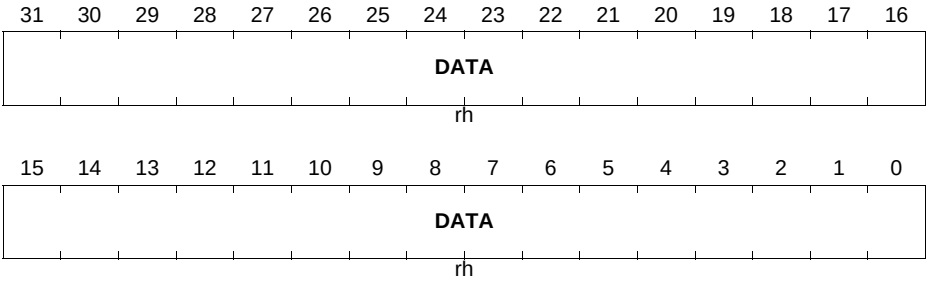
Field	Bits	Type	Description
CLKSEL	[4:0]	rw	**Baud Rate Logic Clock Select** 00000_B No clock supplied 00001_B f_{CLC} 00010_B XTAL Oscillator Clock f_{OSC0} 00100_B f_{ERAY} 01000_B $f_{ASCLINF}$ 10000_B $f_{ASCLINS}$ $..._B$ not allowed
CON	31	rh	**Clock On Flag** Shows if the clock in the bit time domain is switched on or off. Many configuration registers can be written only if this bit shows 0 (see **Table 18-4**). 0_B clock is off 1_B clock is on
0	[30:5]	r	**Reserved** Read as 0; should be written with 0.

RXDATAD

Reading data from this register takes data from the RXFIFO, but does not influence the read pointer. This virtual register provides non-destructive read to the RXFIFO.

(>> **Table 18-4**)

RXDATAD
Receive Data Debug Register (50_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
DATA	[31:0]	rh	**Data** Reading from this bit field takes content from the RXFIFO, depending on the read width - 8, 16 or 32 bit, but dooes not influence the read pointer of the RXFIFO. Write to this register has no effect.

Clock Reconfiguration

The reconfiguration of the clock source has to be done by using two writes: first a write of zero to the CLKSEL bitfield, and then a second write defining the new clock source. Between the first and the second write a delay of minimum $T_W \geq 4 * (1/f_A) + 2 * (1/f_{CLC})$ must be inserted by software, where f_A is the frequency being switched off with the first write. Exception: in case that the f_{CLC} is selected as a baud rate and bit timing logic clock (CSR.CLKSEL = 1), no delay cycles between the writes are necessary. In both cases, simply using one write defining the new clock source is not allowed.

Additionaly, always activate the asynchronous clock for at least two f_A cycles:

- after entering the INIT state and
- after device reset

This is an example of a correct sequence:

- CSR.CLKSEL = No_Clock (equals the reset state)
- Wait T_W or poll for CSR.CON = 0

- FRAMECON.MODE = INIT
- CSR.CLKSEL = Clock_On
- Wait T_W or poll for CSR.CON = 1
- CSR.CLKSEL = No_Clock
- Wait T_W or poll for CSR.CON = 0
- FRAMECON.MODE = ASC (or SPI or LIN)
- CSR.CLKSEL = Clock_On
- Wait T_W or poll for CSR.CON = 1

See also **LIN Master Sequences**

See also **LIN Slave Sequences**

Abort Sequence

If a header has been transmitted in ASCLIN master mode, and the corresponding response does not come, the waiting for the response can be aborted by first entering the INIT mode and then entering the LIN mode. The sequence is identical with the example sequence above.

18.19 Implementation

This section describes the product specific configuration of the ASCLIN module and its interconnection with the rest of the system. The TC27x contains 4 interfaces, ASCLIN0 to ASCLIN3.

18.19.1 BPI_FPI Module Registers

18.19.1.1 System Registers

Figure 18-33 shows all registers associated with the BPI_FPI module, configured for one kernel.

BPI_FPI Registers Overview

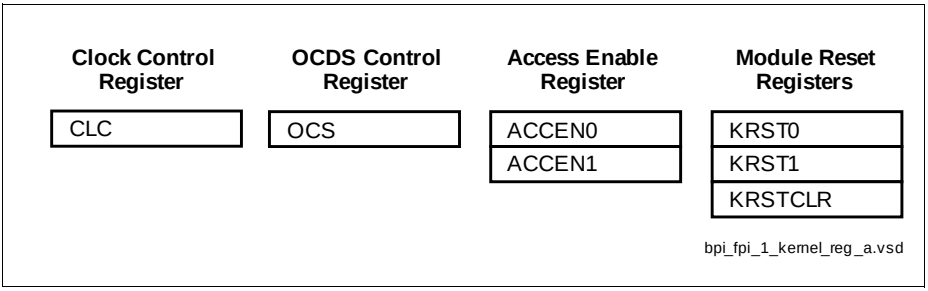


Figure 18-33 BPI_FPI Registers

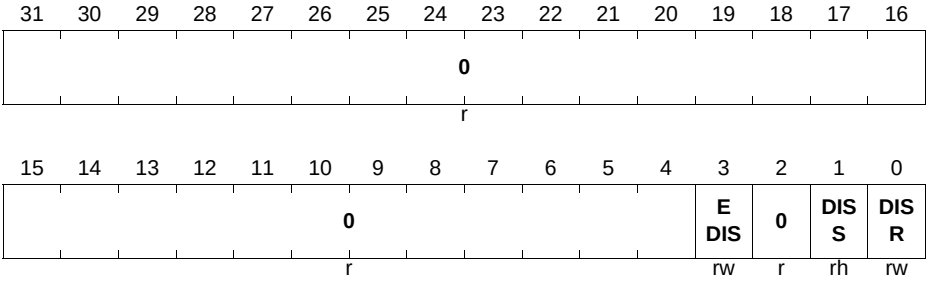
Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_A module clock signal, sleep mode and disable mode for the module.

(>> **Table 18-4** register overview)

CLC

Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode, that is if the sensitivity of the module to the sleep signal is enabled to react to it or disabled to ignore it. 0_B Enabled 1_B Disabled
0	[31:4], 2	r	**Reserved** Read as 0; must be written with 0.

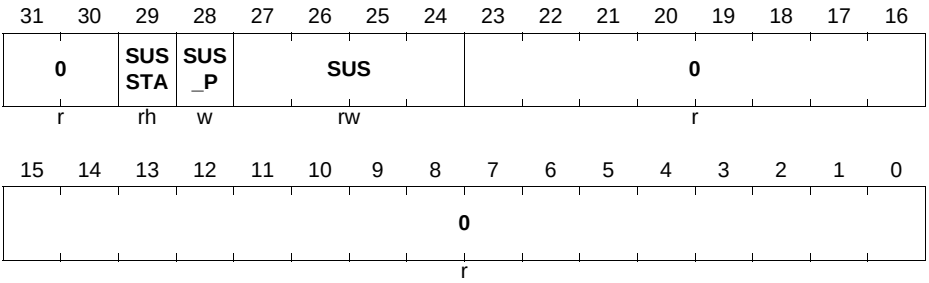
OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode

(>> **Table 18-4** register overview)

OCS
OCDS Control and Status **($E8_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. 2_H Soft suspend **others**, reserved,
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

(>> **Table 18-4** register overview)

ACCEN0
Access Enable Register 0 **(FC_H)** **Reset Value: FFFF FFFF$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN15	**EN14**	**EN13**	**EN12**	**EN11**	**EN10**	**EN9**	**EN8**	**EN7**	**EN6**	**EN5**	**EN4**	**EN3**	**EN2**	**EN1**	**EN0**
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

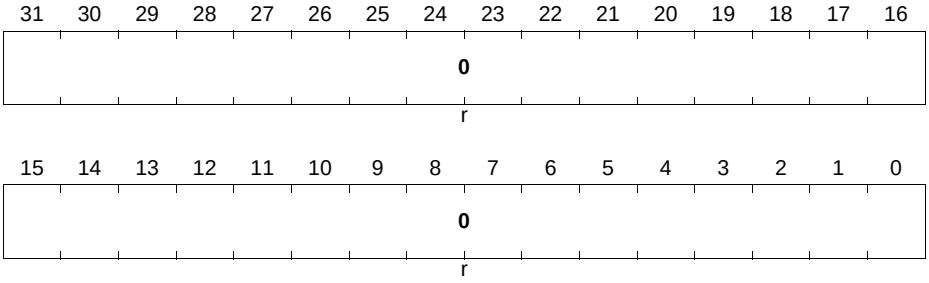
Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

(>> **Table 18-4** register overview)

ACCEN1
Access Enable Register 1 **($F8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

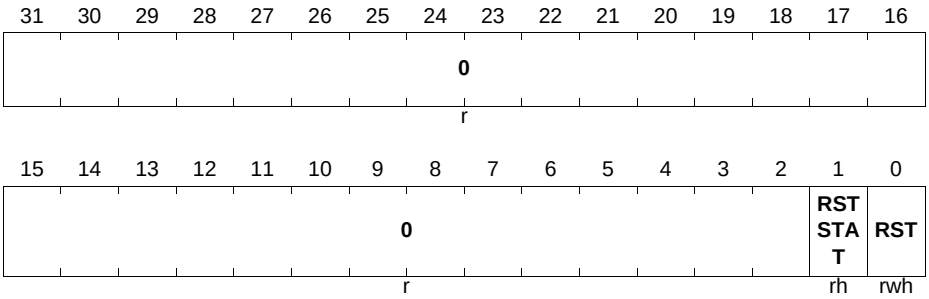
The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

(>> **Table 18-4** register overview)

KRST0
Kernel Reset Register 0 **($F4_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.

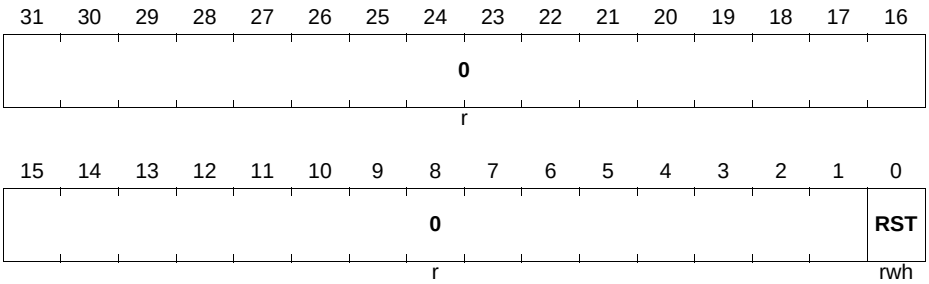
Field	Bits	Type	Description
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

(>> **Table 18-4** register overview)

KRST1
Kernel Reset Register 1 **($F0_H$)** **Reset Value: 0000 0000$_H$**



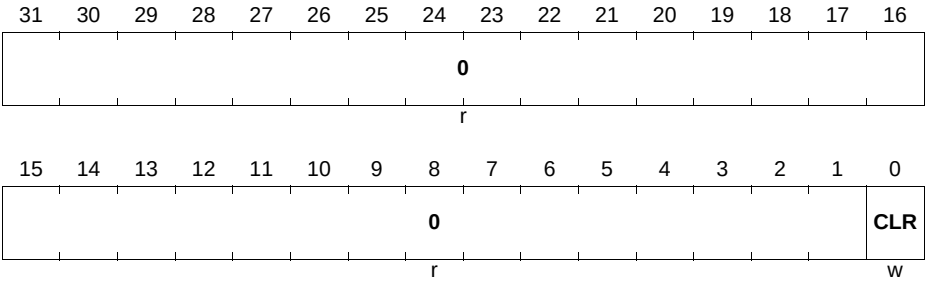
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

(>> **Table 18-4** register overview)

KRSTCLR
Kernel Reset Status Clear Register (EC_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

18.20 On-Chip Connections

This section describes the on-chip connections of the ASCLINx module instances.

Port/Pin Connections

The connections of the ASCLIN modules to the pins / ports is described in the chapters regarding the pinning and the ports.

Input signals not connected to ports/pins are connected to the following voltage levels:

- The unconnected ARX signals in the lower half range (RHA to RXD) are connected to (active) low level, “0”
- The unconnected ARX signals in the upper half range (RXE to RXH) are connected to (inactive) high level, “1”
- The unconnected ACTS signals are connected to low level “0”, which is after reset the inactive level (but disabled via **IOCR**.CTSEN bit field, meaning don’t care)

Table 18-5 shows an overview for TC27x how bits and bit fields must be programmed for the required I/O functionality of the ASCLIN I/O lines.

Table 18-5 ASCLIN I/O Control Selection and Setup

ASCLIN Module	Port Lines	Input Select Register	Input/Output Control Register Bits	I/O
ASC0	ARX0A / P14.1	ASC_IOCR.ALTI = 000_B	P14_IOCR0.PC1 = $0XXXX_B$	I

1) Supports as LVDS inputs in LVDS mode only, CMOS inputs in CMOS mode is not supported.

ASCLIN Connection to Itself

the following connection is defined for each ASCLIN instance:

ARTS -> ACTSD

This connection can be useful in the SPI mode, where frequently the transmission and the reception of data are performed in parallel. If this connection is selected by using **IOCR**.CTS, the TXFIFO will deliver data for transmission only if there is a free space in

the RXFIFO. If not, the TXFIFO will wait for emtying of the RXFIFO by software and then automaticaly continue the transmission.

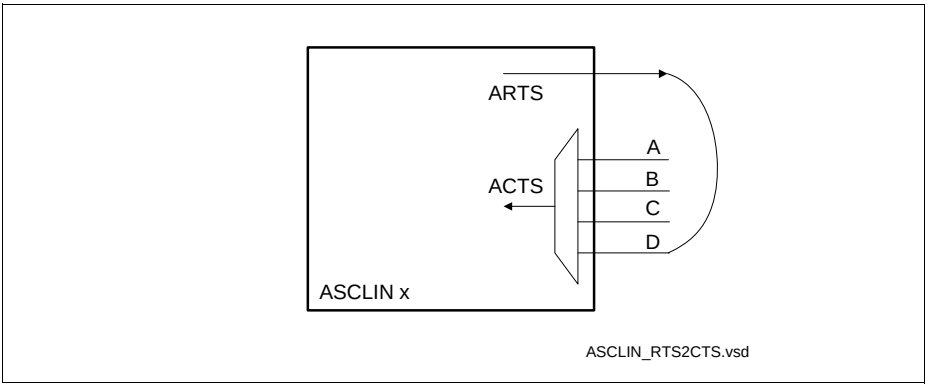

Figure 18-34 ASCLIN ARTS to ACTS Connection

18.21 ASC at CAN Support

The ASC Tx and Rx signals are overlayed with CAN Rx and Tx signal. See the Ports chapter and the Pinning chapter for the particular pin assignements.

A virgin device with a completely erased flash memory can be booted via ASC at CAN pins. See the Boot chapter for details on the implementation.

19 Queued Synchronous Peripheral Interface (QSPI)

The main purpose of the QSPI module is to provide synchronous serial communication with external devices using clock, data-in, data-out and slave select signals. The focus of the module is set to fast and flexible communication: either point-to-point or master-to-many slaves communication.

Parallel requests from on chip bus masters to a module will be executed sequentially via the on chip bus system. Read-modify-write feature provides an atomic read/write sequence where no other master can access the module in between. Module hardware semaphores are not supported.

>> **Registers Overview**

>> **BPI_FPI Module Registers**

19.1 Feature List

This section describes the features of the QSPI module.

- Master and Slave Mode operation
  - Full-duplex operation
  - Half-duplex operation
  - Automatic slave select control
  - Four-wire and three-wire type of connection
- Flexible data format
  - Programmable number of data bits: 2 to 32 data bits (plus parity: 3 to 33 bits)
  - 4 to 32 data bits possible for 50 Mbit/s
  - Programmable shift direction: LSB or MSB shift first
  - Programmable clock polarity: Idle low or idle high state for the shift clock
  - Programmable clock phase: data shift with leading or trailing edge of the shift clock
- Baud rate generation
  - Flexible baud rate and delays (leading, trailing, idle) generation
- Interrupt generation
  - On a transmitter FIFO event
  - On a receiver FIFO event
  - On an error condition (receive, baud rate, transmit error, parity error)
  - On a phase transition (start of frame, end of frame ...)
- QSPI supports control and data handling by the DMA controller
- Flexible QSPI pin configuration
- Hardware supported parity mode
  - Odd / even / no parity
- Seven slave select inputs $\overline{\text{SLSIB..H}}$ in Slave Mode
- Sixteen programmable slave select outputs SLSO[15:0] in Master Mode
  - Automatic SLSO generation with programmable timing
  - Programmable active level and enable control

  - External demultiplexing of the slave select outputs support
- Several module reset options
  - State machine reset per software (only the state machine)
  - Module reset per software (both FIFOs, all registers and the state machine)
  - Automatic stop option of the state machine in slave mode after baud rate error
- Loop-Back mode
- Interoperability with SSC and USIC modules of Infineon microcontroller families, and with popular (Q)SPI interfaces of multiple suppliers
- Communication stop on RxFIFO full
  - Shift register full and RxFIFO full can pause the communication
  - Interrupt generation

19.2 Overview

This section gives a top-level overview of the QSPI.

19.2.1 External Signals

The communication between two devices using QSPI generally uses four signals:

- serial clock SCLK
- data in master to slave direction MTSR (Master Transmit Slave Receive)
- data in slave to master direction MRST (Master Receive Slave Transmit)
- slave select signal SLS

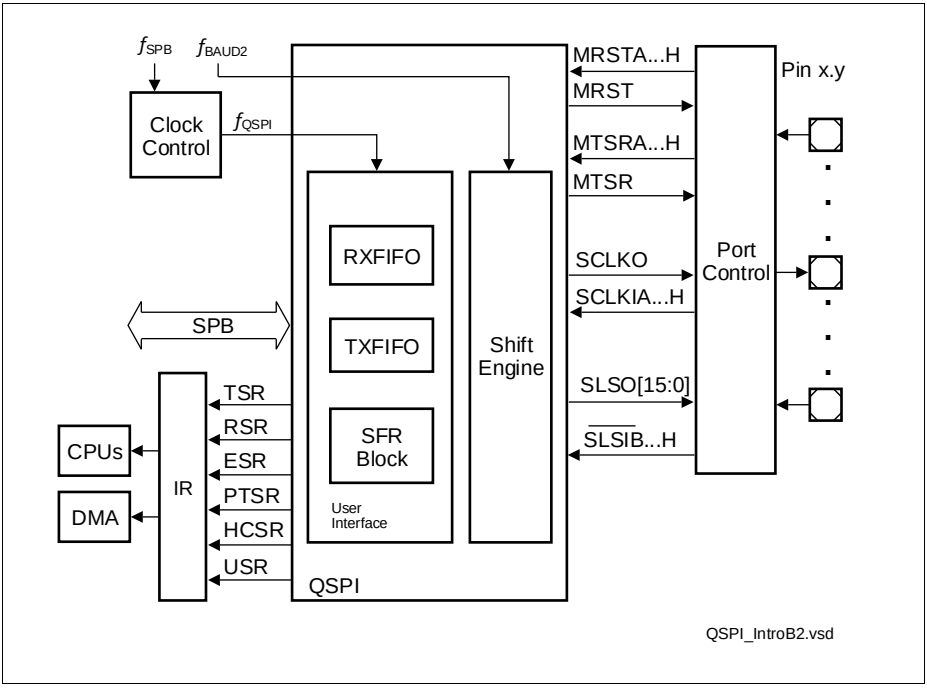

Figure 19-1 External Signals of the QSPI Module

19.2.2 Operating Modes

The QSPI operates in one of two modes regarding the generation of the serial clock and slave select signals: master or slave mode. The master generates and drives the clock and select signals, the slave receives these signals.

The QSPI operates in one of three modes regarding the direction of the communication and depending whether the transmission and the reception appear simultaneously or not: duplex, half-duplex and simplex mode.

This gives six possible combinations for the operating mode of the QSPI: master duplex, half-duplex, and simplex; slave duplex, half-duplex, and simplex.

Note: The half-duplex mode can be implemented either by short-cut connection between two different pins on the pcb, one data output and one data input pin, or by using single pins mapped to both data input and data output signals. See the pinning and port chapters for the pinning definition of a particular product. The module itself does not differentiate between the full-duplex, half-duplex or simplex connection.

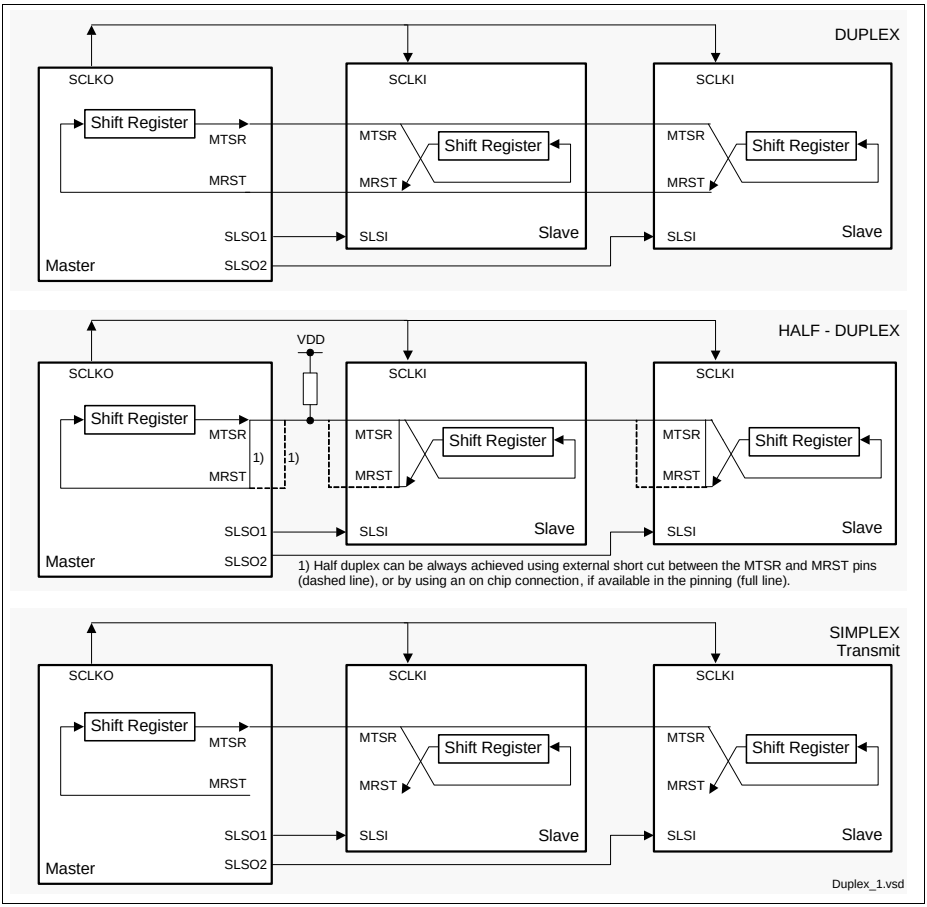

Figure 19-2 Operating Modes and Types of Connections

19.2.3 Queue Support Overview

The term "Queue Support" is used in this context to describe the functionality implemented for comfortable switching of the timing configuration of the QSPI frames, depending on the slave select signal which is to be activated. The main feature of the module is the possibility to take both the configuration and data to the TXFIFO, and to track down which TXFIFO entry is configuration, and which data. The QSPI module expects 32 basic configuration bits to be moved with one move (for example DMA move) from some on-chip general purpose RAM to the TXFIFO. These 32 configuration bits from the TXFIFO and the configuration bits from the 8 configuration extension registers **ECON**z contained in the QSPI module, define together the full configuration of the module (see **Figure 19-3**). One extension register is used for two slave selects: ECON0 for SLSO0 and SLSO8, ECON1 for SLSO1 and SLSO9 ...

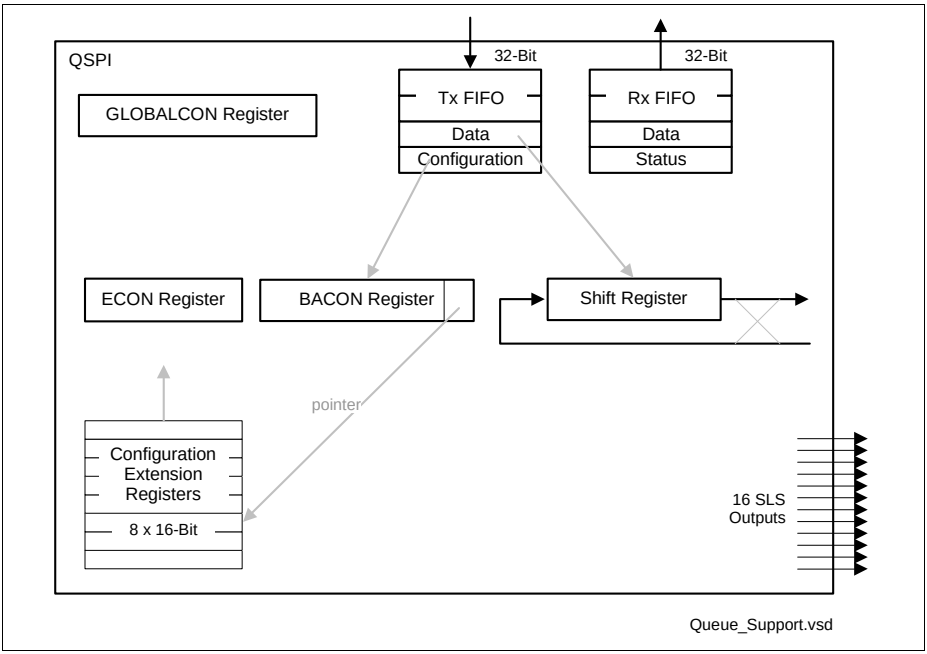

Figure 19-3 Queue Support Overview

19.2.4 Architecture Overview

The **Figure 19-4** shows the main blocks of the QSPI module. The TxFIFO and RxFIFO provide the user interface. The Shift Register and the “Miscellaneous Logic” block build the state machine of the module. The “Configuration Extensions” block provides comprehensive capabilities for configuring the QSPI frames.

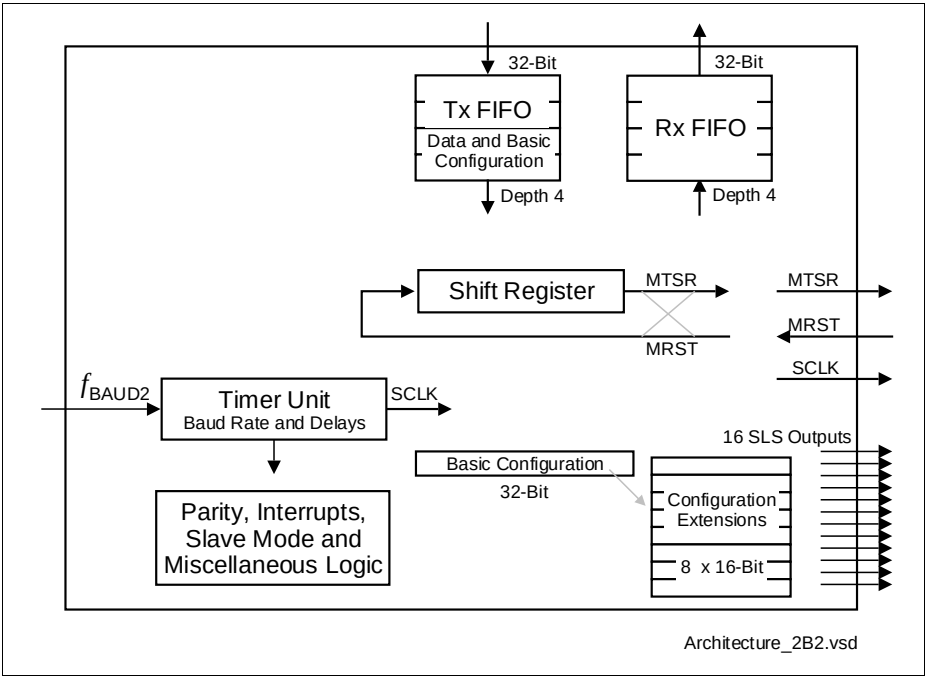

Figure 19-4 QSPI - Architecture Overview

19.2.5 Three Wire Connection

The term "Three Wire Connectiont" is used in this context to describe a connection without slave select signal. This connection relies solely on counting bits for determining the end of the current frame and resetting the shift register state machine, instead of using the slave select signal for this purpose. This way of communication is less robust than communication with slave select, but it saves a pin on both master and slave device.

The name “three wire connection” is true only in case of full-duplex connection, where exactly three signals (clock, data-in, data-out) are needed. In case of half-duplex and simplex connections only two signals (clock, data-in/data-out common data line) are necessary.

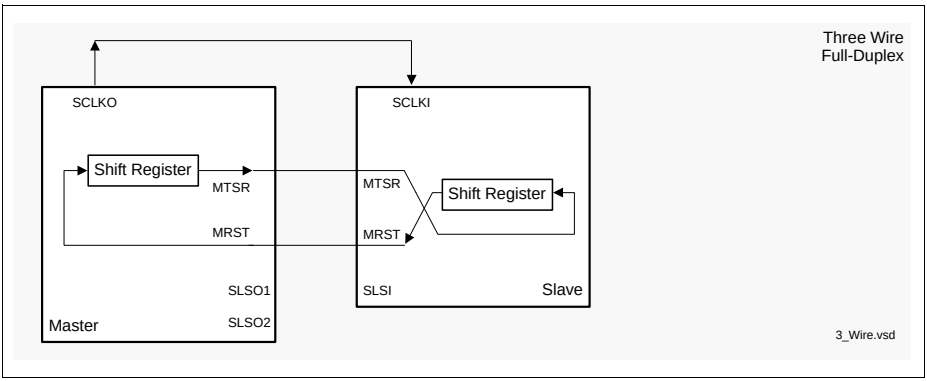

Figure 19-5 Three Wire Connection

19.3 Abstract Overview

An abstract overview of the QSPI module is shown in **Figure 19-6**. This document describes the QSPI module according to this view: the State Machine with its configuration and status capabilities, the User Interface, and the Interrupts (in this order).

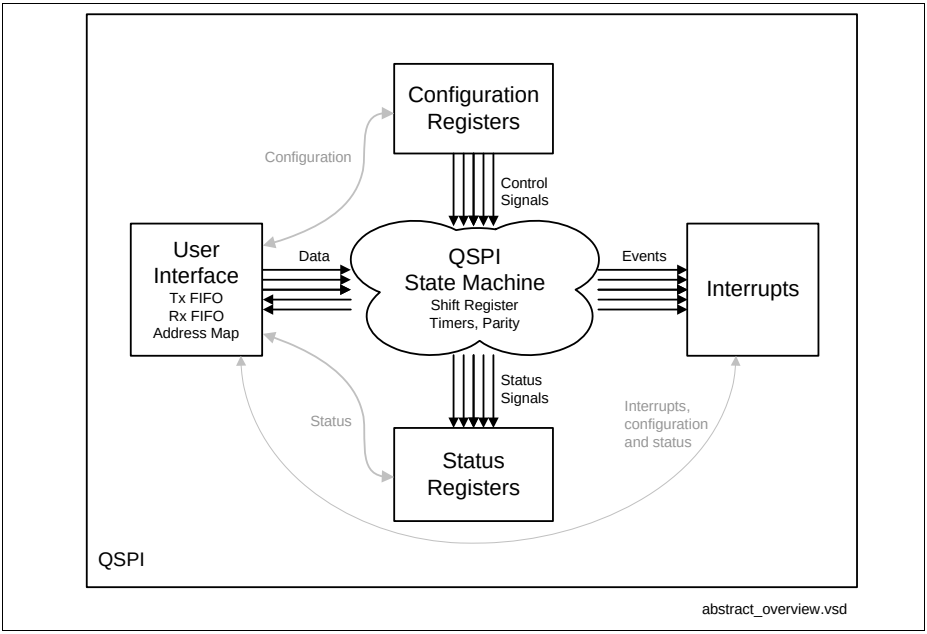

Figure 19-6 QSPI - Abstract Overview

19.4 Frequency Domains

The state machine of the QSPI is placed in a separate frequency domain operating with a frequency f_{BAUD2} which can be:

- integer multiple of the SPB bus frequency
- equal to the SPB frequency
- lower than the SPB frequency, derived by integer division

The baud rate is determined by the f_{BAUD2} frequency divided by an integer equal or greater than four.

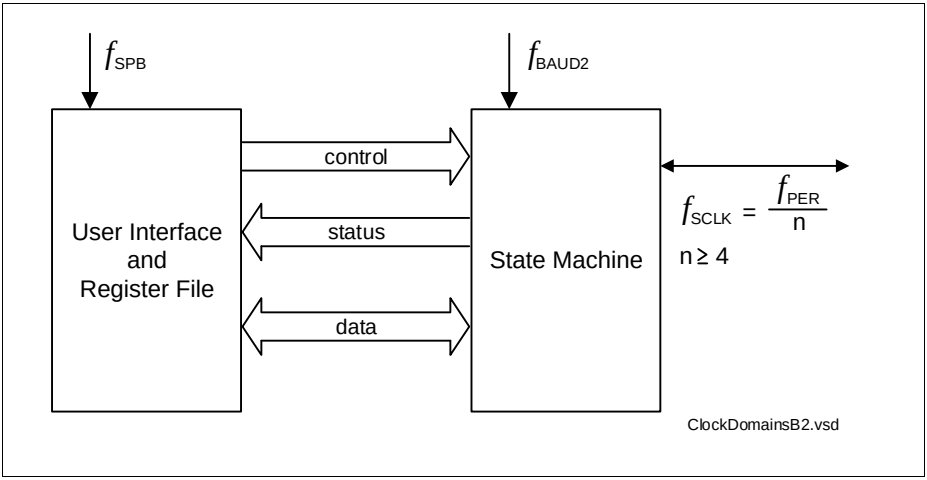

Figure 19-7 QSPI - Frequency Domains

19.5 Master Mode State Machine

In master mode, the QSPI module generates the timings, the serial clock, and the slave select signals.

19.5.1 Phases of one Communication Cycle

This section describes the possibilities available for configuring the length of the phases of the QSPI communication: timing delays, data length, duty cycle and data sampling.

A QSPI frame starts with activating a slave select signal SLSO (at transition from idle to leading delay phase), and ends with its deactivation (at transition from trailing delay to wait or idle phase). It is a sequence of five phases: idle delay, leading delay, data phase, trailing delay and an optional wait phase. The idle phase is subdivided in two phases of equal length: idle A and idle B.

Figure 19-8 shows a full and a compressed view of a QSPI frame and its phases. The full view shows all four signals needed for a QSPI connection. The compressed view represents the phases in a single row, in a way suitable to discuss their properties.

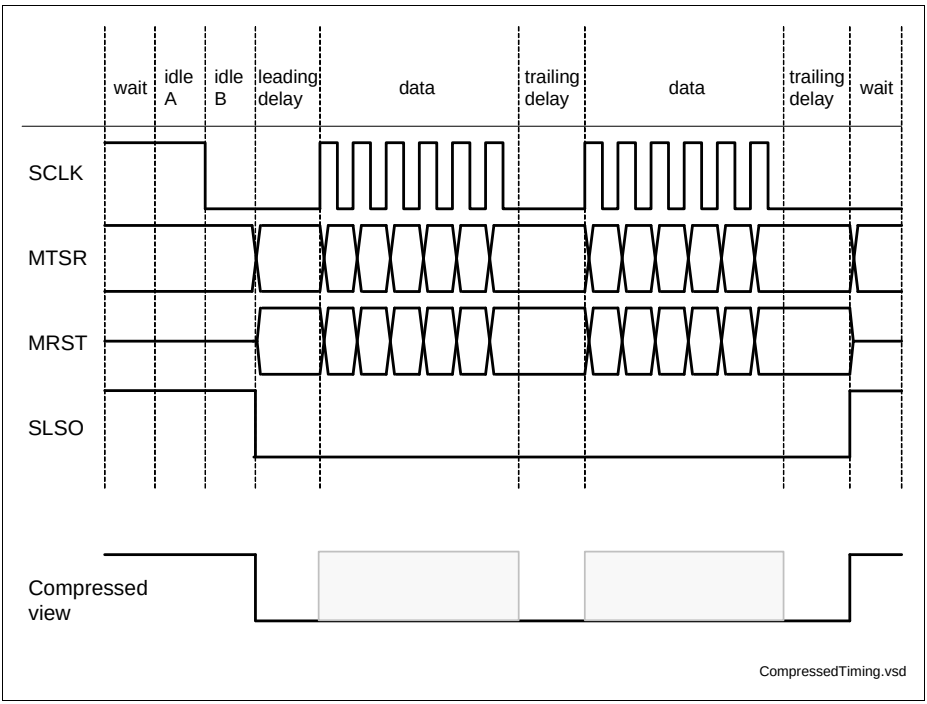

Figure 19-8 Phases of a QSPI Frame (Example for Data Length of 5 Bits)

The flexible timing control of the QSPI allows to program each phase in a very wide time range, with sufficient precision. Some examples of QSPI frames, in compressed view, with different lengths of the phases, are shown in **Figure 19-9**.

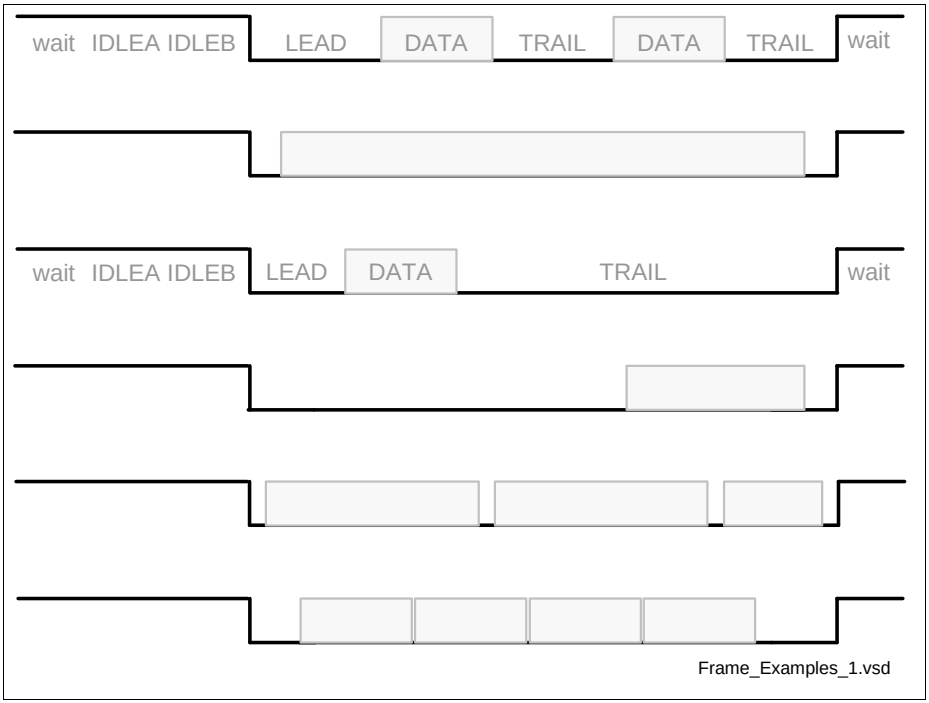

Figure 19-9 Examples of QSPI Frames in Compressed View

The length of the phases is programmed using the corresponding bit fields in the register **BACON**. There are four main bit fields defining the length of the phases in t_Q units and several modifier bit fields defining their range and granularity:

- IDLE
- LEAD
- DATA
- TRAIL

The WAIT phase is simply a loop waiting for a write to the Tx FIFO, without predefined duration, and consequently without a defining bit field.

The IDLE bit field defines two sub-phases with the same length IDLEA and IDLEB. At the transition between them the polarity of the serial clock signal for the next slave is set / changed.

In addition, the flexible timing control allows to program the duty cycle and the sampling point properties of the serial clock. This allows to improve to a certain extent the achievable baud rate taking into account the clock asymmetries and the loop-delay.

The **ECON** bit fields A, B and C define the length of the corresponding bit segments.

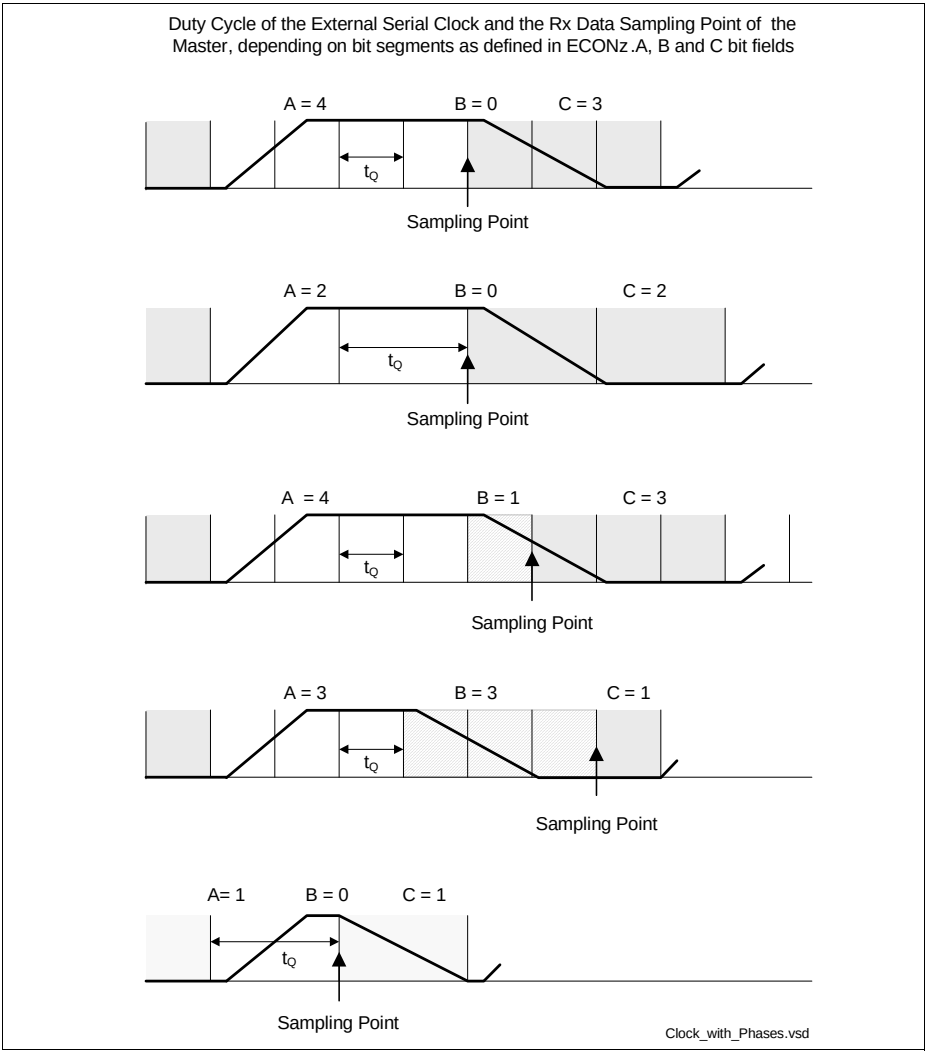

Figure 19-10 Control of the Duty Cycle and the Sampling Point of the Serial Clock

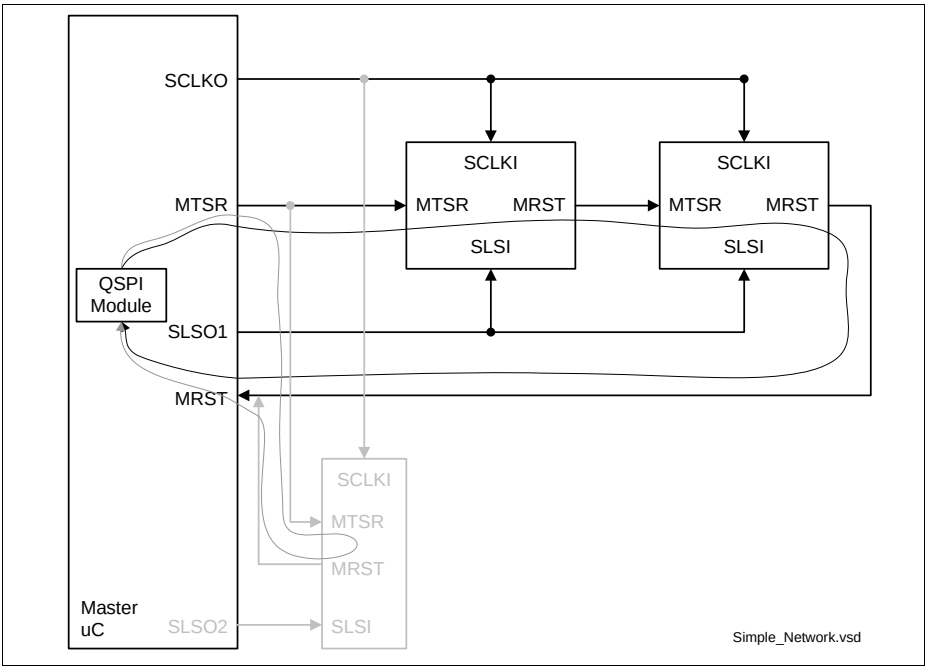

Figure 19-11 Closed-loop delays in a simple network consisting of one daisy-chain and one point to point connection in parallel

The purpose of the duty cycle control is:

- to compensate the influence of the path and pad asymmetry on the duty cycle
- to compensate the considerable asymmetry of the edges in case of half-duplex connection implemented as open-drain driver with pull-up resistor
- to adjust the duty cycle optimally to the timing properties of the master and slave, and to the properties of the connection (distance and capacitive load)
- to help achieve optimal baud rate, especially at higher baud rates which need an odd division factor (for example 5 = 3 high time + 2 low time or 5 = 2 high time + 3 low time)

The purpose of the sampling point control is to allow reliable reception of the data transmitted by the slave, at as high as possible baud rates.

In master receive direction the slave transmitted data reaches the master considerably late relative to the shift edge of the serial clock. This is caused by the loop delay consisting of:

- the traveling time of the shift clock edge from the master to the slave
- the reaction time of the slave
- the traveling time of the data from the slave to the master

Last but not least, the flexible timing control allows to control the phase and the polarity of the shift clock.

The clock polarity is configured by bit field **ECON**z.CPOL. This bit field sets the clock idle polarity to low or high.

The clock phase is configured by bit field **ECON**z.CPH. This bit field sets the initial clock delay to 0 or Bit Segment A, as defined by the bit field **ECON**z.A.

The CPOL and CPH settings control the master mode. The slave mode timing behavior is fixed to CPOL=0 and CPH=1, and these values must be programmed in the **ECON** register pointed by **BACON**.CS.

The **Figure 19-12** shows the QSPI timings for clock phase CPH = 0.

ECON.CPH = 0 is used when communicating with a slave that delivers a valid value of the first bit immediately after being selected with an SLS signal. In such a case the first clock edge in a frame is used to latch the first bit. The second edge delivers the second bit value, and so on. The last edge in a frame delivers a bit with don't care value.

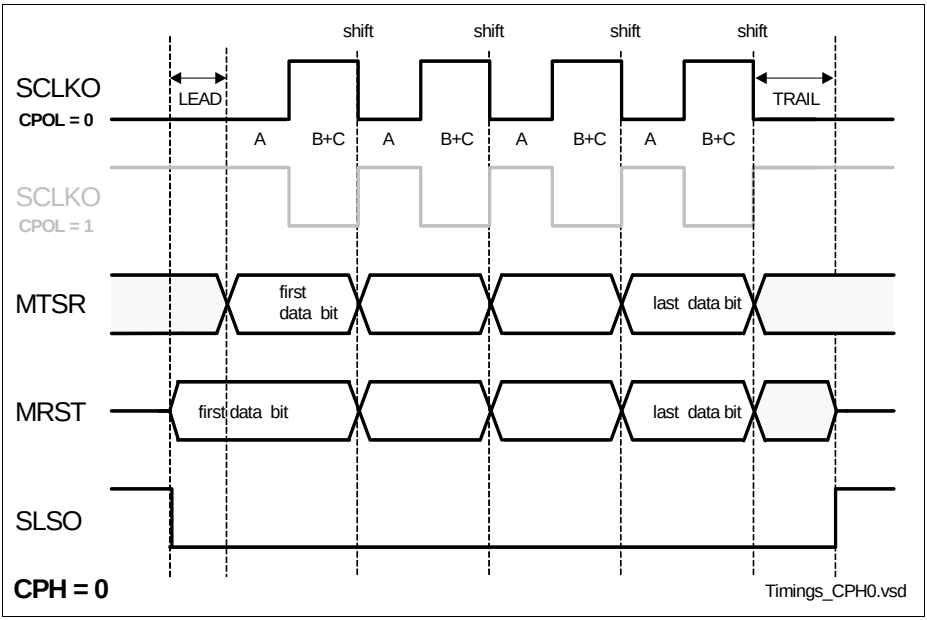

Figure 19-12 Timing of a transfer with CPH = 0 (Example for Data Length of 4 Bits)

The trailing delay starts after the last shift clock period of a data block and is followed either by the deactivating edge of SLSO, or a new data block in continuous mode.

Attention: If CPH = 0, then the total delay between the SLSO activating edge and the first edge of the serial clock SCLKO is LEAD + ECONz.A

Figure 19-13 shows the QSPI timings for clock phase CPH = 1.

ECON.CPH = 1 is used when communicating with a slave that delivers a bit with a random or don't care value immediately after being selected with the SLSO signal. In such a case the first clock edge in a frame is used by the slave to shift out the first valid data bit. The second edge latches this bit value, and so on. The last edge in a frame is used to latch the last valid data bit, which normally remains driven until the end of the frame.

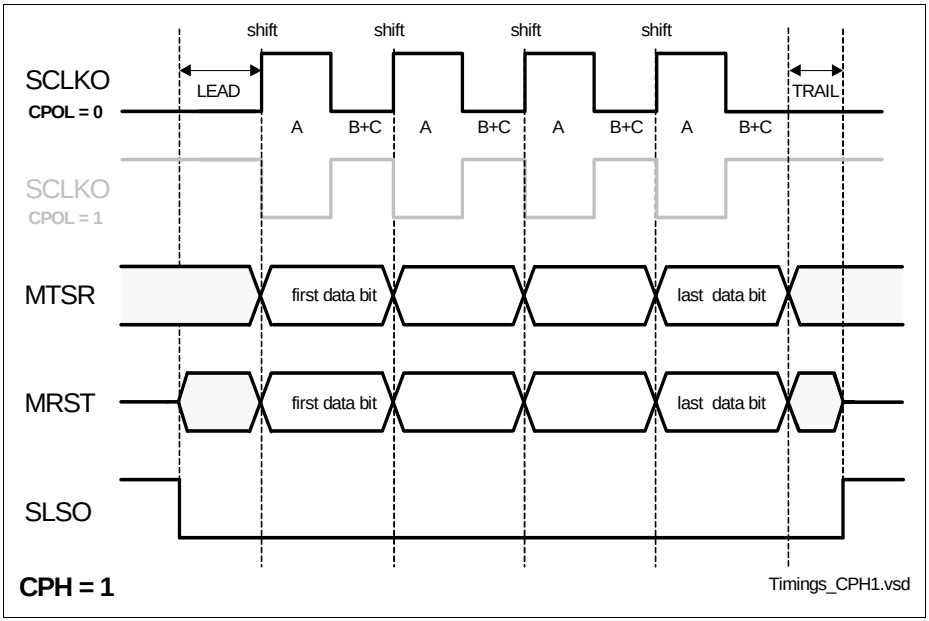

Figure 19-13 Timing of a transfer with CPH = 1 (Example for Data Length of 4 Bits)

The leading delay lasts between the active edge of the SLSO and the first shift clock edge.

Attention: If CPH = 1, then the total delay between the last edge of the SCLKO and the SLSO deactivating edge is TRAIL + ECONz.B + ECONz.C

19.5.2 Configuration Extensions

This section describes the possibilities available for configuring the phases of the QSPI communication: timing delays, data lengths, their ranges and granularity.

The QSPI module controls 16 communication channels, which are individually programmable. Each channel is associated to one slave select output and to the corresponding timing and other properties (baud rate, delays, data width, parity...).

The 16 slave select channels of the QSPI module are subdivided in two groups of 8 slave select channels:

- Channels 0 to 7
- Channels 8 to 15, channel 8 having the same **ECON** settings as channel 0, channel 9 as channel 1, and so on.

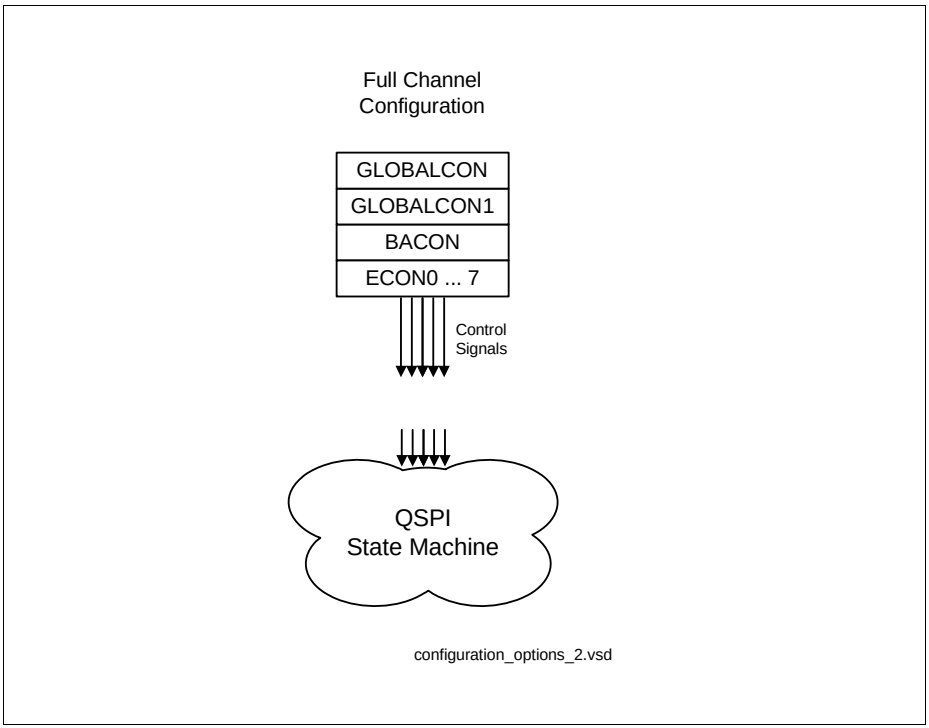

Figure 19-14 Flexible Configuration Concept

19.5.3 Details of the Baud Rate and Phase Duration Control

The QSPI phases correspond to states of a simple state machine defining a sequence of simple states and loops. Due to the strict sequential nature of the communication cycle one timer is enough to define the length of each phase. The length of each phase is defined in time quanta, and the length of a time quantum is defined by a time quantum timer. Each QSPI slave select channel has its own time quantum length, based on the module time quantum length:

T_{BAUD2} clock period -> one module time quantum -> one channel time quantum

Each QSPI module generates a module time quantum which is further downscaled to a channel quantum. This affects both the delays and the baud rates. The assumption is that the pad strength setting, the capacitive load and the corresponding QSPI network layout properties do not allow extreme differences in the baud rates for the different slaves connected to one module. They all have similar speed range: high speed, or medium speed, or low speed. Mixing very high speed and very low speed slaves does not make much sense. Many slaves produce high accumulated capacitive load on the clock and data outputs, which influences the possible baud rates for all slaves. Variations in the baud rates of the slaves of one module in the range of 6:1 is possible by varying the bit segment phases in each channel. Additional two-bit counter per slave allows for additional scaling of 1, 2, 4, or 8, making a total bit-time variation of 48:1 between the channels in one module possible.

Each QSPI slave select channel has its own set of phase lengths, depending on $T_{BAUD2} = 1 / f_{BAUD2}$

- $T_{SCLKz} = T_{BAUD2}$ * **GLOBALCON**.TQ * **ECON**z.Q * (A + B + C)
- $T_{LEAD} = T_{BAUD2}$ * **BACON**.LPRE * **BACON**.LEAD
- $T_{TRAIL} = T_{BAUD2}$ * **BACON**.TPRE * **BACON**.TRAIL
- $T_{IDLEA,B} = T_{BAUD2}$ * **BACON**.IPRE * **BACON**.IDLE
- $T_{STROBE} = T_{BAUD2}$ * **GLOBALCON**.TQ * **ECON**z.Q * **GLOBALCON**.STROBE

*Note: The equations above contain the representative decimal values of the bit-fields in corresponding units, not their actual binary bit-value. For the formulas using the actual binary values of the bit-fields, see **Figure 19-16** and **Figure 19-17**.*

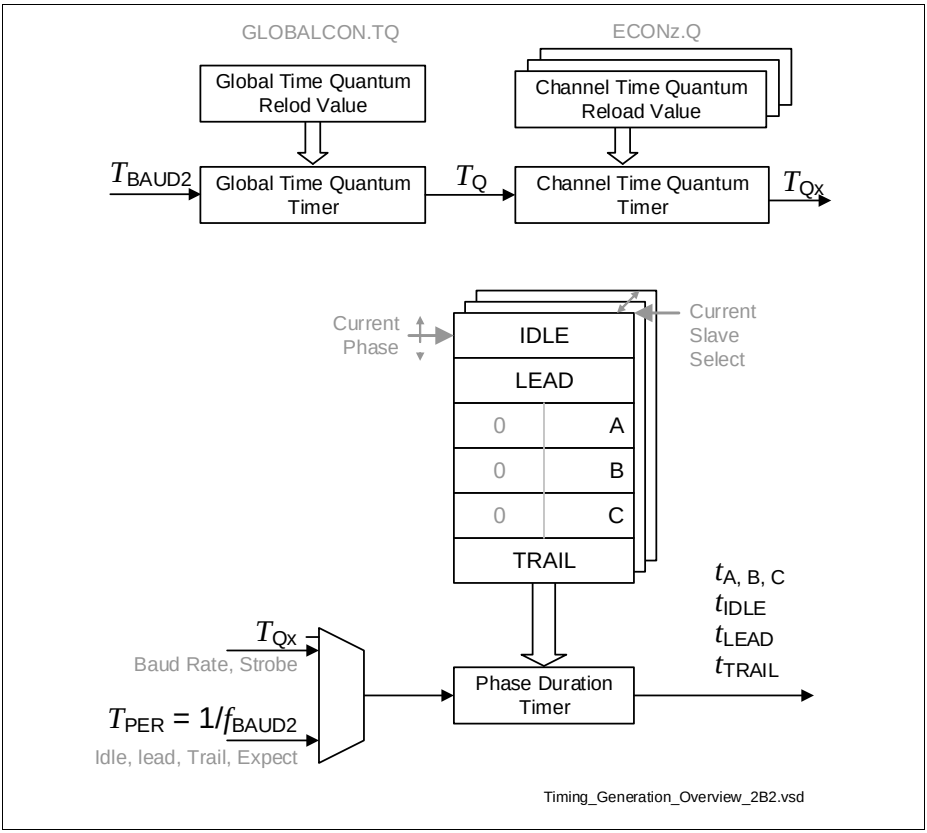

Figure 19-15 Phase Duration Control, Overview

19.5.4 Calculation of the Baud Rates and the Delays

This section gives another alternative view to the calculation of the baud rate and the duration of the delays.

The baud rate generation chain for a channel starts with a common TQ divider. The resulting global time quantum is used by the dedicated Q and A,B,C dividers to generate the baud rates per channel (slave select). See **Figure 19-16**.

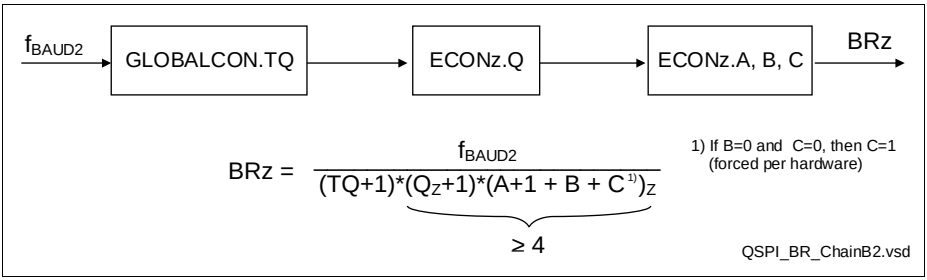

Figure 19-16 Baud Rate Calculation

Attention: The following condition must be satisfied: (Q+1)*(A+1 +B +C) >= 4. Or alternatively formulated: bit length must be at least 4*T_Q.

Each delay of an active channel (slave select) has a separate and independent divider chain starting with a power-of-four prescaler and an n-divider. See **Figure 19-17**.

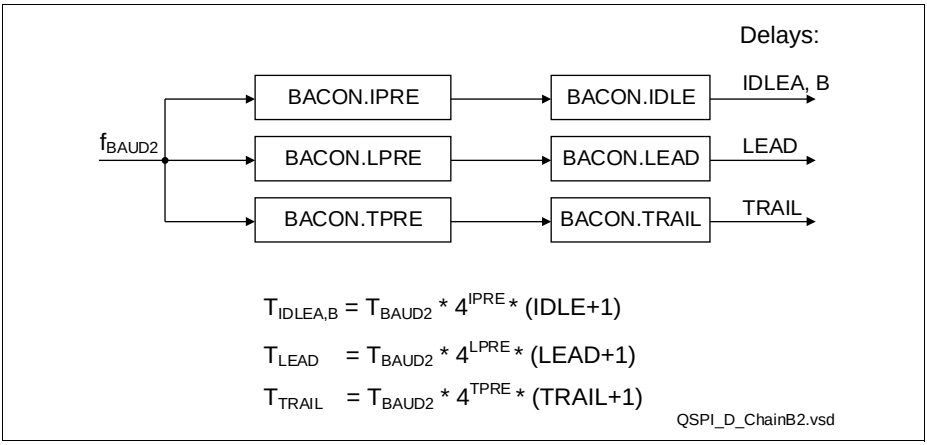

Figure 19-17 Calculation of the delays

19.5.5 State Diagram of Standard Communication Cycle

Figure 19-18 shows the top view of the standard communication cycle of the QSPI state machine in a hierarchical way. The “Data” state consists of a loop of several “Bit” states, where the number of repetitions is defined with the data width bit field. Each “Bit” state consists of a simple sequence of “A”, “B”, and “C” states.

A complete (or standard) communication cycle containing all phases, starting with activating the slave select and ending with its deactivation, is executed only if the bit **BACON**.LAST = 1. Otherwise, the slave select remains active and the module waits for more FIFO data entries.

The Phase Transition Interrupt PT (events PTI1 and PTI2) signal one out of all phase transitions which are shown in **Figure 19-18**, selected by the bit fields **GLOBALCON**.PT1 and PT2.

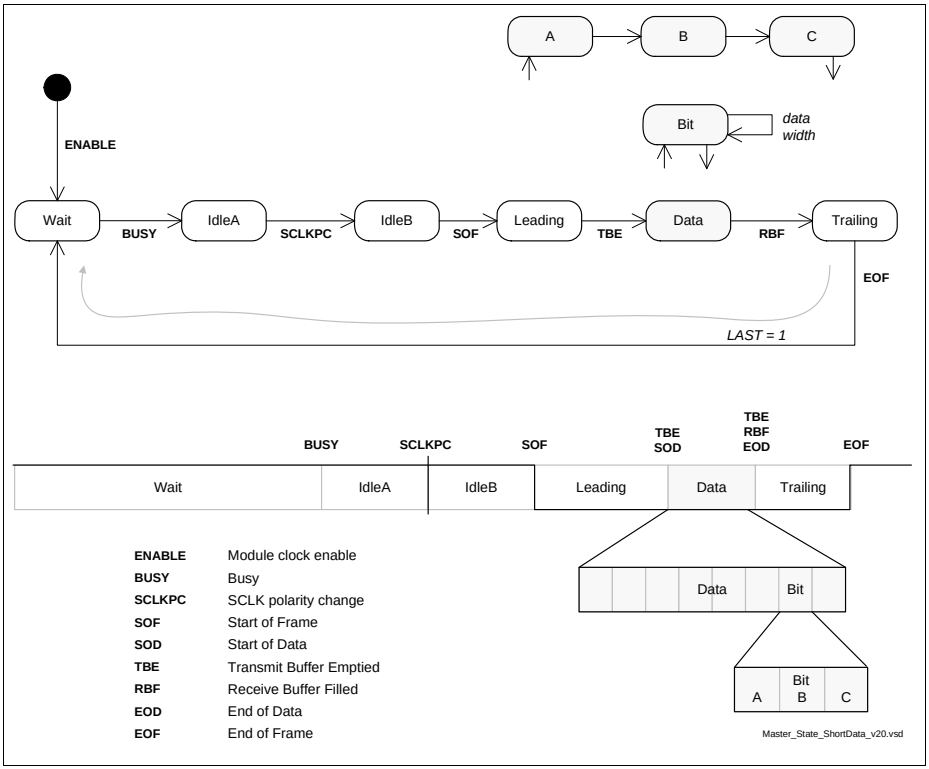

Figure 19-18 Standard Communication Cycle of the State Machine (Short Data)

(>>**Interrupts**)

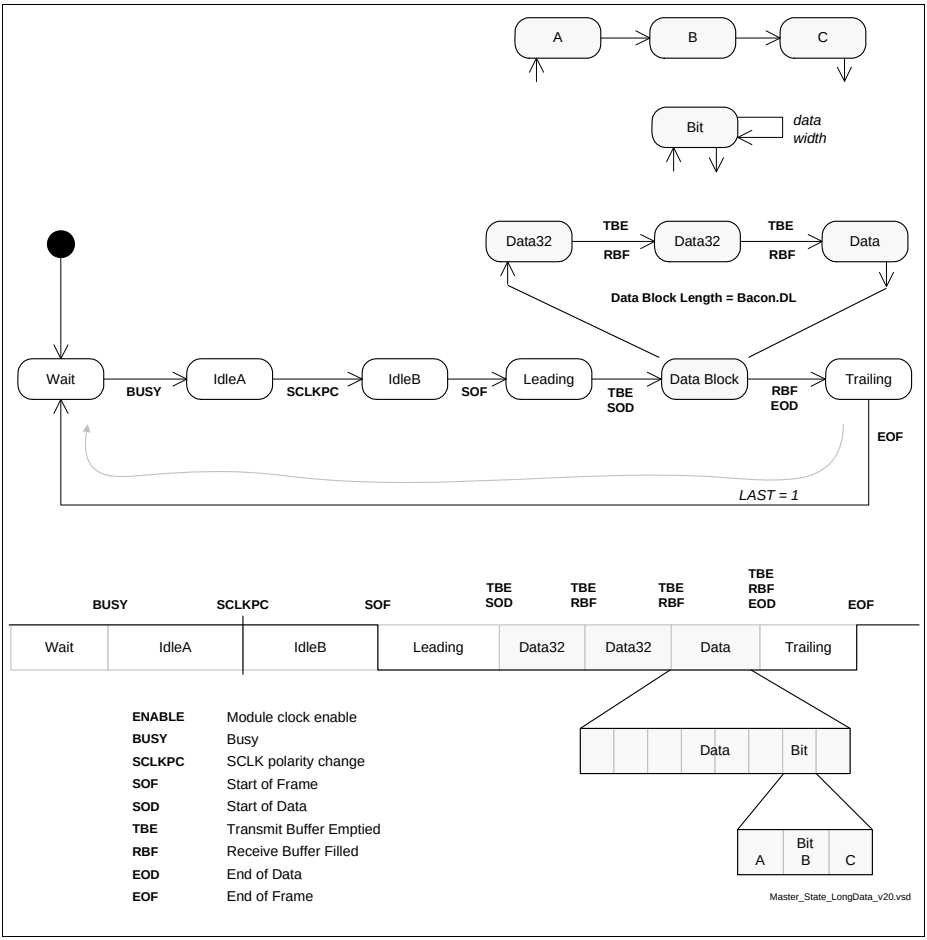

Figure 19-19 Standard Communication Cycle of the State Machine (Long Data)

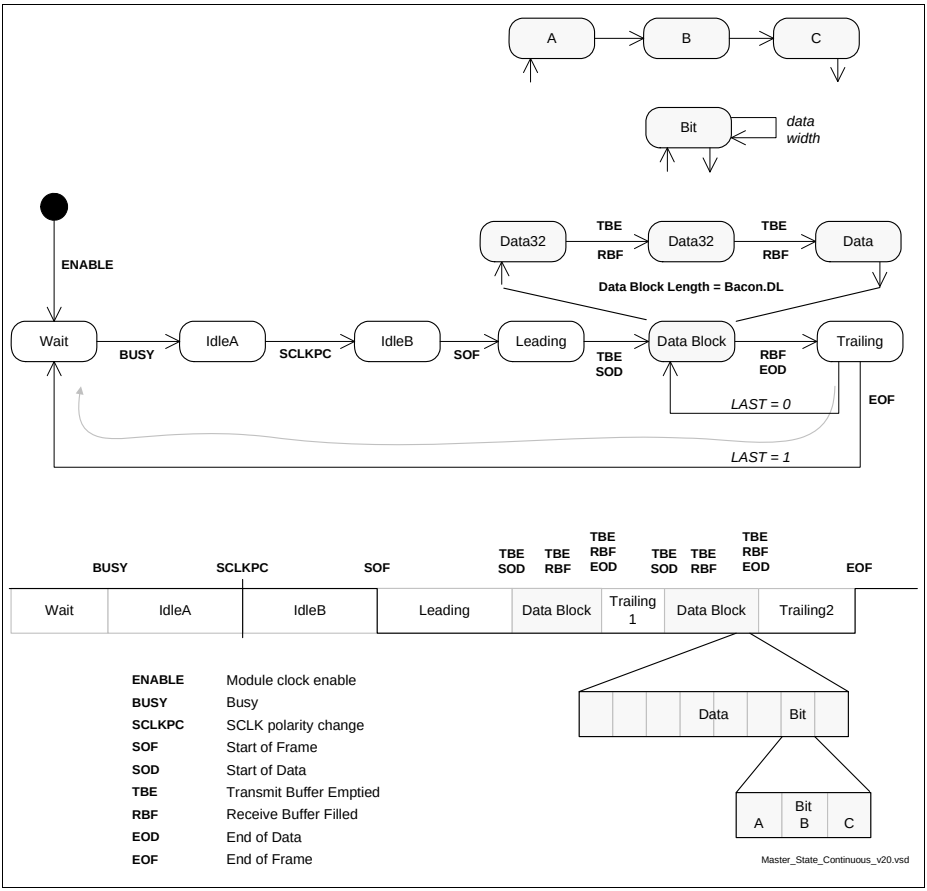

Figure 19-20 Standard Communication Cycle of the State Machine (Continuous)

19.5.6 Expect Phase

Figure 19-21 shows the EXPECT state in the QSPI state machine diagram. This state can be entered in the long data mode and in the continuous mode, where one frame consists of more than one TXFIFO entries. Its purpose is to provide monitoring of the latencies on the FPI bus. In this case, after one FIFO entry has been shifted out and the module expects more bits to shift, according to the **BACON**.DL, a time-out counting starts. If the expected FIFO entry does not come in time, a time-out occurs.

The duration of the EXPECT state is zero if at the end of the current DATA state the new data is already available in the FIFO.

The duration of the EXPECT state can be anywhere between zero and the programmed upper limit, if the next data is written into the TXFIFO any time within the allowed time window. In this case the current frame continues with the SLSO signal remaining active.

The duration of the EXPECT state is exactly maximum if the data did not come in time. Then the current frame is stopped, but the SLSO is not deactivated. A TO (Time - Out) interrupt is raised. The state machine continues the EXPECT state in a loop, waiting for the software intervention, generating an interrupt signal after each expect time interval.

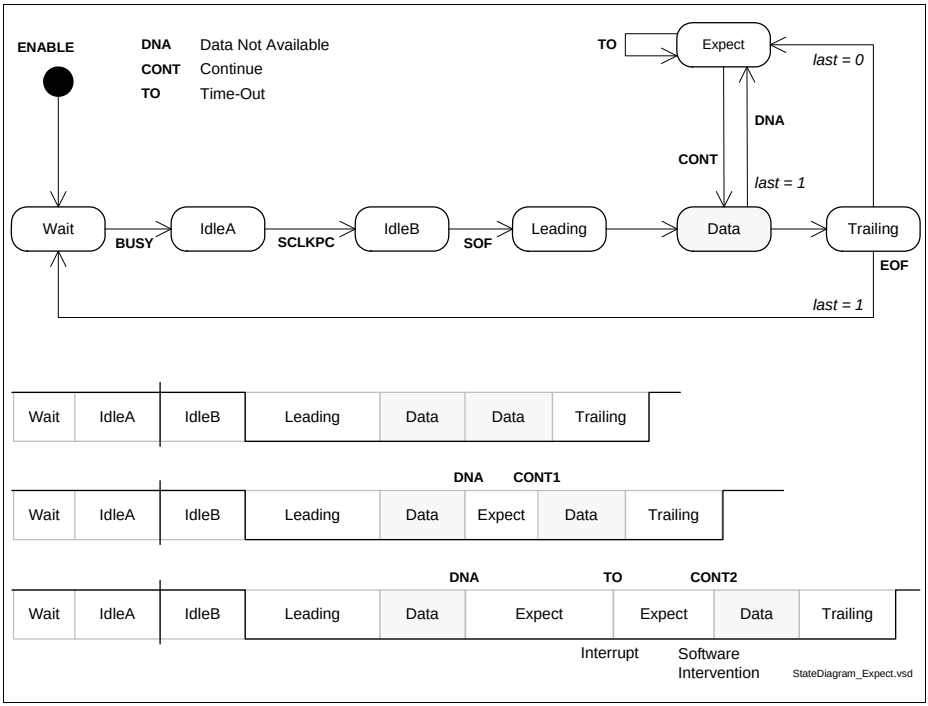

Figure 19-21 EXPECT Cycles of the QSPI State Machine

19.5.7 External Slave Select Expansion

In this mode the bit field **BACON**.CS drives directly the SLSO1 to SLSO4 signals, not demultiplexed by the QSPI, but chip-externally. **SSOC**.AOL bits can invert the SLSO0...4 signal levels individually; **SSOC**.OEN bits enable them. See also **GLOBALCON**.DEL0.

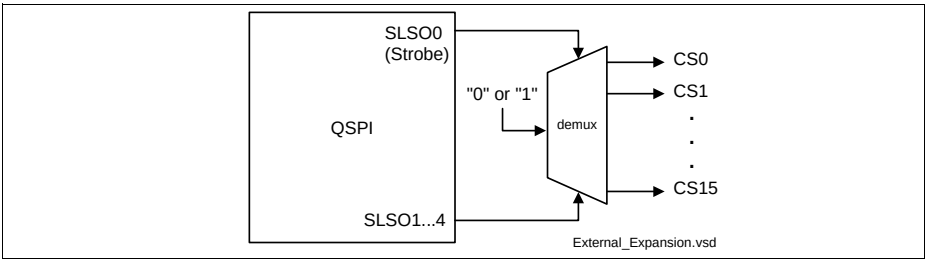

Figure 19-22 Demultiplexing the Slave Select Signals Externally

In order to ensure glitch free selection, a strobe signal is provided, driven at SLSO0 pin. This signal is delayed relative to the SLSO1...4 signals for LS (Lead_Strobe) and TS (Trail_Strobe) delays, equal in duration and configurable in the range of 1 to 16* f_{BAUD2}. The duration of the LS and TS delays is set in the **GLOBALCON**.STROBE.

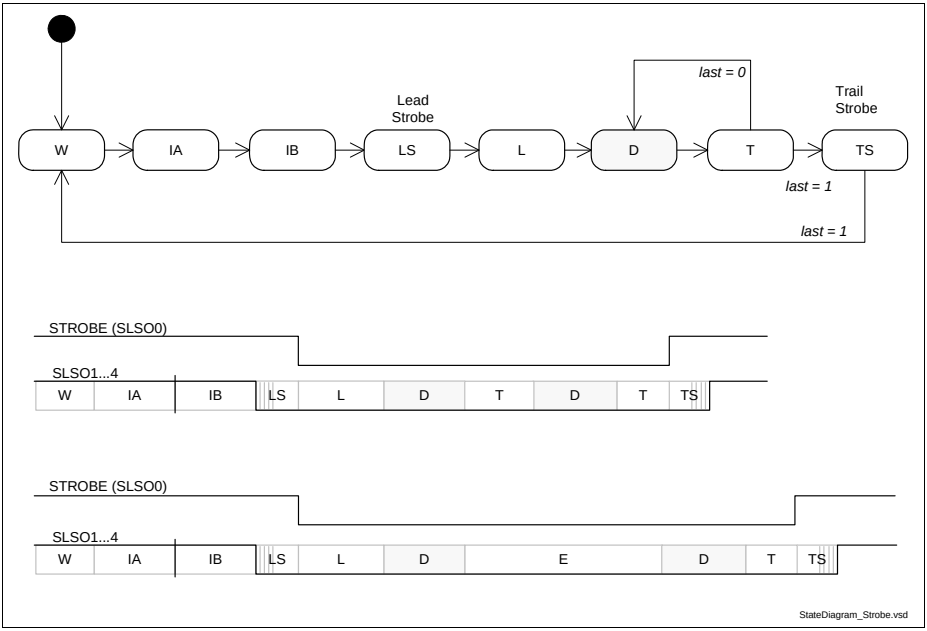

Figure 19-23 State Machine and SLS Signals in Strobed Mode

19.6 User Interface

This section describes the possibilities available for transferring data between the on-chip RAM memories and the QSPI module using the transmit and receive FIFOs. The QSPI features one 4 x 32-bit Tx FIFO and one 4 x 32-bit Rx FIFO. The address ranges for writing data and configuration to the Tx FIFO and for reading data and configuration from the Rx FIFO consist of address locations with special properties:

- Tx FIFO
  - DATA_ENTRY - writes to any of these eight functionally identical locations are always interpreted as data
  - BACON_ENTRY - writes to this location are always interpreted as configuration
  - MIX_ENTRY - writes to this location are interpreted as data or configuration, based on a set of rules
- Rx FIFO
  - RX_EXIT - reads from this location deliver either data or data and status, based on a set of rules.

19.6.1 Transmit and Receive FIFOs

The Tx_FIFO is filled with both configuration and data entries, which are distributed to the **BACON** and the shift register at the exit of the Tx_FIFO. The TxFIFO keeps track if an entry is configuration or data. The control and the data elements are automatically distributed to the **BACON** and shift register. If no data is available, the new BACON is pending.

If a frame is finished and there is data in the FIFO

- in short mode, a new frame starts automatically with the same configuration as the last one.
- in long mode, the extra data are ignored.

TXFIFO error conditions:

- FPI bus write to a full TXFIFO generates an overflow interrupt. The write is ignored.
- In case of slave mode, (**GLOBALCON**.MS = 1X), in case of an underflow, only “1” are delivered.

RXFIFO error conditions:

- FPI bus read from an empty RXFIFO generates an underflow interrupt, and delivers only “1” bits.
- Hardware attempt to write a full RXFIFO with data or status generates an overflow interrupt. The write attempt is ignored by the RXFIFO.
- If the **GLOBALCON**.SRF bit is set, the communication is stopped in case of full FIFO in master mode. In slave mode, the bit is ignored, no stop can be done.
- If the FPI bus frequency is very slow, and the baud rate very high, it can happen that some data is lost on the way between the shift register and a not full RXFIFO. In such a case, an overflow interrupt is generated, although the RXFIFO is not full.

The Rx_FIFO can be filled with both status and received data entries, depending on **GLOBALCON**.SI.

Note: If a 8-bit or 16-bit write is executed to the TXFIFO entry addresses, the data is mapped 1:1 to its location within the 32-bit wide TXFIFO entry, and the rest is padded with zeros.

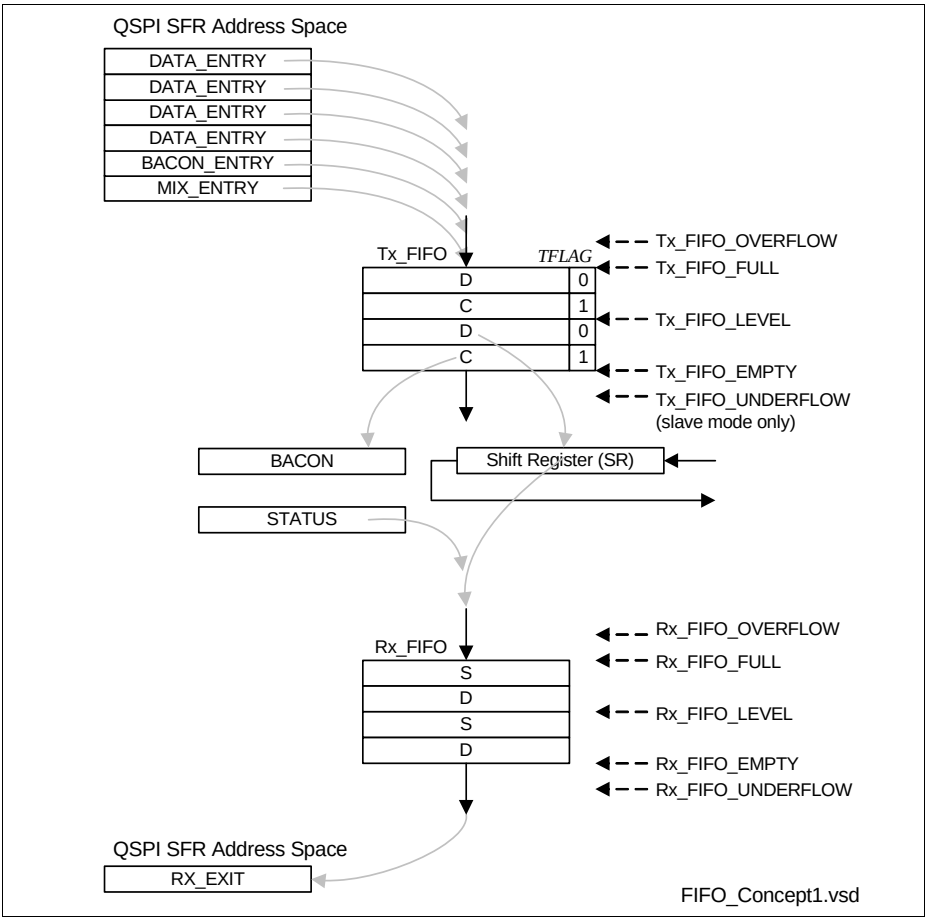

Figure 19-24 Architecture of the Tx and Rx FIFOs

(>>**Interrupts**)

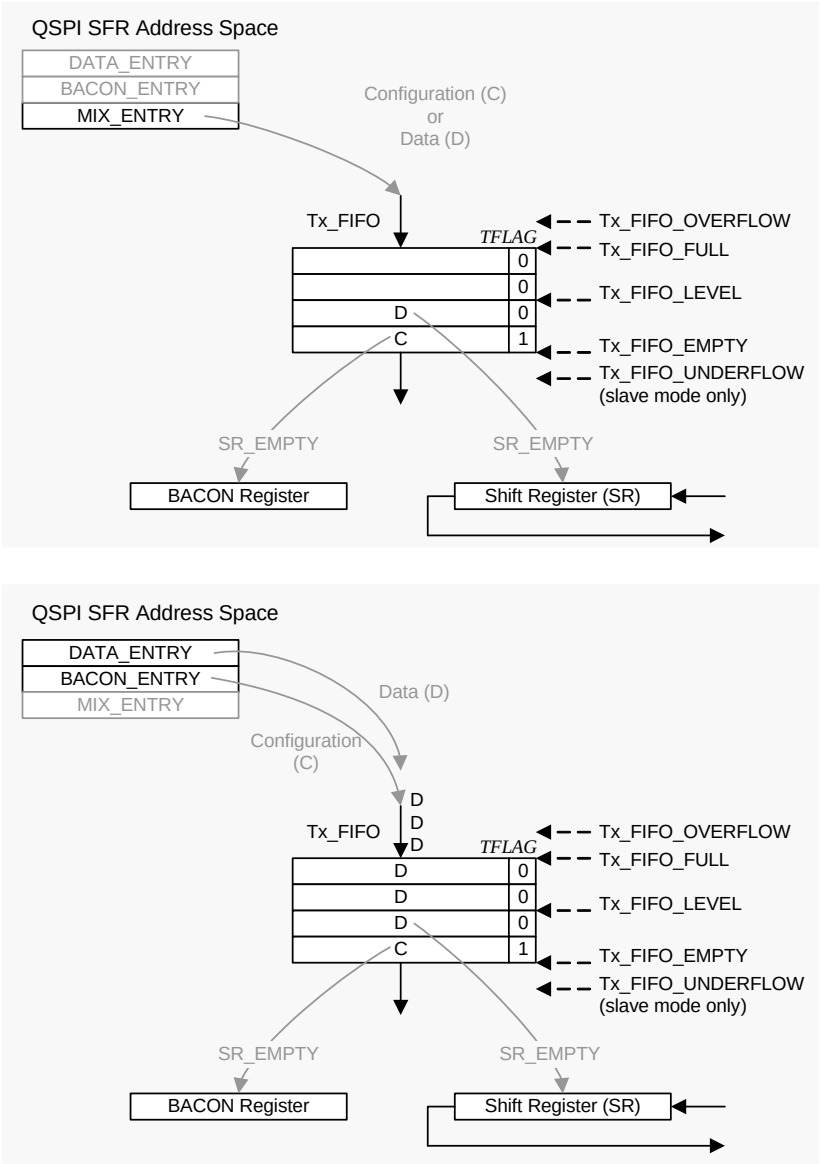

Figure 19-25 Using Tx FIFO Mix and Bacon / Data Entries

19.6.1.1 Short Data Mode

In Short Data Mode, the QSPI module transmits single data with a length of 2 to 32 bits in one frame. This mode is defined by **BACON**.LAST = 1 and **BACON**.BYTE = 0.

The transfer cycle is a sequence of the following phases: W?_I_L_D_T. The symbol “?” means that the phase is optional (duration of 0 allowed).

For example, a Tx_FIFO event can be used to trigger one DMA transfer (consisting of two 32-bit moves) to transfer both the BACON and DATA entries from an on-chip RAM memory to the QSPI module.

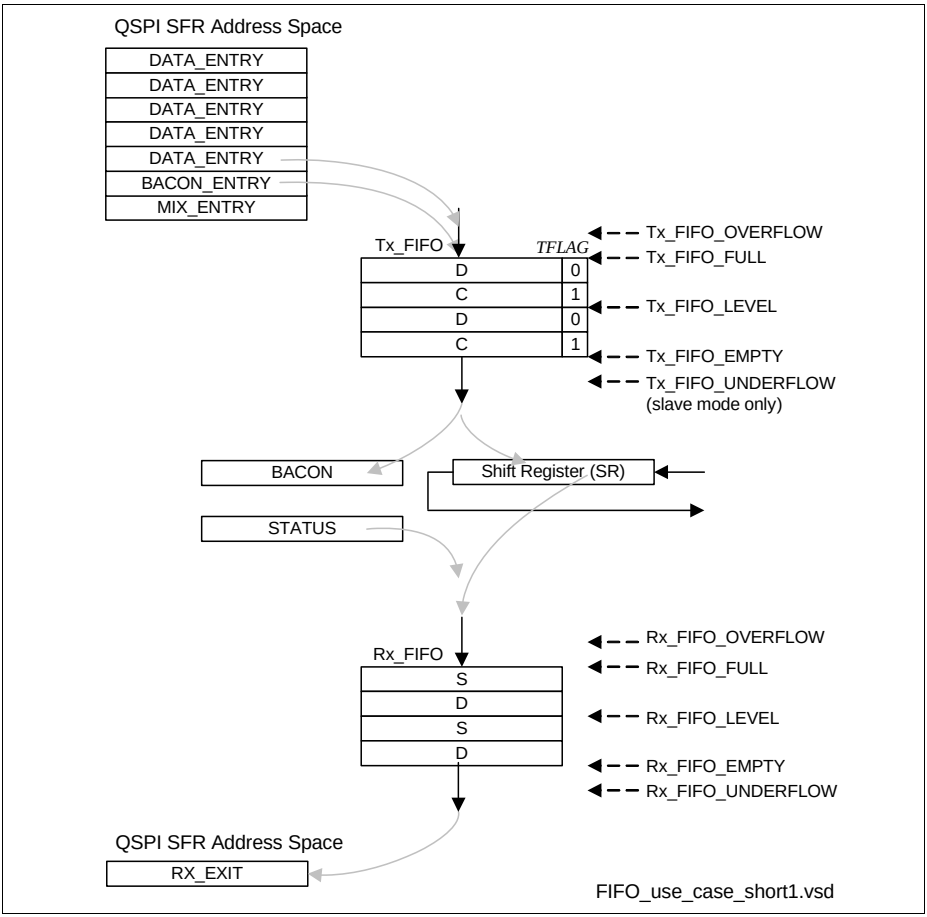

Figure 19-26 User Interface in Short Data Mode

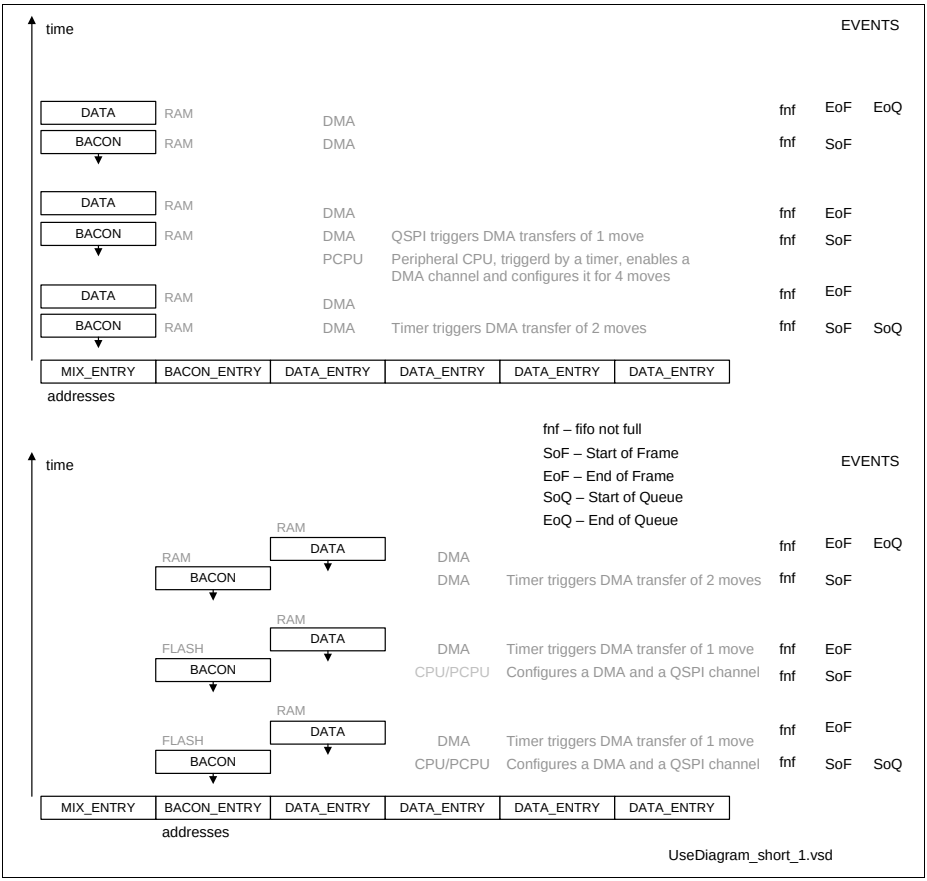

Figure 19-27 Use Diagram of the User Interface in Short Data Mode

19.6.1.2 Long Data Mode

In Long Data Mode, the QSPI module transmits bursts of up to 32 bytes (256 bits) in one frame. This mode is defined by programming **BACON**.LAST = 1 and **BACON**.BYTE = 1.

One transfer cycle in long data mode is a sequence of the following phases: W?_I_L_D_T. The W_I_L_D_T_I_L_D_T sequence is possible. The symbol “?” indicates that the phase is optional (duration of 0 allowed). Each “D” indicates a data length as defined with **BACON**.DL and **BACON**.BYTE, that is, up to 256 bits. One “D” is made of a number of 32-bit TXFIFO entries “d” and one rest at the end “b”, which can be written as D=ddddddb.

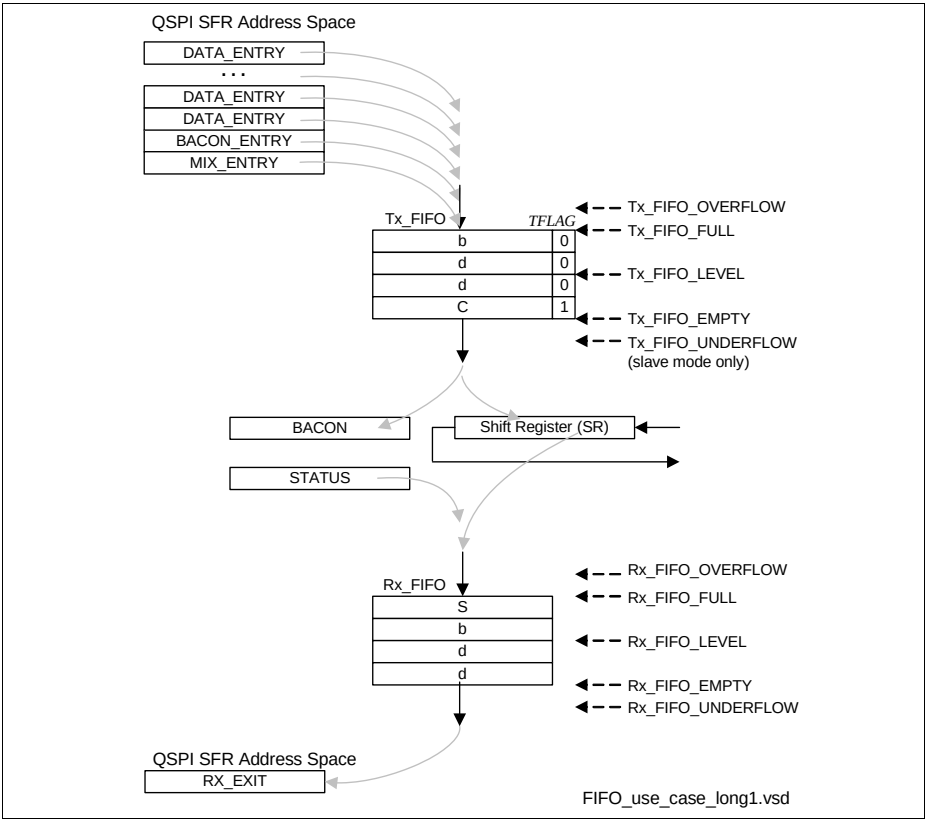

Figure 19-28 User Interface in Long Data Mode

In a DMA transfer example, a Tx_FIFO_EMPTY event can be used to trigger one DMA transfer (consisting of, for example, four 32-bit moves) to transfer the BACON and three DATA entries from RAM memory to the QSPI module. The three data words could

contain 80 bits (10 bytes) of data. The three data words could also contain 40 bits (5 bytes), 64 bits (8 bytes) plus one dummy word. In this way short bursts of up to 96 bits can be transmitted.

In such 4 words DMA transfer example, the Tx_FIFO event can be used to transfer two 32-bit words per transfer.

If a configuration word is written when a data word is expected, the configuration word is ignored, and an Unexpected Configuration Error is raised.

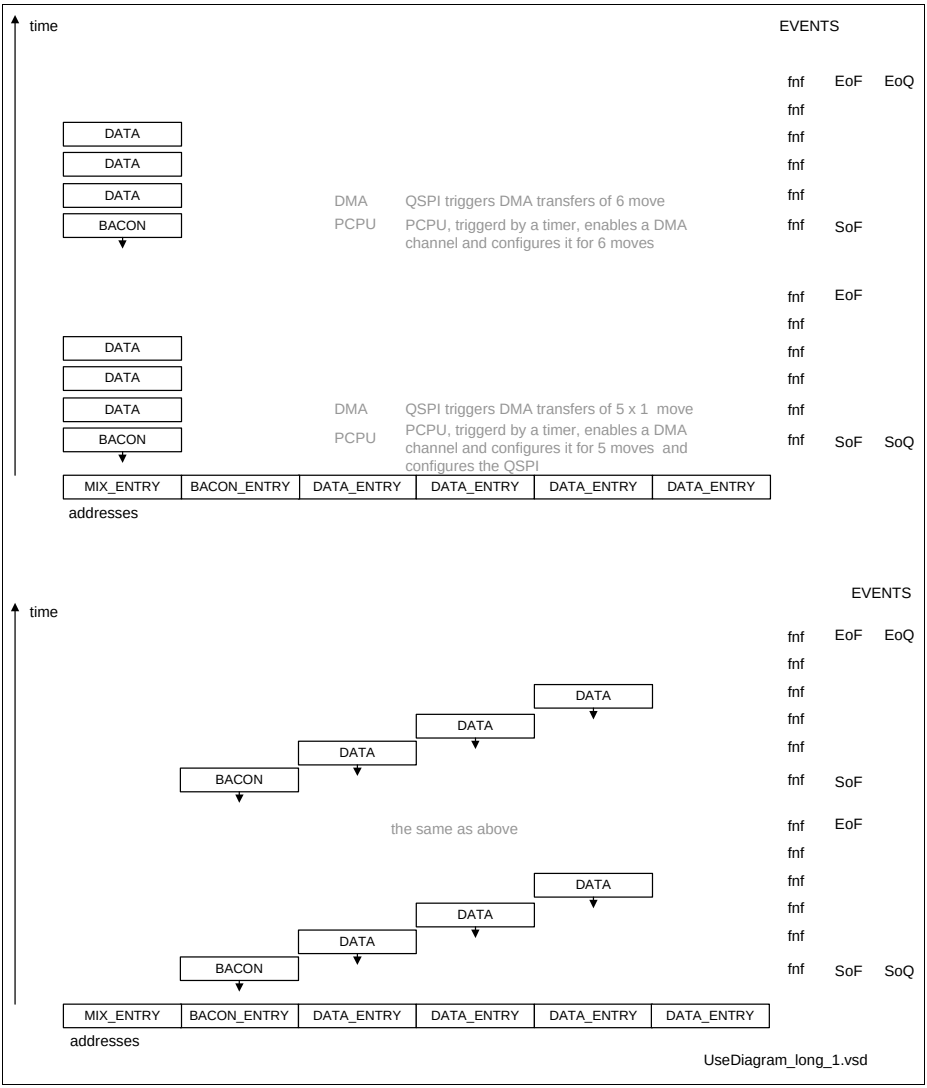

Figure 19-29 Use Diagram of the User Interface in Long Data Mode

19.6.1.3 Continuous Data Mode

In Continuous Data Mode, the QSPI transmits a stream of data with an arbitrary length with an active slave select signal. It can be used with both short and long data.

This mode starts by programming a control word containing **BACON**.LAST = 0 and the first data. The communication continues with the subsequent data entries written. The mode ends with a control word containing **BACON**.LAST = 1 and the last data. If LAST = 0, then TRAIL is a delay between data blocks. The W_I_L_D_T_D_T_D_T sequence appears. Each “D” represents data block as defined with **BACON**.DL and **BACON**.BYTE (up to 256 bits). If LAST = 1 then TRAIL is trailing delay, see **Figure 19-9**.

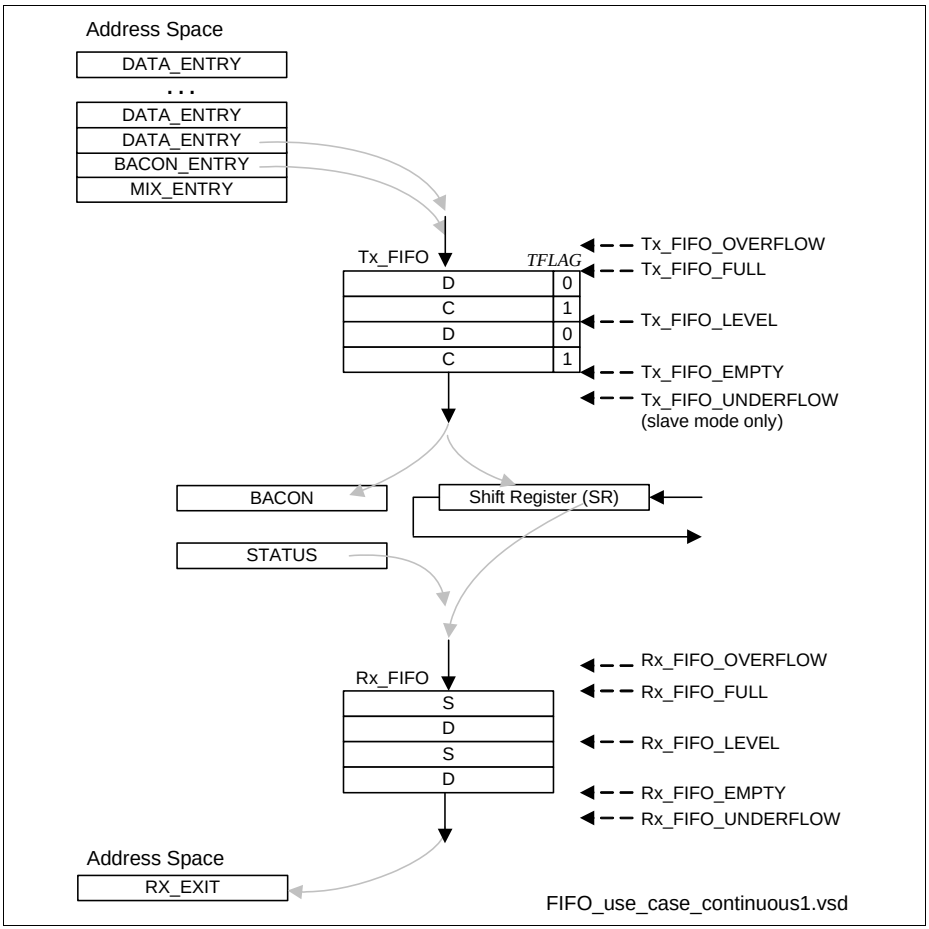

Figure 19-30 User Interface in Continuous Data Mode

The **Figure 19-31** shows an example of continuous data mode using short data. Here, the CPU starts the stream by writing BACON to the BACON_ENTRY address, and afterwards a DMA transfers the whole stream except the last BACON and DATA.

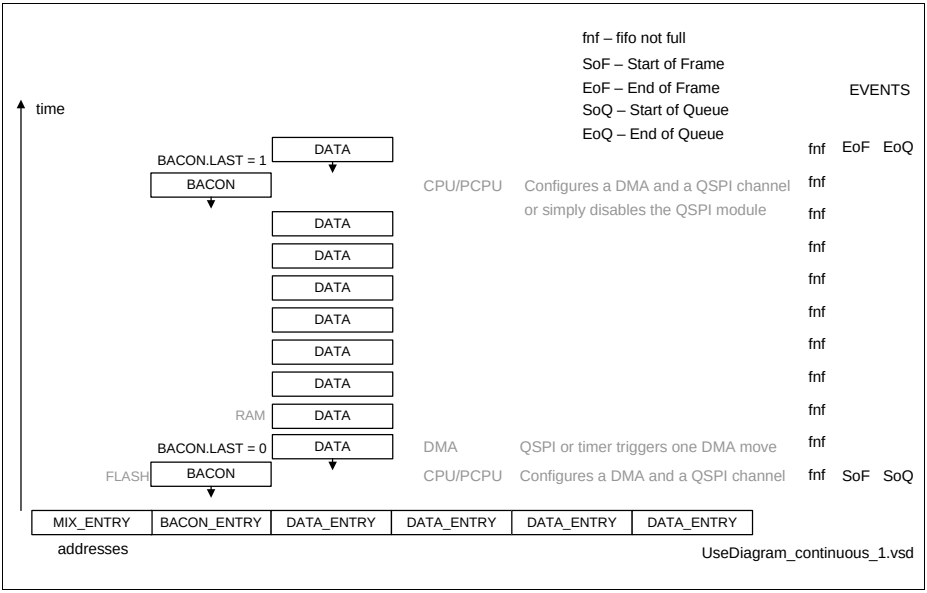

Figure 19-31 Use Diagram of Continuous Data Mode with Short Data

The **Figure 19-32** shows an example of continuous data mode using long data. Here, the first BACON must be repeated after each data block, but on the other hand, the whole transfer can be done using only the MIX entry and one single DMA channel, without CPU involvement. The loss of efficiency because of the unnecessary extra BACONS can be minimized by using long data blocks.

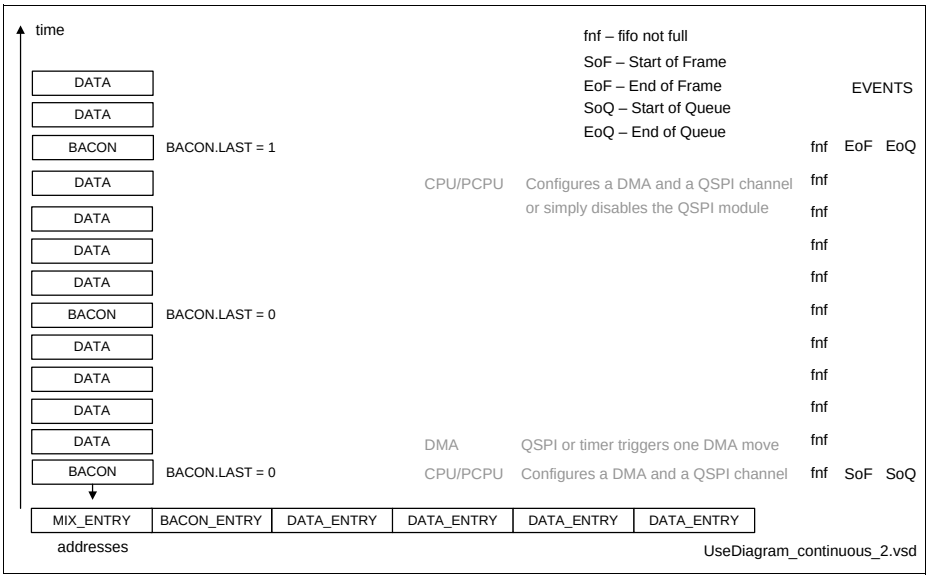

Figure 19-32 Use Diagram of Continuous Data Mode with Long Data

19.6.1.4 Single Configuration - Multiple Frames Behavior

If longer sequences of data with length of up to 16 bit have to be sent to single slave in separate frames, then the DMA move for the repeating configuration word can be saved. An example of a TxFIFO contents and the resulting message sequence is shown in **Figure 19-33**.

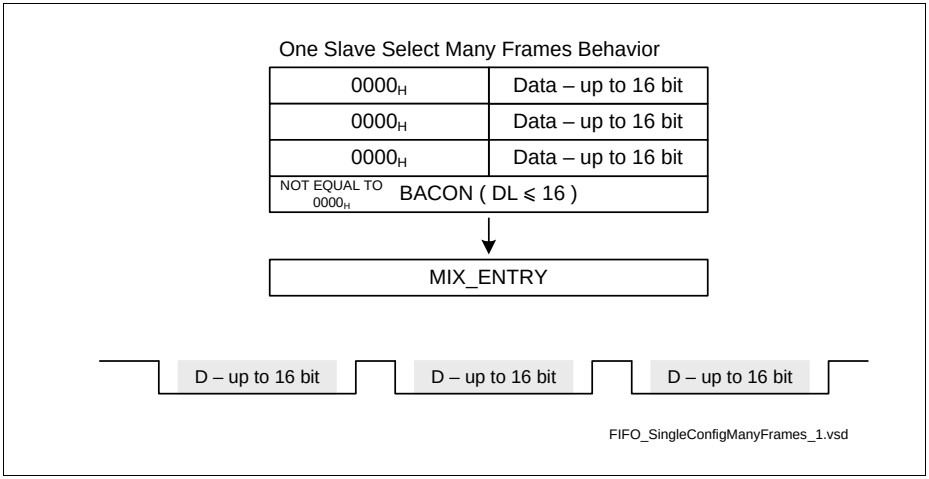

Figure 19-33 Multiple Frames to One Channel (Example of up to 16 Bit Data)

In order to support sending short multiple frames to single channel without having to send the same configuration each time, the TXFIFO follows this rule:

- If **BACON**.DL less or equal 15 (up to 16 bit data length)
- if MIX_ENTRY address is used
- then if the upper 16 bit of a 32-bit MIX_ENTRY are 0, the entry is considered data, else configuration. Note that there is no valid configuration word with upper 16 bits equal to 0.
- In such a case the TXFIFO marks the entry as data.

*Note: In case the **BACON**.LAST = 0, the slave select remains active between the frames. The behavior is equal to the continuous mode. The disadvantage of this method is that only up to 16 bits data can be transferred with one FPI bus move. The advantage is that continuous mode is possible using the mix entry.*

19.6.1.5 Big Endian Data Format

The bit-field **ECON**.BE activates the permutation of the data bytes written to the shift register and read from it to the big endian format and back.

ECON.BE allows for switching between big and little endian per slave (SLSO signal).

See **Figure 19-34** and **Figure 19-35**.

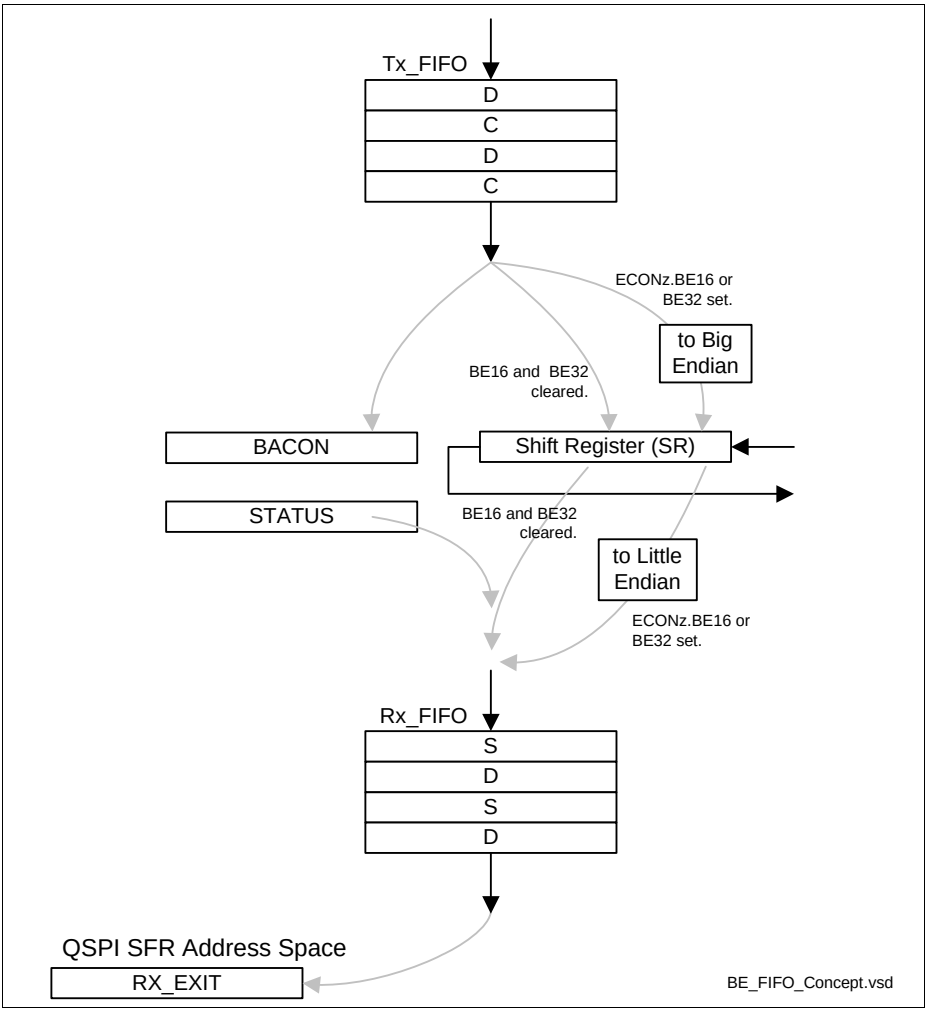

Figure 19-34 Big Endian Data Path

Converting data from little to big endian and other way around requires one and the same permutation of the data bytes, as shown in **Figure 19-34**, One permutation block is located before and one after the shift register, so that only data can be permutated, and not **BACON** or **STATUS**.

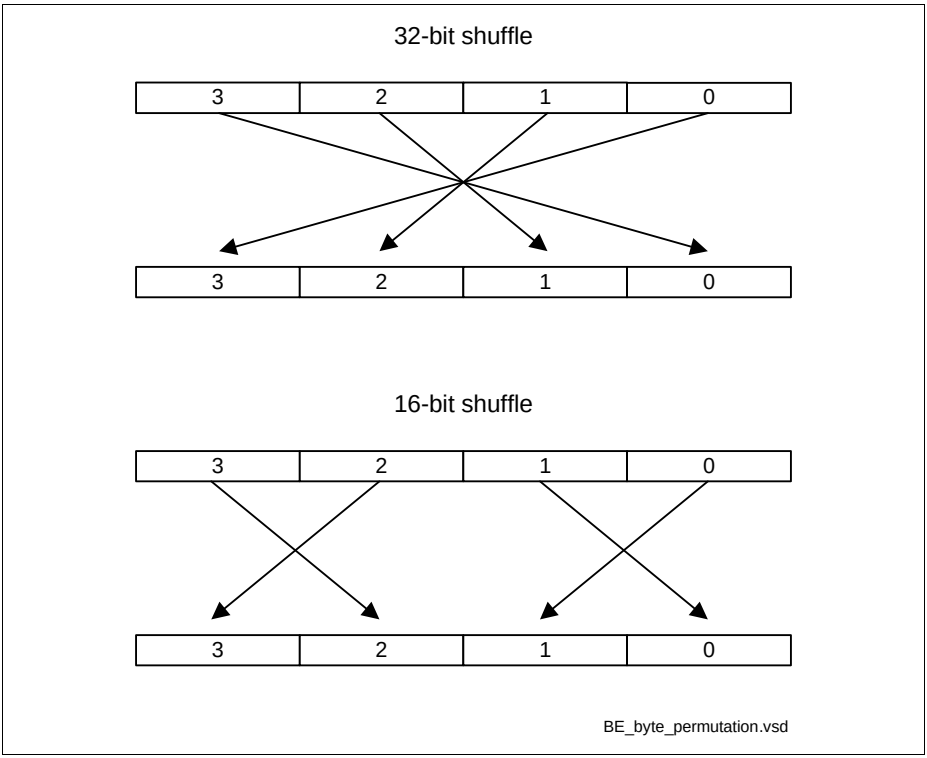

Figure 19-35 Endianness Byte Permutation

The endianness byte permutation should be used only for 16-bit and 32-bit data (and multiples of it), and not for other data lengths.

19.6.2 Loop-Back Mode

Loop Back mode is a master mode test feature used for establishing a module internal connection between the transmit and the receive signal, the same as if the transmit and receive pins would be short connected. It is actived by setting the **GLOBALCON**.LB bit.

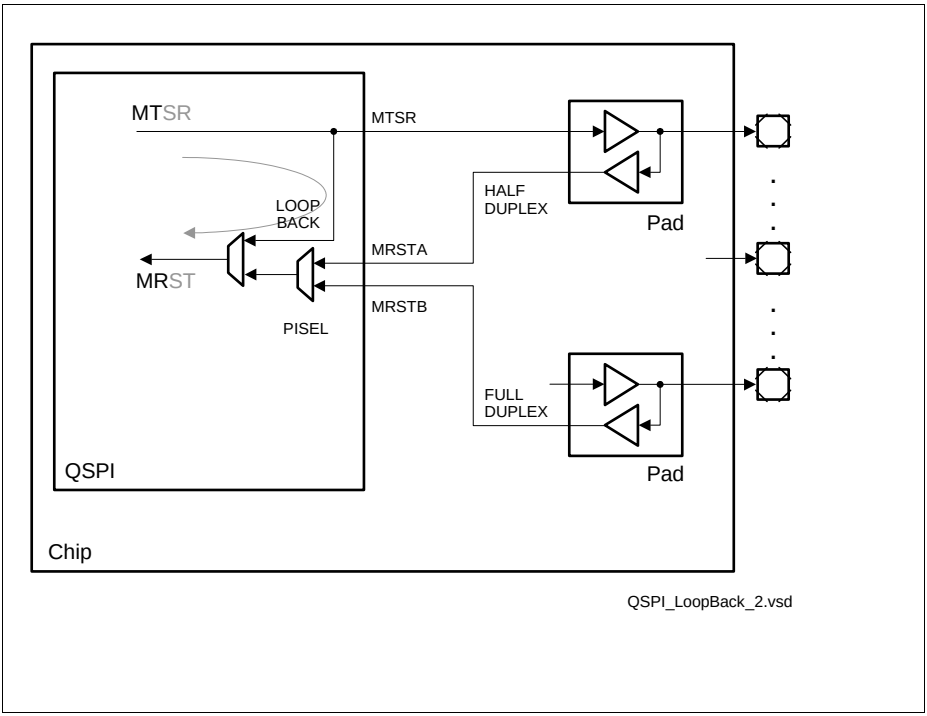

Figure 19-36 Loop-Back Mode

19.7 Interrupts

There are several types of interrupts:

- Interrupts related to the user interface
  - FIFO related interrupts
- Interrupts related to the shift engine (state machine)
  - error interrupts
  - phase transition interrupts

According to this classification, here follows the complete list of all the interrupts:

- FIFO related interrupts
  - TX - Transmit FIFO Interrupt, requests feeding of the TXFIFO, but does not signal the error events of overflow and underflow (see **Figure 19-24**)
  - RX - Receive FIFO Interrupt, requests emptying of the RxFIFO , but does not signal the error events of overflow and underflow (see **Figure 19-24**)
- ERR Error Interrupt
  - signals every error condition
  - signals TX_FIFO_OVERFLOW, TX_FIFO_UNDERFLOW
  - signals RX_FIFO_OVERFLOW, RX_FIFO_UNDERFLOW
- PT - Phase transition interrupt, signalling two out of all phase transitions in the QSPI communication cycle (see **Figure 19-18** and **Figure 19-21**)
  - PT1 event
  - PT2 event
- U - User Interrupt
  - triggered by the PT1 event during the time **BACON**.UINT bit keeps this event enabled.

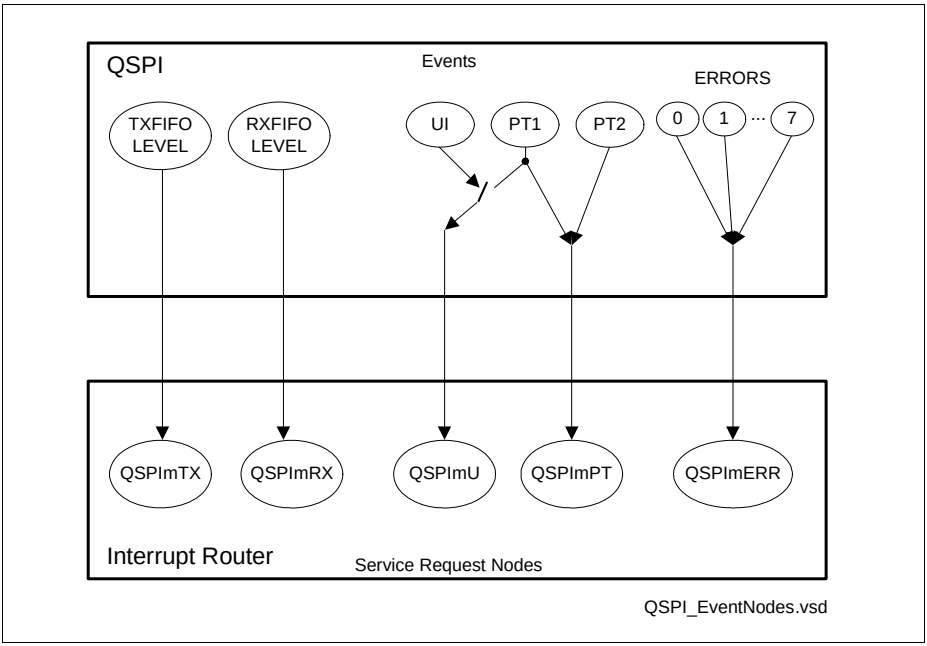

Figure 19-37 Events and Interrupts Overview

19.7.1 Slave Mode SLSI Interrupt

In slave mode, deactivating the SLSI signal (SLSI rising edge) triggers the PT interrupt, if PT2 enabled.

19.7.2 Interrupt Flags Behavior

An state of an event flag (low or high) does not influence the flow of its event signal. If an event occures recurrently, and the event flag remains set (if not cleared by the software interrupt handler), the interrupt flag (which is cleared by hardware, by an ICU, when the interrupt wins an arbitration round) would receive recurrent triggers, and the flag would be constantly set all the time.

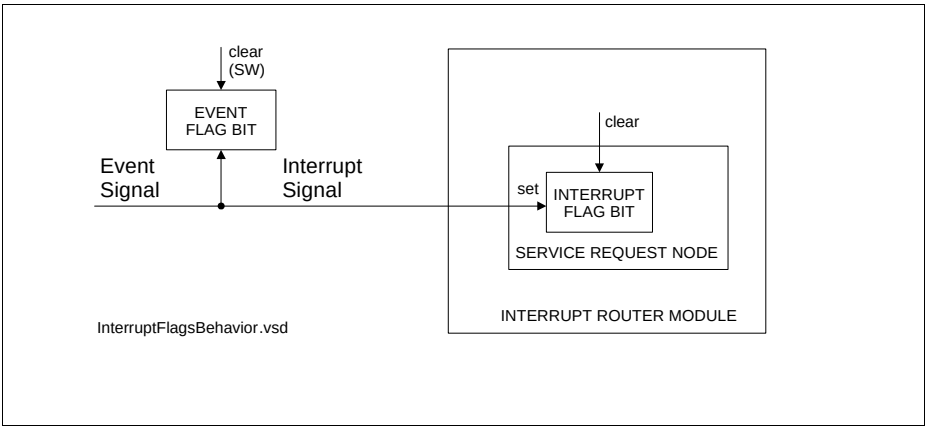

Figure 19-38 Events and Interrupts Overview

19.7.3 TXFIFO Interrupt Generation

The TXFIFO provides two interrupt generation modes, selected by the bit-field **GLOBALCON1**.TXFM:

- Single Move Mode
- Batch Move Mode
- Combined Mode

The RXFIFO and the TXFIFO can use the interrupt generation modes independently of each other.

Single Move Mode

The purpose of the Single Move Mode is to keep the TXFIFO as full as possible, refilling the TXFIFO by writing to it as soon as there is a free element.

The single move mode supports primarily a DMA operation using single move per TXFIFO interrupt. In this mode the DMA keeps the TXFIFO full. A DMA request is triggered each time a write to the TXFIFO is performed, and there is at least one empty element available. If the write makes the TXFIFO full (no more empty elements), an interrupt is not generated in order to prevent overflow. It is generated later when the shift register (or BACON) reads one element from the TXFIFO, making it not full.

The **Figure 19-39**, shows the filling levels of the TXFIFO, and the events associated with each filling level triggering a TXFIFO refill interrupt.

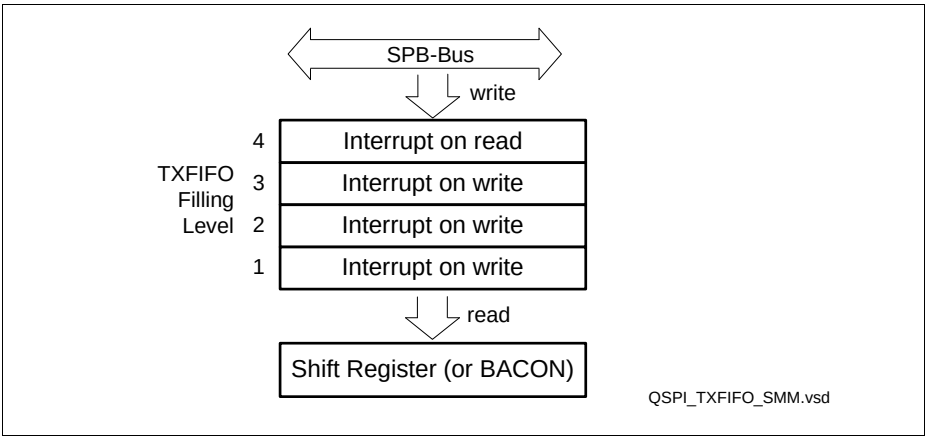

Figure 19-39 Interrupt Generation in the Single Move Mode

In order to initiate the very first chain of the refill interrupts after power-on reset, it is necessary that the software either performs one write to the TXFIFO, or sets the interrupt flag in the TXFIFO interrupt node. Afterwards, the (DMA) interrupt-chain is self sustaining until the whole transaction is over.

Attention: In Single Move Mode multiple software writes or block DMA moves would lead to multiple interrupts and (false) transaction lost events. Therefore they should be avoided - only single moves should be used.

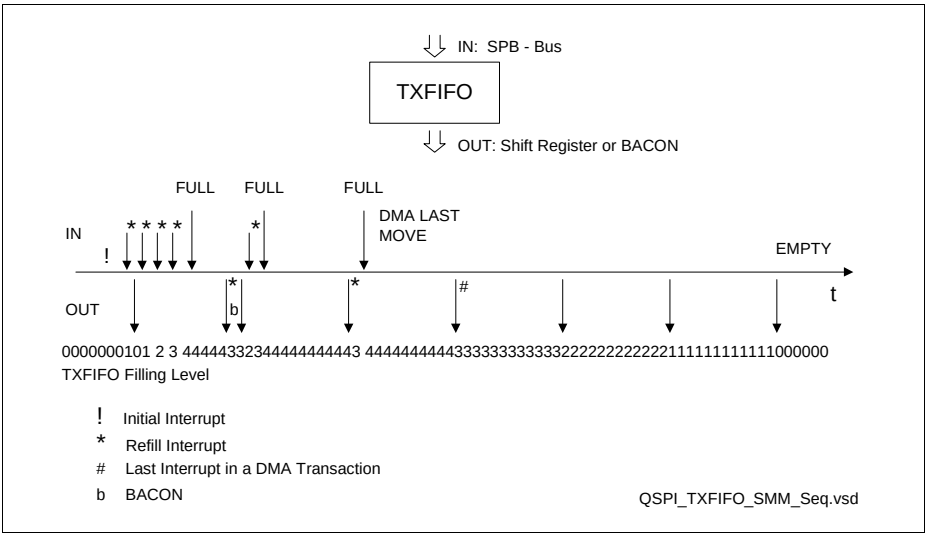

Figure 19-40 TXFIFO - Interrupt Operation in Single Move Mode

Batch Move Mode

Batch Move Mode supports the following use case:

- CPU servicing the TXFIFO

The purpose of the Batch Move Mode is to reduce the number of interrupts by triggering an interrupt when more then one TXFIFO elements are empty. For example, a CPU can be interrupted less frequently and it can perform more than one moves per interrupt.

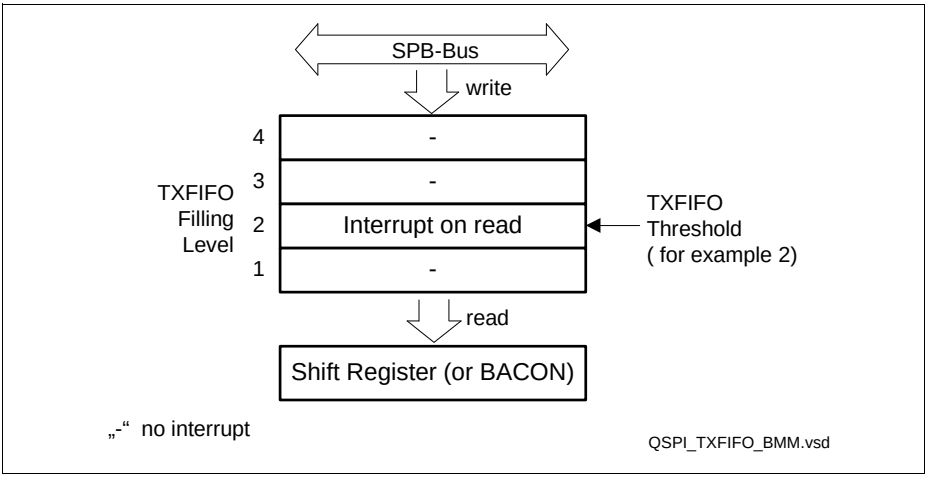

Figure 19-41 TXFIFO - Interrupt Generation in the Batch Move Mode

In Batch Move Mode, an interrupt is generated only at one point in the TXFIFO, when the filling level falls below the programmed threshold, implying that there are at least the predefined number of empty TXFIFO elements available.

Attention: The TXFIFO must be refilled until the filling level has risen above the interrupt threshold (ensured by polling the filling level), in order to guarantee that the next interrupt will occur.

At high baud rates and short frames, it could be possible that a couple of frames have been transmitted until the moment the TXFIFO is refilled. For example, if the threshold is set to three full elements, then the interrupt will be set when the filling level falls below three, making two elements free. If the refill moment of the TXFIFO is delayed so long that two frames have been transmitted (or frame and BACON), the TXFIFO will become empty, and refill sequence of two will not reach the level of three. So, the next interrupt would never come unless the filling level is being polled and the CPU keeps refilling in a loop until the threshold has been passed (ideally the TXFIFO would be filled completely with each batch of moves).

Combined Mode

TXFIFO generates interrupt each time a data is fetched from it below the pre-programmed threshold, as defined in the **GLOBALCON1**.TXFIFOINT. Consequently, it generates two close interrupts when delivering BACON and the first following data. If the BACON TX interrupt is not serviced until the DATA1 TX interrupt comes, which will always be the case due to their time proximity, the BACON TX interrupt will be lost. Therefore, it is recommended that a DMA should always perform two moves per interrupt trigger (transfer size of two). Otherwise, the TXFIFO average filling level will go down with the time and at the end remain oscillating between zero and one (except in continuous mode). The DMA transaction loss event that may be raised by the DMA should be ignored.

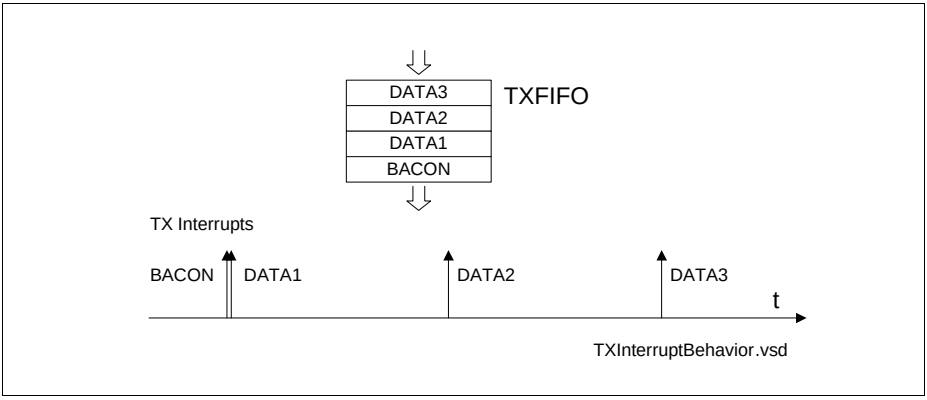

Figure 19-42 Events and Interrupts Overview

19.7.4 RXFIFO Interrupt Generation

The RXFIFO provides two interrupt generation modes, selected by the bit field **GLOBALCON1**.RXFM:

- Single Move Mode
- Batch Move Mode
- Combined Mode

Single Move Mode

The purpose of the Single Move Mode is to keep the RXFIFO as empty as possible, by fetching the received elements one by one as soon as possible.

The single move mode supports primarily a DMA operation using single move per RXFIFO interrupt. In this mode the DMA keeps the RXFIFO as empty as possible. A DMA request is triggered each time a read from the RXFIFO is performed, and the RXFIFO is afterwards still not empty. If the read makes the RXFIFO empty, an interrupt is not generated in order to prevent underflow. It is generated later when the shift register (or STATUS) writes new element to the empty RXFIFO.

The **Figure 19-39**, shows the filling levels of the RXFIFO, and the events associated with each filling level triggering a RXFIFO refill interrupt.

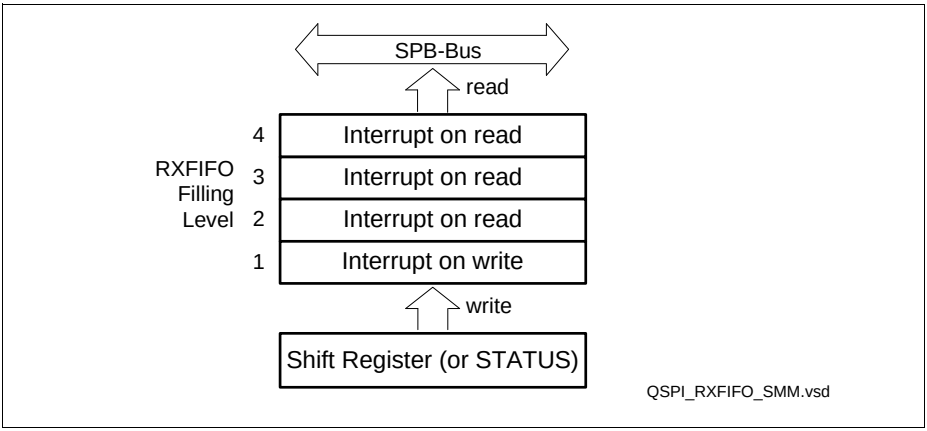

Figure 19-43 RXFIFO - Interrupt Triggering in the Single Move Mode

The initial RXFIFO interrupt is triggered by the Shift Register, after it delivers the first received element. Afterwards, the DMA trigger-chain of refetch interrupts is self sustaining until the whole transaction is over. At the end of the DMA transaction, there is no service request remaining active in the service request node, due to the fact that the read of the last element in the RXFIFO does not trigger an interrupt.

Attention: In Single Move Mode multiple software reads or block DMA moves lead to multiple interrupts and (false) transaction lost events. Therefore they should be avoided - only single moves should be used.

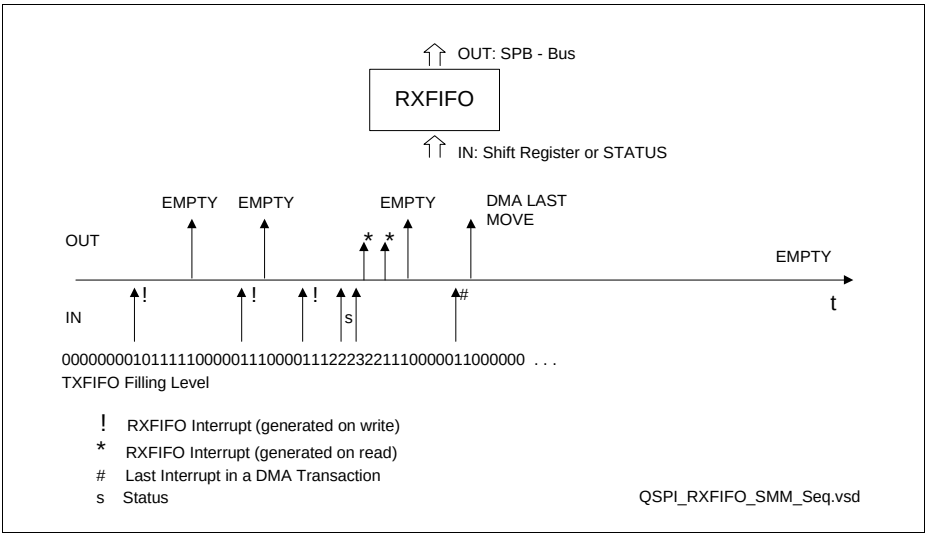

Figure 19-44 RXFIFO - Interrupt Operation in Single Move Mode

Batch Move Mode

The purpose of the Batch Move Mode is to reduce the number of interrupts by triggering an interrupt when more then one RXFIFO elements are full. For example, a CPU can be interrupted less frequently and it can perform more than one move per interrupt.

Batch Move Mode supports the following use case:

- CPU servicing the RXFIFO

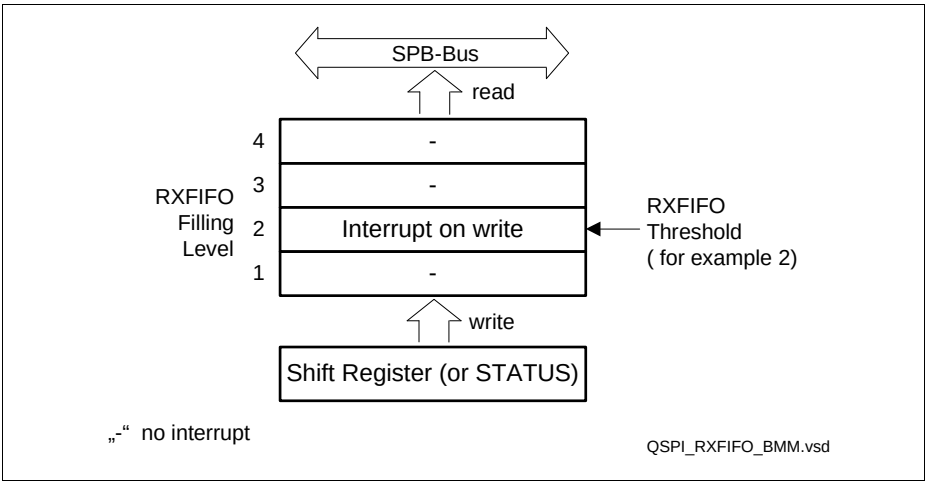

Figure 19-45 RXFIFO - Interrupt Triggering in the Batch Move Mode

In Batch Move Mode, an interrupt is generated only at one point in the RXFIFO, when the filling level rises above the programmed threshold, implying that there are at least the predefined number of full RXFIFO elements available.

Attention: It must be guaranteed that the CPU keeps emptying the RXFIFO and polling the RXFIFO filling level until the filling level has fallen below the interrupt threshold (or the RXFIFO is empty), in order to guarantee that next interrupt will occur.

At high baud rates and short frames, it could be possible that more than one frames have been received until the moment the RXFIFO is reemptied. For example, if the threshold is set to two full elements, then the interrupt will be set when the filling level rises above two. If the emptying moment of the RXFIFO is delayed so long that two additional frames has been received (or a frame and STATUS), the RXFIFO will become full, and reempty sequence of two will not reach the level of two. So, the next interrupt would never come. This effect can not occur with threshold levels of 3 and 4. The threshold level of 1 is possible, but does not make much sense (use single move mode instead).

Combined Mode

RXFIFO generates interrupt each time a data is written to it above the preprogrammed level, as defined in the **GLOBALCON1**.RXFIFOINT. Consequently, it generates two close interrupts when filled with data and STATUS. If the data RX interrupt is not serviced until the STATUS RX interrupt comes, which will always be the case due to their time proximity, the STATUS RX interrupt will be lost. In such a case, it is recommended that the DMA performs two moves per interrupt trigger (transfer size of two). Otherwise, the RXFIFO average filling level will go up with the time and at the end overflow.

19.7.5 DMA Transfer Example

Transmitting one compact RAM queue using DMA could consist of the following steps:

- The user software configures one appropriate DMA channel (source address, destination address, one move per transfer, number of transfers per transaction, gating mode, single mode, interrupt at the end of the transaction etc...)
- A not full TxFIFO from some QSPI module constantly generates pending DMA request
- A timer triggers a software routine that enables the DMA channel
- The DMA channel reads the queue elements from some on-chip general purpose RAM and writes them to the QSPI, one element at a time. One DMA transfer is one move long. One whole queue takes one transaction.
- The DMA channel generates an interrupt at the end of the transaction
- The DMA channel disables itself at the end of the transaction (single mode) and waits for further software actions.

The sequence is identical for the receive direction.

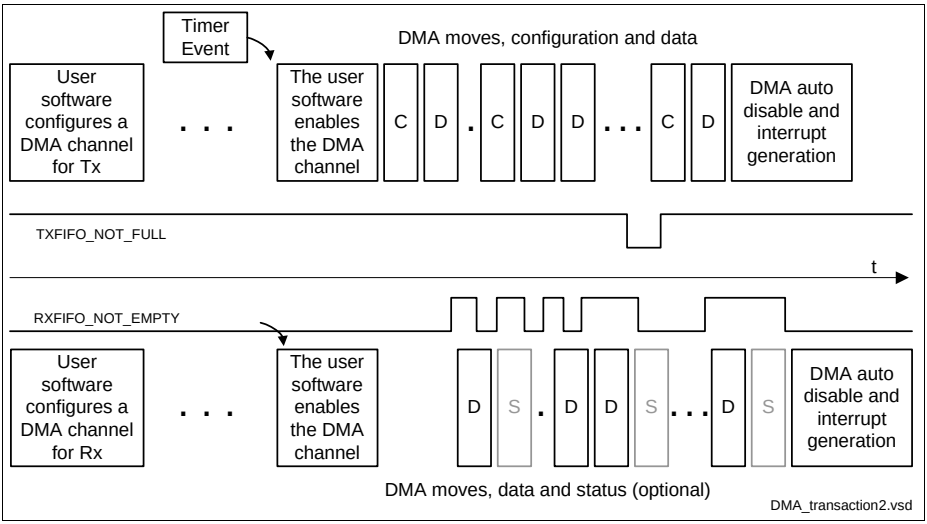

Figure 19-46 Example of transmitting a compact RAM Queue per DMA

19.8 Slave Mode

The slave mode is entered by setting the bit field **GLOBALCON**.MS to value 1x. Before entering the slave mode, the related parameters must be configured, including pin selection for SCLKI, SLSI and MTSR, pin input level, and pull-up/pull-down configuration. Subsequently state machine reset should be performed and afterwards the slave mode should be entered.

In slave mode data is being pushed into or out of the module through the serial pins by an external master. The RXFIFO must be regularly emptied by the system in order to avoid data loss, and the TXFIFO must be regularly fed by the system to avoid delivering all “1” data in case of empty TXFIFO.

If the slave mode relies on a slave select signal to mark the start and, in parallel to the bit counting, the end of a frame, then deactivating the slave signal by the master automatically resets the shift register state machine to wait state.

If the slave mode relies solely on bit counting for determining the frame end, then any SCLKI clock period longer than two bit times is treated as an end of a frame and simultaneously as a baud rate error.

In slave mode, the module simply immediately responds to external clock edges. Therefore, the settings for the leading, trailing, idle delays, and duty cycle and sampling point are irrelevant. From all timing settings, only the data length and the baud rate divider setting are relevant. The baud rate setting is important because of its role of watchdog timer of the incoming serial clock.

Generally, the slave mode supports the same user interface as the master mode. This means the BACON-Data sequences remain the same. The SRF bit is ignored.

Limit the data length setting in the slave mode to the range of 2 to 32 bits. The byte setting **BACON**.BYTE is to be set to zero, that is, it always defines bits.

In case of receive only (simplex receive) the user software must reset the module in order to switch to transmit and receive mode (full duplex). Generally, mode reconfiguration (slave mode to master mode) requires module reset which resets the internal state machines and counters.

In case of slave transmit, the user software must write data to the TXFIFO before the first SCLKI edge of a frame arrives. If the TXFIFO is empty at this point of time, an underflow occures, all “1” data is delivered, and underflow error interrupt is triggered if enabled. If the TXFIFO is written at the same time when the first SCLKI edge starts the shifting, the underflow occures, interrupt will be triggered and data from the TXFIFO will be transmitted possibly corrupted - the first bit will be “1”.

In case of TXFIFO / RXFIFO underflow the fifos deliver all “1” data .

In case of TXFIFO / RXFIFO overflow, the last data is lost. In such case data or optionally status in the RXFIFO can be lost.

The bit counting in the slave mode operates according to the following rules:

- The incoming bits (or shift clock shift edges) are counted and when the number defined in the **BACON**.DL is reached, the bits are transferred in the RXFIFO
- If the SLSI input is deactivated, the internal bit counter is reseted.

In slave mode, sleep requests may be enabled only when there is no pending transmit queue and no pending transmission and the TXFIFO is empty.

19.8.1 Shift Clock Phase and Polarity in Slave Mode

In slave mode the shift clock phase and polarity are fixed to CPH=1 and CPOL=0 (have to be programmed accordingly in the **ECON** register selected by **BACON**.CS) and slave select polarity is fixed to low active. The baud rate that the slave expects is defined in the **ECON** register pointed at by the **BACON**.CS.

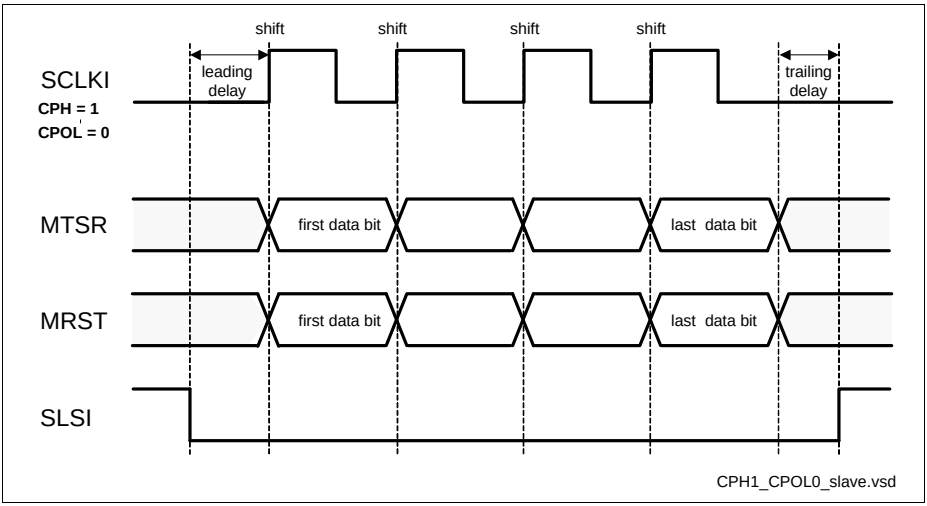

Figure 19-47 Slave transfer, CPH = 1, CPOL = 0

19.8.2 Shift Clock Monitoring

The QSPI module provides two mechanisms for monitoring the shift clock input signal in slave mode. These mechanisms monitor:

- if the receiving shift clock frequency (baud rate) lies within a certain range and
- if there are spikes on the shift clock input.

In case such disturbances are detected, the reaction is always the same:

- the corresponding error flags in **STATUS**.ERRORFLAGS are set, which can be cleared with **FLAGSCLEAR**.ERRORCLEARS
- the common error interrupt is raised if enabled in **GLOBALCON1**.ERRORENS and
- the bit **GLOBALCON**.EN is automatically cleared, if this feature is enabled by the bit **GLOBALCON**.AREN. The user software can activate a reset afterwards

In case of too high baud rate error , baud rate detection and spike detection both react, where spike detection is more effective. Spike detection reacts immediately, baud rate detection requires several bits with higher baud rate. Baud rate detection uses a window two nominal bit times wide and counts the real bit times: double baud rate error requires at least four real shift clock pulses to be detected, triple baud rate error requires six and so on. Baud rate detection does not react to all spikes smaller than one kernel clock period.

In case of too low baud rate error, baud rate detection reacts immediately, spike detection ignores this case.

19.8.2.1 Baud Rate Error Detection

If the shift clock has less than half or more then double the expected baud rate, then:

- the corresponding flag is set in **STATUS**.ERRORFLAGS
- error interrupt is raised if enabled in **GLOBALCON1**.ERRORENS
- automatic clear of **GLOBALCON**.EN follows, if enabled by **GLOBALCON**.AREN.

19.8.2.2 Spike Detection

Short spikes on the clock line due to ground bouncing or clock ringing due to over/undershoots would cause one or more extra bits to be written to the front end receive fifo of the slave. This extra bit, if no measures are taken by the software, would cause all the subsequent received frames to be corrupted (shifted).

The spike detection mechanism operates up to 50MBaud and checks if a bouncing spike has occurred on the clock line near to the correct receiving clock edges.

If a spike is detected, the software should use **GLOBALCON**.RESETS bitfield, and should clear the corresponding status flags. Alternatively a complete module reset may be performed via registers **KRST0**/**KRST1**.

The spike detection is based on two mechanisms:

- detection of two close writes to the front end receive FIFO by detecting filling level of two
- using an inverted watchdog set to ca. 75% to 80% SCLKI clock period, which is the optimal range.

The inverted watchdog is a timer which starts to count triggered on the write event to the front-end receive fifo of the slave.During the time the watchdog counts, no edge is allowed to occur. An edge in the forbidden time raises a spike error event.

If a spike occures in the last 25% of the SCLKI period, when the watchdog has stopped counting, the watchdog will be triggered to count by the spike. The next regular edge will violate the forbidden time and raise a spike event.

The watchdog counts **ECON**.B + **ECON**.C time quantas. The following constraint applies: 50% *T_{SCLKI}<**ECON**.B + **ECON**.C <100%*T_{SCLKI}.

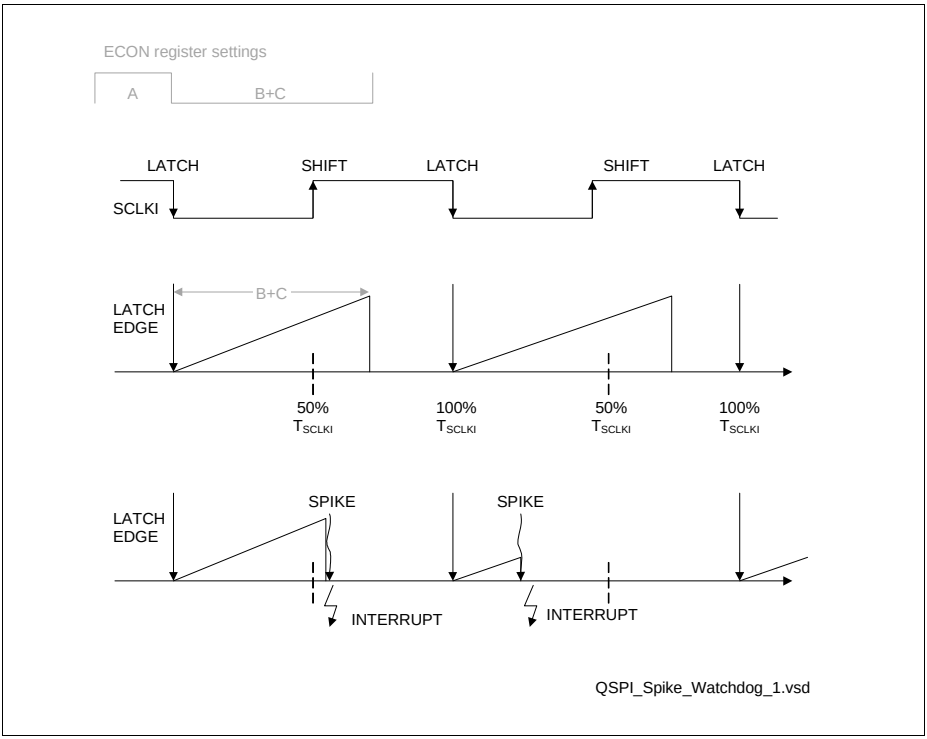

Figure 19-48 Spike Watchdog

19.8.2.3 Shift Clock Monitor Flags

The spike detection mechanism sets the flag **STATUS1**.SPD if it has detected a spike. The baud rate error detection mechanism sets the flag **STATUS1**.BRD if it has detected excessive baud rate deviation.

Writing 1 to SPD and BRD sets the bit and causes an interrupt if enabled. Writing 0 has no effect.

Both signals are ORed. This combined signal is shown in **STATUS**.ERRORFLAGS and raises an interrupt if enabled in **GLOBALCON1**.ERRORENS. Automatic clear of **GLOBALCON**.EN follows, if enabled by **GLOBALCON**.AREN.

If the **STATUS**.ERRORFLAGS[2] bit is cleared via **FLAGSCLEAR**.ERRORCLEARS[2], the both flags SPD and BRD are automatically cleared.

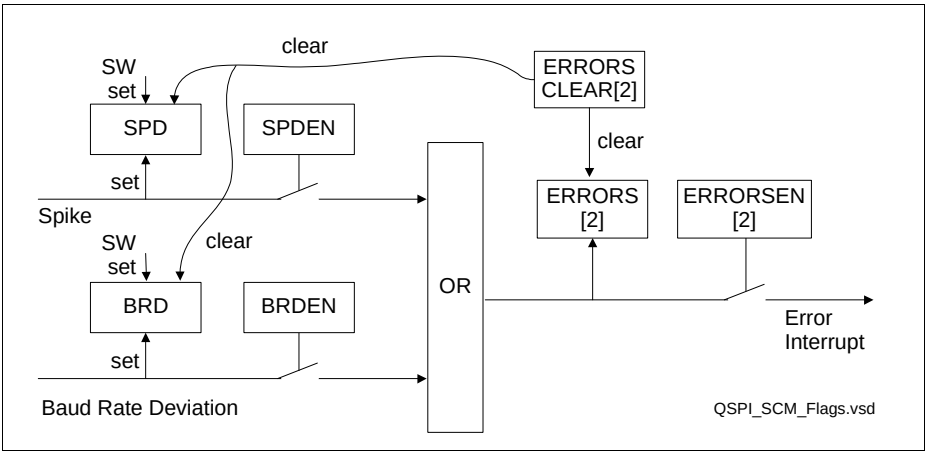

Figure 19-49 Shift Clock Monitor Flags

19.8.3 Parity

Parity settings for transmit and receive are defined by the corresponding bit fields in the **BACON** register.

The parity bit is concatenated to the data bits at transmission time. That means that a frame containing 16 bit data is 17 bits long (data + 1 parity). The transmitted parity bit can be read from the **STATUS**.TPV bit.

The parity bit is removed from the received bits at receive time automatically. The received parity bit can be read from the **STATUS**.RPV bit.

Attention: Parity is available only if the bit field BACON.BYTE = 0, that is, only for data of up to 32 bits length, that is, only in short mode.

Attention: The parity bit is concatenated to the data at the LSB location. If the bit field BACON.MSB = 0 it is shifted out first, else it is shifted out last.

19.9 Kernel Registers

This section describes the kernel registers of the QSPI module. All QSPI kernel register names described in this section will be referenced in other parts of the TC27x User's Manual by the module name prefix "QSPI0_" for the QSPI0 interface, "QSPI1_" for the QSPI1 interface and so on.

All registers in the QSPI address spaces are reset with the application reset (definition see SCU section "Reset Operation").

QSPI Kernel Register Overview

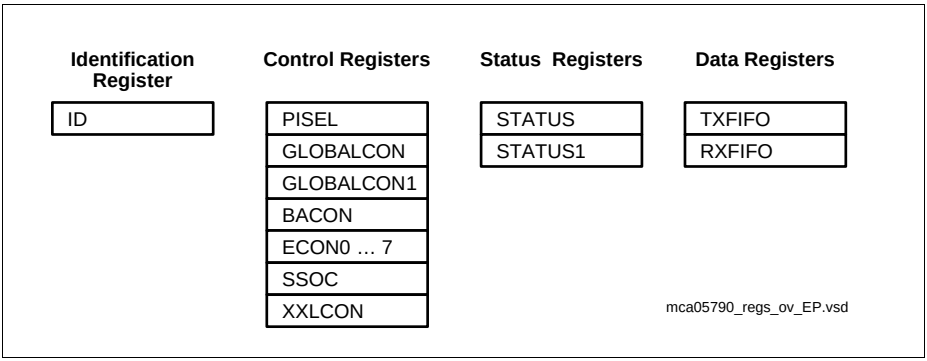

Figure 19-50 QSPI Kernel Registers

The following tables give the overview of the QSPI base addresses and registers.

Table 19-1 Registers Address Space

Module	Base Address	End Address	Note
QSPI0	$F0001C00_H$	$F0001CFF_H$	–
QSPI1	$F0001D00_H$	$F0001DFF_H$	–
QSPI2	$F0001E00_H$	$F0001EFF_H$	–
QSPI3	$F0001F00_H$	$F0001FFF_H$	–

Table 19-2 Registers Overview

Register Short Name	Register Long Name	Offset [1] Address	Write [2] Access	Reset Value (hex)
PISEL	Port Input Select Register	04_H	SV, P	0000 0000

ACCEN0	Access Enable Register 0	FC_H	SV, SE	FFFF FFFF

1) The absolute register address is Module Base Address (**Table 19-1**) + Offset Address (shown in this column)
2) All registers have read access mode U, SV. Read access to reserved addresses delivers bus error (BE). All registers belong to application reset except OCS, which belongs to debug reset.

List of Access Protection Abbreviations

U - User Mode

SV - Supervisor Mode

BE - Bus Error

nBE - no Bus Error

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

SE - SafetyENDINIT

19.9.1 Kernel Registers

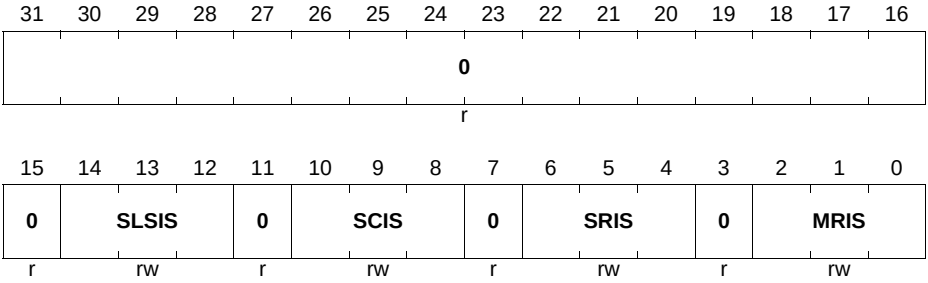
PISEL

The PISEL register controls the input signal selection of the SSC module.

(>> **Table 19-2** register overview)

PISEL

Port Input Select Register **(04_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
MRIS	[2:0]	rw	**Master Mode Receive Input Select** MRIS selects one out of eight MRST receive input lines (0 to 7 correspondingly), used in Master Mode. The signal suffixes “A” to “H” correspond to the bit field values of 0 to 7: MRSTxA ->0, MRSTxB->1 ...
SRIS	[6:4]	rw	**Slave Mode Receive Input Select** SRIS selects one out of eight MTSR receive input lines (0 to 7 correspondingly), used in Slave Mode. The signal sufixes “A” to “H” correspond to the bit field values of 0 to 7: MTSRxA ->0, MTSRxB->1 ...
SCIS	[10:8]	rw	**Slave Mode Clock Input Select** SCIS selects one out of eigjt module kernel SCLK input lines (0 to 7 correspondingly) that is used as clock input line in slave mode. The signal sufixes “A” to “H” correspond to the bit field values of 0 to 7: SCLKIxA ->0, SCLKIxB->1 ...

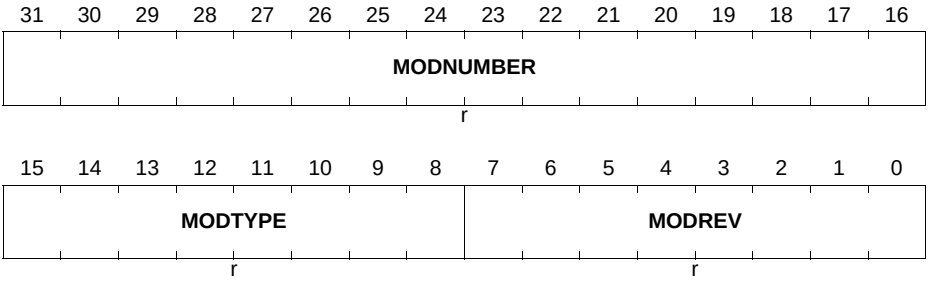
Field	Bits	Type	Description
SLSIS	[14:12]	rw	**Slave Mode Slave Select Input Selection** 000_B Slave select input lines are deselected; QSPI is operating without slave select input functionality. 001_B $\overline{SLSI}$ input line A is selected for operation 010_B $\overline{SLSI}$ input line B is selected for operation 011_B $\overline{SLSI}$ input line C is selected for operation 100_B $\overline{SLSI}$ input line D is selected for operation 101_B $\overline{SLSI}$ input line E is selected for operation 110_B $\overline{SLSI}$ input line F is selected for operation 111_B $\overline{SLSI}$ input line G is selected for operation The SLSIS must be programmed properly before the slave mode is set with **GLOBALCON**.MODE and the module is set to RUN mode.
0	[31:15], 11, 7, 3	r	**Reserved** Read as 0; should be written with 0.

ID

The Module Identification Register ID contains read-only information about the module version.

(>> **Table 19-2** register overview)

ID
Module Identification Register (08$_H$) Reset Value: 00C0 C0XX$_H$



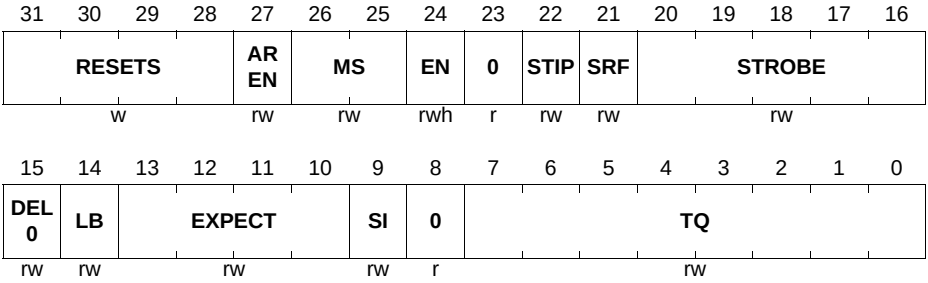
Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field is C0$_H$. It defines a 32-bit module.
MOD NUMBER	[31:16]	r	**Module Number Value** This bit field together with MODTYPE uniquely identifies a module.

GLOBALCON

GLOBALCON contains configuration parameters which affect all channels.

(>> **Table 19-2** register overview)

GLOBALCON
Global Configuration Register (10_H) Reset Value: $000F\ 30FF_H$



Field	Bits	Type	Description
TQ	[7:0]	rw	**Global Time Quantum Length** Common n-divider scaling the baud rates of all channels in direction of higher or lower baud rates. Must not be changed during a running transaction. 0_D division by 1 1_D division by 2 $\ldots_D$ ... 255_D division by 256
SI	9	rw	**Status Injection** Selects if the status register content injection into the RxFIFO is enabled or disabled. The status injections, if enabled, is performed after each data block, depending on the **BACON**.DL and BYTE setting. 0_B disabled 1_B enabled
EXPECT	[13:10]	rw	**Time-Out Value for the Expect Phase** expressed in T_{QSPI} units 0_D 64 (2^6) 1_D 128(2^7) $\ldots_D$ ... 15_D 2097152 (2^{21} = 2 Mega)

Field	Bits	Type	Description
LB	14	rw	**Loop-Back Control** Selects if the transmit output is internally connected to the receive input for test purposes. 0_B Loop-Back inactive 1_B Loop-Back active For detailed description, see the **Loop-Back Mode** section.
DEL0	15	rw	**Delayed Mode for SLSO0** Switches the delayed mode for external multiplexer enabling on and off 0_B Delayed mode off 1_B Delayed mode on
STROBE	[20:16]	rw	**Strobe Delay for SLSO0 in Delayed Mode** Defines the length of the SLSO0 delay in T_Q time units as defined for channel z (T_Q units) selected by the current **BACON**.CS, if **GLOBALCON**.DEL0 = 1. 00000_B 1 00001_B 2 $\ldots_B$ ... 11111_B 32
SRF	21	rw	**Stop on RxFIFO Full** If this bit is set, the data fetching out of the TxFIFO by the shift register stops when the RxFIFO is full, in order to prevent RxFIFO overflow. Master mode only. 0_B Feature disabled 1_B Feature enabled
STIP	22	rw	**Slave Transmit Idle State Polarity** This bit determines the logic level of the Slave Mode transmit signal MRST when the QSPI slave select input signals are inactive (PISEL.SLSIS $\neq 000_B$). 0_B MRST = 0 when QSPI is deselected in Slave Mode. 1_B MRST = 1 when QSPI is deselected in Slave Mode

Field	Bits	Type	Description
EN	24	rwh	**Enable Bit** Used to request transition between PAUSE and RUN mode per software. Cleared by hardware automatically at leaving the following states: disabled, suspend and sleep. In order to determine if the requested state has actually been reached, the **STATUS**.PHASE bit field should be polled. See also **Operation Modes**. 0_B PAUSE requested 1_B RUN requested
MS	[26:25]	rw	**Master Slave Mode** Selects if the module operates in master or slave mode. This bit field must be configured before the first write to the TXFIFO. 00_B Master Transmit and Receive 01_B Reserved 10_B Slave Transmit and Receive 11_B Slave Transmit and Receive
AREN	27	rw	**Automatic Reset Enable** Enables the reset of the **GLOBALCON**.EN on baud rate and spike error in slave mode. 0_B disabled 1_B enabled
RESETS	[31:28]	w	**Bits for resetting sub-modules per software** Write to this bit field triggers a reset operation. The reset operation is not a single cycle operation, but takes several clock cycles, not more than the least common multiple of CCUCON0.SPBDIV and CCUCON0.BAUD2DIV (the configured division ratios, not the content of the bit fields). 0000_B No reset triggered 0111_B State Machine, TXFIFO and RXFIFO reset, registers not reseted 1111_B Module reset **others**, reserved For resetting the whole module, use **KRST0** / **KRST1** reset mechanism.

Field	Bits	Type	Description
0	8, 23	r	**Reserved** Read as 0; should be written with 0.

Note: If the EN bit is cleared first, and then the partial state machine reset activated, then the state machine goes into PAUSE state.

GLOBALCON1

GLOBALCON1 contains bit fields for control of the extension of the slave select signals by using an external demultiplexer.

(>> **Table 19-2** register overview)

GLOBALCON1
Global Configuration Register 1 (14_H) Reset Value: $0005\ 0000_H$

Field	Bits	Type	Description
ERRORENS	[8:0]	rw	**Error Enable Bits** Bits for enabling interrupt on all available error types 000000000_B All errors disabled 000000001_B Parity Error (PAREEN) 000000010_B Unexpected Configuration Error 000000100_B Baud Rate Error (slave mode) BEN 000001000_B TXFIFO overflow (software error) 000010000_B TXFIFO underflow (slave mode) TEN 000100000_B RXFIFO overflow REN 001000000_B RXFIFO underflow (software error) 010000000_B EXPECT timeout 100000000_B SLSI misplaced inactivation enable
TXEN	9	rw	**Tx Interrupt Event Enable** Enables the Tx interrupt. 0_B Disabled 1_B Enabled
RXEN	10	rw	**RX Interrupt Event Enable** Enables the Rx interrupt. 0_B Disabled 1_B Enabled

Field	Bits	Type	Description
PT1EN	11	rw	**Interrupt on PT1 Event Enable** Enables the PT interrupt on an PT1 event, as selected by the PT1 bit field. 0_B Disabled 1_B Enabled
PT2EN	12	rw	**Interrupt on PT2 Event Enable** Enables the PT interrupt on an PT2 event, as selected by the PT2 bit field. 0_B Disabled 1_B Enabled
USREN	15	rw	**Interrupt on USR Event Enable** Enables the USR interrupt on an USR event, as selected by the PT1 bit field. 0_B Disabled 1_B Enabled
TXFIFOINT	[17:16]	rw	**Transmit FIFO Interrupt Threshold** If the TXFIFO filling level is equal or less than this threshold, than each move of data or configuration from the TXFIFO triggers a transmit interrupt. Reset value of the level is 01_B. 00_B 1 01_B 2 10_B 3 11_B 4
RXFIFOINT	[19:18]	rw	**Receive FIFO Interrupt Threshold** If the RXFIFO filling level is equal or greater than this threshold, than each move of data or status (if enabled) into the RXFIFO triggers a receive interrupt. Reset value of the level is 01_B. 00_B 0 01_B 1 10_B 2 11_B 3

Field	Bits	Type	Description
PT1	[22:20]	rw	**Phase Transition Event 1** Selects the first phase transition to trigger the PT interrupt. 000_B BUSY (end of WAIT phase) 001_B SCLKPC (serial clock polarity change) 010_B SOF (Start of Frame) 011_B TBE (Transmit Buffer Emptied) 100_B RBF (Receive Buffer Filled) 101_B EOF (End of Frame) 110_B DNA (Data not Available = Start of Expect) 111_B CONT (End of EXPECT phase)
PT2	[25:23]	rw	**Phase Transition Event 2** Selects the second phase transition to trigger the PT interrupt. In master mode, the following events are available: 000_B BUSY (end of WAIT phase) 001_B SCLKPC (serial clock polarity change) 010_B SOF (Start of Frame) 011_B TBE (Transmit Buffer Emptied) 100_B RBF (Receive Buffer Filled) 101_B EOF (End of Frame) 110_B DNA (Data not Available = Start of Expect) 111_B CONT (End of EXPECT phase) In slave mode, the SLSI deactivated event is the only option available for PT2. For this purpose, always use the setting 101 (EOF).
TXFM	[27:26]	rw	**TXFIFO Mode** Selects between the Single Move Mode and the Batch Move Mode. 00_B Combined Move Mode 01_B Single Move Mode 10_B Batch Move Mode 11_B reserved
RXFM	[29:28]	rw	**RXFIFO Mode** Selects between the Single Move Mode and the Batch Move Mode. 00_B Combined Move Mode 01_B Single Move Mode 10_B Batch Move Mode 11_B reserved

Field	Bits	Type	Description
0	30, 31, 13,14	r	**Reserved** Read as 0; should be written with 0.

BACON

Defines the basic configuration parameters for the current slave select. It can be read by software, or written through a write to the TXFIFO.

(>> **Table 19-2** register overview)

BACON
Basic Configuration Register (18_H) Reset Value: 0F87 1C71$_H$

rh			rh			rh			rh			rh			rh

Field	Bits	Type	Description
LAST	0	rh	**Last Word in a Frame** Defines if the following data word is last in the current frame or not 0_B Not Last 1_B Last
IPRE	[3:1]	rh	**Prescaler for the Idle Delay** Length in T_{BAUD2} units 000_B 1 001_B 4 010_B 16 $\ldots_B$ ... 111_B 16384
IDLE	[6:4]	rh	**Idle Delay Length** Defines the length of both idle delays, IDLEA and IDLEB, in T_{BAUD2} units pre scaled with IPRE 0_D 1 units 1_D 2 unit $\ldots_D$ ... 7_D 8 units

Field	Bits	Type	Description
LPRE	[9:7]	rh	**Prescaler for the Leading Delay** Length in T_{BAUD2} units 000_B 1 001_B 4 010_B 16 $\ldots_B$ ... 111_B 16384
LEAD	[12:10]	rh	**Leading Delay Length** Defines the length of the leading delay, in T_{BAUD2} units pre scaled with LPRE 0_D 1 units 1_D 2 unit $\ldots_D$ ... 7_D 8units
TPRE	[15:13]	rh	**Prescaler for the Trailing Delay** Length in T_{BAUD2} units 000_B 1 001_B 4 010_B 16 $\ldots_B$ ... 111_B 16384
TRAIL	[18:16]	rh	**Trailing Delay Length** Defines the length of the leading delay, in T_{BAUD2} units pre scaled with TPRE 0_D 1 units 1_D 2 unit $\ldots_D$ ... 7_D 8 units
PARTYP	19	rh	**Parity Type** Valid for both receive and transmit direction 0_B Even parity 1_B Odd parity

Field	Bits	Type	Description
UINT	20	rh	**User Interrupt at the PT1 Event in the Subsequent Frames** This bit is an enable signal for the PT1 event routed to the User Interrupt Service Request. The interrupt signals are generated until disabled with the next BACON. 0_B Disabled 1_B Enabled
MSB	21	rh	**Shift MSB or LSB First** This bit sets the shift direction of the shift register. If the MSB option is set, and the data is a block longer than 32 bits, the block must be fed into the TXFIFO in reverse direction, from the end of the block until its beginning. 0_B Shift LSB first 1_B Shift MSB first
BYTE	22	rh	**Byte** Defines if data length is expressed in bits or bytes 0_B DL defines the data length in bits 1_B DL defines the data length in bytes
DL	[27:23]	rh	**Data Length** Defines the data length in bits or bytes of one data block, depending on the setting of the bit field BYTE 0_D 2 bits if BYTE=0; XXL mode if BYTE=1 1_D 2 bits or bytes $\cdots_D$ ... 31_D 32 bits or bytes For the maximum baud rate of 50 MBaud, the minimum data length possible is four.
CS	[31:28]	rh	**Channel Select** Selects the channel to which the subsequent data entry belongs (channel = the SLSO signal to be activated and the corresponding **ECON** configuration extension) This bit field selects one slave in a range of 0 to 15, by driving one SLSO signal out of 16 available. In case of an external demux mode, this bit field appears on the lines SLS01 to SLSO4 as it is, additionally inverted or not, as defined in the **SSOC** register.

If an application does not use the SLSO signals of the QSPI module, but uses software channel selection, then the alternate function multiplexer in the ports must be configured so that the signal SLSO is not selected, but the coresponding bit Pn.OUT.

Alternatively, to emulate SLSO functionality, the software can disable (low) all the **SSOC**.OEN bits, and then toggle the **SSOC**.AOL bits.

ECON

Configuration extensions for channels 0 to 15. Register x defines several timing characteristics for two channels: z and z+8.

(>> **Table 19-2** register overview)

(>> **Figure 19-12**, **Figure 19-13** timing diagrams)

ECONz (z = 0 - 7)

Field	Bits	Type	Description
Q	[5:0]	rw	**Time Quantum** Defines the time quantum length used by A, B, and C to define the baud rate and duty cycle by. This prescaler cascades the prescaler **GLOBALCON**.TQ. 000000_B 1 000001_B 2 $..._B$ ... 111111_B 64
A	[7:6]	rw	**Bit Segment 1** Length expressed in time quantums of **ECON**z.Q. 00_B 1 01_B 2 10_B 3 11_B 4

Field	Bits	Type	Description
B	[9:8]	rw	**Bit Segment 2** Length expressed in time quantums of ECONz.Q. 00_B 0 01_B 1 10_B 2 11_B 3
C	[11:10]	rw	**Bit Segment 3** Length expressed in time quantums of ECONz.Q. 00_B 0 (if B=0, than C is minimum 1 per hardware) 01_B 1 10_B 2 11_B 3
CPH	12	rw	**Clock Phase** Delay of one half SCLK clock cycle. 0_B Disabled 1_B Enabled
CPOL	13	rw	**Clock Polarity** Idle level of the shift clock signal at the SCLK pin 0_B Idle level low 1_B Idle level high
PAREN	14	rw	**Enable Parity Check** This bit field enables both the parity generation in transmit and parity check in receive direction. 0_B Disabled 1_B Enabled
BE	[31:30]	rw	**Permutate bytes to / from Big Endian** 00_B Disabled 01_B 16-bit big endian 10_B 32-bit big endian 11_B Disabled
0	[29:15]	r	**reserved**

STATUS

Status register contains bits flagging the current status of the module and its sub-modules.

Note: It is not recommended to set the STATUS register flags per software for purposes other than testing. In such cases, use write instructions only, not read-modify-write instructions or bit instructions which compile to read-modify-write instructions.

Note: When using the RXFIFO status injection feature, only bits 22 to 31 reflect the status at the moment of injection, that is for the latest frame. Due to pipeline effects, the other bits contain not-latest information.

(>> **Table 19-2** register overview)

STATUS
Status Register **(40_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PHASE				TPV	RPV	SLAVESEL				RXFIFO LEVEL			TXFIFO LEVEL

USRF	0	0	PT2F	PT1F	RXF	TXF	ERRORFLAGS								
rwh	r	r	rwh	rwh	rwh	rwh	rwh								

Field	Bits	Type	Description
ERROR FLAGS	[8:0]	rwh	**Sticky Flags Signalling Errors** Writing 1 sets the error Flag and triggers an error interrupt, if enabled. Writing 0 has no effect. 000000000_B No Error 000000001_B Parity Error 000000010_B Unexpected Configuration Error 000000100_B Baud Rate Error (slave mode) 000001000_B TXFIFO overflow (software error) 000010000_B TXFIFO underflow (slave mode) 000100000_B RXFIFO overflow 001000000_B RXFIFO underflow (software error) 010000000_B EXPECT time out error 100000000_B SLSI misplaced inactivation (slave mode)

Field	Bits	Type	Description
TXF	9	rwh	**Transmit Interrupt Request Flag** Flags an occurrence of a request to feed the TXFIFO, which is generated when an element is fetched from the FIFO, and the FIFO filling level is equal or less than the set threshold level. Writing 1 sets the flag and triggers an interrupt if **GLOBALCON1**.TXEN = 1. Writing 0 has no effect.
RXF	10	rwh	**Receive Interrupt Request Flag** Flags an occurrence of a request to empty the RXFIFO, which is generated when an element is written into the FIFO, and the FIFO filling level is equal or greater than the set threshold level. Writing 1 sets the flag and triggers an interrupt if **GLOBALCON1**.RXEN = 1. Writing 0 has no effect.
PT1F	11	rwh	**Phase Transition 1 Flag** Flags an occurrence of a PT1 event, as selected with the **GLOBALCON1**.PT1, and triggers an interrupt if **GLOBALCON1**.PT1EN = 1. Writing 1 sets the flag and triggers an error interrupt. Writing 0 has no effect.
PT2F	12	rwh	**Phase Transition 2 Flag** In master mode, flags an occurrence of a PT2 event, as selected with the **GLOBALCON1**.PT2, and triggers an interrupt if **GLOBALCON1**.PT2EN = 1. In slave mode, set by the SLSI deactivated event. Writing 1 sets the flag and triggers an error interrupt. Writing 0 has no effect.
USRF	15	rwh	**User Interrupt Request Flag** Flags an occurrence of an USR event. Writing 1 sets the flag and triggers an interrupt if **GLOBALCON1**.USREN = 1. Writing 0 has no effect.

Field	Bits	Type	Description
TXFIFO LEVEL	[18:16]	rh	**TXFIFO Filling Level** Shows how many entries in the TXFIFO are waiting for transmission 000_B 0 001_B 1 010_B 2 011_B 3 100_B 4 $..._B$ reserved
RXFIFO LEVEL	[21:19]	rh	**RXFIFO Filling Level** Shows how many entries in the RXFIFO are waiting for software to move them to RAM 000_B 0 001_B 1 010_B 2 011_B 3 100_B 4 $..._B$ reserved
SLAVESEL	[25:22]	rh	**Currently Active Slave Select Flag** Displays the currently active slave select.
RPV	26	rh	**Received Parity Value** Displays the last received parity bit, if parity was enabled. Else if the parity is disabled, reads 0.
TPV	27	rh	**Transmitted Parity Value** Displays the last transmitted parity bit, if parity was enabled. Else 0.

Field	Bits	Type	Description
PHASE	[31:28]	rh	**Flags the ongoing phase** Displays the current phase number. Relevant only in master mode. In slave mode this bit field indicates always 0. 0000_B Wait 0001_B Idle A 0010_B Idle B 0011_B Lead 0100_B Data 0101_B Trail 0110_B Expect 0111_B Lead Strobe 1000_B Trail Strobe Not 0 means busy.
0	13, 14	r	**Reserved** Read as 0; should be written with 0.

Note: Slave TXFIFO underflow error is activated if the transmission has been started by the master at the time when the slave FIFO was empty, or at the same moment updated. In the second case inconsistent data will be transmitted.

Note: Reading the TXFIFO filling level bit field returns a value which can be used to calculate how many writes can be performed by a CPU without causing an overflow (in case no DMA is programmed to access the TXFIFO in parallel). For example, if the TXFIFO level was one, maximum three (TXFIFO depth of four minus one) write accesses are possible. Due to the volatility of the bit field, the filling level can go down in some nanoseconds after the read.

Note: Reading the RXFIFO filling level bit field returns a value which shows directly how many reads can be performed by a CPU without causing an underflow. Due to the volatility of the bit field, the filling level can go up in some nanoseconds after the read.

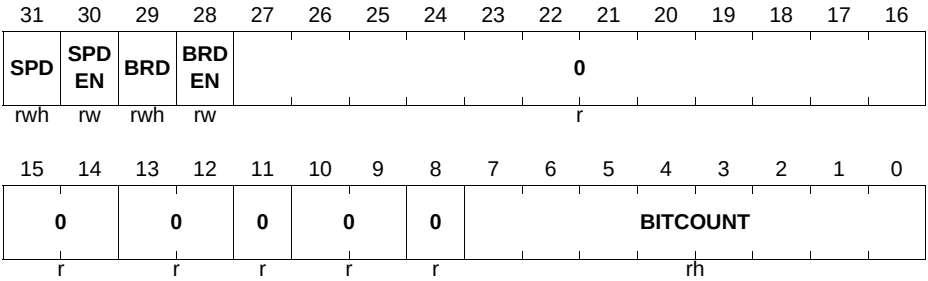
Note: Reading the PHASE bit field shows a previous phase of the frame, and a PT1F and PT2F flags indicate previous phase transitions.
If the communication speed is not too high or the phases duration not very short compared to the software latency delays, which would normally be the case, these would be the latest completed phase and the latest phase transitions.
Nevertheless, in case of high baud rates, the duration of the phases must be taken

into consideration, but only if these bit fields are used in an application, and not only for debugging purposes.

STATUS1

(>> **Table 19-2** register overview)

STATUS1
Status Register 1 **(44_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
BITCOUNT	[7:0]	r	**Number of the bit shifted out** Supports up to 256 bits. BITCOUNT = 0 indicates two states: no transmission and transmission of the first bit. The differentiation can be made by reading the phase information. BITCOUNT = 1 indicates transmission of the second bit and so on until 256. After transmission of the last bit the counter goes to zero.
BRDEN	28	rw	**Baud Rate Deviation Enable** Enables the signal path. 0_B disabled 1_B enabled
BRD	29	rwh	**Baud Rate Deviation Flag** Shows if baud rate deviation has been detected. Write of 1 sets the bit and raises the event per software. Write of 0 has no effect. 0_B no event 1_B event detected
SPDEN	30	rw	**Spike Detection Enable** Enables the signal path. 0_B disabled 1_B enabled

Field	Bits	Type	Description
SPD	31	rwh	**Spike Detection Flag** Shows if spike has been detected. Write of 1 sets the bit and raises the event per software. Write of 0 has no effect. 0_B no event 1_B event detected
0	[27:8]	r	**Reserved** Read as 0; should be written with 0.

If the **STATUS**.ERRORFLAGS[2] bit is cleared via **FLAGSCLEAR**.ERRORCLEARS[2], the both flags SPD and BRD are automatically cleared.

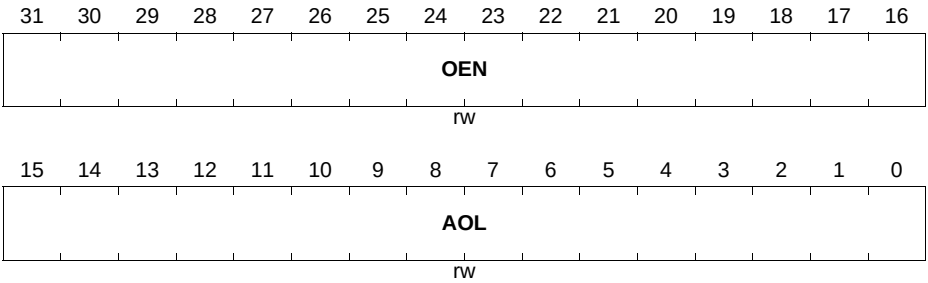
SSOC

SSOC controls the level of each slave select and enables/disables each one individually.

(>> **Table 19-2** register overview)

SSOC

Slave Select Output Control Register (48$_H$) **Reset Value: 0000 0000$_H$**

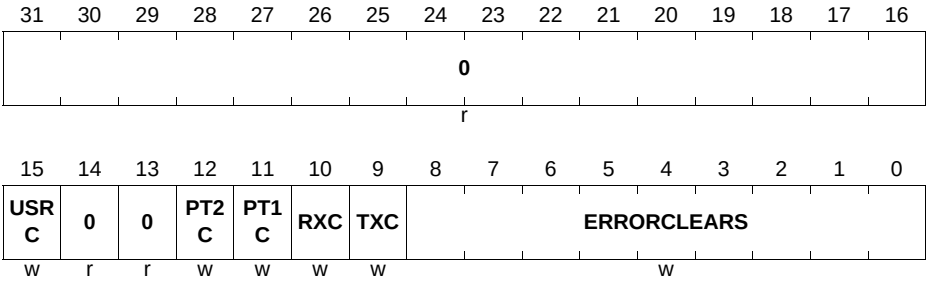


Field	Bits	Type	Description
OEN	[31:16]	rw	**Enable Bits for the SLSO Outputs** In disabled state the SLSO output drives the idle level as defined by the AOL bit field. “0” at certain position means that the corresponding SLSO is disabled. “1” means enabled.
AOL	[15:0]	rw	**Active Output Level for the SLSO Outputs** The idle level is the inverted one. “0” at certain position means active low level for the corresponding SLSO. “1” means active high.

FLAGSCLEAR

(>> **Table 19-2** register overview)

FLAGSCLEAR
Flags Clear Register **(54_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
ERROR CLEARS	[8:0]	w	**Write Only Bits for Clearing the Error Flags** Writing 1 clears the corresponding error flag in the ERORRFLAGS bit field. Reading returns 0. 000000000_B No clear 000000001_B Parity Error clear 000000010_B Unexpected Configuration Error clear 000000100_B Baud Rate Error clear 000001000_B TXFIFO overflow clear 000010000_B TXFIFO underflow clear 000100000_B RXFIFO overflow clear 001000000_B RXFIFO underflow clear 010000000_B EXPECT time out clear 100000000_B SLSI misplaced inactivation clear
TXC	9	w	**Transmit Event Flag Clear** Write of 1 clears the **STATUS**.TXF bit. Write of 0 has no effect. Read delivers 0. 0_B no action 1_B clear

Field	Bits	Type	Description
RXC	10	w	**Receive Event Flag Clear** Write of 1 clears the **STATUS**.RXF bit. Write of 0 has no effect. Read delivers 0. 0_B no action 1_B clear
PT1C	11	w	**PT1 Event Flag Clear** Write of 1 clears the **STATUS**.PT1F bit. Write of 0 has no effect. Read delivers 0. 0_B no action 1_B clear
PT2C	12	w	**PT2 Event Flag Clear** Write of 1 clears the **STATUS**.PT2F bit. Write of 0 has no effect. Read delivers 0. 0_B no action 1_B clear
USRC	15	w	**User Event Flag Clear** Write of 1 clears the **STATUS**.USRF bit. Write of 0 has no effect. Read delivers 0. 0_B no action 1_B clear
0	13, 14	rw	**Reserved** Read as 0; should be written with 0.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

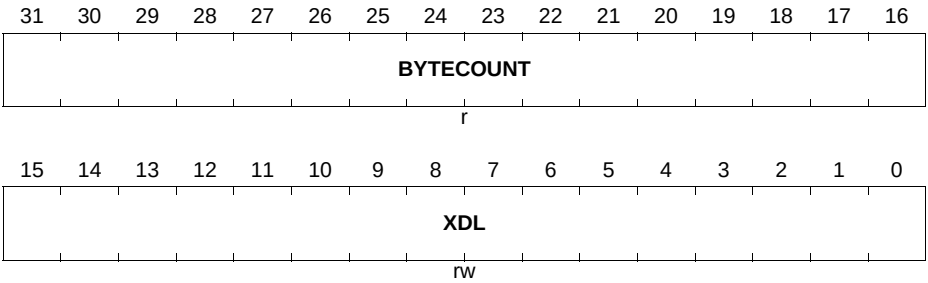
XXLCON

The XXLCON register provides counter for sending frames with very long blocks of data by extending the long data mode. It avoids a need for further BACON entries, like those needed in continuous mode.

Data length in this register overrides the **BACON**.DL setting in XXL mode, when **BACON**.BYTE=1 and **BACON**.DL=0. The data is sent to the slave as defined by **BACON**.CS bit field.

(>> **Table 19-2** register overview)

XXLCON
Extra Large Data Configuration Register(58_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
XDL	[15:0]	rw	**Extended Data Length** Defines the length of the data block in bytes in range of 2 to 65536. Overrides **BACON**.DL when **BACON**.BYTE=1 and and **BACON**.DL=0. 0_D 2 bytes 1_D 2 bytes $\ldots_D$ ... 65535_D 65536 bytes

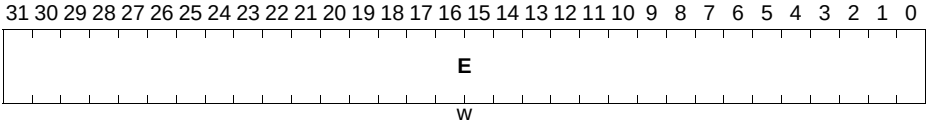
Field	Bits	Type	Description
BYTECOUNT	[31:16]	r	**Extended Data Length** In the XXL mode, shows the current state of the internal byte down counter (bytes remaining to be sent). In short and long modes, the value of this bit field is don't care. 0_D zero bytes 1_D two bytes $..._D$ ... 65535_D 65536 bytes

MIXENTRY

(>> **Table 19-2** register overview)

MIXENTRY

MIX_ENTRY Register **($5C_H$)** **Reset Value: $0000\ 0000_H$**



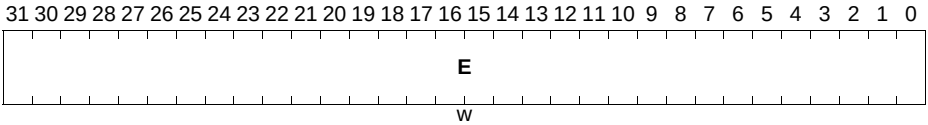
Field	Bits	Type	Description
E	[31:0]	w	**Entry Point to the TxFIFO**

BACONENTRY

(>> **Table 19-2** register overview)

BACONENTRY

BACON_ENTRY Register **(60_H)** **Reset Value: $0000\ 0000_H$**



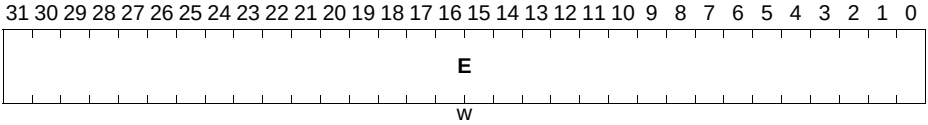
Field	Bits	Type	Description
E	[31:0]	w	**Entry Point to the TxFIFO**

DATAENTRY

(>> **Table 19-2** register overview)

DATAENTRYx (x=0-7)

DATA_ENTRY Register x **(64_H + x*4_H)** **Reset Value: 0000 0000_H**



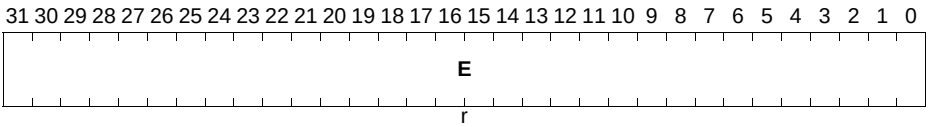
Field	Bits	Type	Description
E	[31:0]	w	**Entry Point to the TxFIFO**

RXEXIT

(>> **Table 19-2** register overview)

RXEXIT

RX_EXIT Register **(90_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
E	[31:0]	r	**Read Point from the RxFIFO**

Note: The RXFIFO has a property that a read access from an empty RXFIFO generates an underflow interrupt, and delivers only “1” bits, which overrules the reset value. Therefore reading from a non initialized RXFIFO delivers all “1” and not all ”0”.

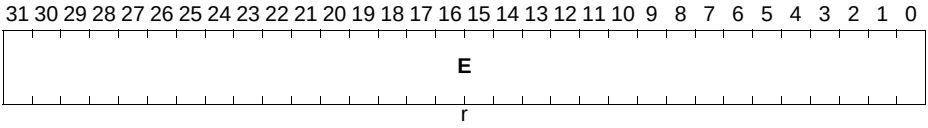
RXEXITD

The register **RXEXITD** provides a non-destructive address, showing the next available value in the RXFIFO.

(>> **Table 19-2** register overview)

RXEXITD

RX_EXIT Debug Register **(94_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
E	[31:0]	r	**Read Point from the RxFIFO**

*Note: This register provides a non-volatile access to the RXFIFO. It delivers the same value as **RXEXIT**, but without affecting read pointer and the filling level of the RXFIFO .*

19.10 Operation Modes

Generally, the QSPI module transmits a RAM queue of an arbitrary length, fed by a DMA module, and makes pauses between the queues. The QSPI module does not know anything about the queue length or the current position within the queue or the future schedule of the messages that may come.

If the QSPI module gets a request for switching off the clock or pausing the module, it disables all service request lines.

The QSPI module provides two options for switching off the clocks or pausing the module: hard suspend (as soon as possible regarding for example the length of interrupt request pulses), and soft suspend (transition to the PAUSE state with finishing the current frame). The requests can be triggered by hardware signals (disable, suspend, sleep) or by software write to **GLOBALCON**.EN bit.

Disable, Pause and Run

After being enabled by clearing the CLC.DISR bit, the QSPI enters the PAUSE state. In this state, the QSPI module can be initialized, the TXFIFO pre-filled, and then, by setting the **GLOBALCON**.EN bit, put into a RUN state.

The software requests PAUSE state of the running module by clearing the **GLOBALCON**.EN bit. The software can detect that the QSPI module has reached the PAUSE state by polling for the **GLOBALCON**.EN=0 and **STATUS**.PHASE=0 (indicating WAIT state, master mode only).

In PAUSE state, the user interface of the module is active. The registers and the FIFOs can be read and written. However, both the receive and transmit state machines are inactive, in master as well as in the slave mode. This allows for reconfiguration of the module without affecting the serial bus.

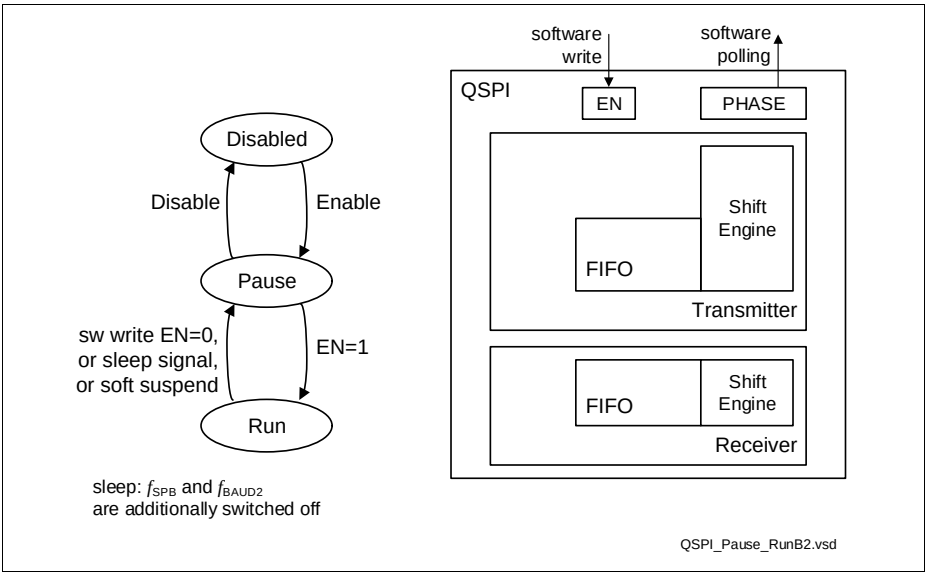


Figure 19-51 Pause and Run Overview

The concept of the PAUSE state is reused for handling the soft OCDS suspend and Sleep requests. In contrast to active Pause state and OCDS suspend, the sleep state has the special property that (due to the low power requirement) both FPI and QSPI clocks are switched off.

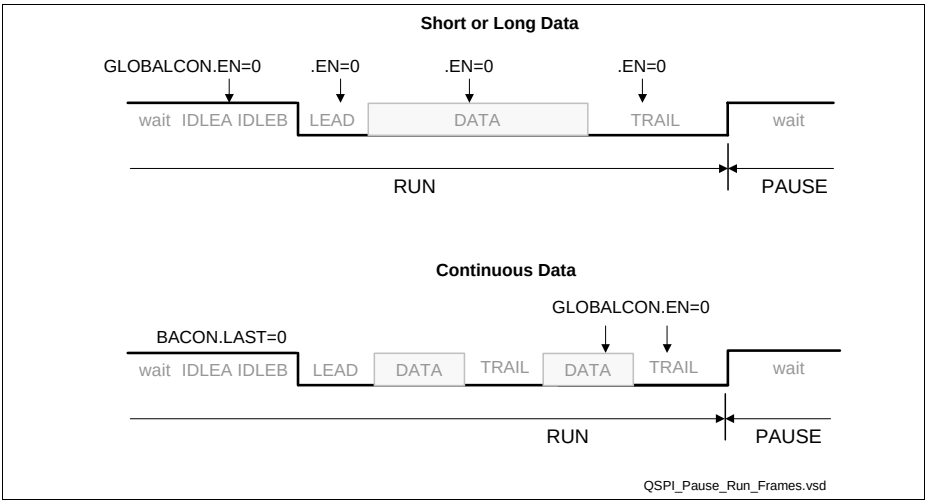

Figure 19-52 Entering the Pause State

If a running module receives a request to PAUSE, it waits for the end of the TRAIL phase.

For all modes (Short, Long and Continuous), the PAUSE state is indicated by **GLOBALCON**.EN=0 and **STATUS**.PHASE=0, master mode only.

19.10.1 OCDS Suspend

The OCDS hard suspend request, for debugging purposes, simply freezes the QSPI module in the current state. No signal is changed including the service request lines, which remain frozen in the current state.

The QSPI responds to an OCDS soft suspend request by entering the PAUSE state immediately after the subsequent end of a trail phase, and then sending acknowledge (see **Figure 19-53**). The behavior is the same as for entering the **Sleep Mode**.

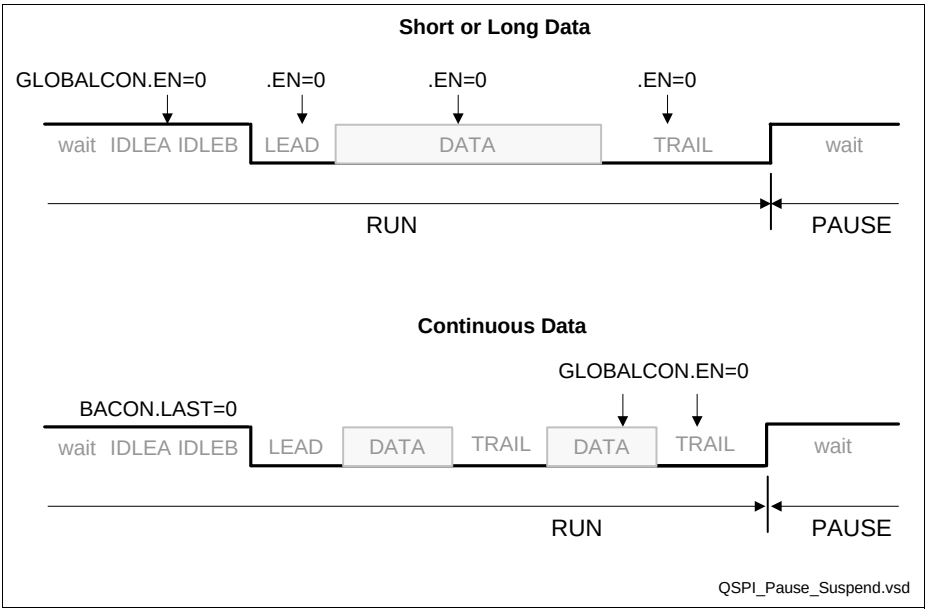

Figure 19-53 Entering the Sleep, Soft Suspend, and Disable State

Reading the FIFO entries by the Cerberus (detected by the FPI master tag) does not modify the FIFO content nor the read and write pointers.

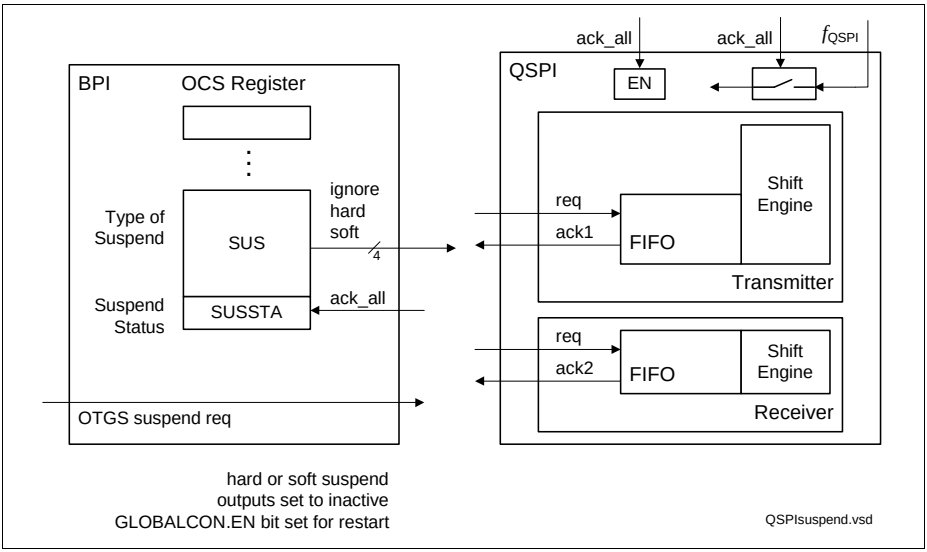

Figure 19-54 Suspend Overview

Note: In Hard Suspend Mode the QSPI kernel clock is switched off immediately. Reading and writing of registers is possible but will enable the kernel clock for a few cycles. Attention: register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a QSPI kernel reset might not be sufficient to bring the system into a defined state.

19.10.2 Sleep Mode

Sleep signal is a system wide hardware signal requesting from all modules to go to low power saving state as soon as possible. For the QSPI module, going to sleep mode can be disabled or enabled by setting or clearing the CLC.EDIS bit. The module enters the sleep as soon as possible and remains in this state as long as the hardware sleep signal is active. Upon deactivation of the sleep signal, the QSPI wakes in PAUSE state (**GLOBALCON**.EN bit is cleared by the QSPI module) and waits for the software to enable the **GLOBALCON**.EN bit.

If CLC.EDIS bit is cleared, the sleep mode is enabled and the module enters the sleep state:

in master mode

- after ending the TRAIL delay if a transmission is in progress
- or immediately if the module is in WAIT state

in slave mode

- after the bit counter has counted the full predefined number of bits as defined in GLOBALCON.DL and BYTE bit fields.
- immediately if the module is in wait state, no transmission ongoing and shift register empty and TXFIFO empty
- or immediately if the SLSI is inactive (the one selected by PISEL)

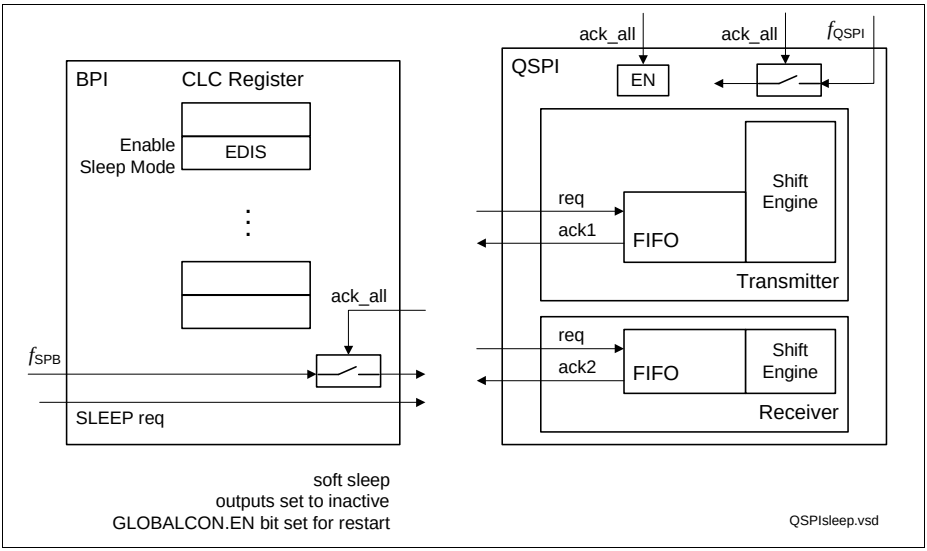

Figure 19-55 Sleep Overview

It is responsibility of the user software to have the sleep enabled in a safe time intervals, where no race conditions or pipeline effects between the QSPI module and the DMA can occur in case of sleep request.

Note: CLC disable request and sleep request block immediately kernel register write accesses. This includes also the TXFIFO access. Therefore if the module expects more data (like in long or continuous mode), it will enter the expect phase and remain there and never do an acknowledge and enter the required state. Periodic timeout interrupts will be generated. Therefore it is not recommended to request a sleep or disable during an ongoing long or continuous transfer.

19.10.3 Disabling the QSPI

The software can switch off the QSPI module by setting the CLC.DISR bit. It is responsibility of the user software to issue a disable request in a safe time interval, where no race conditions or pipeline effects between the QSPI module and the DMA can occur. This is no issue if the switch-off procedure is one-way, that is no continuation of operation without reinitialization/reset of the module is expected. **GLOBALCON**.EN bit is cleared.

The QSPI module itself behaves in the following way.

in master mode like entering the sleep mode:

- after ending the TRAIL delay if a transmission is in progress
- or immediately if the module is in WAIT state

in slave mode

- after the bit counter has counted the full predefined number of bits as defined in GLOBALCON.DL and BYTE bit fields, if a transmission is ongoing or
- immediately if the module is in wait state, no transmission ongoing and shift register empty and TXFIFO empty

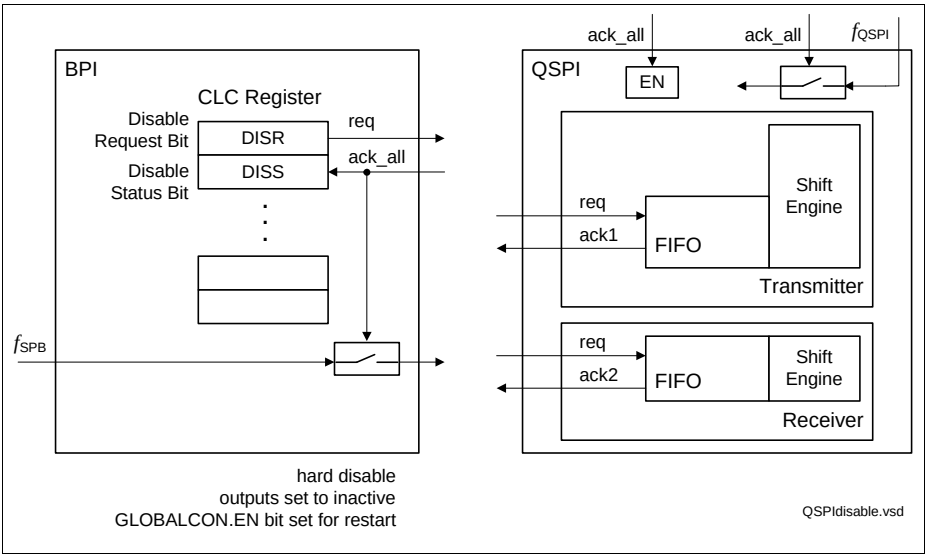

Figure 19-56 Disable Overview

19.11 Reset Behavior

There are two sources of reset:

- BPI (Bus Peripheral Interface)
- Reset bits in the kernel register - **GLOBALCON**.RESETS

BPI reset puts the whole QSPI module in reset state. All outputs get the reset value.

Software writing the **GLOBALCON**.RESETS bit field contains bits for resetting: TXFIFO, RXFIFO, shift state machine, register file. Setting all the bits in a single write resets the whole module.

19.12 QSPI Module Implementation

This section describes the interfaces of the QSPI module instances with the clock control, port connections, interrupt control, and address decoding. There are 4 module instances, QSPI0 to QSPI3.

19.12.1 Module Identification Registers

The reset values of the QSPIx_ID module identification registers are 00C0 C0XX$_H$.

19.12.2 Interfaces of the QSPI Modules

Figure 19-57 shows the implementation details and interconnections of the QSPI module.

Each of the QSPI modules is supplied with a separate clock control, interrupt control, and address decoding logic. Two interrupt outputs can be used to generate DMA requests. The QSPIx I/O lines are connected to the ports as described in the pinning and ports chapters.

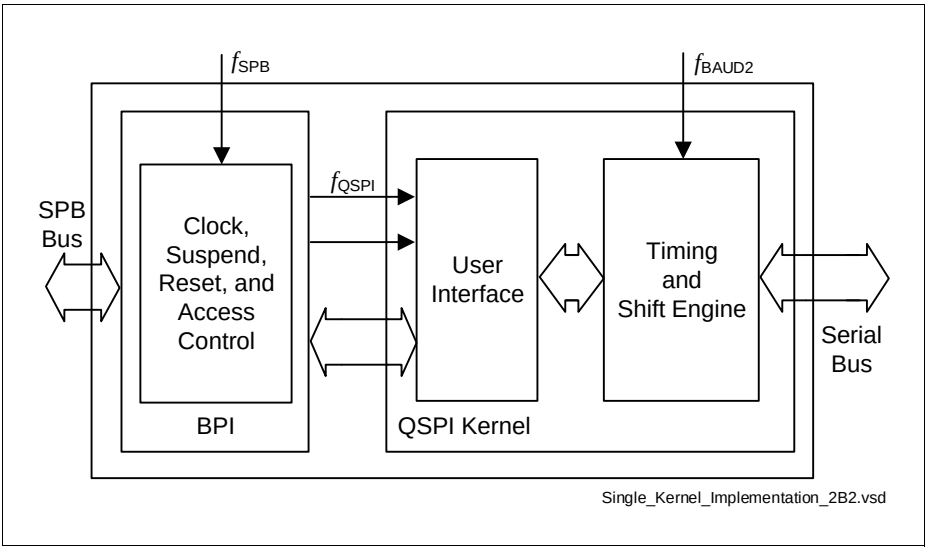

Figure 19-57 Module Implementation Overview

19.12.3 On-Chip Connections

This section describes the on-chip connections of the QSPIx module instances.

SCU Connections

Wake-up from sleep is done by the SCU.ERU triggering a software interrupt on a programmable edge on SLSI pin.

DMA Requests

There are no dedicated DMA request lines. The interrupt or service request signals are general purpose request signals that can be routed to each service provider.

Port/Pin Connections

The connections of the QSPI modules to the pins / ports is described in the chapters regarding the pinning and the ports.

The MTSR and MRST signals are also mapped to LVDS output and input pads. For details see the Ports chapter and the Pinning chapter.

Note: If LVDSH receiver pad is used, the software must take into account the corresponding control and configuration bits, located in the HSCT module and in the corresponding port registers.

Input signals not connected to ports/pins are connected to the following voltage levels:

- The unconnected SCLKI signals are connected to low level “0”
- The unconnected SLSI signals are connected to (inactive) high level “1”
- The unconnected MRST input signals are connected to low level “0”.

19.12.4 QSPI Related External Registers

Figure 19-58 summarizes the module-related external registers which are required for QSPI programming. These are:

- port registers and
- service request node registers,

described in the corresponding chapters.

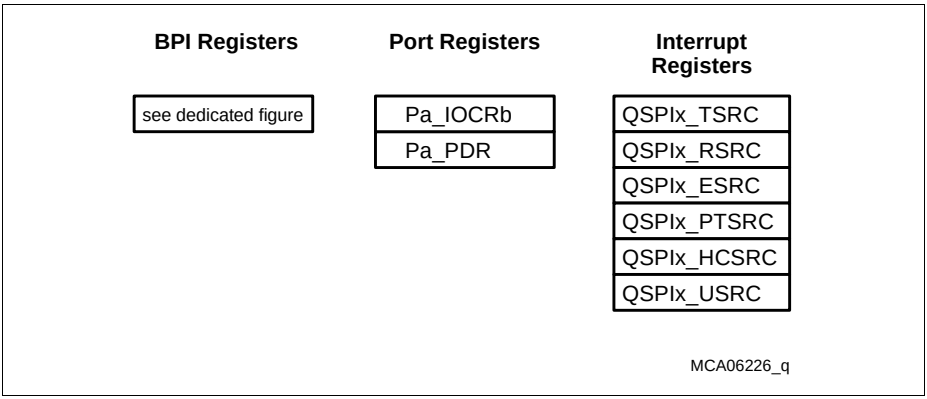

Figure 19-58 Implementation-specific Special Function Registers

19.12.4.1 BPI_FPI Module Registers

System Registers

Figure 19-59 shows all registers associated with the BPI_FPI module, configured for one kernel. The Offset Address in the following BPI_FPI register table and in the BPI_FPI register descriptions are proposals. In a standard 32 bit peripheral the CLC should be mapped to offset address 00h, module ID to 08h. The proposal for the new BPI_FPI register is to map them to the end of the peripheral address range.

BPI_FPI Registers Overview

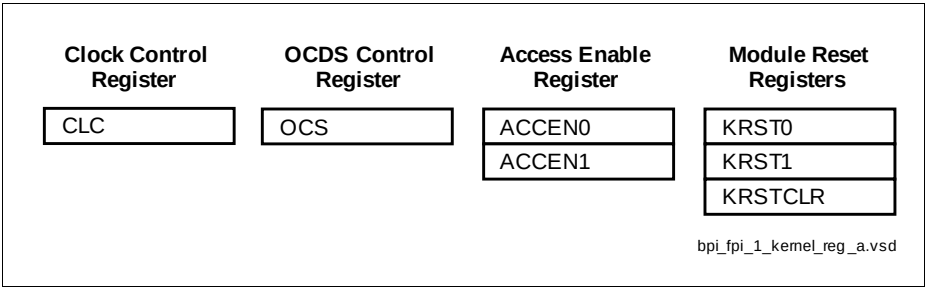

Figure 19-59 BPI_FPI Registers

The writes of the bus masters to the QSPI module is controlled by Access Protection registers ACCENx.

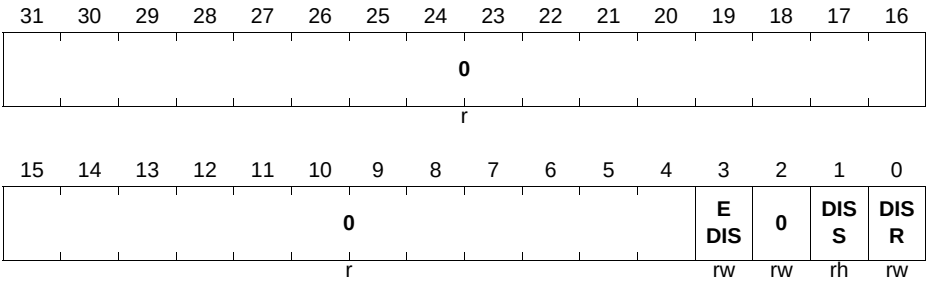
The QSPI implements two ACCENx registers, ACCEN0 and ACCEN1.

The ACCENx registers are protected by Safety Endinit mechanism.

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the $f_{<>}$ module clock signal, sleep mode and disable mode for the module.

CLC
Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to enable the module's sleep mode. 0_B Enabled 1_B Disabled
0	[31:4]	r	**Reserved** Read as 0; should be written with 0.
0	2	rw	**Reserved** Should be written with 0.

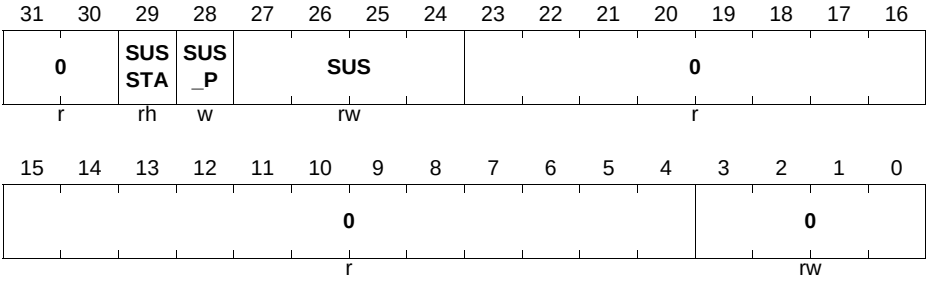
OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode

OCS

OCDS Control and Status (E8$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. 2_H Soft suspend **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0. The bits [4:0] are rw (readable and writable).

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

ACCEN0

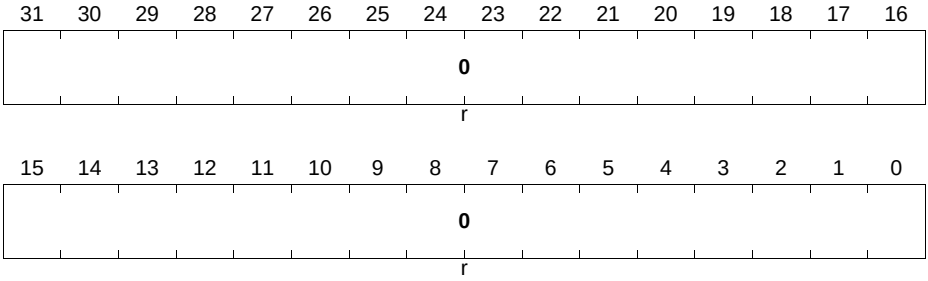
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ACCEN1
Access Enable Register 1 **($F8_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

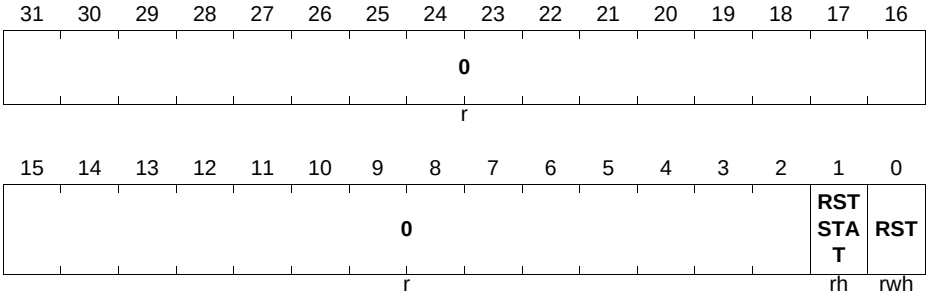
Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **($F4_H$)** **Reset Value: 0000 0000$_H$**



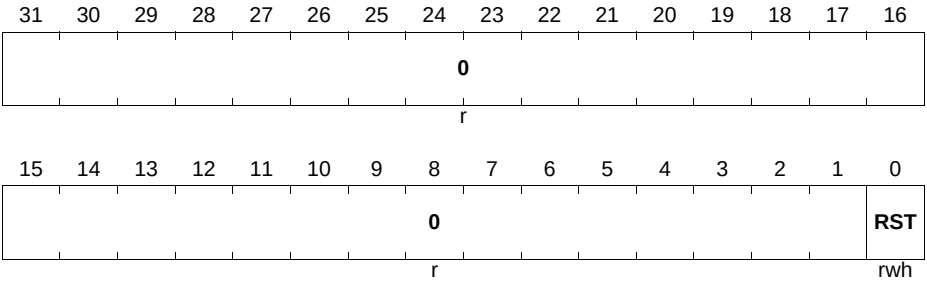
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST

bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($F0_H$)** **Reset Value: $0000\ 0000_H$**



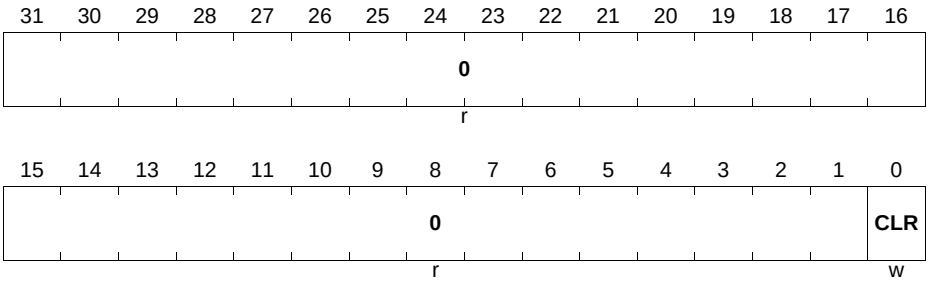
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (EC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

19.12.4.2 Interrupt Control Registers

The interrupts of the QSPI module are controlled by six service request control registers, located in the IR (Interrupt Router) module:

- QSPIxTX Transmit Interrupt
- QSPIxRX Receive Interrupt
- QSPIxERR Error Interrupt
- QSPIxPT Phase Transition Interrupt
- QSPIxHC High Speed Capture Interrupt
- QSPIxU User Interrupt

20 High Speed Serial Link (HSSL)

The HSSL module provides point-to-point communication of both single data values and of large data blocks, called streams. The communicating devices can be complex microcontrollers, or a microcontroller and a device with only basic execution capabilities. There are four channels to transfer single values to/from target. They support direct writing of 8/16/32 bit data from the initiator into a target's register, as well as reading a value from a target, performed by a modules internal master on the target side. For transferring large data blocks there is a channel containing FIFOs. The HSSL module implements Transport Layer tasks and hands over the data to another module which provides Data Link Layer and Physical Layer services, data serialization and transmission. All transfers are protected by safety features like CRC and timeout.

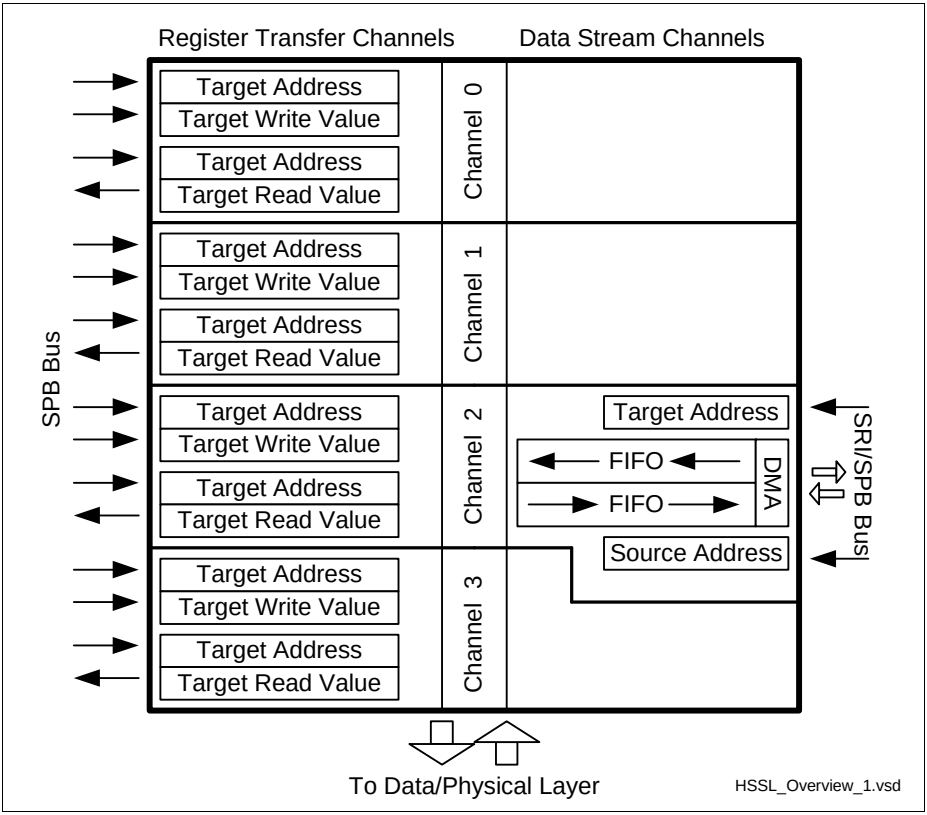


Figure 20-1 Block Diagram HSSL

Features

- Connects microcontroller to microcontroller or to any digital device
- Writing a single 8 / 16 / 32 bit data value into the register of a target device
- Reading single data from an 8 / 16 / 32 bit register of a target device
- Support of 32-bit address range
- Transfers protected by CRC16
- Programmable time outs for detection of blocked answer transfers
- Automatic frame transfer ID generation for detection of dropped frames
- Support of DMA driven multiple register write / read transfers
- Efficient transmission and reception of large data blocks / streams
- Acknowledge for command and stream frames to reduce latency of error detection
- Two stage FIFOs for transmitting and receiving streaming data
- Automatic FIFO flush when entering the run mode, for error handling
- Write protection by an external Memory Protection Unit MPU
- Remote trigger of event / interrupt in the target device by the initiator
- Identification of the target by the JTAG ID number
- Feature set identification of the HSSL module possible by using the JTAG ID number
- Access protection from an external master

Description

The HSSL module generates all necessary protocol formats in order to enable two devices to communicate to each other. Two basic modes are supported.
In register transfer mode the transmitter (“sending device”) provides an address and a data value by writing them into dedicated registers of the HSSL module. The HSSL module puts it into an envelop (called frame) and forwards it via physical layer to the target device. The target takes the information out of the frame and writes the received data into the address which came in the same frame as the data. If the sender wants to read the content of a register or a memory location, it simply sends only the address. The target device reads the value from the specified location and replies it to the sender by transferring it through an answer frame, which has a format of it’s own.

The transfer of register / memory contents is protected by several security levels. A 16 bit CRC value (called CRC16) is attached to the end of each frame. Each transfer process triggers a watchdog, which makes sure that the communication happens within a deterministic schedule. The target device itself offers the capability to define access windows, which allow reading or writing only from / into certain address ranges.

Each frame must be acknowledged by the target by sending an appropriate response frame. If the response frame does not come inside a predefined time window, the initiator module triggers a timeout interrupt.

In data stream mode data blocks of user defined size can moved from the memory of the sending device into the memory of the target device. A DMA master, which can be configured with any source address and source length, autonomously fetches data, breaks it into smaller blocks of programmable size, and puts it into a FIFO. The lower level companion module of the HSSL module empties the FIFO from the “other side” to the physical lines, which connect two devices. In the target device receives a structure, which is inverse to the sender system, the data blocks, puts them into a FIFO, which is in turn emptied by a DMA master into the target memory.

All streaming data transfers are subject to the protection features which are available for the register transfer mode.

After module reset, most registers are only released for read for remote access. They have to be unlocked by the local SW.

In order to ensure consistent initialization of the communication channel there is a possibility to determine the feature set of the module by using the JTAG ID of the device, which uniquely identifies the available HW options of the module. ASIC versions of the HSSL interface may only employ stripped down instances.

20.1 Lower communication layers module (HSCT)

The lower level companion module/logic controls the lower communication layers positioned between two devices, the data and the physical level.

The chip to chip interface employs a digital interface for inter chip communication between a master IC and a slave IC. The interface is capable of running in a master or in a slave mode. During configuration phase the role of the Interface (master or slave) has to be defined. It is not intended to change the system role during an application.

The interface consists of a full-duplex RX and TX high-speed data interface based on double ended differential signals (in total 4 lines) and a master clock interface (SYS_CLK). The master IC owns the crystal and provides the clock to the slave. The interface reset is derived from the System reset and provided by chip internal reset signaling.

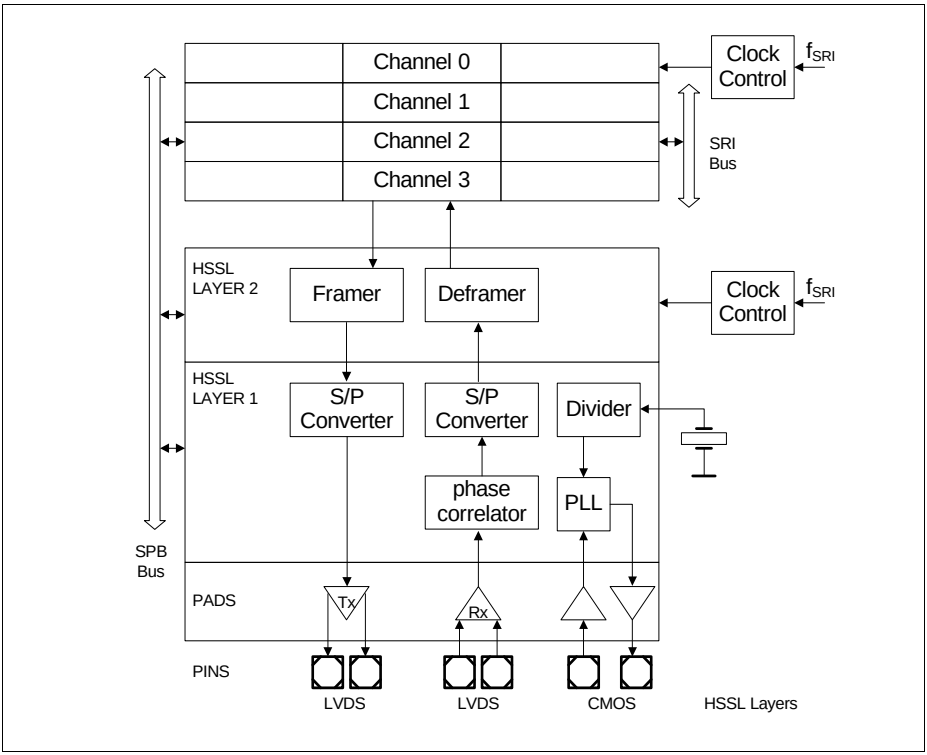

Figure 20-2 Physical Layer

Features:

- Transmission of symbol information from the master IC to the slave IC
- Receive symbol information sent from the slave IC to the master IC
- System Clock provided by the master IC (crystal owner) to the slave IC
- Exchange of control information in both directions
- Clear To Send indication in both directions
- Unsolicited status in both directions
- Regular data transfer in both directions based on data channels
- Master IC data transfer speed 5 MBaud and 320 MBaud
- Three slave IC data transfer speeds available based on 20 MHz SYS_Clk:
  5 MBaud (low speed)
  20 MBaud (medium speed)
  320 MBaud (high speed)
- Two slave IC data transfer speeds available based on 10 MHz SYS_Clk (lower EMI):
  5 MBaud (low speed)
  320 MBaud (high speed)
- The interface is based on IEEE 1596.3 LVDS IOs
- To reduce the voltage swing a configuration option is available

20.2 HSSL Protocol Definition

This section describes the high level protocol definition of the HSSL interface.

The HSSL communication normally consists of two stage transactions, sending a command and an receiving a response. It involves two participants:

- an initiator, which starts a transaction by sending a command
- a target, which responds to the command

20.2.1 List of Abbreviations, Acronyms, and Term Definitions

ACK - Acknowledge Frame

NACK - Not Acknowledge Frame (Target Error Frame)

CRC - Cyclic Redundancy Check

HSSL - High Speed Serial Link

TO - Time Out

TT - Transaction Tag

TTERR - Transaction Tag Error

SPB - Serial Peripheral Bus

SRI - Shared Resource Interconnection

SoC - System on Chip

Initiator - Device that starts a HSSL transaction by sending a command frame

Target - Device that responds to a command frame sent by an initiator

20.2.2 Frame Types

The HSSL module generates a serial frame by:

- taking the payload delivered by a CPU or a DMA
- first wrapping it in a HSSL frame by adding header and CRC fields, and then
- wrapping the HSSL frame in a HSCT frame by adding Sync, Header and End bit fields (see **Figure 20-3**)

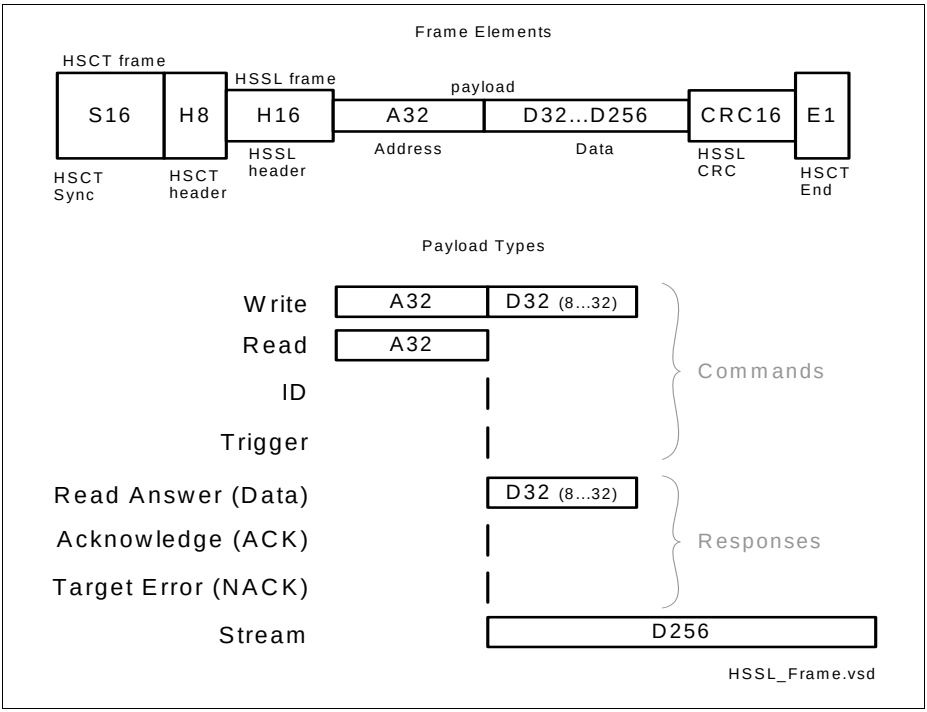

Figure 20-3 HSSL Frame Types

There are several types of frames:

Command Frames

Command frames are sent by the initiator to request an action by the target. There are four types of command frames:

- **Write Frame**
  - Used by the initiator to request the target controller to write the data to the address, both provided by the initiator.
- **Read Frame**
  - Used by the initiator to request the target controller to read and deliver a content from an address from its address space.
- **Read ID Frame**
  - Used by the initiator to request the target controller to read and deliver a content uniquely defining the target device. The answer is a standard Read Data Answer Frame.
- **Trigger Frame**

– Used by the initiator to trigger the trigger interrupt in the target module.

In this document, the command frames are sometimes referred to as WRT frames.

Response Frames

Response frames are sent by the target either to deliver the requested data or to report a successful or unsuccessful completion of a request. There are three types of response frames:

- **Read Data Answer Frame**
  – Used by the target to deliver the data, requested by the initiator with a read command frame. It is frequently referred to as a Data frame.
- **Acknowledge Frame**
  – Used by the target to confirm the completion of a write or trigger command. It is frequently referred to as an ACK frame.
- **Target Error Frame**
  – Used by the target to report the unsuccessful attempt to complete a write or read command. It is frequently referred to as a NACK frame.

Stream Frame

Used by the initiator controller for sending data streams. It behaves similar to a write command frame which contains long 256-bit data block, is acknowledged in the same way, but the acknowledge uses sliding window with depth of 2 (instead of 1 as for the simple command frames).

20.2.2.1 Frame and Payload Lengths

Each type of frame has a single data length associated with it. The length of the frame depends on the length of the payload. Different frame types have different payload lengths, but the payload length for one type is constant for all variations of the frame type.

For example all data frames have the same length, although they can carry 8, 16 or 32 bit data. This is due to the fact that the data field in the frame is always 32 bit long, and if the data itself is shorter, it is copied several times to fill in the whole field. The same behavior is valid for the read answer frames.

The rest of the frame, consisting of sync and header fields, has always the same length (see **Figure 20-7**).

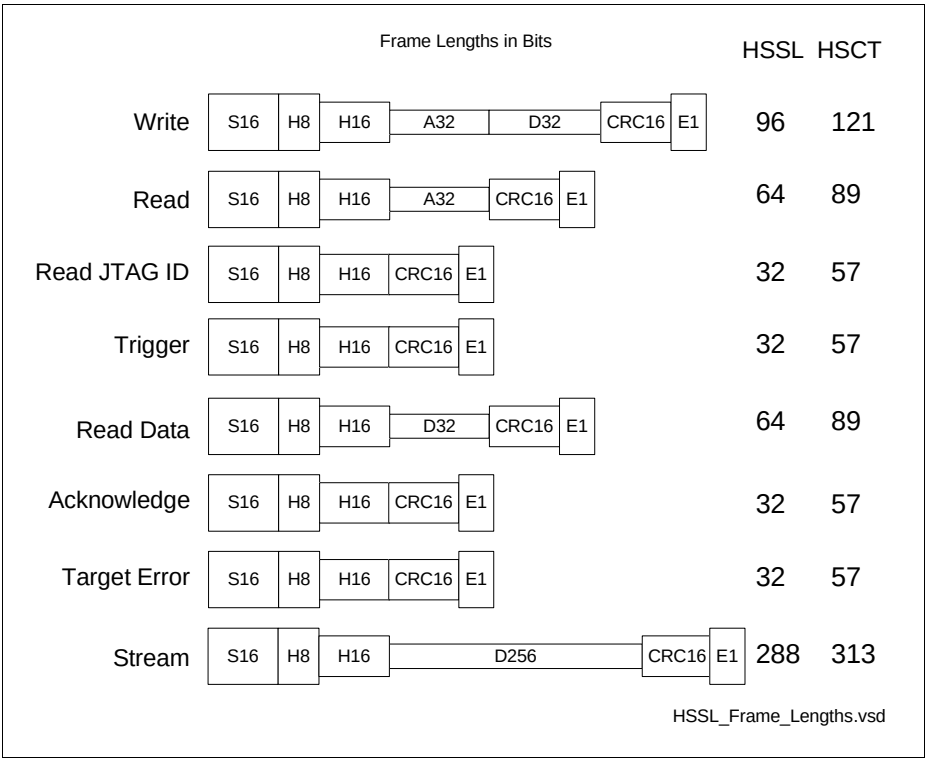

Figure 20-4 Frame Lengths

20.2.2.2 Data Types

There are four types of HSSL data:

- 8-bit
- 16-bit
- 32-bit
- 256-bit stream block

The in case of 8/16/32 bit data types, the transmitted number of bits is always 32, where the shorter data types are copied several times to fill up this length (see **Figure 20-5**).

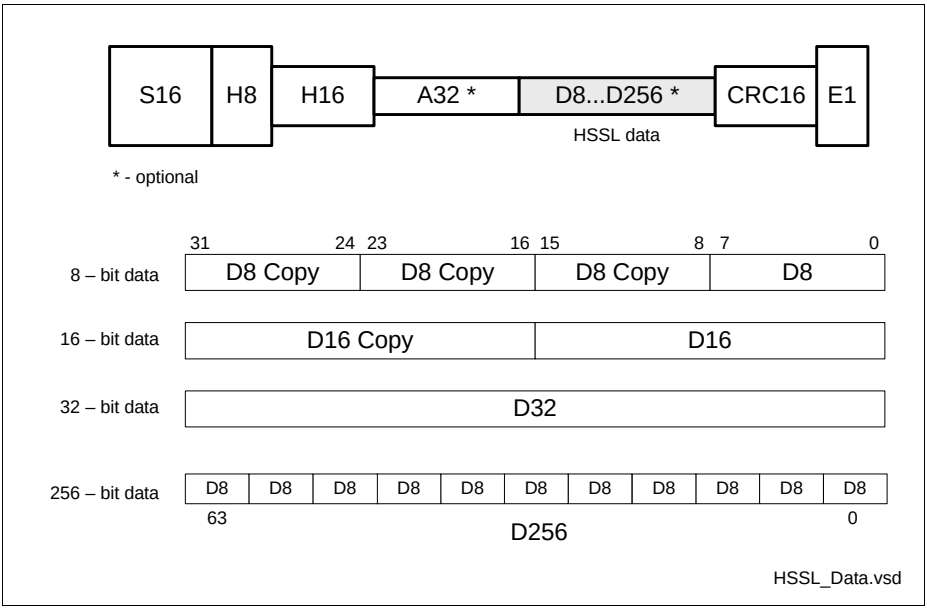

Figure 20-5 Data Types

20.2.2.3 Cyclic Redundancy Check Field - CRC

The HSSL protocol uses the CRC-16-CCITT polynomial: $x^{16} + x^{12} + x^5 + 1$ with the following standard properties:

- seed: 0xFFFF
- calculation direction: MSB first (header msb to lsb, then payload msb to lsb)
- CRC result direction: MSB first

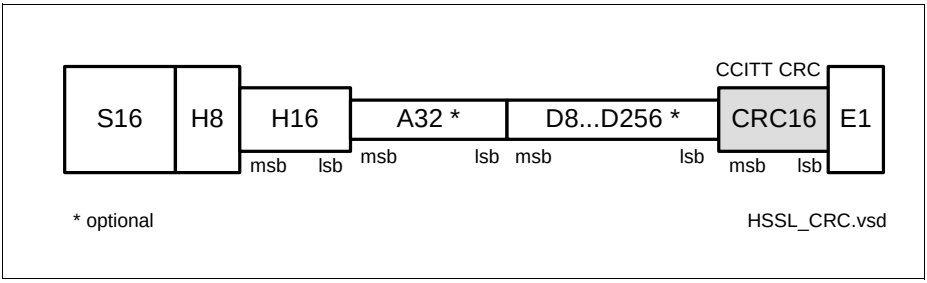

Figure 20-6 CRC Field

20.2.2.4 Header Structure

The HSSL header contains the protocol information that is required additionally to the raw payload data. The HSSL header describes the payload data regarding the length and the type, and carries additional information like channel number code and transaction tag. It also carries stand-alone information in case of frames without payload, like acknowledge and trigger frames.

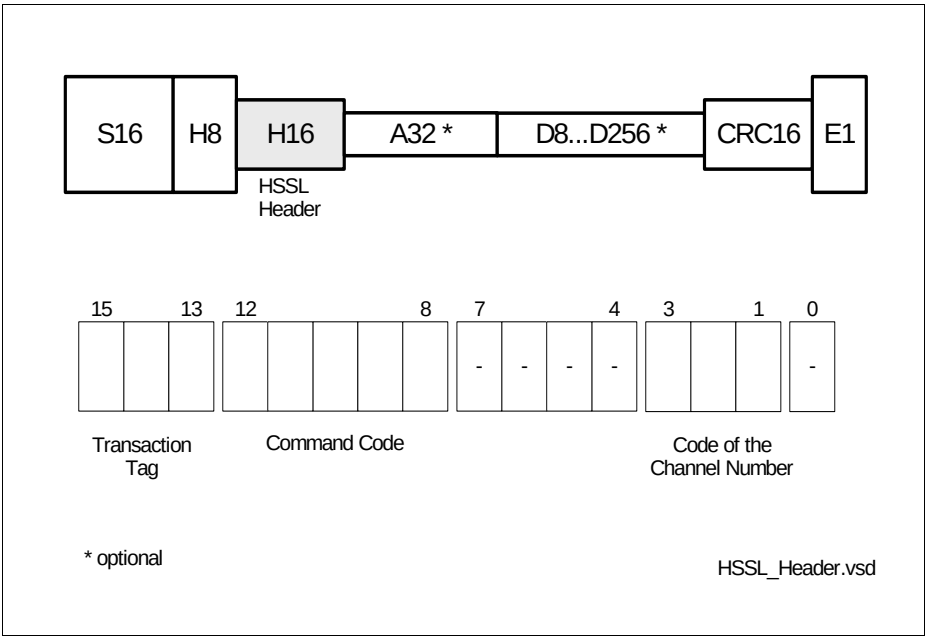

Figure 20-7 Header Types

Note: The unused bits in the header are padded with 0.

Table 20-1 Mapping of HSSL to HSCT channel codes

HSSL Channel Number	HSSL Channel Number, Binary Code	HSSL Channel Number, Special Code	HSCT Channel	HSCT Channel Code
0	000	100	A	0100
1	001	101	B	0101
2	010	110	C	0110
3	011	111	D	0111
4 (reserved)	100	000	E	1000
5 (reserved)	101	001	F	1001
6 (reserved)	110	010	G	1010
7 (reserved)	111	011	H	1011

Note: The HSSL module supports four channels, 0 to 3.

Table 20-2 List of Command Codes

Command Code	Command Description	HSSL Frame Size
00000	Read 8 bit	64
00001	Read 16 bit	64
00010	Read 32 bit	64
00011	RFU (Reserved for Future Use)	-
00100	Write 8 bit with ACK (Acknowledge)	96
00101	Write 16 bit with ACK	96
00110	Write 32 bit with ACK	96
00111	RFU	-
01000	ACK OK	32
01001	ACK Target Error	32
01010	Read Answer OK	64
01011	RFU	-
01100	Trigger with ACK	32
01101	RFU	-
01110	RFU	-

Table 20-2 List of Command Codes

Command Code	Command Description	HSSL Frame Size
01111	RFU	-
10000	RFU	-
10001	RFU	-
10010	Read JTAG ID 32-bit	32
10011	RFU	-
10100	RFU	-
10101	RFU	-
10110	RFU	-
10111	Stream Data with ACK (32 Byte Data)	288
11000	RFU	-
11001	RFU	-
11010	RFU	-
11011	RFU	-
11100	RFU	-
11101	RFU	-
11110	RFU	-
11111	RFU	-

20.2.3 Single and Block Transfers

Single frame transfers are always performed expecting an acknowledge.

20.2.4 Streaming Interface

Stream frame transfers are always performed with acknowledge.

There are only write streams possible. Read streams are not possible.

20.2.5 Sliding Window Protocol

For flow control the HSSL module implements two variants of the “Sliding Window” protocol regarding the sliding window depth:

- depth of one used for command frames
  - The depth of one means that a single timer tracks the arrival of the corresponding response frame. A new command can be sent only after the response to the previous command has been received, or a timeout occurred

- depth of two used for streaming frames
  – the depth of two means that there are two timers tracking the acknowledge times for the two latest streaming frames. In this case, a second stream frame can be sent although an acknowledge / timeout to the previous stream frame has not been received yet. After the second stream frame, no third stream frame can be sent before the first one has been acknowledged

An example of communication using sliding window with depth of one protocol is shown in **Figure 20-8**. Here, the initiator sends commands originating from one and the same channel, for example channel 0 (labeled with the capital letter “A”), and the corresponding acknowledge frames from the target are labeled with the small letter “a”.

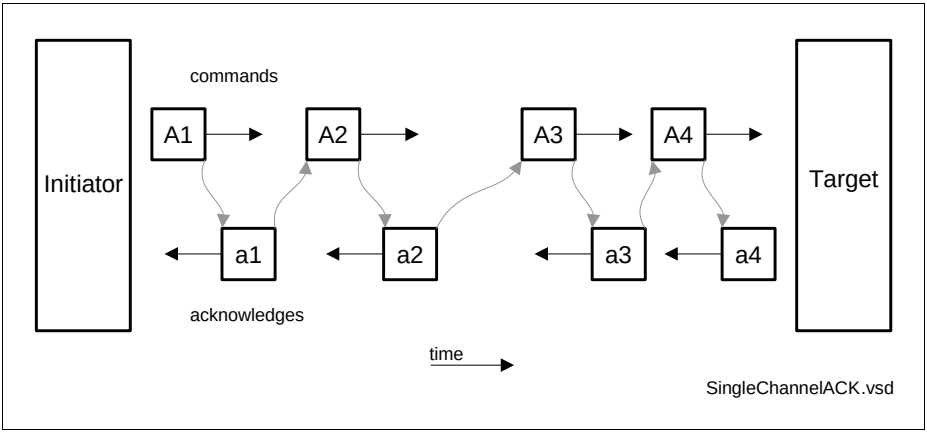

Figure 20-8 Flow Control, Single Channel, Sliding Window With Depth of One

The sliding window protocol requires capability of sending acknowledge frames in the target and timeout timers in the initiator. Every time the target receives a frame without detecting an error, it sends a response / acknowledge to the initiator. If the target detects a frame with a CRC error, it does not send an acknowledge. The missing acknowledge causes a timeout event in the initiator channel.

If the command frames are longer than the acknowledge frames plus the reaction time, like for example in case of streaming, back to back transfers are easily possible, see **Figure 20-9**.

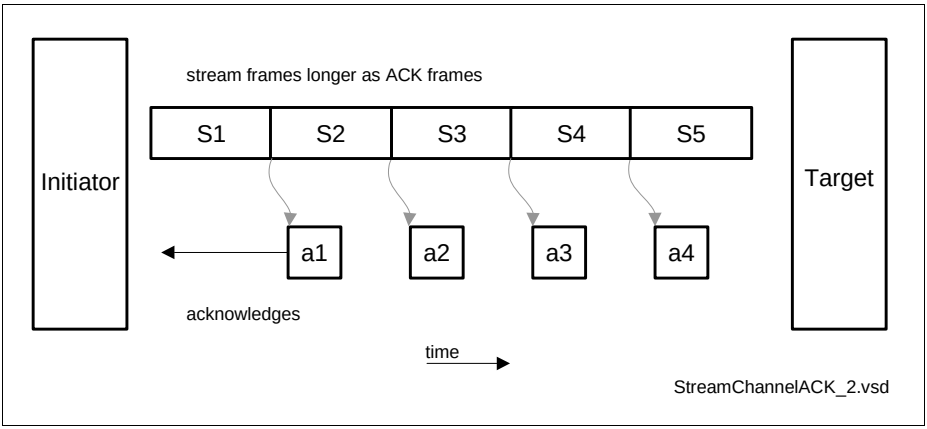

Figure 20-9 Flow Control, Streaming Frames

20.2.6 Error Management

The HSSL protocol defines four types of errors:

- Time Out
- Transaction Tag Error
- CRC Error
- Target Error

Time Out Error

A time out error is detected at the initiator side, if the expected ACK frame was not received within the expected time window. This can occur if a frame had been sent by the initiator, and the target detected an CRC error and did not answer with an acknowledge, or the connection between the initiator and the target is physically damaged in one or the other direction.

Transaction Tag Error

A transaction tag error occurs at the initiator side, if instead the expected ACK frame with the expected TAG number, an acknowledge with an unexpected transaction tag was received. This would indicate a missing frame or missing acknowledge. Transaction tag error generate frames that pass the CRC checking stage.

CRC Error

A CRC Error can occur:

- at the target side, in which case:

  - the CRC error flag is set
  - the received command frame with a CRC error is discarded
  - no acknowledge frame is sent and
  - a channel unspecific EXI error interrupt is generated, if enabled.
- at the initiator side, in which case:
  - the CRC error flag is set
  - the received response frame with a CRC error is discarded
  - a channel unspecific EXI error interrupt is generated, if enabled

Both scenarios lead to a time out at the initiator side.

In both cases the CRC error flag is set at the side receiving the erroneous frame (either initiator or target) and an interrupt is generated, if enabled.

For the purpose of CRC error injection, a bit field with an XOR mask used for toggling the bits of the calculated CRC is provided, see **CRC**.XORMASK. In order to switch on this feature, the E (Endinit) protected bit must be set by the application software. The error injection only influences the generation of the transmitted CRC.

Target Error

A Target Error can occur at the target side, when accessing the target memory a bus error or memory protection error occurs. In such a case, the target responds with an NACK frame indicating the error.

20.2.7 Shift Direction

In general, the HSSL interface makes a copy of a memory location or block from the address space of one microcontroller into the address space of the other microcontroller.

The HSSL module delivers 32-bit parallel data.

The transfer over HSCT serial link is done by using MSB first shifting at 32-bit level.

The overview of the path from the memory to the serial bus is shown in the **Figure 20-10**.

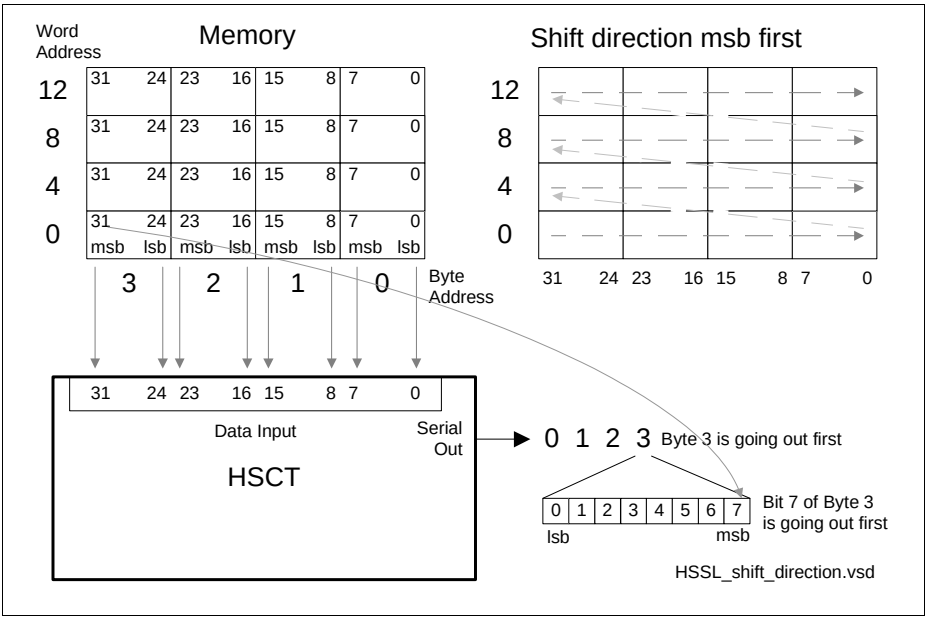

Figure 20-10 Shift Direction in Case of HSCT Layer

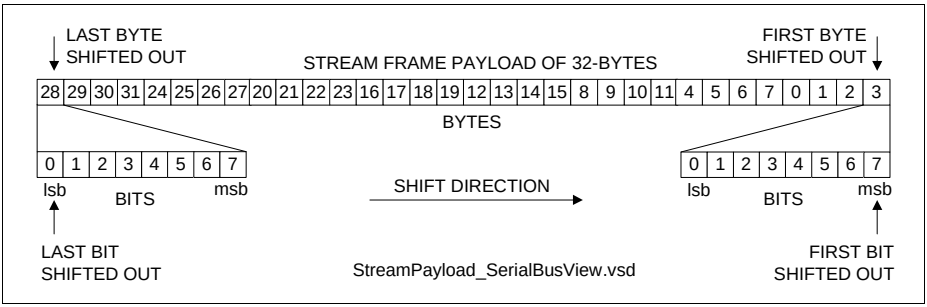

Figure 20-11 Stream Frame in Case of HSCT Layer

20.3 HSSL Implementation

This section describes the implementation of the HSSL protocol.

20.4 Overview

The HSSL module is connected to the SRI bus using a master interface and to the SPB bus using a BPI slave interface.

Additionally, it is connected to the SPB bus using a master interface.

The SRI master interface is capable of performing single and burst reads and writes on the SRI bus. Additionally, the HSSL kernel provides logic for performing streaming communication. The write and read accesses are always performed in User Mode.

The SPB BPI slave interface is used by an SPB master (DMA, CPU, HSSL SPB Master) for writing the HSSL registers, thus configuring the module and performing single read and write operations.

The SPB master interface is capable of performing single read operations, write operations, and streaming communication using BTR4 burst accesses on the SPB bus. The SPB master accesses are always performed in User Mode.

The HSSL module to use the SRI or the SPB master depending on the address of the access. Accesses to the SPB address space are automatically routed to the SPB master, accesses to the SRI address space are automaticaly routed to the SRI master. The address window F000 0000_H - F7FF $FFFF_H$ is used for the SPB bus, otherwise SRI.

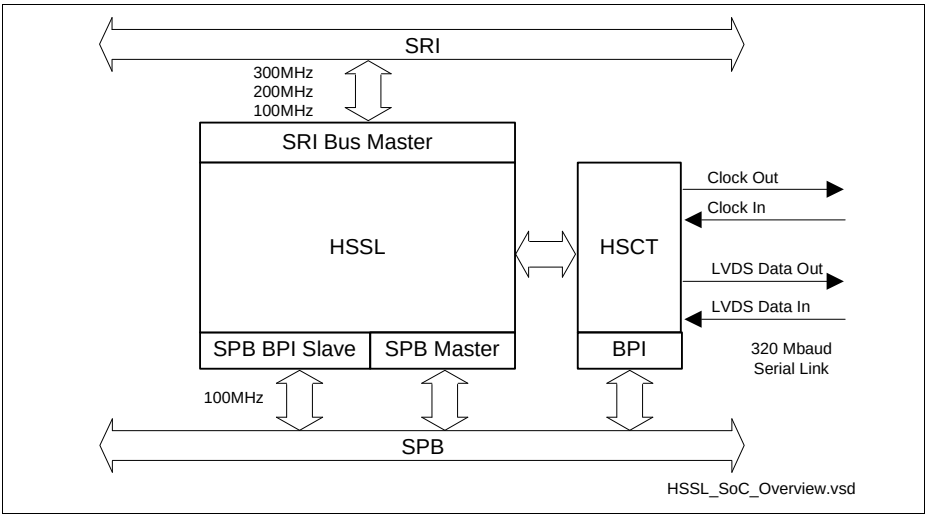

Figure 20-12 HSSL Subsystem Overview

20.4.1 HSSL Module Operation

The HSSL module consists of separate transmitter and receiver, each containing four channels.

The transmitter contains an arbiter block and a wrapper block, which are common for all channels. The arbiter provides fixed arbitration between the channels which are ready to send when the serial link is available, with channel 0 having the highest priority, and the channel 3 having the lowest priority. The wrapper block generates the CRC.

The receiver unwraps the HSSL frame, discards the frames with a CRC error, and distributes the error free commands and acknowledges to the channels.

A common prescaler generates the time basis for all channels, in particular for their timeout timers.

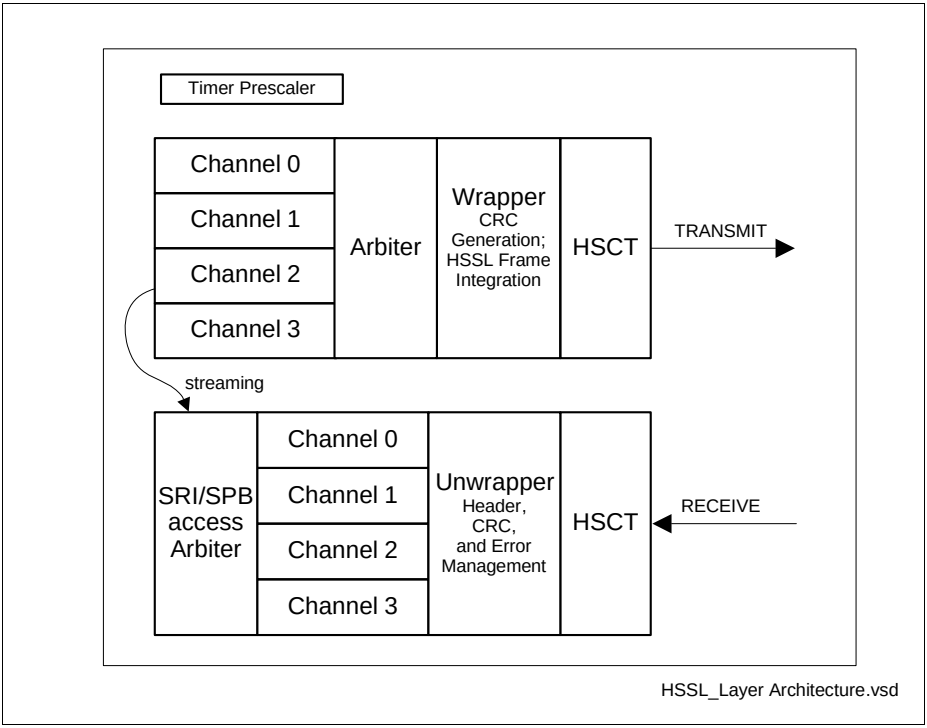

Figure 20-13 HSSL Layer Architecture

20.4.1.1 Frame Transmission Priorisation

When more than one frames are pending, an arbitration is performed between them.

Each channel activates two flags: initiator command flag and response flag: channel 0 I0 and R0, channel 1 I1 and R1...

Between the response and command frame request types, the response request type has higher priority. Among the requests of a same type, lower channel number has higher priority, see **Figure 20-14**. A pending frame is indicated with a corresponding request flag in the register **QFLAGS**.

The SRI/SPB bus master sets the response requests (“R” flags).

The software write accesses via the SPB bus set the initiator requests (“I” flags).

The transmit arbiter clears the “I” and “R” flags of the arbitration winner.

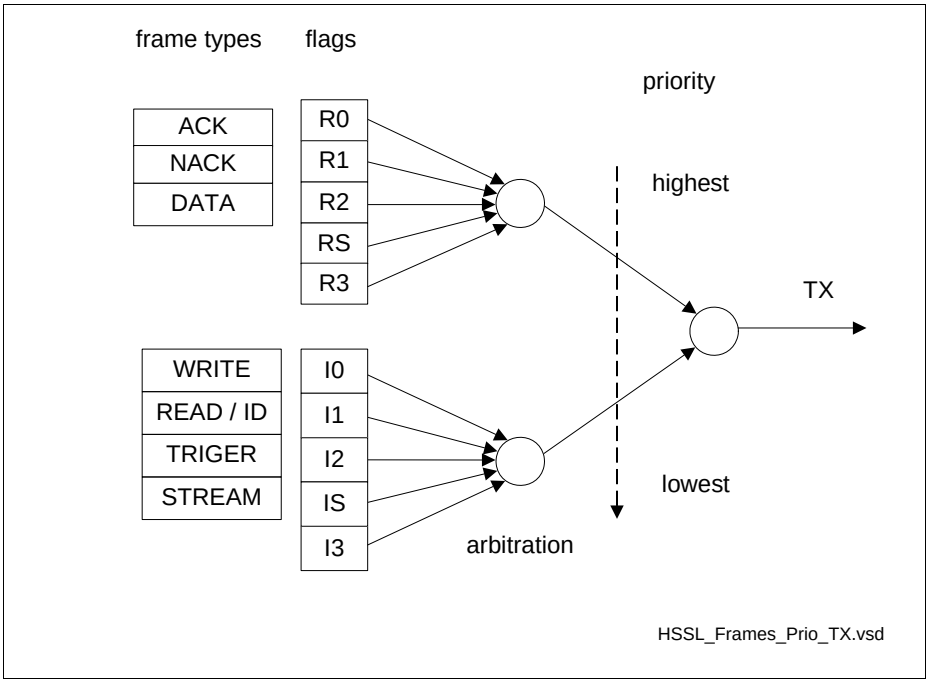

Figure 20-14 Frame Priorities in the HSSL module

20.4.1.2 Received Frame Management and Command Execution

After a frame passes the CRC check, it is checked for its type. A received command frame sets a request flag for the SRI/SPB master, a received response frame resets the expect flag and stops the appropriate channel timeout, see **Figure 20-15**.

The target flags “T” are set by the frame distributor, and cleared by the arbiter of the SRI/SPB master.

The expect flags “E” are set by the Tx arbiter, and reset by the Rx distributor.

The ISB and ISF flags operate together to control the streaming process. The ISB flag (Initiator Stream Block flag) is set by the software to enable the streaming. The ISF flag (Initiator stream FIFO flag) is set/cleared by the TXFIFO according to its filling level.

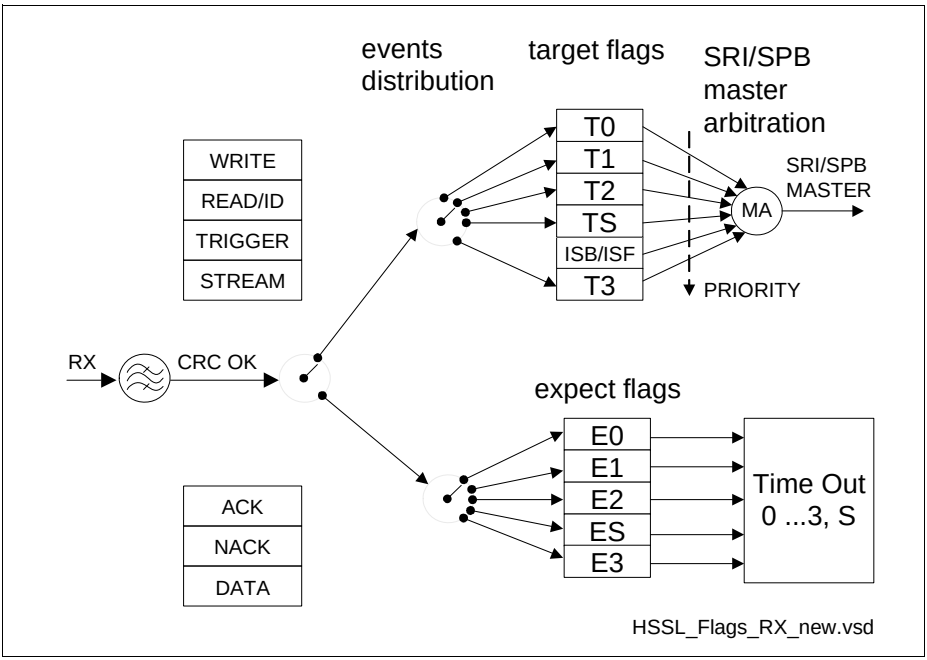

Figure 20-15 Received Frames Management

The CRC and Transaction Tag error flags are located in the **MFLAGS** register.

An overview of a full communication cycle over all sections of a channel (initiator, target or receive, transmit) is shown in **Figure 20-16**.

See also the **QFLAGS** register description.

If the channel does not have a command pending and does not expect a response, it is ready.

Note: In case of a trigger command frame, the target command distributor sets the corresponding Rx flag, and not the corresponding Tx flag, due to the fact that the service request is triggered directly, and not by the SRI/SPB master.

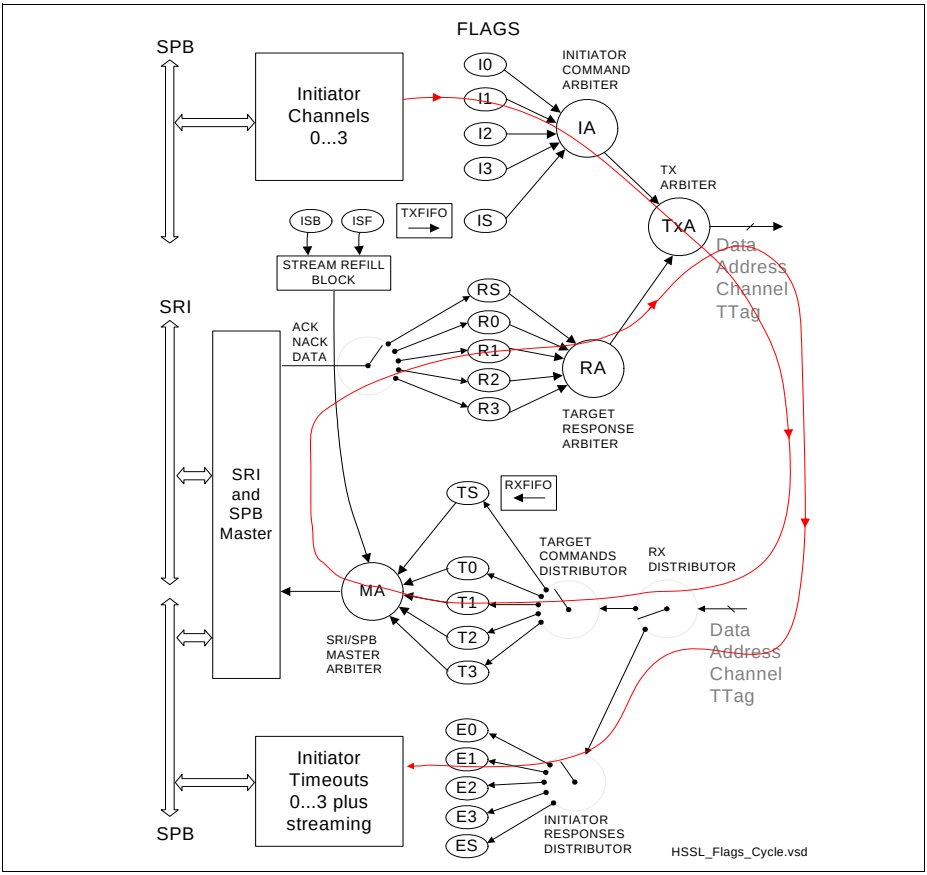

Figure 20-16 Request Flags Overview and a Communication Cycle Example

Table 20-3 Set and Clear of Request Flags

	I	R	T	E	ISB	ISF
SPB Software Write	set	-	-	-	set	-
Tx Arbiter	clear	clear	-	set	-	-
Rx Distributor	-	-[1)]	set	clear	-	-

Table 20-3 Set and Clear of Request Flags

	I	R	T	E	ISB	ISF
SRI / SPB Master	-	set	clear	-	-	-
Stream Refill Block	-	-	-	-	clear	clear
TXFIFO	-	-	-	-	-	set

1) In case of a trigger command, an R flag is set by the Rx Distributor instead of a T Flag, because a trigger command is not executed by the SRI/SPB master.

20.4.2 HSSL Channel Architecture

The HSSL module contains four channels. The functionality of each channel can be subdivided in two ways:

- transmitter and receiver functionality
  - The transmit functionality generates an appropriate header for each frame
  - The receiver generates an appropriate acknowledge header with the tag and channel number code. The read and writes are performed by the SRI/SPB master. Therefore, the module can send back to the transmitter a target error frame if an SRI/SPB bus error occurs and the transfer on the bus can not be executed.
  - The timeout monitoring on one hand and the acknowledge management on the other hand involve both the transmitter and receiver channels
- initiator and target functionality
  - The initiator functionality transmits write, read or trigger command frames in random sequence, after the previous command has been responded to.
  - Generation/comparison of a Transaction Tag per channel is an initiator functionality
  - The timeout management is a pure initiator functionality.
  - The target functionality is to receive commands, executes them, and generates and transmits responses.

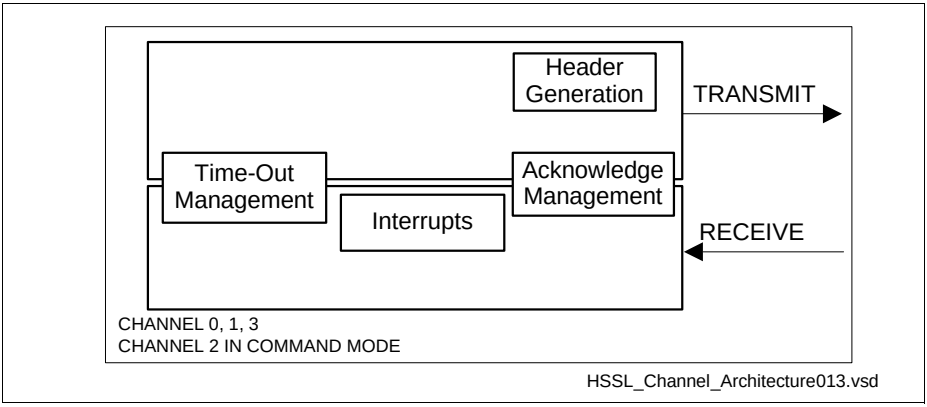

Figure 20-17 Architecture of Channels 0,1, 3 and Channel 2 in Command Mode

Channel 2 can be switched between command and streaming mode of operation. In single mode a single data register is used and in streaming mode a FIFO is used.

Channel 2 contains one initiator and one target address counter which are used to fill a memory range with data. Each counter contains two start address registers and one stream frame count register.
At reaching the predefined frame count, a wrap around is automatically executed.

The granularity of the start address is 256-bit.

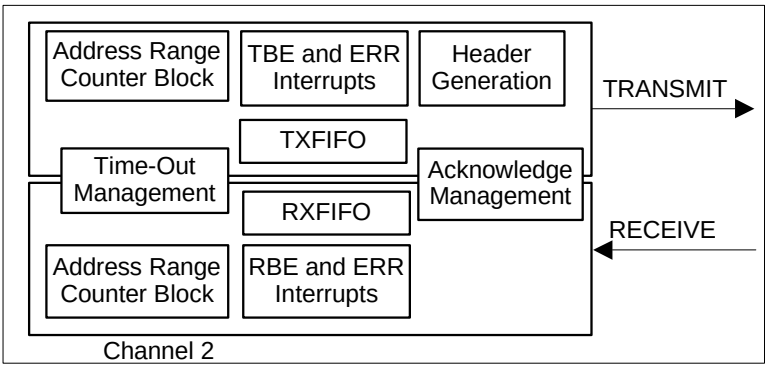

Figure 20-18 HSSL Architecture of Channel 2

A classification of the various channel functions is shown in **Figure 20-19**.

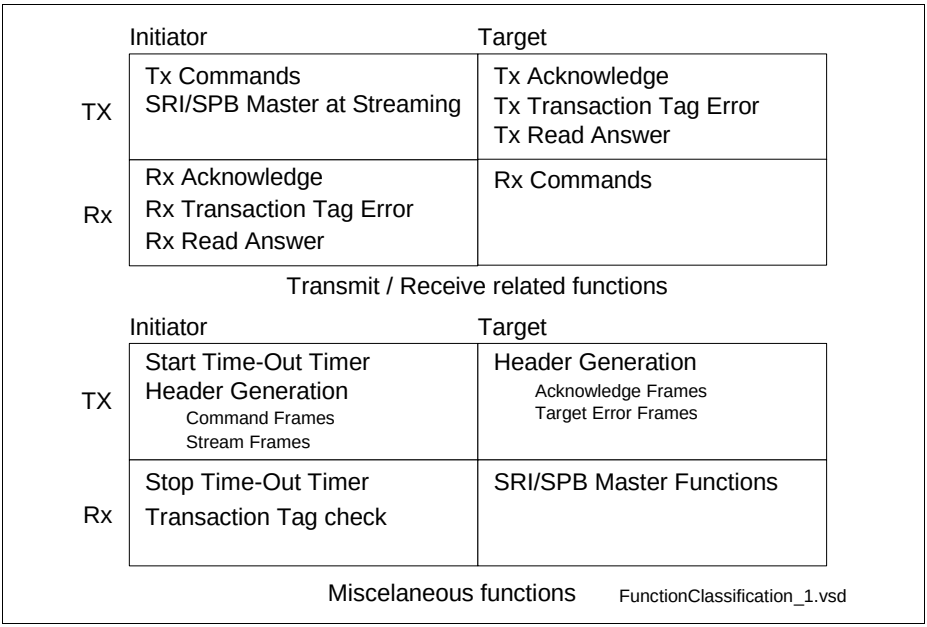

Figure 20-19 Overview of Channel Functions

20.4.3 Acknowledge Responses

A read or write command is executed by the SRI / SPB master. The SRI / SPB master reads or writes to the SRI / SPB bus and signals either a successful transaction or an error. The are the following cases:

- When the SRI master writes or reads an SRI memory, both cases are acknowledged so that the HSSL module receives a feedback in any case.
- When the SPB master writes or reads an SPB module or memory, both cases are acknowledged so that the HSSL module receives a feedback in any case.

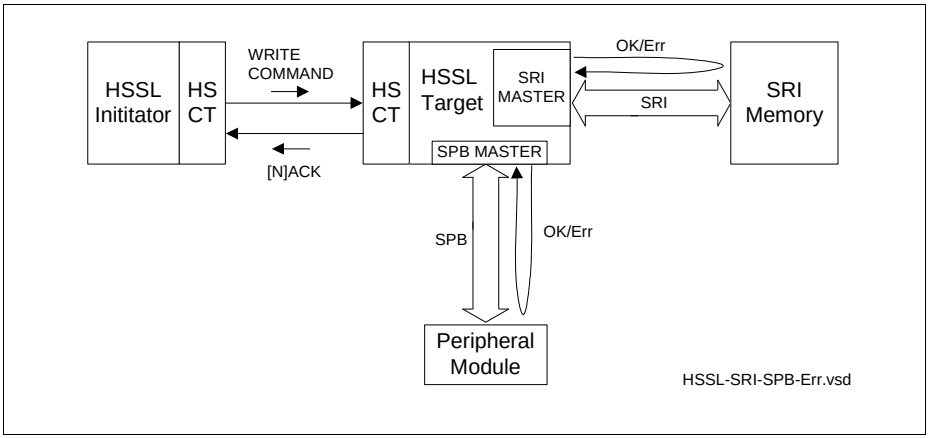

Figure 20-20 Bus Error Feedback Paths

20.4.4 Cross Dependencies Between the Frame Types

For a channel in a target role, there are cross-dependencies between command frame arrival and triggering of an ACK or NACK frame for a channel. Each command frame received with correct CRC of types Write, Stream, or Trigger Frame will result in either ACK or NACK (target error) response frame. Each Read Frame received with correct CRC will result either with Data Frame (Read Response Frame) or with NACK (Target Error Frame), see **Figure 20-21**.

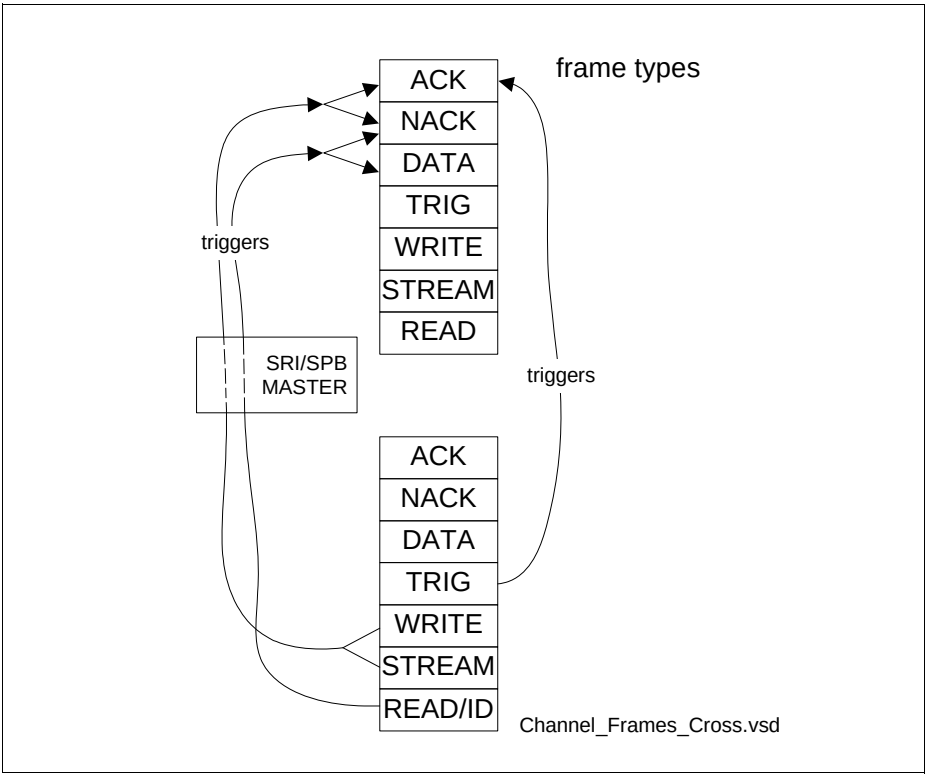

Figure 20-21 Channel 2 Cross Dependencies Between Stream and Command Frames and their Responses in a Target Role

Additionally, generating a response frame involves copying of the transaction tag of the command frame into the response frame. The response frame is triggered by an SRI/SPB master signalling either a successful SRI/SPB bus transaction or an SRI/SPB bus error. Only a Trigger Command Frame triggers immediate acknowledge, because it results in an interrupt flag being set, and not in a bus transaction.

On the initiator side, there is a forward looking cross dependency between a command frame and the expected response, see **Figure 20-22**. Setting a transmission request flag for a certain command is accompanied in parallel with:

- capturing the current transaction tag in the bit field **ICONx (x=0-3)**.CETT.
- generating the next transaction tag by incrementing a three bit counter per channel, the **ICONx (x=0-3)**.ITTAG.
- starting the timeout counter at the moment when the command wins the arbitration
- setting an expect tag indicating that the timeout is running and a response frame is expected. See **MFLAGS**.Ex bit fields.

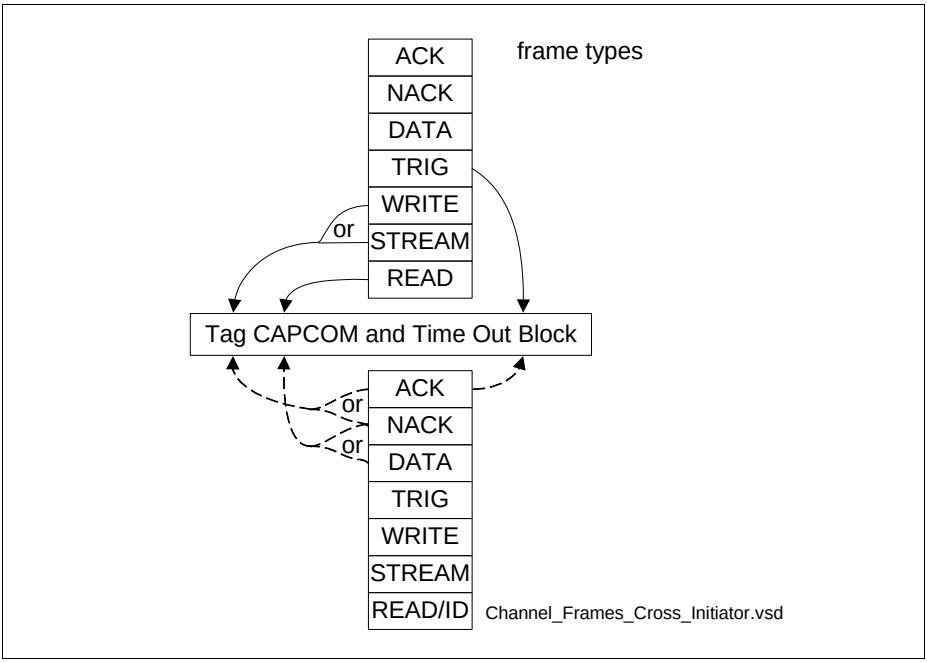

Figure 20-22 Channel 2 Cross Dependencies Between Stream and Command Frames and their Responses in an Initiator Role

20.4.5 Command Timeout

A timeout timer is started when a frame wins the arbitration and is delivered by the channel for transmission. The timeout timer is stopped if an appropriate response frame has arrived in time (without a CRC error). If an appropriate response has not arrived, and the timeout timer reaches zero, the timer is stopped, a timeout error is triggered and the expect flag is cleared.

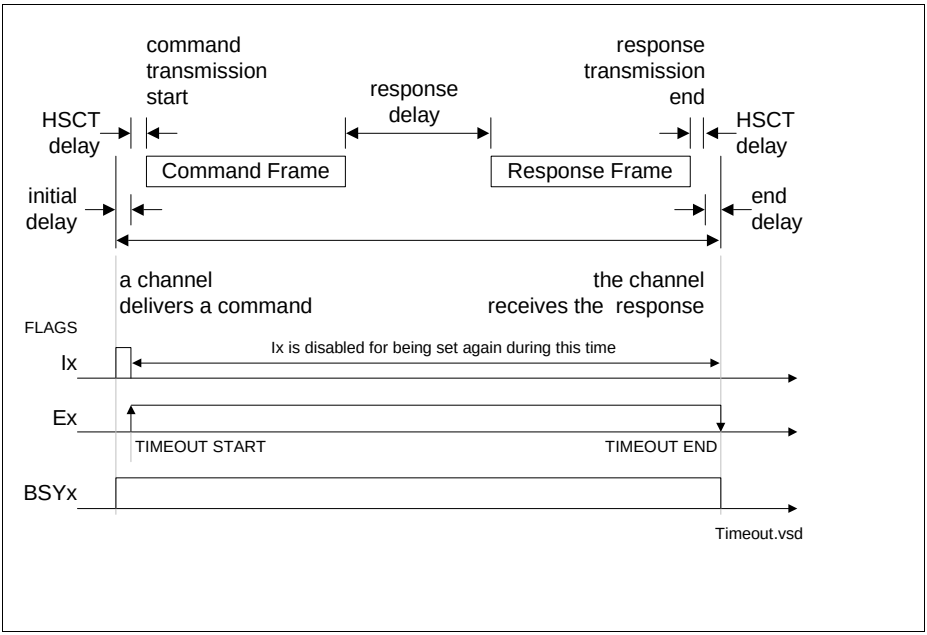

Figure 20-23 Command Timeout Measurement

20.4.5.1 Command Timeout Operation

The HSSL module contains one prescaler common to all channels, and one channel specific timer block per channel. The timer block generates the transaction tag for the channel by incrementing a three bit counter, captures the current transaction tag and compares it with the arrived response. In case of an error sequence CRC and timeout error, the timeout block generates a timeout signal. The timeout timer is reloaded and starts down-counting when the command transmission process starts.

The current timeout timer current value is indicated in the bit field **ICON**.TOCV, and the timeout reload value is configured in the bit field **ICON**.TOREL.

The currently expected transaction tag is indicated in the bit field **ICON**.CETT, the captured value of the latest erroneous transaction tag is indicated in the bit field **ICON**.LETT.

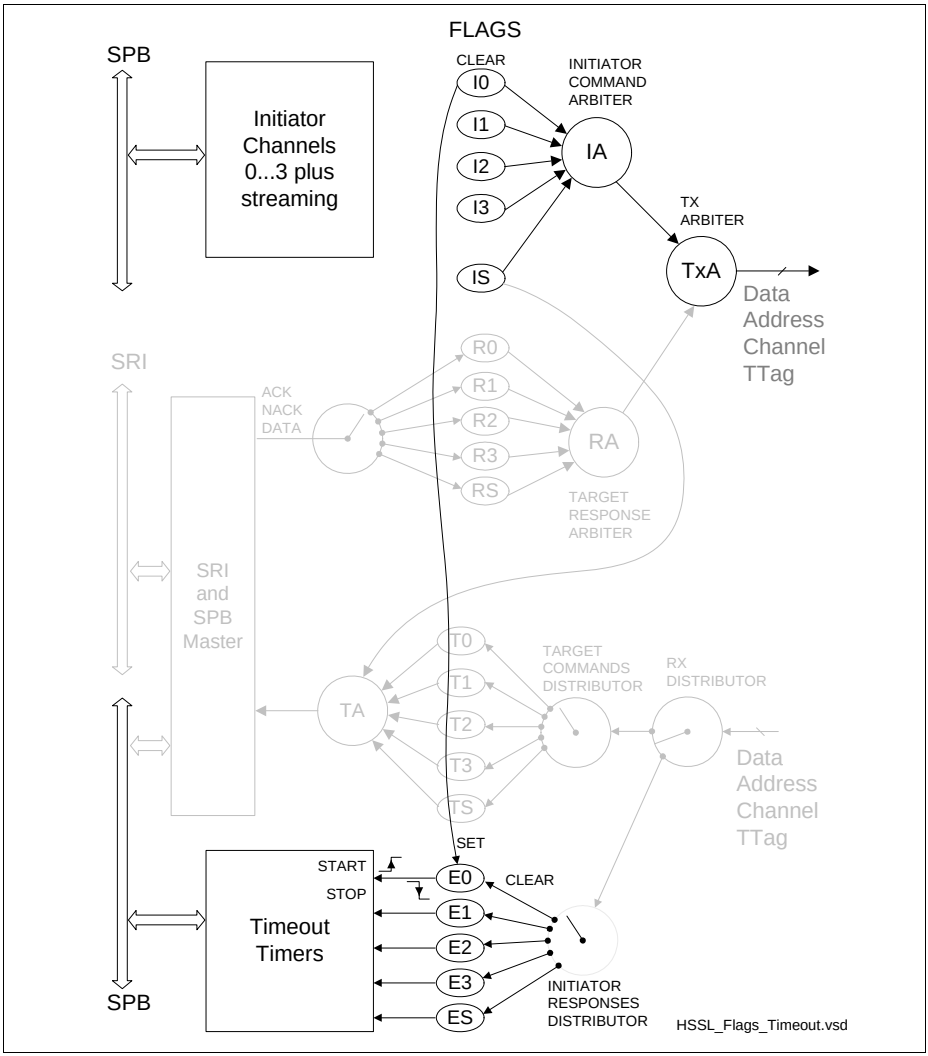

Figure 20-24 Request Flags Overview and a Communication Cycle Example

From the point of view of the flags, the timeout starts with the rising edge of the **QFLAGS**.Ex flag and ends with its falling edge, see **Figure 20-22**. The Ex flag is set by the falling edge of the Ix flag, which is reset when its command request wins the transmit arbitration, see **Figure 20-24**.

20.4.6 Stream Timeout

A free timeout timer block is started when a frame wins an arbitration round and is delivered by the channel for transmission. The timeout timer block is reset to zero and stopped if an appropriate response frame has arrived in time (without a CRC error). If an appropriate response has not arrived, a timeout error is triggered and the timeout timer block is reset.

The stream initiator keeps track of the expected acknowledges using a virtual expect fifo having a virtual filling level EXFL. Each new stream frame transmission increment the EXFL, receiving a correct acknowledge decreases the EXFL. As long as the expect fifo is full (filling level 2) no new transmit request can be issued. In order a new stream frame request to be issued, which means the flag IS to be set by the module, three conditions must be met:

- EXFL<2 - the expect level must be below two,
- TXFL>0 - the TXFIFO must be not-empty and
- ISB = 1 - the bit ISB bit must have been set by the software.

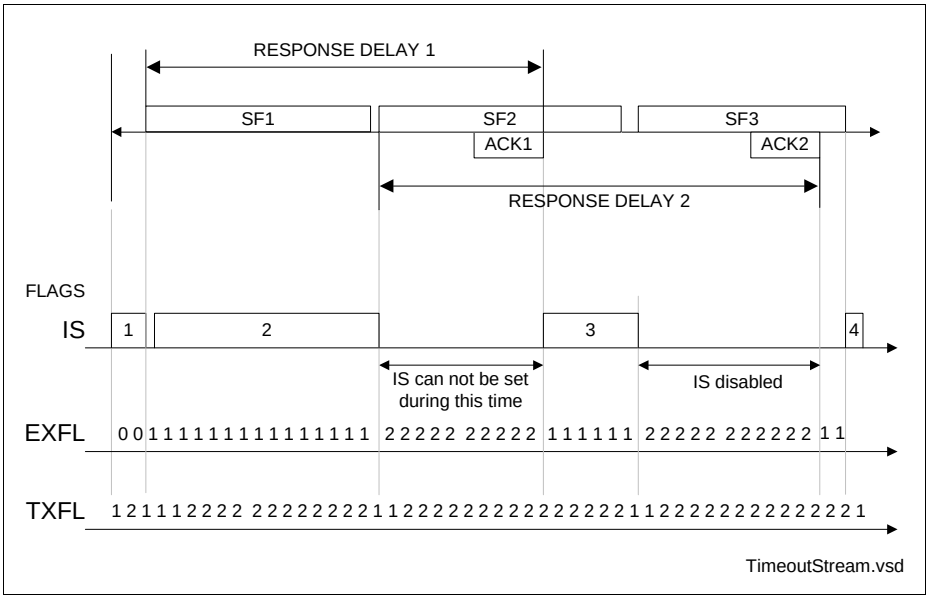

Figure 20-25 Stream Timeout Measurement

20.4.6.1 Stream Timeout Operation

The stream channel monitors the arrivals of the stream frame responses by using two timeout timer blocks. A single timer block is shown in **Figure 20-26**.

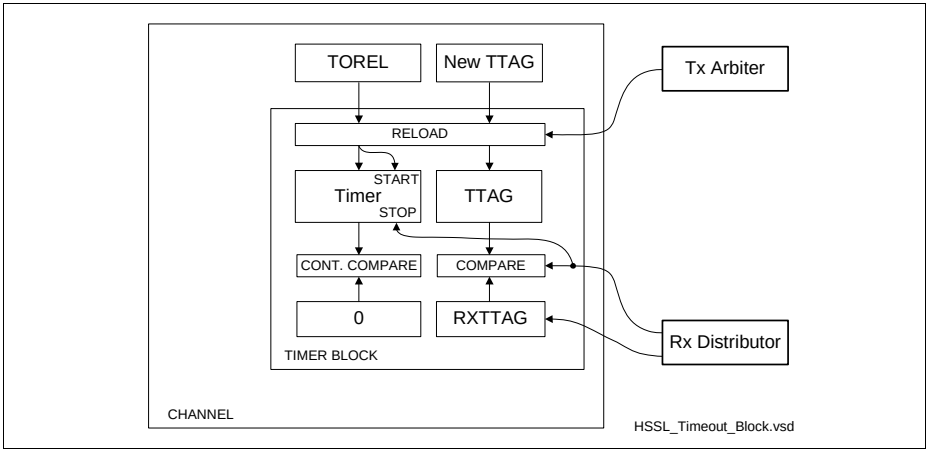

Figure 20-26 Single Timeout Block

The new initiator TTAG value which will be used for the next frame is visible in the bit field **ICON**x.ITTAG. The **ICON**x register also contains the TOREL and the TOCV bit fields.

The streaming functionality uses two timers sharing the same reload value, as defined by the **ICON**2.TOREL. The timeout timer blocks simulate the behavior of a FIFO (named Expect FIFO), by having additionally a “write” and “read” pointer:

- the “write” or transmit pointer points to the timer block where the next command frame will trigger the writing of the timer reload value and the transaction tag,
- the “read” or receive pointer points to the block which performs the transaction tag comparison with the currently arrived stream acknowledge TTAG.
- The EXFL or virtual filling level indicating how many timers are active 0, 1 or 2

The EXFL is visible in the register **SFSFLAGS**.

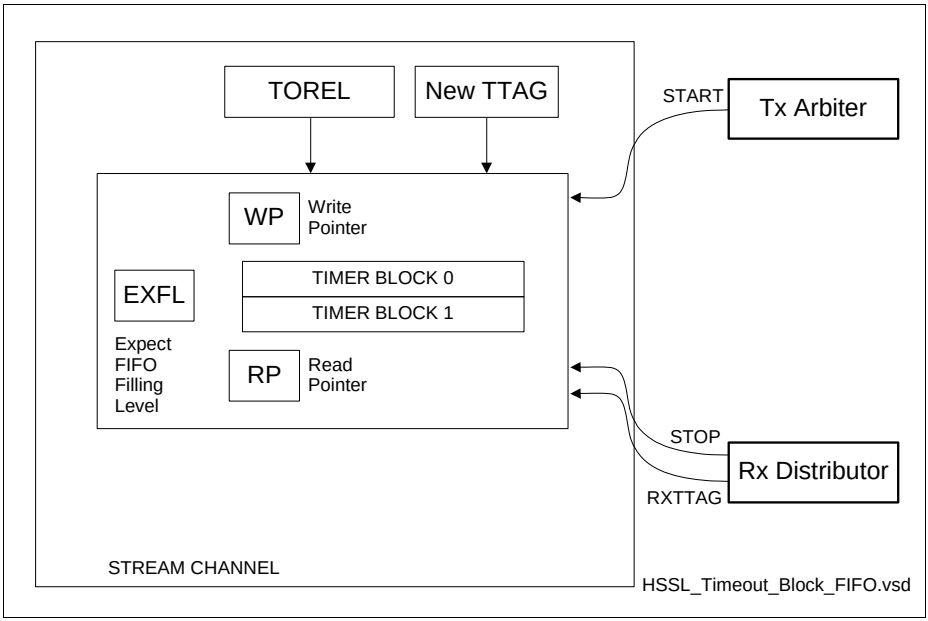

Figure 20-27 Stream Timeout Block

20.4.7 Data FIFOs of the Streaming Channel 2

Each stream frame delivers 256 bit data. This data is transferred by the SRI/SPB bus master in a memory by using BTR4 bursts. The start address and the end address is aligned at 256-bit block border, see **ISSAx (x=0-1)**, **ISFC**, **TSSAx (x=0-1)**, **TSFC**.

The channel expects one full streaming frame of 256 bit to be delivered before triggering either the SRI/SPB master or the HSCT module for fetching the data. The streaming is full duplex capable, which means one FIFO for each direction is available, and also Priorisation for the requests to the SRI/SPB master.

Emptying the RXFIFO has higher priority than filling the TXFIFO.

A service request to the SRI/SPB master is generated when the complete payload of a streaming frame is available in a FIFO.

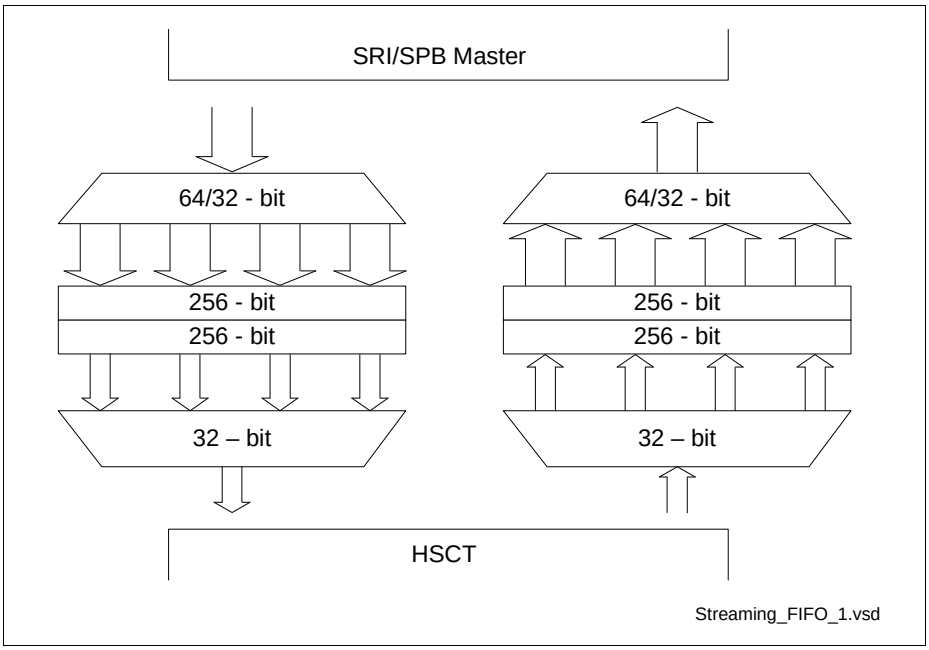

Figure 20-28 Streaming FIFO

20.5 Modes of Operation

The HSSL module has the following modes:

- Disabled mode (software controlled via DISR bit)
- Initialize mode (software via INI bit, sleep & suspend signals)
- Run mode (INI bit, sleep and suspend signals)
- OCDS soft suspend mode (OCDS suspend signal)
- Sleep mode (sleep signal)

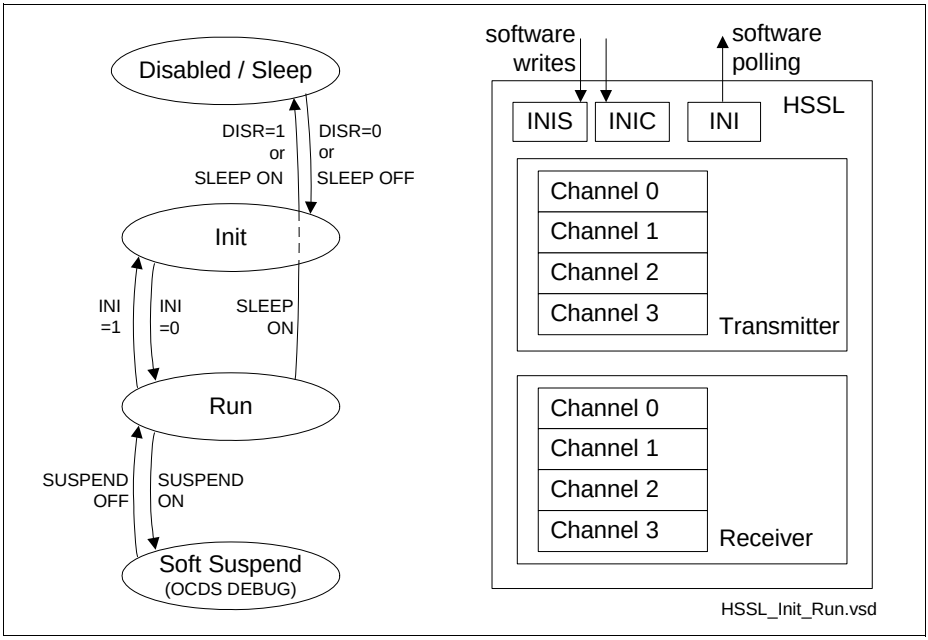

Figure 20-29 Modes of operation

After Init state has been requested by using the **MFLAGSSET**.INIS bit, the HSSL module immediately stops starting new SRI/SPB transactions and new command, response and stream frame transmissions by resetting all request bits (I, T and R) in the **QFLAGS** register and disabling these bits for being set again. The already started transactions/transmissions will be finished. Afterwards, it waits for all pending response frames to arrive or the corresponding timeout events to be raised. This condition is achieved when all expect bits in the **QFLAGS** register has been cleared by the hardware, and there are no ongoing transmission and SRI/SPB master activities. Subsequently the module enters the Init state and the **MFLAGS**.INI flag is set. The CTS signal is deactivated in order to inform the peer module about the Init state.

During the transition from run to sleep state, triggered by the sleep signal, the **MFLAGS**.INI bit is automatically set by the hardware (behaves as INI bit was set by software). When the sleep period is over and the sleep signal is deactivated, the module goes into the Init state and must be set to Run state by software, by writing **MFLAGSCL**.INIC=1.

At the state transition of Init -> Run the timeout timers and all the flags are reset. The RUN state starts with all channels inactive.

At the state transition SoftSuspend -> Run the timers are not reset but continue to run and the flags states are preserved, because the module continues operating from the point at which it was suspended.

When leaving the Run state towards Sleep the CTS signal is deactivated and the transmission of the pending commands is stopped.

When a soft suspend is requested, the module stops the transmission of the pending command and stream frames, waits until all expect flags are cleared, then deactivates the CTS signal and at the end acknowledges the soft suspend request and sets the bit **OCS**.SUSSTA. Incoming target frames are served until the CTS signal stops the other side from sending new command and stream frames.

Hard Suspend request causes immediate switching off of the module clocks. After ending the Hard Suspend state both HSSL and HSCT modules must be reset by the application software and communication restarted from reset state.

Note: Reading and writing of registers is possible but will enable the kernel clock f_{CLC} for a few cycles. Attention: register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a HSSL kernel reset might not be sufficient to bring the system into a defined state.

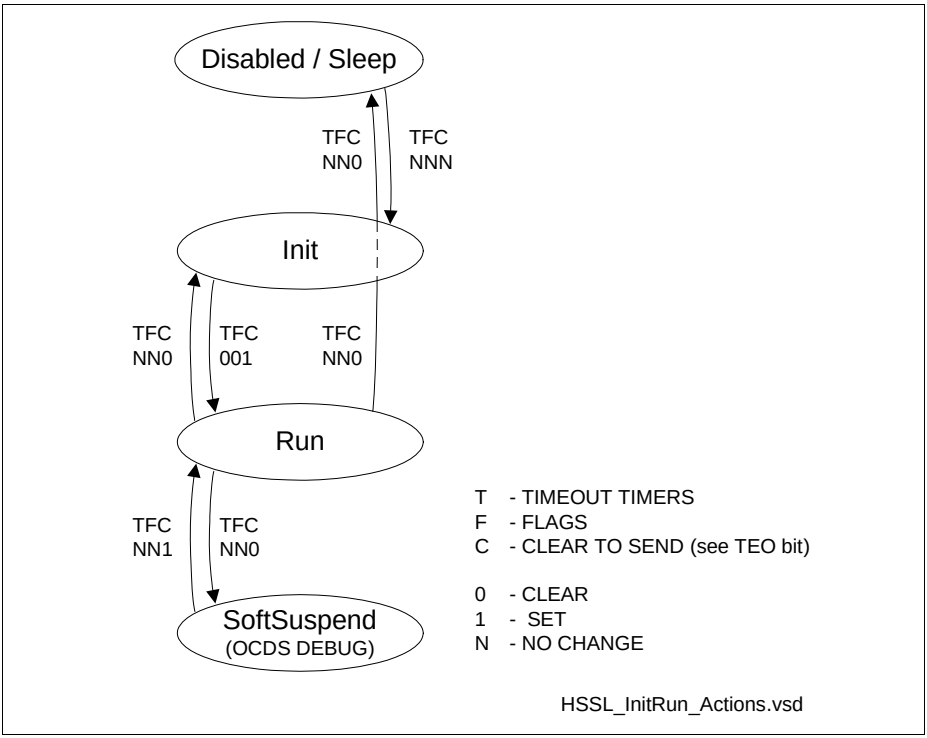

Figure 20-30 Actions on State Transitions

20.6 Interrupts

The HSSL module generates four types of interrupts per channel and one channel unspecific module interrupt.

Command Channel Interrupts

Each HSSL command channel generates four interrupts:

- Command OK interrupt COK
- Read Data interrupt RDI
- Error interrupt ERR
- Trigger interrupt, triggered by a trigger command frame TRG

An arrival of an error free frame response (ACK frame) triggers a COK interrupt, otherwise an ERR interrupt is triggered. An arrival of a read response frame triggers at the initiator side, additionally to the COK interrupt, an RDI interrupt.

An arrival of a trigger frame at the target side triggers a TRG interrupt there.

ERR interrupt is disjunct to COK and RDI interrupts, meaning that for one frame, either ERR or COK and optionally RDI can occur. After an ERR interrupt, normal transmission must be resumed by software, because an optional DMA would remain not retriggered and would wait for COK indefinitely.

Stream Channel Interrupts

The HSSL stream transmit sub-channel generates three interrupts:

- TBE - Transmit Block End interrupt, shared with the COK interrupt of the command mode of the channel 2
- error interrupt ERR, shared with the ERR interrupt of the command mode of the channel 2
- RBE - Receive Block End interrupt, shared with the TRG interrupt of the command mode of the channel 2.

Exception Interrupt EXI

If the receive stage of the HSSL module detects a CRC error or any inconsistency in the received data the global EXI Interrupt is activated, which is not channel specific.

Note: The HSCT module uses channels A to D for the HSSL channels 0 to 3. So, HSCT channel 0100_B corresponds to 000_B (binary code) or 100_B (special code) in the HSSL header.

The EXI interrupt is also raised on an edge of the TEI signal (HSCT CTS output).

In total, the HSSL module provides 4*4 + 1 = 17 interrupt lines.

20.7 Operating a Command Channel

All HSSL command channel provide identical functionality.

20.7.1 Initiating a Single Write Command

In order to initiate a write command, the software must

- configure the data width and the type of the request which will follow (read or write)
- provide the new data (most frequently, but not necessary)
- provide new address

Write to the address register requests the predefined type of the transfer

20.7.2 Initiating a Single Read Command

In order to initiate a read command, the software must

- configure the data width and the type of the request which will follow (read or write)
- skip providing of the data step, or provide dummy data
- provide new address

Write to the address register requests the predefined type of the transfer

20.7.3 Initiating a Single Trigger Command

In order to initiate a trigger command, the software can either

- request a trigger type of frame and provide dummy data and address
- directly request a trigger frame by writing **ICONx (x=0-3)**.TQ

20.7.4 DMA Operated Command Queues

It is possible to use DMA to initiate lists of commands, by moving memory blocks containing the command lists to the HSSL module. In order to support such a way of operation, each channel provides three registers arranged in a particular way: first **IWD**, followed by **ICON** and **IRWA** at the end. For executing a list of write commands all three registers must be written for each command; for executing a list of read commands the first register **IWD** is optional (dummy write possible) but the last two **ICON** and **IRWA** are mandatory; for executing a trigger command only writing **ICON**.TQ is mandatory, but optionally even all three registers can be written: dummy write to **IWD**, write to **ICON**.RWT and write to **IRWA** to issue the request.

The answer data to a read command is available in the **IRD** register.

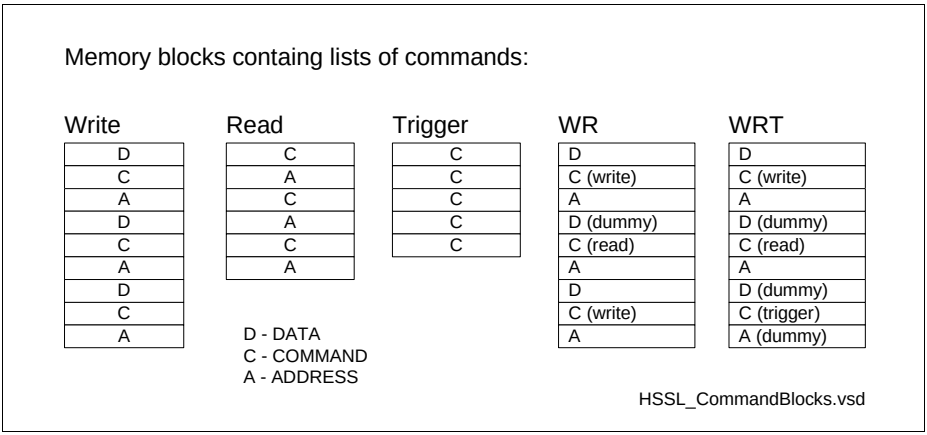

Figure 20-31 Command Queues

20.7.5 Receiver Error Handling

The HSSL receiver generates three error signals, two channel specific and one general:

- channel specific timeout and transaction tag errors and
- channel unspecific CRC error
- command frames, which pass the CRC check, containing an RFU command code are ignored
- Command frames, which pass the CRC check, containing invalid (greater than 3) channel number are ignored.
- If a command frame is received and the acknowledge of the previous command has not been sent yet, the new command frame is discarded.
- If a response frame comes, and the channel does not expect any more a response (the E flag is 0), than an incoming response is discarded without any error interrupts, additional to the timeout interrupt. This scenario can occur if a response is received after a timeout, and before the next command has been sent.
- If a channel in command mode receives a stream frame, the stream frame will be ignored.
- if a channel in streaming mode receives a command frame, the command frame will be ignored.

20.7.5.1 Timeout Error

Error triggered by the initiator.

20.7.5.2 Transaction Tag Error

Error triggered by the initiator.

20.7.6 Global Error

Global, channel not specific error is triggered if a CRC error, inconsistency between the HSCT and HSSL header, and SRI/SPB error occurs.

CRC error is triggered:

- by the target: when erroneous command frames has been received and
- by the initiator for erroneous response frames.

There is a dedicated interrupt named EXI which signals the CRC error. There is no indication if the CRC error was caused by a command or response frame. The CRC error caused by a response frame will be followed by a timeout interrupt. The received data is discarded; it is not available for the software in any register(s).

Additionally, the CRC error interrupt signals an inconsistency between the data length and channel number code delivered by the HSCT module and the information contained in the HSSL header. The differentiation between the two types of error can be done by reading the **MFLAGS**.CRCE, PIE1 and PIE2 flags. All three error types can occur and are detected independently of each other, so that more than one flag can be set at the same time.

An SRI error interrupt (EXI) is triggered if there was a transaction ID error, ECC error or SRI error acknowledge on the SRI bus. The flag **MFLAGS**.SRIE indicates this type of error. In case of an SRI read data ECC error, this event is additionally signalled to the SMU module.

An SPB error also triggers the global error interrupt (EXI) and sets the **MFLAGS**.SRIE flag.

20.8 Memory Block Transfer Modes of the Stream Channel

HSSL streaming channel is capable of transmitting one stream and receiving one stream in parallel. Streaming operates either in single block mode or continuous mode.

In single block mode, after triggering/enabling the streaming by using the **MFLAGS**.ISB/TSE bit, the SRI/SPB master of the HSSL module transmits/receives the preconfigured memory block, generates an interrupt signal and waits for the next trigger.

In continuous mode, after triggering/enabling the streaming by using the **MFLAGS**.ISB/TSE bit, the SRI/SPB master of the HSSL module transmits/receives two memory blocks of the same size in a round robin fashion indefinitely, or after being stopped by the software.

The streaming mode of the initiator/transmitter is configured by using the **CFG**.SMT bit. The streaming mode of the target/receiver is configured by using the **CFG**.SMR bit.

Triggering/enabling a block or continuous stream is done by using the Stream Block Request bit **MFLAGS**.ISB/TSE bit. In single block mode, the hardware resets this bit after performing a block transfer. In continuous mode, the transfer is ongoing continuously (**MFLAGS**.ISB/TSE remains set) and a stop of the transfer must be requested by writing one to **MFLAGSCL**.ISBC/TSEC bit.

On the initator side, after completing the transfer of the current memory block that is currently read from the memory, the transmitter will be stopped and the **MFLAGS**.ISB will be cleared.

On the target side, after completing the transfer of the current memory block that is currently written to the memory, the receiver will be stopped and the **MFLAGS**.TSE will be cleared.

SRI/SPB error on the target triggers an error interrupt and the hardware stops. The TSE bit (and the RXFIFO) will be cleared by the hardware and the incoming frames are ignored.

Any error on the initiator side (like SRI/SPB error, target error, timeout, transaction tag error) triggers an error interrupt and the hardware stops streaming. The bit ISB (and the TXFIFO) will be cleared by hardware. All the incoming frames will be ignored, including the acknowledge frames of the previous frames.

Error can also occur at the beginnging of a new memory block, while the last frames of the previous memory block are still in the TXFIFO. These frames are also lost, and the previous memory block remains incompletely received.

After an error while streaming in one direction the software must restart the streaming in that direction at both sides. The streaming will restart with a new block.

An error while streaming in most cases leaves the target waiting in the middle of a block. The target receiver can be stopped immediately (and afterwards restarted) by clearing the **MFLAGS**.TSE only when **TSFC**.CURCOUNT equals **TSFC**.RELCOUNT. Normally, CURCOUNT equals RELCOUNT before the start of a transfer of a block or between block transfers. Otherwise, while waiting in the middle of a block transfer, RELCOUNT can be made equal to CURCOUNT by writing the CURCOUNT value to RELCOUNT. This can be done either locally, by the target itself, or remotely, by the initiator using HSSL command frames.

The two initiator start addresses are configured in **ISSAx (x=0-1)**. The single block size is configured in the **ISFC** register. The current address being transferred is indicated in the read only (rh) **ISCA** register. The bit **MFLAGS**.IMB selects the corresponding **ISSAx (x=0-1)** register. This bit is not modified by the hardware in single block mode, and is toggled by the hardware in the continuous mode. At the start of the transfer, the selected start address **ISSAx (x=0-1)** is copied to the **ISCA** register.

The two target start addresses are configured in **TSSAx (x=0-1)**. The single block size is configured in the **TSFC** register. The current address being transferred is indicated in the read only (rh) **TSCA** register.The bit **MFLAGS**.TMB selects the corresponding

TSSAx (x=0-1) register. This bit is not modified by the hardware in single block mode, and is toggled by the hardware in the continuous mode. At the start of the transfer, the selected start address **TSSAx (x=0-1)** is copied to the **TSCA** register.

The HSSL stream transmitter generates one dedicated interrupt and several error events:

- transmit block end interrupt, generated after the acknowledge of the last frame has been received.
- error events that can trigger a channel error interrupt (target, timeout, transaction tag, unexpected error)
- a global SRI/SPB error interrupt (check if the ISB bit is cleared by hardware)

The HSSL stream receiver generates one dedicated interrupt and several error events:

- receive block end interrupt event, generated after the last stream frame in a block has been written to the memory and the SRI/SPB master has received a confirmation (an acknowledge, but not an error).
- error event (target error that triggers an NACK frame)
- a SRI/SPB global error interrupt (check if the TSE bit is cleared by hardware)

As long as the ISB bit is low, the TXFIFO and the expect FIFO are cleared and kept in the empty state.

As long as the TSE bit is low, the RXFIFO is cleared and kept in the empty state.

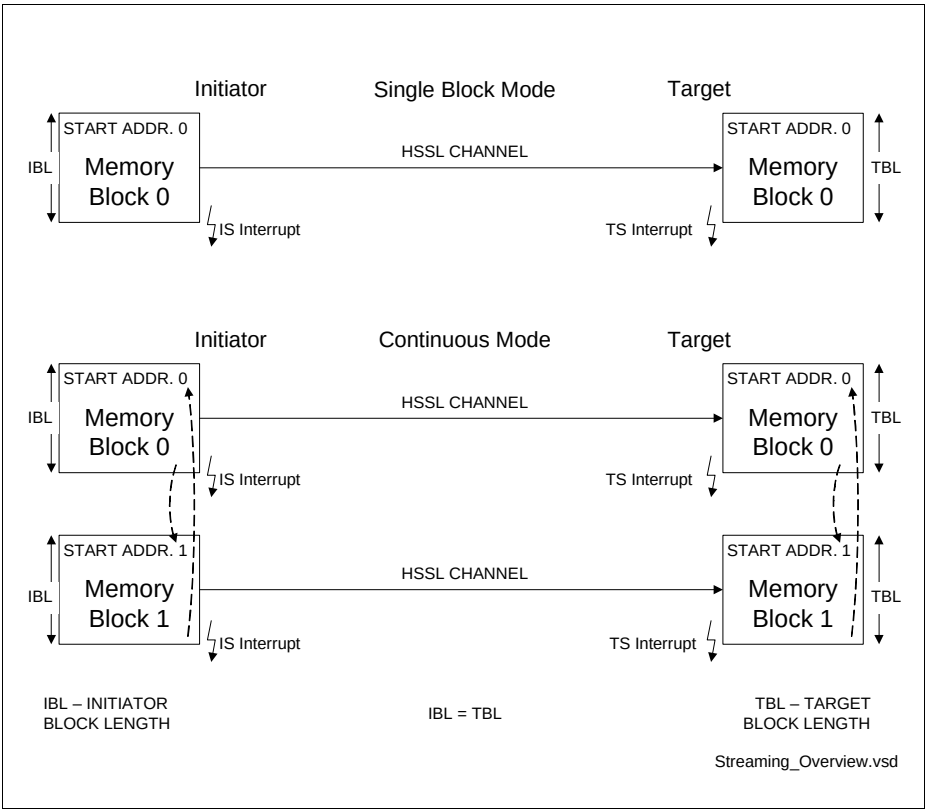

Figure 20-32 Stream Modes of Operation

20.9 HSSL Reset

Both HSCT and the HSSL modules must be reset together.

20.10 OCDS SRI / SPB Master Suspend

The SRI /SPB master access on the bus can be suspended by using the OCDS suspend request. When the master reaches idle state the suspend acknowledge signal is activated.

20.11 OCDS Trigger Sets

In order to support the debugging activities, the HSSL module provides a set of internal signals to the on-chip debug system OCDS. An overview of this feature is shown in **Figure 20-33**. Its configuration is done by using the bits **OCS**.TGS and TGB.

An edge on any module internal signal belonging to the selected set going out on one of the two OTGB busses triggers an action of the OCDS system.

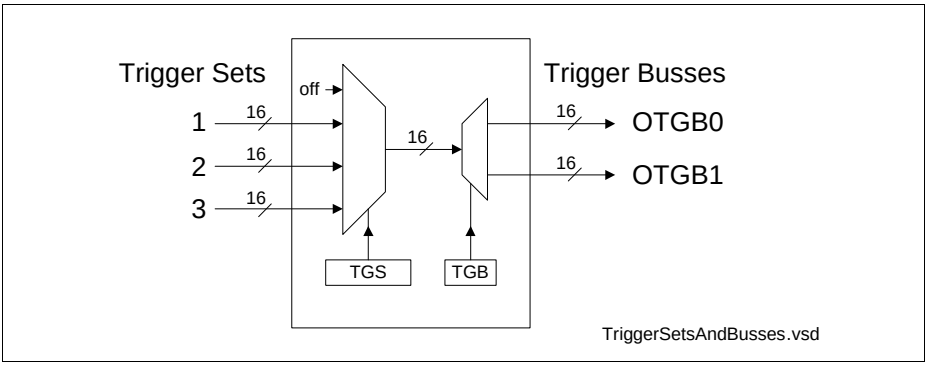

Figure 20-33 Overview of the Trigger Sets and Busses

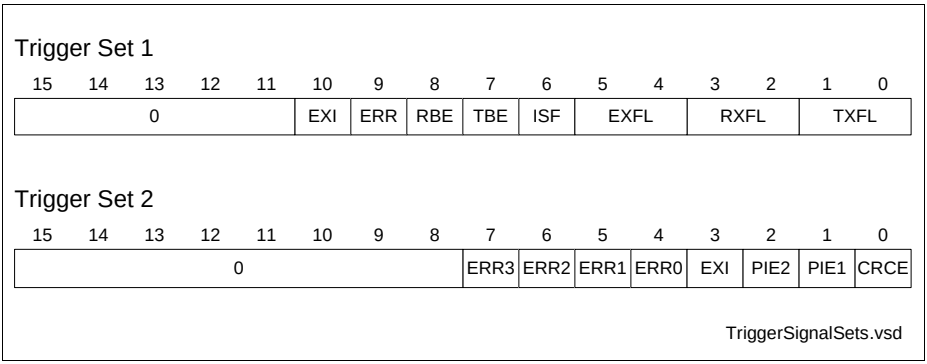

Figure 20-34 Overview of the Trigger Signal Sets

Table 20-4 HSSL Trigger Sets

Name	Description
TS16_STR	Streaming Channel Trigger Set (Trigger Set 1)
TS16_ERR	Error Trigger Set (Trigger Set 2)

The trigger sets 1 and 2 are used, the set 3 is not used (padded with 0).

Set 1, streaming channel debugging:

- 2 bits: TXFIFO filling level **SFSFLAGS**.TXFL
- 2 bits: RXFIFO filling level **SFSFLAGS**.RXFL
- 2 bits: Expect FIFO filling level **SFSFLAGS**.EXFL
- 1 bit: Initiator Stream Frame Request **SFSFLAGS**.ISF
- 4 bits: streaming channel interrupt signals TBE, RBE, ERR, EXI, see **Interrupts**.
- others: not used

Set 2, timeout errors caused by unspecific errors debugging:

- 1 bit: CRC error **MFLAGS**.CRCE
- 1 bit: Phy Inconsistency error, inconsistent channel number code, **MFLAGS**.PIE1
- 1 bit: Phy Inconsistency error, inconsistent data length, **MFLAGS**.PIE2
- 5 bits: error interrupt signals 1 x EXI and 4 x ERR, see **Interrupts**.
- others: not used

Note: The signal lists from above are mapped to the trigger sets in the following way: first item from the list to the trigger signal 0,... to 15.

20.12 Access Protection

The HSSL module provides memory access protection in form of four memory access windows. Each window can be located anywhere within the address space, having an arbitrary size with the granularity of 256 bytes.

Each window defines a memory range where an access is allowed. All four windows create a sort of an access filter that protects the memory from external writing or reading. A window can be a read only, write only or read and write window.

Each window is defined with:

- window start address, see register **AWSTARTx (x=0-3)**
- window end address, see register **AWENDx (x=0-3)** and
- access rule: read only, write only or read and write, see register **AR**

If two access windows overlap, one read only and one write only, the common address range is read and write accessible. If no access window overlaps with r, w or rw window, the r, w or rw window wins. No access window means window disabled.

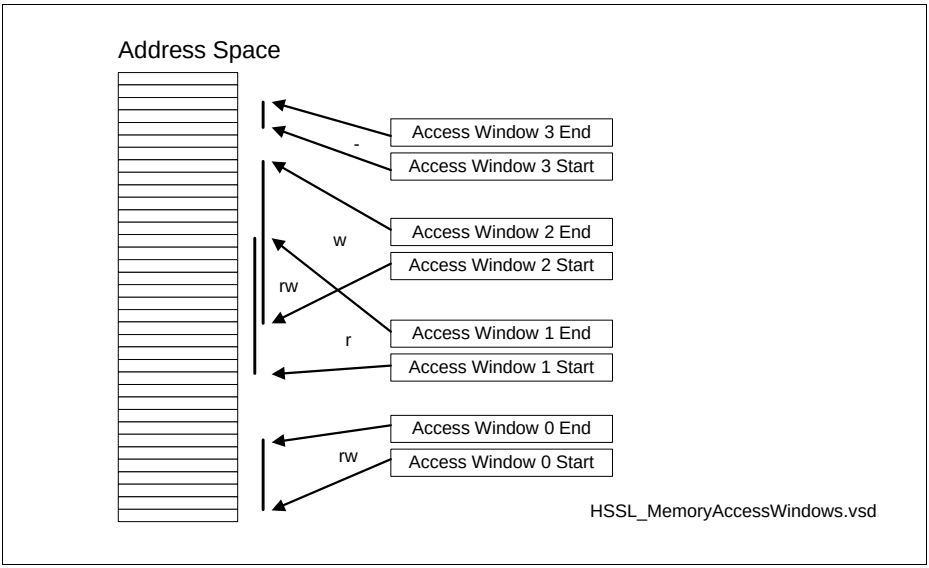

Figure 20-35 HSSL Access Windows

Normally, it is expected that the End Address is higher then or equal to the Start Address. Otherwise, the window is invalid and no commands can pass through the up-side-down range.

The **AWSTARTx (x=0-3)** registers define the first address of the first 256-byte block of an address window. The **AWENDx (x=0-3)** registers define the first address of the last

256-byte block of an address window. The following diagram shows the details of the address window definition.

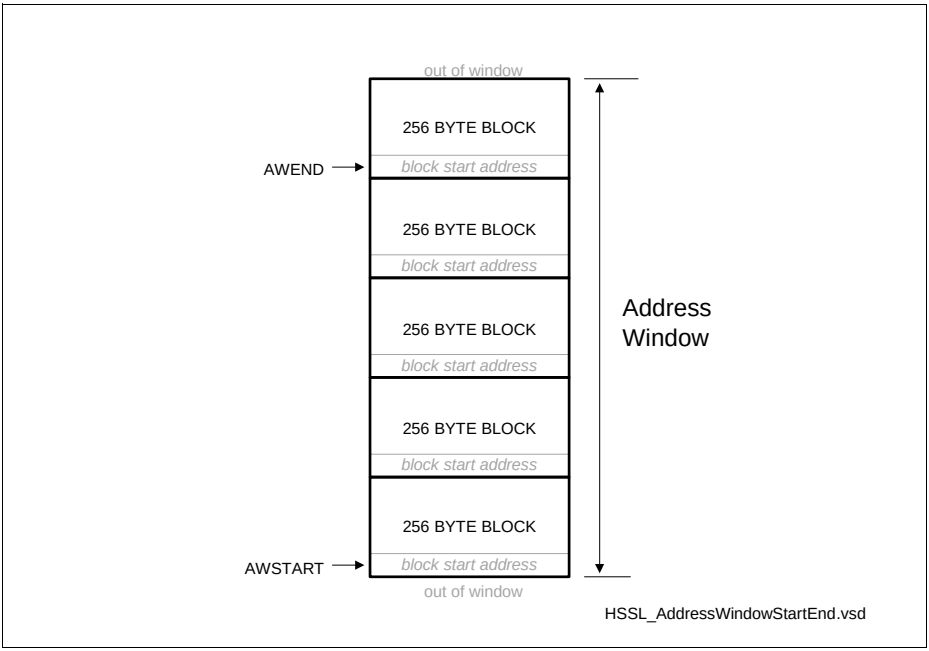

Figure 20-36 Access Windows Definition

These command frames are subject to filtering:

- Register Read
- Register Write and
- Stream Frame

These command always pass through:

- Read Answer
- ACK
- NACK
- Trigger
- ID Request

Command Frames Access Protection

If a HSSL target receives a read or write command frame with an address which passes through one of the windows, the command is executed and a response frame is sent back.

If a HSSL target receives a command frame with an address which does not pass through any windows, the command is not executed, a NACK response is sent back. The memory access violation flag **MFLAGS**.MAV is set, the access violating channel is captured in the bit field **AR**.MAVCH, and the EXI interrupt is triggered in the target.

Streaming Access Protection

In contrast to the read and write command frames, the stream frames do not contain an address information. There are two cases to distinguish, target side and initiator side.

At the target side, when the streaming starts, the initiator has already programmed the target addresses in the **TSSAx (x=0-1)** registers by using write frames, which pass through and carry the stream address in their data field. Therefore, the memory filtering uses the current access address, visible in the **TSCA** register, and if the current streaming address passes through the access protection filter, the read or write is executed, else a NACK frame is sent as a response.

If a HSSL target receives a stream frame and the current access address does not pass through any windows, the access is not executed, a NACK response is sent back, . The TSE bit will be cleared by hardware and the incomming frames will be ignored. The memory access violation flag **MFLAGS**.MAV is set, the access violating channel is captured in the bit field **AR**.MAVCH, and the EXI interrupt is triggered in the target.

At the initiator side, the **ISSAx (x=0-1)** registers, which are externally accessible, define the memory range to be transmitted. Therefore, the access filtering at the initiator side covers the streaming read accesses by using the current access address, visible in the **ISCA** register.

At the initiator side, access violation stops the streaming, and the ISB bit is cleared by hardware. The memory access violation flag **MFLAGS**.MAV is set, the access violating channel is captured in the bit field **AR**.MAVCH, and the EXI interrupt is triggered.

Public and Private Registers

The HSSL module contains two types of registers:

- public registers, which can be both read and written by the HSSL module itself
- private registers, which can be only read by the HSSL module itself

This behavior of the HSSL module registers is implemented by using the User Mode (U) and Supervisor Mode (SV) of writing registers. The private registers are writable in SV mode, the public registers are writable in U and SV mode.

The memory access protection registers **AWSTARTx (x=0-3)**, **AWENDx (x=0-3)** and **AR** including the **TIDADD** register are all writable only in Supervisor Mode, and are consequently private. The HSSL itself makes only User Mode accesses, so that it can not write these registers.

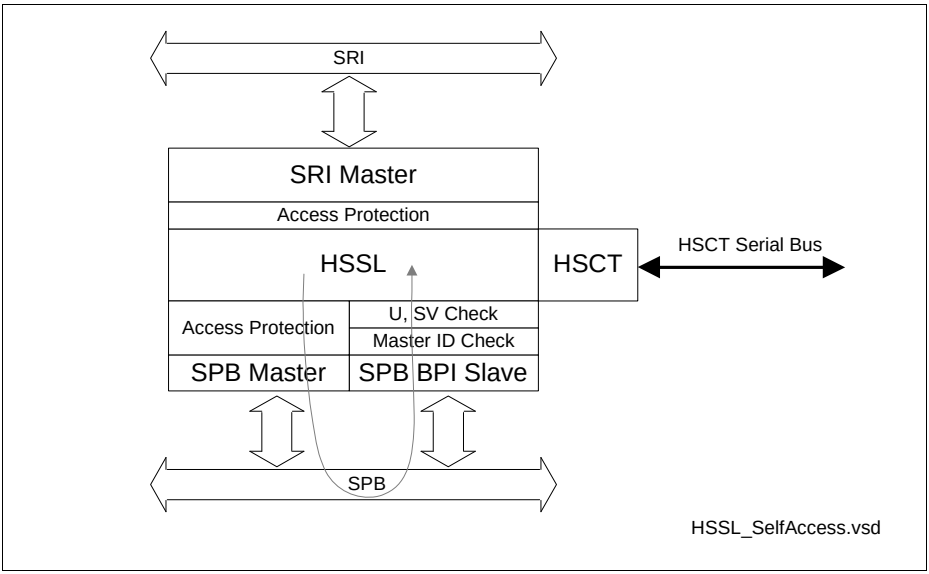

Figure 20-37 HSSL access to its own registers

20.13 Kernel Registers

This section describes the registers of the HSSL module.

Note: The HSSL module occupies 1KByte of address space, although only the first 256 bytes are used. Accessing a not used address location generates a bus error.

There are no registers in the HSSL with the destructive read property, where a read access would generate some action in the hardware.

Table 20-5 Registers Address Space

Module	Base Address	End Address	Note
HSSL	$F0080000_H$	$F00803FF_H$	–

ACCEN0	Access Enable Register 0	FC_H	SV, SE	FFFF FFFF

1) All registers have read access mode U, SV, except the access protection registers AWSTART, AWEND and AR, which have read access mode SV.
Read access from reserved addresses delivers bus error (BE).
All registers belong to reset class 3 except OCS, which belongs to reset class 1.

2) Read access mode: SV only.
This register delivers 0 to a read access in User Mode, but BE is not triggered.

List of Access Protection Abbreviations

U - User Mode

SV - Supervisor Mode

BE - Bus Error

nBE - no Bus Error

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

SE - Safety ENDINIT

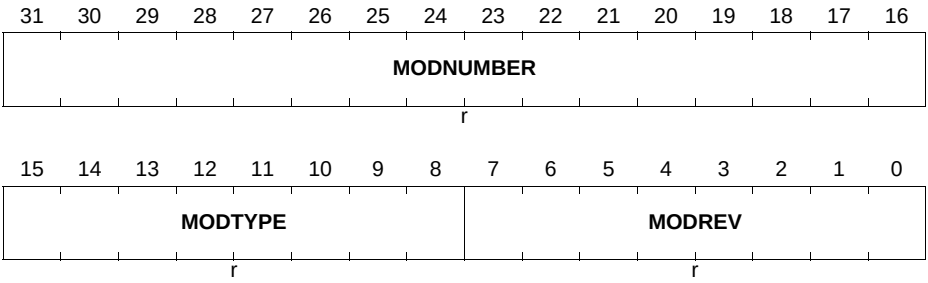
20.13.1 Global Registers

ID

The Module Identification Register ID contains read-only information about the module version.

(>> **Table 20-6** register overview)

ID
Module Identification Register **(08_H)** **Reset Value: 00CB C0XX$_H$**



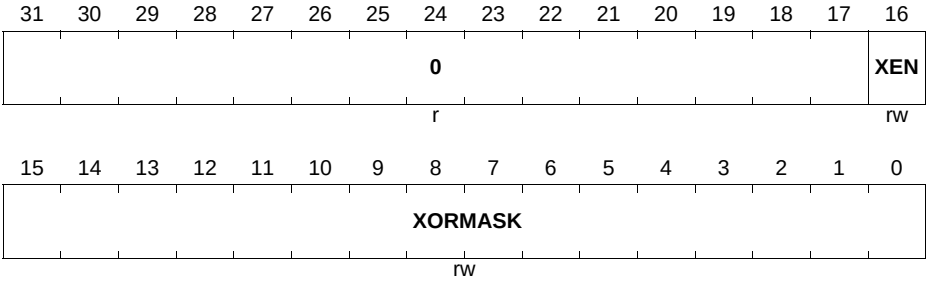
Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field is $C0_H$. It defines a 32-bit module.
MOD NUMBER	[31:16]	r	**Module Number Value** This bit field together with MODTYPE uniquely identifies a module.

CRC

(>> **Table 20-6** register overview)

This register only influences the generation of the CRC in the transmit direction.

CRC
CRC Control Register **($0C_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
XORMASK	[15:0]	rw	**Value to be XORed with the Calculated CRC** Used for error injection / test purposes.
XEN	16	rw	**Enable the Error Injection via XORMASK** 0_B disabled 1_B enabled
0	[31:17]	r	**reserved**

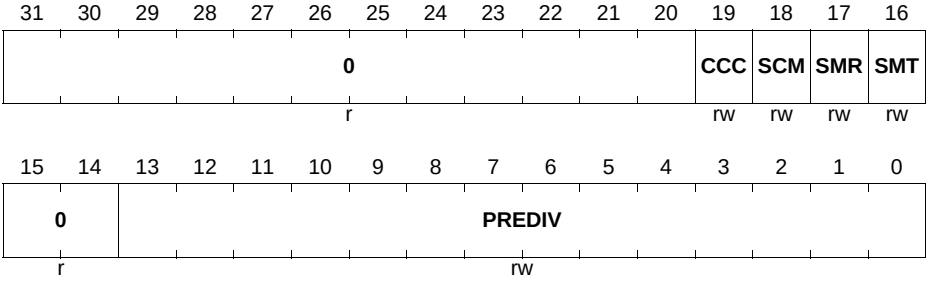
CFG

The CFG register is used to configure the HSSL module. It shall only be written in the Initialize Mode.

(>> **Table 20-6** register overview)

Note: The duration of a timeout interval may vary for an amount of one predivider clock period. Therefore the predivider should be set as low as possible, and the timeout length as many predivider periods as possible.

CFG
Configuration Register (10_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
PREDIV	[13:0]	rw	**Global Predivider** Defines the down-scaled module clock to be used by all channel timeout timers. 0_D 1 1_D 2 2_D 3 **others**, corresponding down-scale factor
SMT	16	rw	**Streaming Mode Transmitter** 0_B Continuous 1_B Single
SMR	17	rw	**Streaming Mode Receiver** 0_B Continuous 1_B Single

Field	Bits	Type	Description
SCM	18	rw	**Streaming Channel Mode** Defines if the channel 2 is used in a streaming or command mode. 0_B Command 1_B Streaming
CCC	19	rw	**Channel Code Control** Defines the coding of the channel number in the HSSL header. 0_B Binary 1_B Special
0	[31:20], [15:14]	r	**reserved**

20.13.2 Channel.Flags Registers

QFLAGS

This register contains flags indicating if an appropriate action request is pending or not. The action request can be pending in different stages of a communication cycle, see **Figure 20-16**.

(>> **Table 20-6** register overview)

QFLAGS
Request Flags Register **(14_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ES	**TS**	**RS**	**IS**	**0**				**E3**		**E2**		**E1**		**E0**	
rh	rh	rh	rh	r				rh		rh		rh		rh	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				**R**				**T**				**I**			
r				rh				rh				rh			

Field	Bits	Type	Description
I	[3:0]	rh	**Request Flags for Initiated Commands** These flags are set by the corresponding channel when a WRTS command is initiated. The WRT commands are initiated via the SPB bus. The S(tream) commands are initiated by the module internally, by the TXFIFO, except for the first stream frame start, which is done via the SPB bus. See **MFLAGS**.ISB and ISF flags. 0000_B No request pending 0001_B Channel 0 request pending 0010_B Channel 1 request pending 0100_B Channel 2 request pending 1000_B Channel 3 request pending **others**, corresponding combination of requests

Field	Bits	Type	Description
T	[7:4]	rh	**Request Flags for Commands Arrived at Target** These flags are set by the hardware according to the header information of a frame arrived at the target without a CRC error. They are used by the arbiter of the SRI/SPB master and cleared when the appropriate command is executed. 0000_B No request pending 0001_B Channel 0 request pending 0010_B Channel 1 request pending 0100_B Channel 2 request pending 1000_B Channel 3 request pending **others**, corresponding combination of requests
R	[11:8]	rh	**Request Flags for Response Frames at the Target** After a command has been executed by the SRI/SPB master, an appropriate flag is being set which indicates that an ACK/NACK/DATA is pending. 0000_B No request pending 0001_B Channel 0 request pending 0010_B Channel 1 request pending 0100_B Channel 2 request pending 1000_B Channel 3 request pending **others**, corresponding combination of requests
E0	[17:16]	rh	**Expect Flags for Activated Timeout Timer 0** An appropriate two bit flag is set by the hardware when a timeout timer for a channel is started. The hardware clears the appropriate flag when any response frame arrives at the initiator. In case of an unexpected response the flag UNEXPECTED is additionally set. 00_B No request pending 01_B write request pending 10_B read request pending 11_B trigger request pending
E1	[19:18]	rh	**Expect Flags for Activated Timeout Timer 1**
E2	[21:20]	rh	**Expect Flags for Activated Timeout Timer 2**
E3	[23:22]	rh	**Expect Flags for Activated Timeout Timer 3**

Field	Bits	Type	Description
IS	28	rh	**I Flag for Stream Frames** See the “I” flag description above. 0_B No request pending 1_B Request pending
RS	29	rh	**R Flag for Stream Frames** See the “R” flag description above. 0_B No request pending 1_B Request pending
TS	30	rh	**T Flag for Stream Frames** See the “T” flag description above. 0_B No request pending 1_B Request pending
ES	31	rh	**E Flag for Stream Frames** See the “E” flag description above. 0_B No request pending 1_B Request pending
0	[27:24], [15:12]	r	**reserved**

MFLAGS

(>> **Table 20-6** register overview)

(>> **Memory Block Transfer Modes of the Stream Channel**)

MFLAGS

Miscellaneous Flags Register (18_H) Reset Value: $8000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INI	TEO	TEI	TSE	0	0	CRCE	PIE2	PIE1	SRIE	MAV	ISB	IMB	TMB	0	
rh	rh	rh	rh	r	r	rh	rh	rh	rh	rh	rh	rh	rh	r	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
UNEXPECTED				TIMEOUT				TTE				NACK			
rh				rh				rh				rh			

Field	Bits	Type	Description
NACK	[3:0]	rh	**Not Acknowledge Error - Target Error** Indicates that a target error frame has been received.
TTE	[7:4]	rh	**Transaction Tag Error** Indicates for each channel if a CRC correct acknowledge frame with an unexpected transaction tag number has been received.
TIMEOUT	[11:8]	rh	**Timeout Error** Indicates for each channel if an timeout event has occurred.
UNEXPECTED	[15:12]	rh	**Unexpected Type of Frame Error** Indicates for each channel if an unexpected or inappropriate response is received. For example a NACK for a Trigger frame or DATA for WRITE frame.

Field	Bits	Type	Description
TMB	18	rh	**Target Memory Block** Selects the currently active memory block used by the target as a target for the streaming data, with its start address and frame counter. Switching the active block in the middle of a block transfer is not allowed. 0_B Memory block 0 1_B Memory block 1
IMB	19	rh	**Initiator Memory Block** Selects the currently active memory block used by the initiator as a source for the streaming data, with its start address and frame counter. Switching the active block in the middle of a block transfer is not allowed. 0_B Memory block 0 1_B Memory block 1
ISB	20	rh	**Initiator Stream Block Request** Indicates if stream block request is pending. Set by the software to start a stream block transfer by using the **MFLAGSSET**.ISBS bit; clear by the software possible (if needed) by using the **MFLAGSCL**.ISBC bit; cleared by hardware at the end of the current block transfer in single mode, but not in continuous mode. 0_B No request or streaming ongoing 1_B Streaming ongoing
MAV	21	rh	**Memory Access Violation** Indicates a memory access violation. 0_B No violation 1_B Violation
SRIE	22	rh	**SRI/SPB Bus Access Error** Indicates an error on the SRI bus - transaction ID, ECC error or error acknowledge. Indicates an error on the SPB bus, error acknowledge or timeout. 0_B No error 1_B Error

Field	Bits	Type	Description
PIE1	23	rh	**PHY Inconsistency Error 1** Indicates if HSCT to HSSL channel number code comparator has detected an inconsistency error. 0_B No error 1_B Error
PIE2	24	rh	**PHY Inconsistency Error 2** Indicates if HSCT to HSSL data length comparator has detected an inconsistency error. 0_B No error 1_B Error
CRCE	25	rh	**CRC Error** Indicates if CRC checker has detected a CRC error. 0_B No error 1_B Error
TSE	28	rh	**Target Stream Enable** Used by the hardware to handle the single and continuous streaming. In single mode, cleared by hardware after the current block transfer ends. The module ignores afterwards the incoming steam frames. 0_B Disabled 1_B Enabled
TEI	29	rh	**Transmit Enable Input** Indicates the state of the TEI input signal of the HSSL module, which is driven by the CTS output signal of the HSCT module. Any edge on this signal triggers an EXI interrupt. This low level signal stops the transmission of both command and response frames.
TEO	30	rh	**Transmit Enable Output** Indicates the state of the TEO output signal of the HSSL module, which drives thee CTS input signal of the HSCT module. This bit is cleared by hardware at entering the INIT and Soft Suspend state.
INI	31	rh	**Initialize Mode** Indicates if the module is in the Initialize or Run mode. 0_B Run mode 1_B Initialize mode

Field	Bits	Type	Description
0	[27:26], [17:16]	r	**reserved**

MFLAGSSET

(>> **Memory Block Transfer Modes of the Stream Channel**)

SFSFLAGS

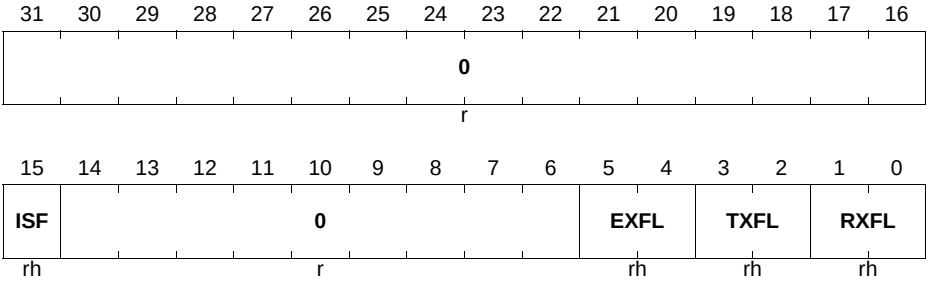
Stream FIFOs Status Flags Register (28$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RXFL	[1:0]	rh	**Stream RxFIFO Filling Level** Indicates the filling level of the FIFO with granularity of 32 bytes (one stream frame payload size). 00_B 0 01_B 1 10_B 2 11_B reserved (not possible)
TXFL	[3:2]	rh	**Stream TxFIFO Filling Level** Indicates the filling level of the FIFO with granularity of 32 bytes (one stream frame payload size). 00_B 0 01_B 1 10_B 2 11_B reserved (not possible)
EXFL	[5:4]	rh	**Stream Expect FIFO Filling Level** Indicates the filling level of the FIFO with granularity of 32 bytes (one stream frame payload size). 00_B 0 01_B 1 10_B 2 11_B reserved (not possible)

Field	Bits	Type	Description
ISF	15	rh	**Initiator Stream Frame Request** Indicates if stream TXFIFO request is pending. Set and cleared by the TXFIFO. 0_B TXFIFO fill request not pending 1_B TXFIFO fill request pending
0	[31:16], [14:6]	r	**reserved**

20.13.3 Channel.Initiator Registers

This section describes the channel specific registers of the HSSL module, associated to both the initiator and the target functions. In order to support command queues, the addresses of the **IWD**, **ICON**, **IRWA**, and **IRD** registers are ordered in a sequence of IWD0, ICON0, IRWA0, IRD0, IWD1, ICON1, IRWA1, IRD1, IWD2, ICON2, IRWA2, IRD2, IWD3, ICON3, IRWA3, IRD3, see **DMA Operated Command Queues**. For the timeout handling description, see **Command Timeout Operation**.

IWD

The IWD register contains the data part of a write command.

(>> **Table 20-6** register overview)

IWDx (x=0-3)
Initiator Write Data Register x **(30_H + x*10_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA																															
rw																															

Field	Bits	Type	Description
DATA	[31:0]	rw	**Data Part of the Payload of a Write Frame** For 8-bit and16-bit write command frames, the whole frame payload width of 32-bit is automatically filled with copies of the lower 8-bits or 16-bits of the register.

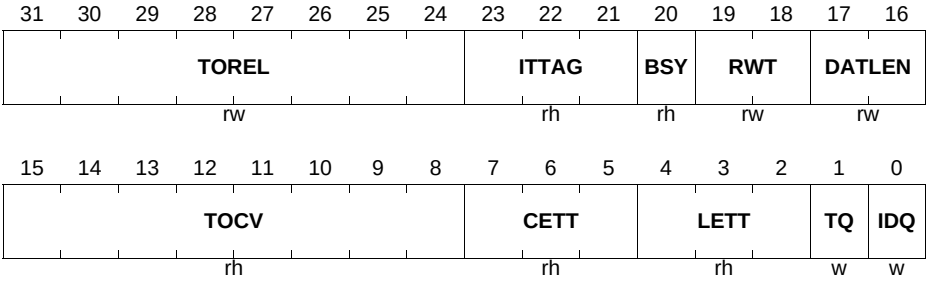
ICON

The ICON register contains the control and the configuration bits of a channel.

Bitfields TOREL and ITTAG are used for command frames, and also reused for streaming frames in channel 2. All other bit fields are used only for command frames.

(>> **Table 20-6** register overview)

ICONx (x=0-3)
Initiator Control Data Register x (34_H + x*10_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
IDQ	0	w	**Read ID Request** This bit provides the only way to request a read ID frame. Reads always 0. Write of 1 commences a request. In case of parallel write of 1 to TQ and IDQ, the IDQ request has higher priority. 0_B No read ID request 1_B Read ID frame request
TQ	1	w	**Trigger Request** This bit provides an alternative way to request a trigger frame, without having to write to the channel address register. Reads always 0. Write of 1 commences a request. In case of parallel write of 1 to TQ and IDQ, the IDQ request has higher priority. 0_B No trigger request 1_B Trigger frame request
LETT	[4:2]	rh	**Last Error Transaction Tag**
CETT	[7:5]	rh	**Currently Expected Transaction Tag**
TOCV	[15:8]	rh	**Time Out Current Value**

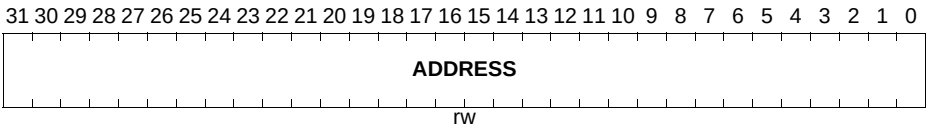
Field	Bits	Type	Description
DATLEN	[17:16]	rw	**Data Length** Defines the length of the data in bits of the write and read command. 00_B 8-bit 01_B 16-bit 10_B 32-bit 11_B reserved (implemented as 32-bit)
BSY	20	rh	**Channel Busy**
RWT	[19:18]	rw	**Read Write Trigger Command Type** Defines if the write to the IRWA register will trigger read, write or trigger request. 00_B No action 01_B Read Frame 10_B Write Frame 11_B Trigger Frame
ITTAG	[23:21]	rh	**Initiator Transaction Tag** This bit displays the current value of the three bit counter generating the new transaction tag value.
TOREL	[31:24]	rw	**Time Out Reload Value** Defines the duration of the timeout in units of prescaled clock periods. This parameter is valid both in command and stream mode of the channel 2.

IRWA

The IRWA register contains the address part of a write command. Writing the IRWA register triggers a transmit request for the appropriate channel.

(>> **Table 20-6** register overview)

IRWAx (x=0-3)
Initiator Read Write Address Register(38_H + x*10_H) **Reset Value: 0000 0000_H**



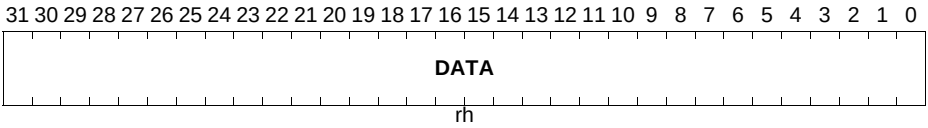
Field	Bits	Type	Description
ADDRESS	[31:0]	rw	**Address Part of the Payload of a Write Frame** Writing to this registers triggers transmission of a Write Frame. The address must be aligned according to the data width: byte addresses for 8-bit data, word addresses for 16-bit data, double word addresses for 32-bit data.

IRD

The IRD register contains the data read from the target, which has been fed back as a response to a read command.

(>> **Table 20-6** register overview)

IRDx (x=0-3)
Initiator Read Data Register **($3C_H$ + x*10_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DATA	[31:0]	rh	**Data Delivered by a Read Response Frame**

20.13.4 Channel.Target Registers

This section describes the channel specific registers of the HSSL module, associated to both the initiator and the target functions.

TCD

The TCD register contains the data part of a write command which is currently being processed by the channel on the target side, or the latest data which has been read by the SRI/SPB master in case of a read command.

(>> **Table 20-6** register overview)

TCDx (x=0-3)
Target Current Data Register x (70_H + x*8_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
D																															
rh																															

Field	Bits	Type	Description
D	[31:0]	rh	**Data Part of the Payload of a Write Command Frame or Read Data of a Read Command Frame**

TCA

The TCA register contains the address part of a read or write command which is currently being processed by the channel on the target side.

In case of Read ID frame, the address is copied from the register **TIDADD**.

(>> **Table 20-6** register overview)

TCAx (x=0-3)
Target Current Address Register x (74_H + x*8_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
A																															
rh																															

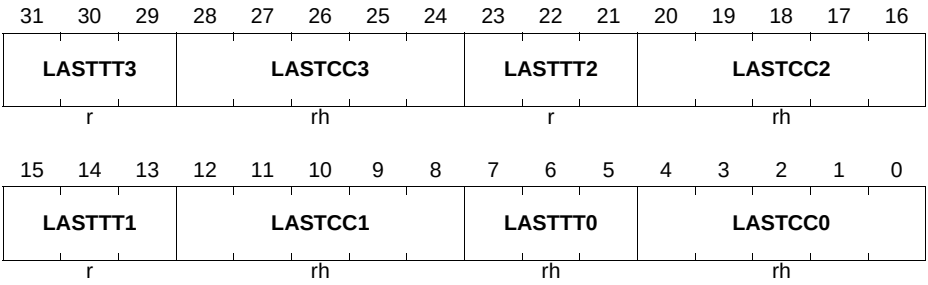
Field	Bits	Type	Description
A	[31:0]	rh	**Address Part of the Payload of a Write Command Frame or a Read Command Frame or ID Frame**

TSTAT

The TSTAT register contains the status bits of the common target functionality.

(>> **Table 20-6** register overview)

TSTAT
Target Status Register **(90_H)** **Reset Value: 0000 0000$_H$**



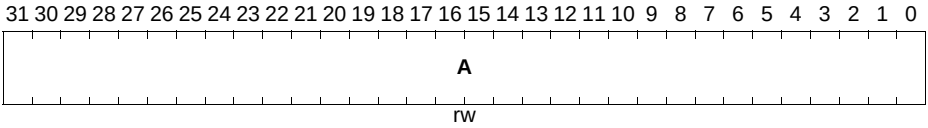
Field	Bits	Type	Description
LASTCCx (x=0-3)	[8*x+4: 8*x]	rh	**Last Command Code** Indicates the latest command code from the header for the corresponding channel.
LASTTTx (x=0-3)	[8*x+7: 8*x+5]	rh	**Last Transaction Tag** Indicates the transaction tag of the latest command or stream frame for the corresponding channel.

TIDADD

The TIDADD register contains the address from which the target ID is fetched.

(>> **Table 20-6** register overview)

TIDADD
Target ID Address Register **(94_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
A	[31:0]	rw	**Address Pointer** Address pointer containing the address of the memory location containing the unique ID data.

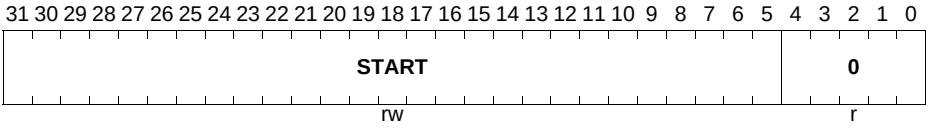
20.13.5 Initiator Stream Registers

(>> **Table 20-6** register overview)

(>> **Memory Block Transfer Modes of the Stream Channel**)

ISSAx (x=0-1)

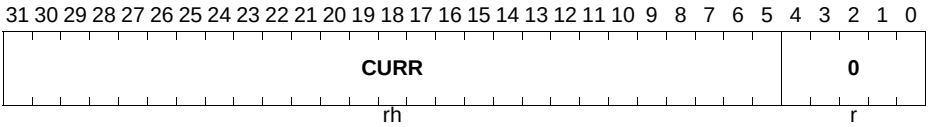
Initiator Stream Start Address Register($A0_H$ + x*4_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
START	[31:5]	rw	**Start Address for the Memory Range** Aligned on 256-bit limit (stream frame payload size).
0	[4:0]	r	**reserved**

ISCA

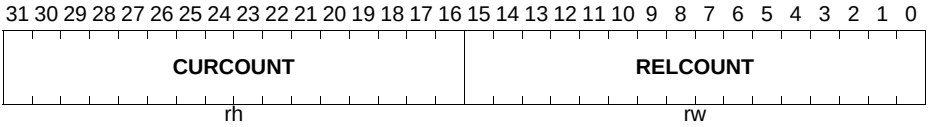
Initiator Stream Current Address Register($A8_H$) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CURR	[31:5]	rh	**Address of the Memory Location for the Current Transfer** Aligned on 256-bit limit (stream frame payload size).
0	[4:0]	r	**reserved**

ISFC

Initiator Stream Frame Count Register(AC_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RELCOUNT	[15:0]	rw	**Reload Count Number** Contains the number of frames to transfer per memory block. Bit field length depends on application requirements. 0_D 1 1_D 1 2_D 2 3_D 3 **others**, corresponding number of frames
CURCOUNT	[31:16]	rh	**Current Count Number** Displays the current count number, which is generated by down-counting from the RELCOUNT value. Bit field length depends on application requirements.

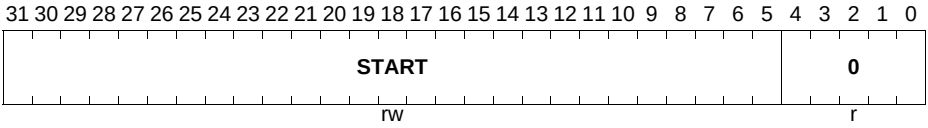
20.13.6 Target Stream Registers

(>> **Table 20-6** register overview)

(>> **Memory Block Transfer Modes of the Stream Channel**)

TSSAx (x=0-1)

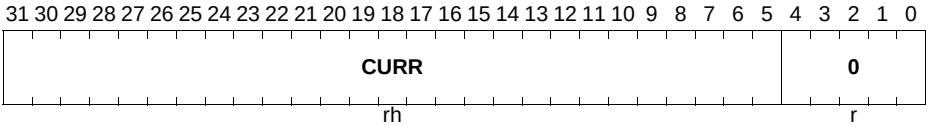
Target Stream Start Address Register x($B0_H$ + x*4_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
ADDR	[31:5]	rw	**Start Address for the Memory Range** Aligned on 256-bit (or 32 byte) limit (stream frame payload size).
0	[4:0]	r	**reserved**

TSCA

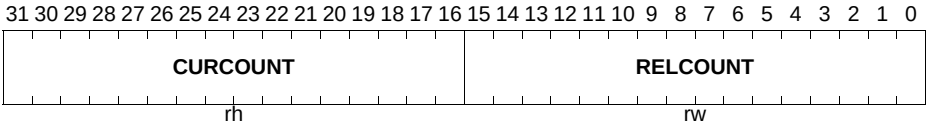
Target Stream Current Address Register ($B8_H$) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CURR	[31:5]	rh	**Address of the Memory Location for the Current Transfer** Aligned on 256-bit (or 32 byte) limit (stream frame payload size).
0	[4:0]	r	**reserved**

TSFC

Target Stream Frame Count Register (BC_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RELCOUNT	[15:0]	rw	**Reload Count Number** Contains the number of frames to transfer per memory block. Bit field length depends on application requirements. 0_D 1 1_D 1 2_D 2 3_D 3 **others**, corresponding number of frames
CURCOUNT	[31:16]	rh	**Current Count Number** Displays the current count number, which is generated by down-counting from the RELCOUNT value. Bit field length depends on application requirements.

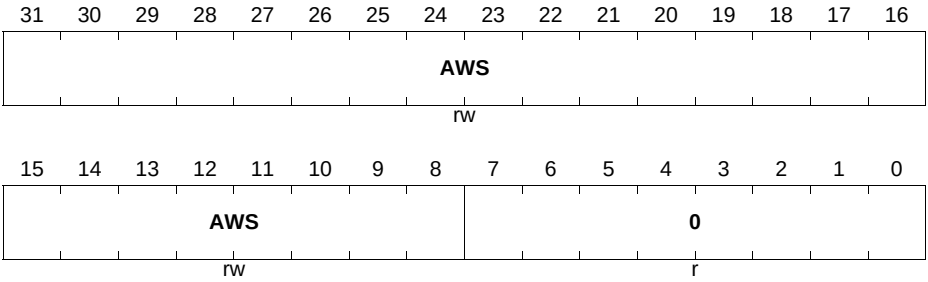
20.13.7 Access Protection Registers

This sub section describes the registers defining the access windows where the HSSL accesses are allowed. These registers are writable only in supervisor mode, which makes them not writable by the HSSL itself.

(>> **Table 20-6** register overview)

AWSTARTx

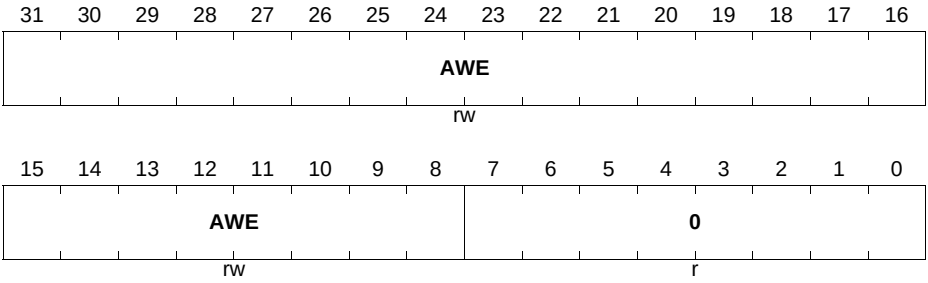
AWSTARTx (x=0-3)
Access Window Start Register x ($C0_H$ + x*8_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
AWS	[31:8]	rw	**Access Window Start Address** This bit field defines the upper 24 bits of the start address of the corresponding access window. This results in a granularity of 256 bytes for the start address.
0	[7:0]	r	**reserved**

AWENDx

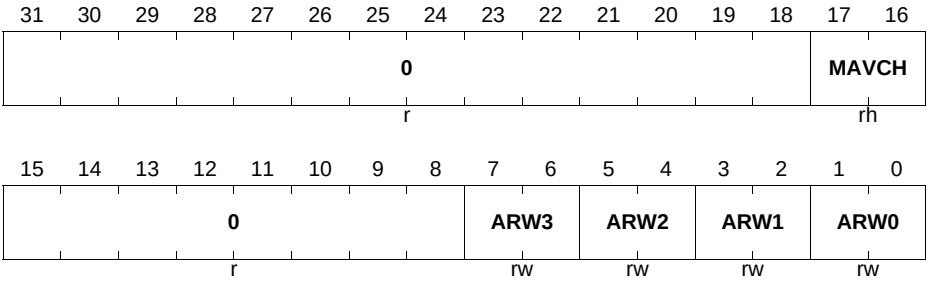
AWENDx (x=0-3)
Access Window End Register x **($C4_H + x*8_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
AWE	[31:8]	rw	**Access Window End Address** This bit field defines the upper 24 bits of the end address of the corresponding access window. This results in a granularity of 256 bytes for the end address.
0	[7:0]	r	**reserved**

AR

AR
Access Rules Register **($E0_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
ARWx (x=0-3)	[1+2*x: 0+2*x]	rw	**Access Rule for Window x** 00_B No access (window disabled) 01_B Read access allowed 10_B Write access allowed 11_B Read and write access allowed
MAVCH	[17:16]	rh	**Memory Access Violation Channel** This bit field shows the number of the latest channel that attempted a not allowed access. 00_B Channel 0 01_B Channel 1 10_B Channel 2 11_B Channel 3
0	[31:18], [15:8]	r	**reserved**

20.14 Module Implementation

The following section describes the topics regarding the integration of the module on chip.

20.14.1 BPI_SPB Module Registers

20.14.1.1 System Registers

Figure 20-38 shows all registers associated with the BPI_FPI module, configured for one kernel. The Offset Address in the following BPI_FPI register table and in the BPI_FPI register descriptions are proposals. In a standard 32 bit peripheral the CLC is mapped to offset address 00h, module ID to 08h. The proposal for the new BPI_SPB register is to map them to the end address of the peripheral address range together with the peripherals SRNs.

BPI_FPI Registers Overview

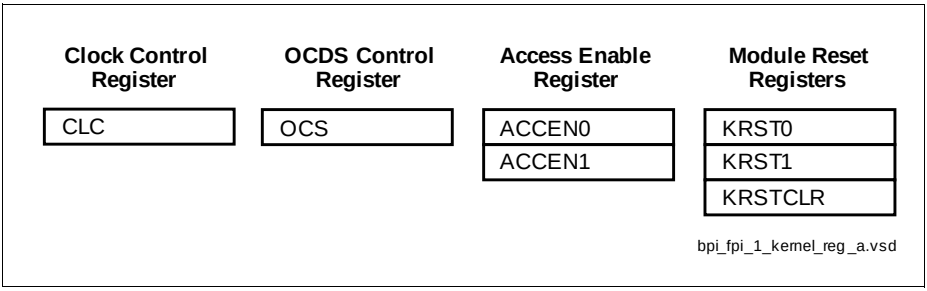


Figure 20-38 BPI_FPI Registers

The writes of the bus masters to the HSSL module is controlled by Acces Protection registers ACCENx.

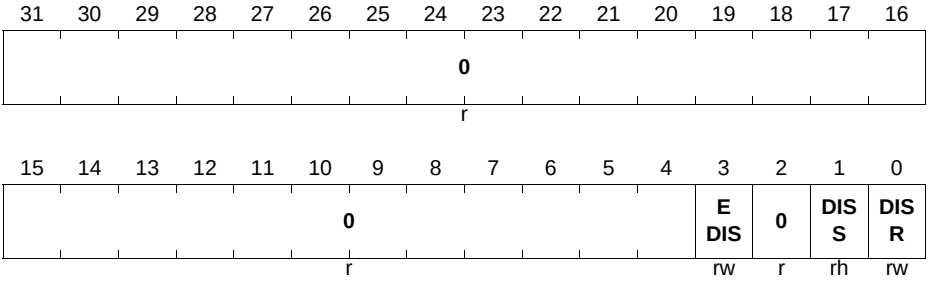
The HSSL implements two ACCENx registers, ACCEN0 and ACCEN1.

The ACCENx registers are protected by Safety Endinit mechanism.

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the $f_{<>}$ module clock signal, sleep mode and disable mode for the module.

CLC
Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
0	[31:4], 2	r	**Reserved** Read as 0; should be written with 0.

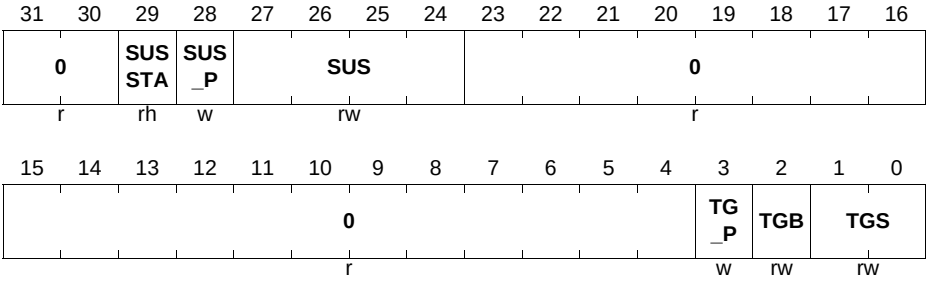
OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode

OCS

OCDS Control and Status **($E8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TGS	[1:0]	rw	**Trigger Set for OTGB0/1** 0_H No Trigger Set output 1_H TS16_STR, Streaming Channel Trigger Set 2_H TS16_ERR, Errors Trigger Set 3_H reserved
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1
TG_P	3	w	**TGS, TGB Write Protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. 2_H Soft suspend **others**, reserved,
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:4], [31:30]	r	**Reserved** Read as 0; must be written with 0.

*Note: The bit SUSSTA is set only at entering the suspend state from the run state, according to the **Figure 20-29**. It will not be set if the soft suspend request comes in any other state than run state, like init or disabled/sleep state.*

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B,..., EN31 -> TAG ID 011111B.

ACCEN0
Access Enable Register 0 (FC_H) Reset Value: FFFF FFFF$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

EN 15	**EN 14**	**EN 13**	**EN 12**	**EN 11**	**EN 10**	**EN9**	**EN8**	**EN7**	**EN6**	**EN5**	**EN4**	**EN3**	**EN2**	**EN1**	**EN0**
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register (ACCEN1)

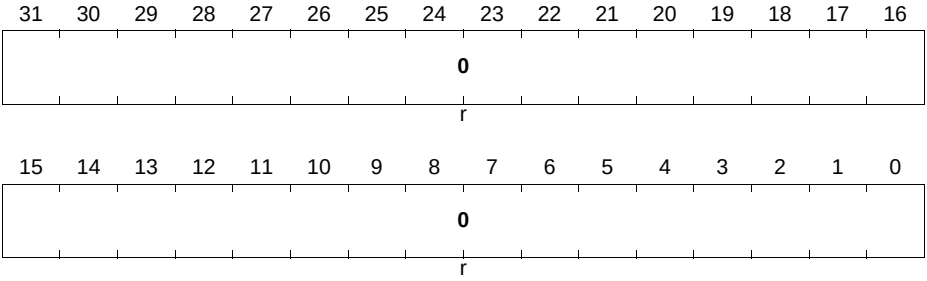
The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B,..., EN31 -> TAG ID 111111B.

ACCEN1
Access Enable Register 1 **($F8_H$)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

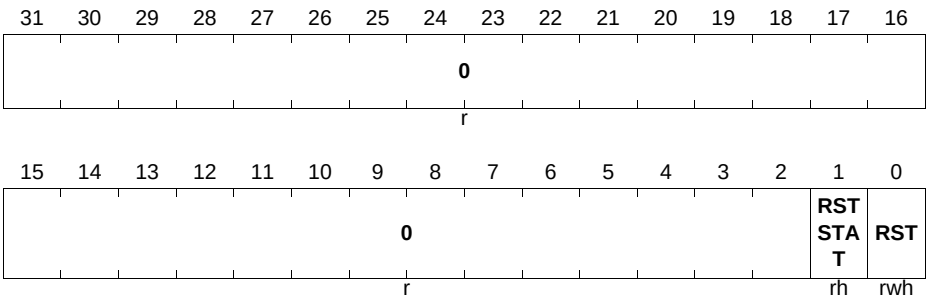
Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **($F4_H$)** **Reset Value: 0000 0000$_H$**



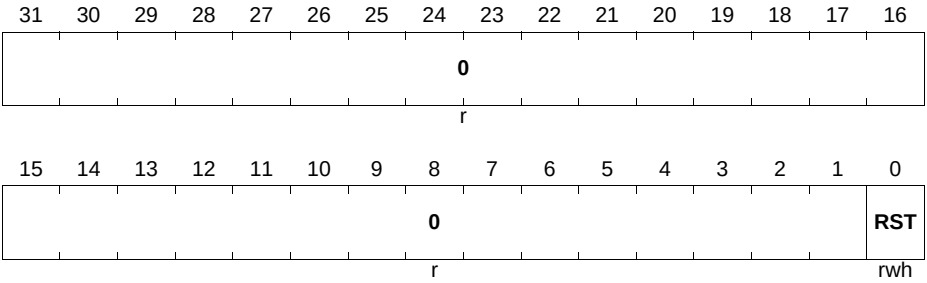
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST

bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($F0_H$)** **Reset Value: $0000\ 0000_H$**



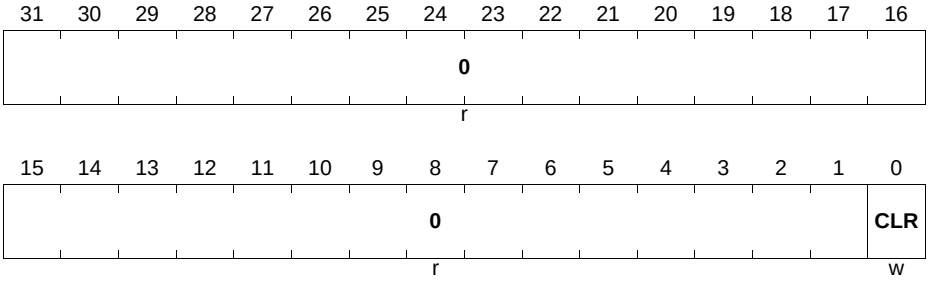
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (EC_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

20.15 High Speed Communication Tunnel (HSCT)

This chapter describes the High Speed Communication Tunnel interface for the Microcontroller high speed data communication including the physical layer and the control (link) layer.

20.15.1 Overview

The HSCT chip to chip communication interface employs an interface for inter chip communication between a master interface and a slave interface. The interface is based on LVDS IO technology and developed to function as a master or a slave interface. During initialization phase the role of the Interface (master or slave) must to be defined. It is not intended to change the system role during an application.

The interface is a full-duplex interface for TX and RX data transfer. The data transfer speed can be configured to function in low or high speed and allows to configure in each transfer direction an independent transfer speed in order to reduce power and EMI, based on transfer speed requirements. A sleep mode for the LVDS IO's is implemented, which reduces power on the IO, if the interface is not in use.

The master interface is defined to own the crystal and provides the clock (**SysClk**) to the slave interface. The slave interfaces allows a master interface generated SysClk routing through the SysClk IO or the XTAL1 IO. The second one allows to use SysClk as reference clock for the System PLL. The HSCT Master/Slave interface in the system allows one crystal only. The interface reset is derived from the System reset and provided by chip internal reset signaling.

In **Figure 20-39** a system level view of the interface and interface connection is shown.

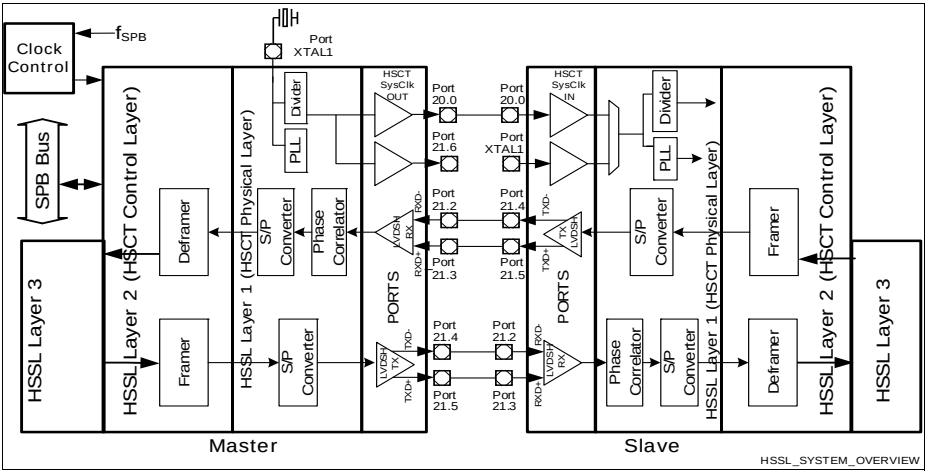


Figure 20-39 Overview of Interface Signals.

Note: The HSCT SysClk path from Master to Slave device can be done using Master Port 20.0 (5 V) or using Port 21.6 (3.3V). Only one of this two signal path shall be used on a PCB design. It is recommended to use P20.0 signaling path. HSCT SysClk connection to XTAL1 is not supported by FlexRay PLL.

20.15.1.1 Features

The HSCT interface is intended to carry:

- Transmit Symbol information from the master interface to the slave interface
- Receive Sample information from the slave interface to the master interface
- System Clock provided by the master interface (crystal owner) to the slave interface
- Control information on Master TX link and RX link
- Clear To Send indication in both directions
- Unsolicited Status in both directions
- Regular data transfer in both directions based on data channels
- Master interface data transfer speed 5 MBaud and 320 MBaud.
- Three slave interface data transfer speeds available based on 20 MHz SysClk:
  5 MBaud (low speed)
  20 MBaud (medium speed)
  320 MBaud (high speed)
- Two slave interface data transfer speeds available based on 10 MHz SysClk:
  5 MBaud (low speed)
  320 MBaud (high speed)
- The interface is based on IEEE 1596.3 LVDS IO's
- To reduce the voltage swing a configuration option is available

20.15.2 Functional Description

20.15.2.1 Introduction

The first HSCT communication is always established from master interface. The LVDS IO's are based on standard IO technology following IEEE 1596.3 specification. The HSCT LVDS IO common voltage is defined to be a 1.2V. Compared to IEEE 1596.3 the differential voltage level can be reduced via configuration option to reduce EMI. Additionally the HSCT SysClk can be configured to run at Crystal/2 to reduce EMI instead of Crystal frequency used as single ended clock.

The intention is to implement the interface either as a master interface or as a slave interface. So the interface is able to handle both roles (master or slave). The following detailed description should describe both roles. This requires the following definitions:

- TX line or TxData link (TX_DAT, TX_DATX) defines the data transfer from the master interface to the slave interface.
- RX line or RxData link (RX_DAT, RX_DATX) defines the data transfer from the slave interface to the master interface.
- Transmit direction, outbound data (or transmission) describes to send out data independent of the role the interface does have.
- Receive direction, inbound data (or receiving) describes to receive data independent of the role the interface does have.

20.15.2.2 Physical Layer

RX / TX Data Interface

During initialization the associated TxData link starts in low-speed mode, with the high-speed clock generators turned off and the RxData Link disabled. An interface control sequence, initiated by software, allows to switch the interface in high-speed mode.

The data interface can transmit up to 320 Mbit/s in the RX and the TX direction (full-duplex). The data is recovered from RX data stream (RX_DAT, RX_DATX) in the master interface and from TX (TX_DAT,TX_DATX) data stream in the slave interface. **Table 20-7** shows the interconnects of the differential data lines for control and data transfer between the master interface and the slave interface.

In transmit direction a 320 Mbit/s data signal is transmitted from the master interface to the slave interface. Proper phase selection is processed at receiver side via six different phases of a 320 MHz clock.

In RxData direction a 320 Mbit/s differential data signal is supplied from the slave interface to the master interface. A proper phase selection is processed for data recovery at the master receiver path via six different phases of a 320 MHz clock. The slave interface reference clock must be the SysClk, driven by the interface Master. The Slave must receive the SysClk from the master interface to be enabled to transfer data. In the slave interface the 320 MHz data clock is generated internally from the SysClk. The slave interface PLL reference clock is based on the **SysClk** interface signaling or on a clock provided via the Oscillator input. The selection can be done via configuration register setting. Also the slave receiver path is using the six different phases of a 320 MHz clock to recover the data.

Note: A local crystal at the slave interface taken as reference clock for the interface PLL is not allowed as the data recovery based on clock phase shift does work on a common reference clock source! It is allowed to use the oscillator input of the chip and connect the master interface SysClk to it. In this case also other chip internal PLL's can be supplied with the SysClk master interface reference clock.

Table 20-7 Physical Interconnects

Direction	Name	Description
Transmit	**TX_DAT**, **TX_DATX**	Channel TX data and control information at a max rate of 320 Mbit/s from the master interface to the slave interface
Receive	**RX_DAT**, **RX_DATX**	Channel RX data and control information at a max rate of 320 Mbit/s from the slave interface to the master interface

The interface driver in shutdown mode provides a pull-down to 0V on both differential pins to ensure that the signals are held in a defined state. The RxDAT link enters shutdown mode by Interface control logical channel command and exit shutdown mode by control command, again. The slave transmission line is disabled by default and must be enabled by the master. The master is using control commands to link operation modes.

Payload content is transferred most significant bit first. For example, if a 32-bit payload contains a message that is built in a 32-bit register in the sending interface, b31 of the register (the MSb) shall be the first bit of payload transmitted and b0 (LSb) shall be the last. Larger payloads should be built up according to the same principle.

Differential Signaling Principle Based on LVDS

The voltage at the termination resistor of the receiver is either positive or negative, which depends on the direction of the current flowing through it. This is determined by the state of the switches at the transmit stage. The voltage V_{OD} should be evaluated by a comparator with hysteresis.

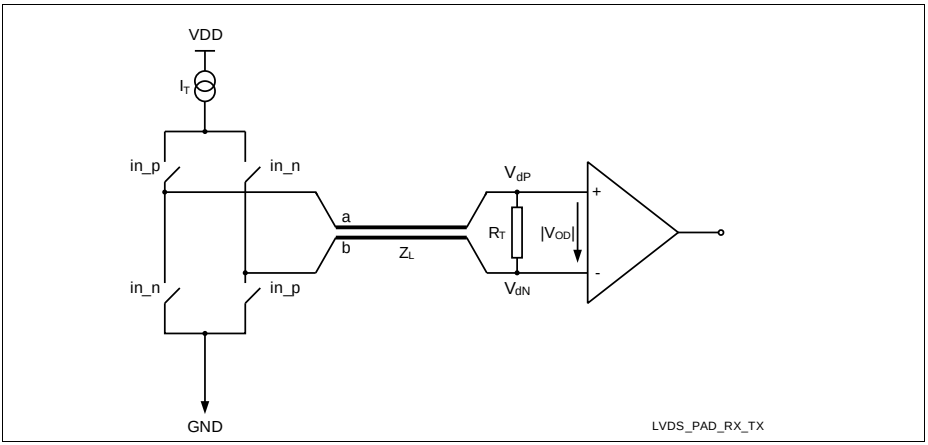

Figure 20-40 Pad Driver and Pad Receive

The HSCT interface does not define specific test for an error-free transmission, although the signal quality of course suffers from attenuation and noise and in particular it depends on proper wave propagation. Therefore the interconnect lines need to have a characteristic wave impedance Z_L equal to 100 Ω differential, corresponding to the termination resistor R_T at the receiver side.

Note: Due to the nature of wave propagation a termination other than with the characteristic line impedance leads to inevitable signal degradations. Therefore any operation mode other than 100 Ω termination is only supported from a functional point of view (i.e. the corresponding electrical configuration is possible) without any further guarantee of an error-free transmission.

Note: The interface receiver provide an input termination impedance of 100 Ω +/- 20% at the IO. If a more precise termination is required the design offers to disable the internal termination impedance and allow an external termination on the PCB.

The differential output voltage V_{OD} is defined as the difference of the voltages V_{dP} and V_{dN} at the receiver input pins.

$$V_{OD} = V_{dP} - V_{dN} \quad (20.1)$$

The common-mode voltage V_{OS} is defined as the arithmetic mean value of the voltages at the receiver input pins:

(20.2)

$$V_{OS} = \frac{V_{dP} + V_{dN}}{2}$$

V_{OD}, V_{OS}, and the corresponding minimum differential eye opening V_{eye} considering LVDS transmitter jitter are graphically shown in **Figure 20-41** and **Figure 20-42** for ideal signals.

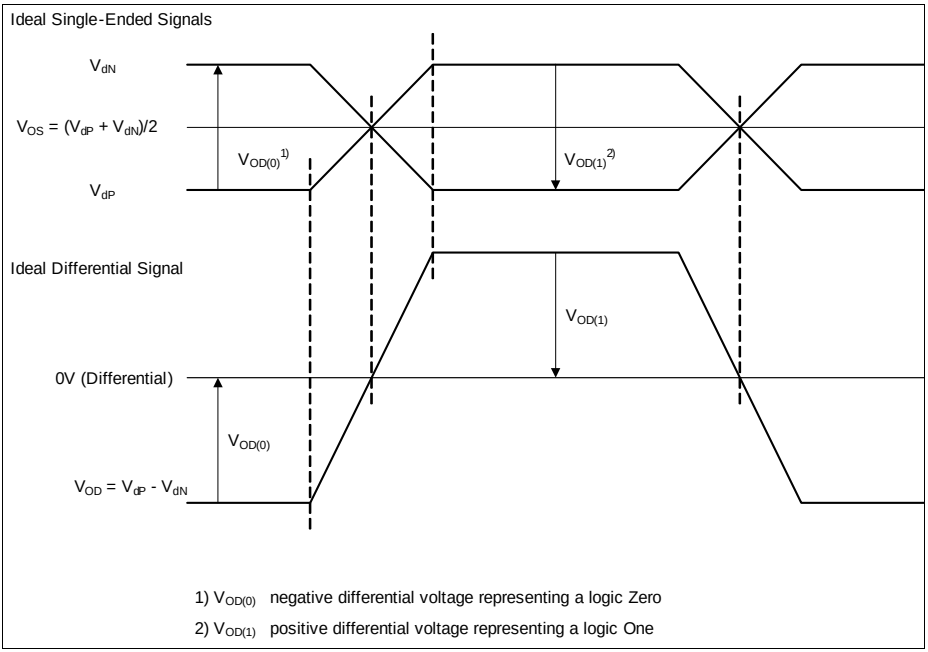

Figure 20-41 Ideal Single-Ended and Ideal Differential Signals

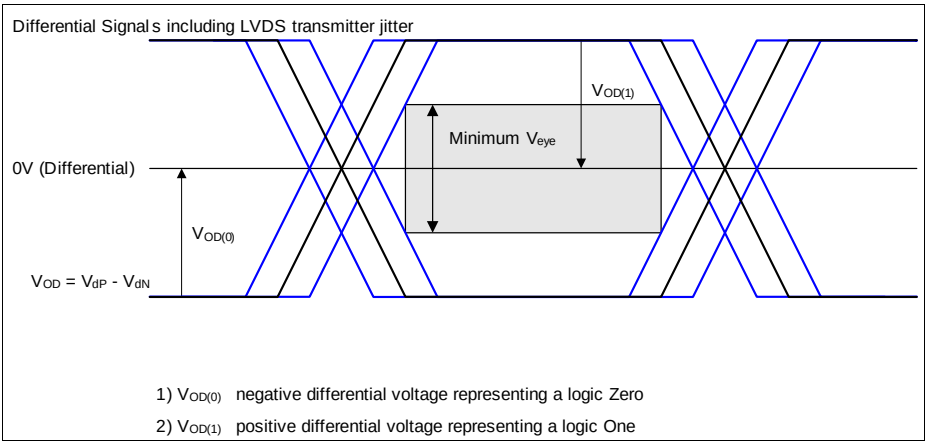

Figure 20-42 Differential Eye Opening

20.15.2.3 Electrical Characteristics Based on LVDS for Reduced Link trace length

The characteristics are based on the LVDS standard IEEE P1596.3-1995. It is adapted for low power consumption and lower supply voltages for short ranges. It is assumed that the master interface and the slave interface may have different supply voltages, but common mode voltage for the differential signaling is based on 1.2V.

Operating Modes

The HSCT interface comprises the following operating modes:

- **Terminated Mode**: The data transmitter requires a 100 Ω external termination at the pins **TX_DAT** and **TX_DATX**. The termination is given by a 100 Ω resistor at the receiver input, of the opposite LVDS device, for matching the differential characteristic impedance of the line with the impedance of the receiver. PCB design has to follow guidelines on differential signal routing. The PCB placed termination resistor can be chosen very precise. Via configuration option an 100 Ω LVDS receiver internal resistor can be enabled with a +/- 20% tolerance.
- **Power up**: The line receiver shall always be enabled after power up and SysClk is active. The data decoder behind the receiver is not enabled at this point. It is enabled when the first transition on the data lines is detected by the line receiver. The line driver must be enabled on the master side via SW control. On the slave side the line driver must be enabled by sending interface message control commands from the master. After power up the link starts in low speed mode. After line driver enable some time is required to power up the LVDS transmitter line. The LVDS driver will be activated after a startup time of max. 3 ms. The data link in RX and TX direction is ready to transmit and receive data after the defined setup time.

- **Sleep mode**: In terminated operation the differential voltage across the resistor will be reduced to nominally zero (-5mV to 20mV at 100 Ω +/- 20%) and hence, the line driver current requirement will reduce to internal bias currents. The common-mode voltage, however, should be maintained. Also the PLL is not switched off during sleep mode and being in high speed mode.
- **Power down**: When any interface driver supply voltage is removed, the driver shall provide a weak pull-down to 0 V to ensure that the signals are held in a well-defined state. It is a requirement to be free of cross- and bias current during power down.

Note: The line driver in the master interface shall be turned on before the line driver in the slave interface is activated, i.e. before sending the transmitter activation command to the slave interface, in order to avoid receiving undefined data in the slave interface.

The implementation of the output driver is based on a bridge topology of current sources. Accordingly the equivalent differential source impedance is high-ohmic (>10kΩ). This mismatch with regards to the immediate termination at the Microcontroller chip edge (100 Ω line) is common practice among LVDS interface designs.

Due to the strong dependency on link length and layout, as well as the susceptibility to noise and interference, it is recommended, to have the termination available on the PCB:

- Receiver **internal termination mode** not active (PCB termination): can be programmed in register **INIT**. The data transmitter is operated without a termination inside the differential receiver pair.
- Receiver **internal termination mode** active: allows to have a 100 Ω resistor internally with a +/-20% tolerance. Programming via the same register bit as PCB termination (in register **INIT**).

Data Rates

Both, master and slave interface shall be ready to receive frames whenever the SysClk is running. The link shall initialize in low-speed mode with the high-speed clock generators turned off and the RxData link disabled. Subsequent speed and mode changes shall be commanded by the master interface, except sleep mode on the RXData link, which is controlled by the slave interface. Except when using sleep mode, both links shall default to the logic zero state, while dormant and between frames. This is required, to ensure that data will not be lost during a speed change.

Interface data rate change on both the TxData and the RxData link shall be possible without losing data. It is highly recommended to keep the link quiet during the time the interface transfer speed is changed. Changing transfer data rate on an active link does not guarantee stable data transfer.

The HSCT standard defines three different data speed modes:

- Low speed mode
- Medium speed mode
- High speed mode

Additionally the HSCT standard defines the different data speed modes to be derived from the crystal frequency. Taking the Automotive common crystal frequency of 20 MHz the following data rates can be produced based on the available multiplication factors.

SysClk; RefClk = Crystal frequency = 20 MHz:

- 5 MHz = Crystal frequency / 4 (Low Speed)
- 20 MHz = Crystal frequency (Medium Speed)
- 320 MHz = Crystal frequency * 16 (High Speed)

SysClk; RefClk = Crystal frequency / 2 = 10 MHz:

- 5 MHz = SysClk frequency / 2 (Low Speed)
- 20 MHz = Medium Speed - **not available**
- 320 MHz = SysClk frequency * 32 (High Speed)

Low Speed mode and Medium Speed mode frequencies are generated directly out of the Crystal frequency. High Speed mode frequency requires a PLL, which takes the Crystal clock as reference clock.

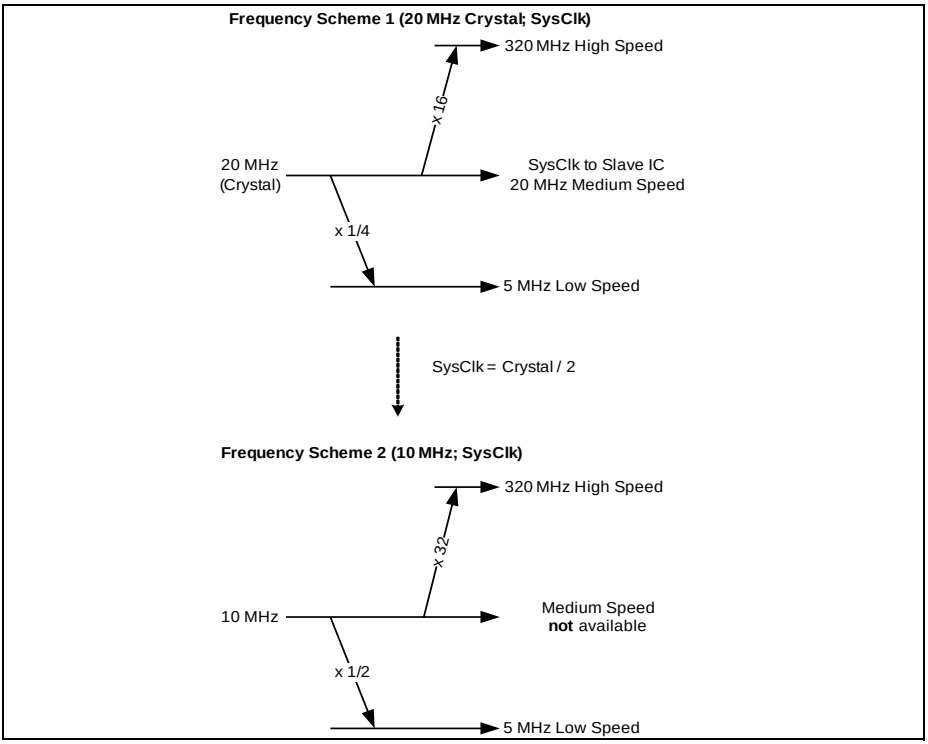

Figure 20-43 Frequency Scheme

Connecting a 20 MHz Crystal to the system allows to generate the Automotive frequency scheme.

The following table (**Table 20-8**) shows the data transfer direction and the available Automotive transfer speed based on Crystal clock frequency.

Table 20-8 HSCT Data Rates

Direction	Data Rate	Operating Mode
Master interface to Slave interface	5 Mbit/s	“low speed mode” for startup / fallback
Master interface to Slave interface	320 Mbit/s	“high speed mode”
Slave interface to Master interface	5 Mbit/s	“low speed mode” for startup / fallback

Table 20-8 HSCT Data Rates (cont'd)

Direction	Data Rate	Operating Mode
Slave interface to Master interface	20 Mbit/s	"medium speed mode" *Note: only available, if reference clock; SysClk is at 20 MHz (Crystal)*
Slave interface to Master interface	320 Mbit/s	"high speed mode"

*Note: To fulfill the requirement - having reduced EMI on the single ended **SysClk** - the interface can be configured to operated on a **SysClk = Crystal/2** frequency. Choosing the **crystal/2** mode excludes the medium speed mode available in slave to master data transfer direction (receiver line). Low speed mode devices divide SysClk by 2 to achieve the low speed clock. Another possibility to reduce EMI is reducing SysClk driver strength based on the 20 MHz clock, which is the recommended way as BER is better than using 10 MHz.*

PLL configuration and Baud Rates

The PLL supports different speed modes and frequency modes, which will be described in this section in detail. Each mode and transfer direction can be configured separately.

Table 20-9 High Speed Mode selection

PLL Speed [MHz]	320	320	280	280	240	240	200	200
PLL reference frequency [MHz]	20	10	20	10	20	10	20	10
PLLWMF [hex]	10	20	0E	1C	0C	18	0A	14
TXHD 1/1 [MBaud]	320	320	280	280	240	240	200	200
TXHD 1/2 [MBaud]	160	160	140	140	120	120	100	100
TXHD 1/4 [MBaud]	80	80	70	70	60	60	50	50
TXHD 1/8 [MBaud]	40	40	35	35	30	30	25	25
TXHD 1/16 [MBaud]	20	20	17.5	17.5	15	15	12.5	12.5

PLL reference frequency and PLL frequency control word Multiplication factor (PLLWMF) defines the PLL speed and are used to configure the output frequency of the PLL. The interface baud rate can be configured separately in TX direction (TXHD) and RX direction (RXHD). The table above exemplarily shows the TX direction.

Correlator

Data transfer from the master interface to the slave interface can either be in “high speed mode” or “low speed mode” (**Crystal**/4 at 20 MHz SysClk or SysClk/2 at 10 MHz SysClk). A correlator is used for finding the optimum sample phase for the transfer. The correlator configuration differs in high speed and low speed mode.

Phase Selection

Every frame starts with a 16-bit sync field (see **Figure 20-44**) containing a synchronization pattern. Note that the sync pattern starts with 1, so a new frame always starts on the rising edge. In between frames, there is always at least one bit 0 in normal mode. By sending 1 immediately after the last bit in a frame, the master interface controller demands sleep mode as described in Section Sleep Mode. Neither the master interface nor the slave interface may assume that the other side will maintain data phasing between frames. The receiving interface shall use the sync pattern to determine the start time of the frame relative to the local clock.

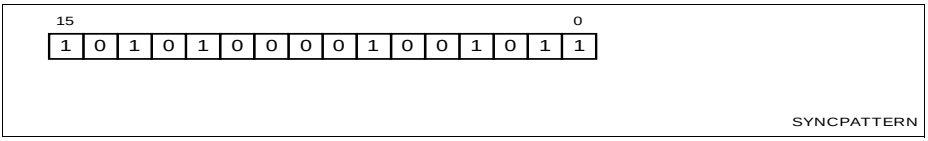

Figure 20-44 Synchronization Pattern

The synchronization pattern is only needed for selecting the optimum sample phase, so it is not feed through to the output register of the correlator.

Payload Size Decoding

Every frame consists of three parts: a 16-bit synchronization pattern, an 8-bit header and the payload field which can be 8, 32, 64, 96, 128, 256 or 512 bits. The header contains information about payload size and logical channel type. Although decoding the header is task of the deframer, the payload size shall also be evaluated inside the correlator for finding the end of a frame.

The header is sent most significant bit first. The first 3 bits (bit5, bit6 and bit7) contain the payload size of this frame (see **Table 20-10**).

Table 20-10 Payload Size Coding

b7 … b5	Payload Size (bits)	Total Frame Size (bits)
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152

Table 20-10 Payload Size Coding (cont'd)

b7 … b5	Payload Size (bits)	Total Frame Size (bits)
101	256	280
110	512	536 (not supported)
111	288	312

Note: In a harsh Automotive environment a payload of 512 bit may cause increased error bit streams, due to the long distance from one synchronization pattern to the next. This is the reason why this data transfer length is not supported.

The correlator shall decode the payload size field and count the number of received bytes. After the last byte in a frame has been fed through to the correlator output register, the tuning of the multiplexer unit becomes invalid. In between frames at least one bit 0 shall be transmitted. The comparison procedure is started again as soon as there is a 1 at the MSB position in the shift registers.

The 8-bit header and the payload are used as input for the deframer block.

Note: The sync pattern and inter-frame bits are not passed to the deframer. An error in the sync pattern generates an error and is detected by the Physical layer.

Transmission initiated Sleep Mode - bringing receiver path into sleep mode.

By sending a 1 immediately after the last bit in a frame, the interface indicates that its LVDS line driver is sent to sleep mode, and suggests sleep mode to the receiver LVDS.

To leave sleep mode, the master interface shall send 8 bits of 0. This is performed in high speed mode and in low speed mode.

Jitter Budget

The system clock is distributed directly from the master interface to the slave interface.

Subsequently, all jitter investigations considered in the following sections are referenced to the system clock, i.e., 20 MHz as the base oscillator frequency or 10 MHz as the base oscillator frequency divided by 2.

Each system clock distribution has an associated filter function that comprehends the worst case combination of PLL bandwidth/peaking and equivalent jitter. The effective jitter seen at the LVDS receivers clock-data recovery inputs is a function of the difference in LVDS receiver and LVDS transmitter PLL bandwidth and peaking convolved with the jitter spectrum of the system clock.

System Clock variations contain jitter over a wide range of frequencies, some of which will be tracked by the LVDS receiver or otherwise removed by the combination of the LVDS transmitter and the LVDS receiver PLLs. Consequently, the nature of the filter functions is in part dependent on the way of how the system clock is distributed. In general, the system clock jitter is filtered by the PLL difference function which

comprehends the “mismatch” between LVDS transmitter and LVDS receiver PLL and also accounts for the impact of the transport delay.

Direct System Clock Distribution

This architecture implies direct distribution of the crystal clock as system clock from the master interface to the slave interface. Hence, the system clock is directly supplied to both LVDS transmitter PLL and LVDS receiver PLL. Hence, a major part of the clock jitter is sourced equally through LVDS transmitter and LVDS receiver PLLs. The amount of jitter appearing at the data recovery block is then defined by the transfer function difference of the LVDS transmitter and LVDS receiver PLLs, and by the sum of the clock jitter of the LVDS transmitter PLL, $X_{clkMaster}(s)$, and the LVDS receiver PLL, $X_{clkSlave}(s)$.

Based on the above clock architecture, a difference function may be defined that describes the “mismatch” between LVDS transmitter and LVDS receiver PLLs. As a first approximation second order transfer functions are assumed.

The jitter of the direct system clock distribution is described by the phase noise power spectral density function as the absolute square of $X_d(s)$, as follows.

$$|X_d(s)|^2 = |X(s)|^2|H_1(s)e^{-sT} - H_2(s)|^2 + |X_{clkMaster}(s)|^2 + |X_{clkSlave}(s)|^2 \quad (20.3)$$

where

$$H_1(s) = \frac{2s\,\zeta_1\omega_{n1} + \omega^2_{n1}}{s^2 + 2s\,\zeta_1\,\omega_{n1} + \omega^2_{n1}} \quad (20.4)$$

and

$$H_2(s) = \frac{2s\,\zeta_2\omega_{n2} + \omega^2_{n2}}{s^2 + 2s\,\zeta_2\,\omega_{n2} + \omega^2_{n2}} \quad (20.5)$$

H2

Conversion between the natural PLL frequency ω_n and the -3 dB point is given by the following expression.

$$\omega_{3dB} = \omega_n\sqrt{1 + 2\,\zeta^2 + \sqrt{(1 + 2\,\zeta^2)^2 + 1}} \quad (20.6)$$

Under the assumption that crystal clock jitter can be ignored, i.e.,

$$X(s) \approx 0 \tag{20.7}$$

and LVDS transmitter to LVDS receiver transport delay can be neglected, i.e.,

$$e^{-sT} \approx 1 \tag{20.8}$$

the phase noise power spectral density of the direct system clock distribution can be simplified, as follows.

$$|X_d(s)|^2 = |X_{clkMaster}(s)|^2 + |X_{clkSlave}(s)|^2 \tag{20.9}$$

Note: The slave interface requires a SysClk from the master always as reference clock. It is not supported by the interface to have a separate crystal connected to the SysClk input as reference clock at the slave interface. The master interface generated SysClk needs to be enabled.

Jitter Budgeting

To estimate the total rms jitter of LVDS transmitter PLL and LVDS receiver PLL for data recovery the following procedure has to be followed.

- Piece wise linear integration of the additive SSB (Single Sideband) phase noise for direct clock distribution to obtain the total phase noise power of the LVDS transmitter PLL.
- Calculation of the rms jitter of the LVDS transmitter PLL as shown in **Figure 20-45**.
- Calculation of the total rms jitter RJ as the square root of the sum of the squares of the rms jitter from the LVDS transmitter PLL and the LVDS receiver PLL.
- Calculation of total jitter, i.e., random and deterministic, considering duty-cycle distortion and other effects to guarantee minimum eye opening at the interface.

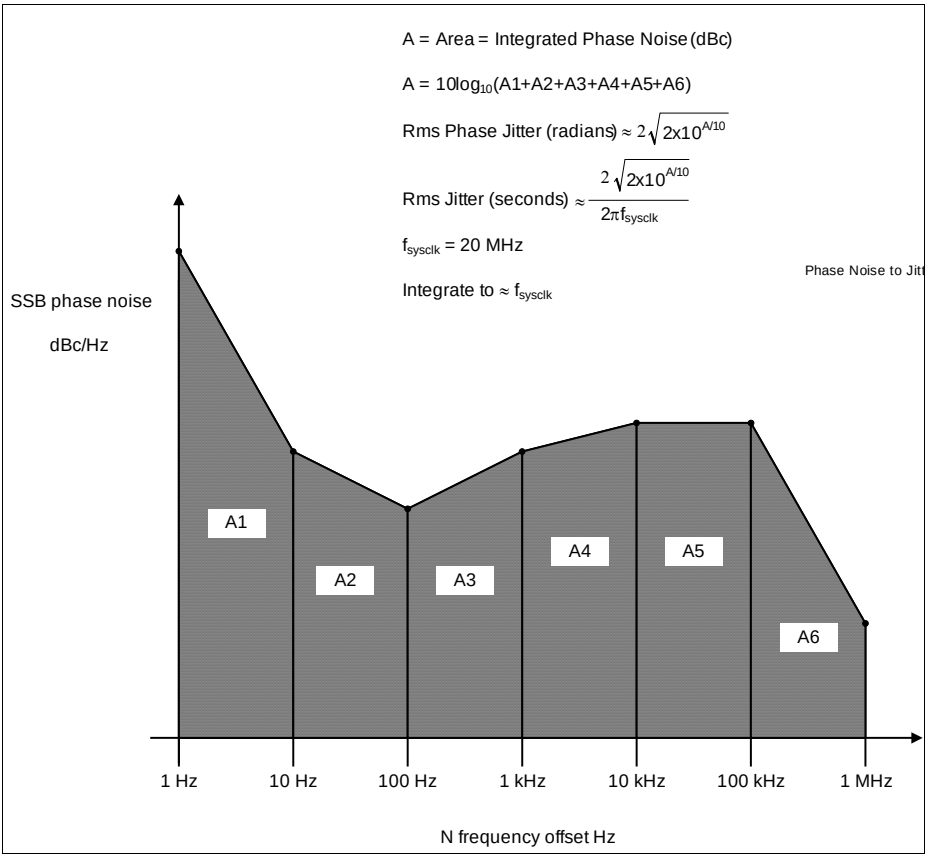

Figure 20-45 Calculation of Jitter from SSB Phase Noise

Calculation of Total Jitter Budget

To estimate the total jitter budget allowed for the random rms jitter RJ as described in the sections before, the following procedure for direct clock distribution has to be followed.

- Calculation of the jitter headroom available for the ideal jitter-free case given by the minimum eye opening, i.e., 55% of a 320 MHz period.
- Calculation of the total jitter headroom required under the assumption that the total long-term jitter TJ will not exceed the maximum peak-to-peak jitter specified.
- Subtraction of two phases of the oversampling frequency used for data recovery taking into account the data-recovery uncertainty in multiples of phases of the oversampling frequency. The data-recovery uncertainty is implementation specific

and determined by the data-recovery oversampling factor DR_{OS}. **Figure 20-46** depicts the case where the selected sampling phase of the data recovery is almost one sample phase away from the ideal sampling point. Thus, the budget left for the peak jitter is reduced by almost one sample phase and hence, the peak-to-peak jitter is reduced by almost two phases.

- The remaining sum represents the jitter budget which is the upper limit for the peak-to-peak jitter calculated from the random rms jitter distribution *RJ* described in the sections before. Given a required *bit error rate BER = 10-12 for SysClk 20 MHz and BER = 10-9 for SysClk 10 MHz*.

The jitter budget is given by the following equation.

$$TJ_{pp} = DJ_{PP} + RJ_{PP} = (DJ_{TX} + DJ_{RX}) + 2 * Q * \sqrt{J_{ABS}^2 + J_{ACC}^2} \quad (20.10)$$

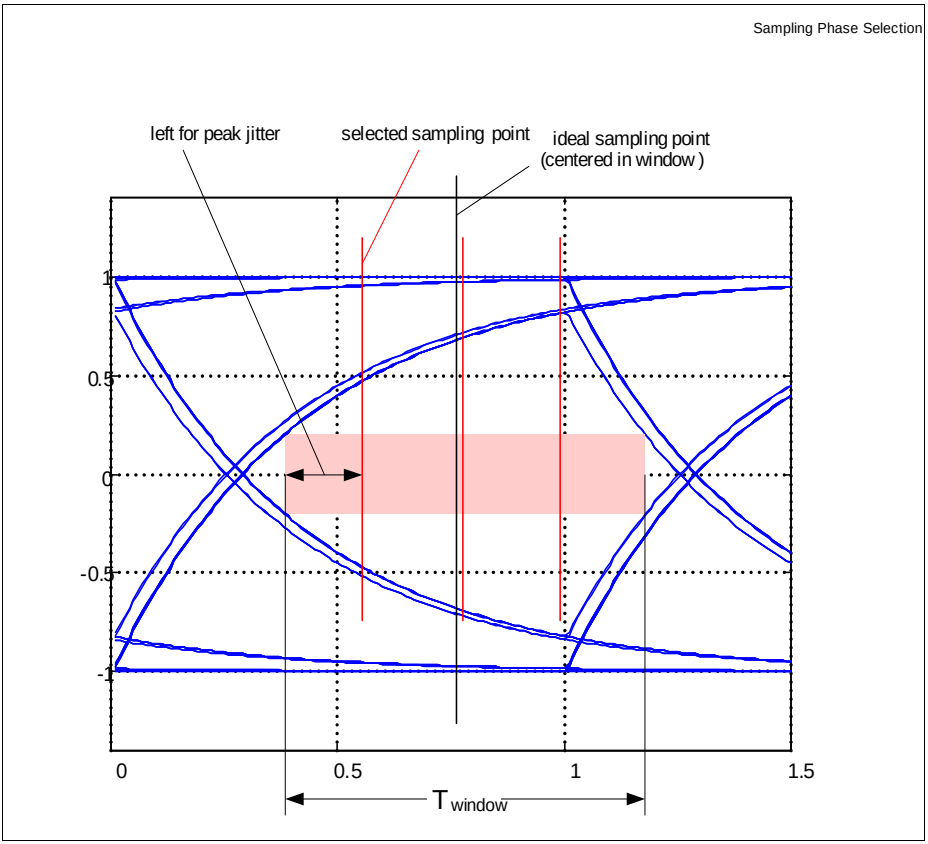

Figure 20-46 Sampling Point Selection

20.15.2.4 Protocol Layer

The protocol layer is between the higher layer protocol (HSSL) and the physical layer. The protocol Layer is performing the frame generation in transmit direction and extracts the payload out of a frame in receive direction, called deframing.

Deframer

The deframer's tasks are decoding the 8-bit header and separating the data stream according to the logical channel type.

During Microcontroller reset, the deframer shall ignore all data coming in from the correlator. This is a precaution measure to eliminate possible malfunctions due to floating HSCT lines.

Additionally the deframer does check the header for potential errors, e.g. size is matching received data or size is allowed and received type is allowed. An error in the header discards the received data.

Header Decoding

The first 8-bit in a frame, after the sync pattern has been filtered out by the correlator, is the header or frame type field. It contains information about the payload size and logical channel type coding (see **Figure 20-11**). Please note again that all transfers are most significant bit first.

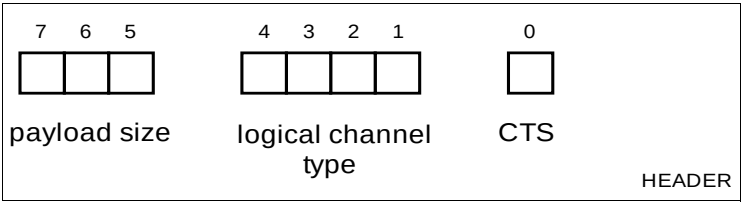

Figure 20-47 Header (Frame Type Field)

- The payload size coding can be seen in **Table 20-10** in the previous.
- Bits 1 to 4 define the logical channel type. See **Table 20-11** for details on the logical channel type coding. Note that some kinds of transfer are exclusively used from the master interface to the slave interface or from the slave interface to the master interface.
- Bit 0 is used as Clear To Send bit CTS for transfers from the slave interface to the master interface (Requires an enable via configuration). For transfers from the master interface to the slave interface also the master interface can send CTS, which must also be enabled via configuration before. Also CTS from master interface indicates the master to the slave, no more data can be accepted. This feature requires for the master interface as well as for the slave interface that higher layer FIFO provides a configuration watermark allowing to tune the CTS signaling - dependant on the transferred payload size.

Table 20-11 Logical Channel Type Coding

b4 … b1	Logical Channel Type Master interface to Slave interface (TX Link)	Logical Channel Type Slave interface to Master interface (RX Link)
0000	Interface Control	Interface Control (PING answer, 32-bit value)
0001	Master interface Unsolicited Status (32-bit only)	Slave interface Unsolicited Status (32-bit only)
0010	Slave interface Control (not supported, receiver generates an error)[1]	Slave interface Solicited Read (not supported, receiver error)[2]
0011	CTS Transfers	CTS Transfer
0100	Data Channel A	Data Channel A
0101	Data Channel B	Data Channel B
0110	Data Channel C	Data Channel C
0111	Data Channel D	Data Channel D
1000	Data Channel E (not supported, receiver generates an error interrupt)	Data Channel E (receiver error interrupt)
1001	Data Channel F (not supported, receiver error interrupt)	Data Channel F (receiver error interrupt)
1010	Data Channel G (not supported, receiver error interrupt)	Data Channel G (receiver error interrupt)
1011	Data Channel H (not supported, receiver generates an error interrupt)	Data Channel H (receiver error interrupt)
1100	Reserved - receiver error interrupt	Reserved - receiver error interrupt
1101	Reserved - receiver error interrupt	Reserved - receiver error interrupt
1110	Reserved - receiver error interrupt	Reserved - receiver error interrupt
1111	Reserved - receiver error interrupt	Reserved - receiver error interrupt

1) Solicited control command for slave interface control is not supported - instead a higher layer two-way protocol is available.

2) Solicited read command for slave interface read is not supported - instead a higher layer two-way protocol is available.

Note: A logical channel type TX transfer request of not supported or reserved types is not stopped or prevented to be send out. Receiver side is expected to react with an error indication.

*Note: The received header information can be checked by SW reading Header status register (**STAT**). An error in the header is a severe error in a running system. Application SW must handle the situation by interface link checks (PING). Additionally it is suggested to restart a running stream, if data loss cannot be tolerated. Received header frames are discarded, the same as the CTS information inside this error frame.*

Payload Size for transmission Data

For a transmission data transfer it is recommended to use max 288-bit payload size.

Logical Channel Separation

Reflecting the logical channel type to the higher level interface, the deframer sends the frame payload. The payload, as all other parts in a frame, is sent most significant bit first.

- All data received on and decoded as channel A to D data are sent via an 32-bit data interface to the RX-FIFO.
- Data from one HSCT interface to the other can be sent using the 32-bit, 64-bit, 96-bit or 288-bit payload size.

Note: Receiving a 8-bit header size on a logical channel results in an header error.

Framer

The framer combines data and control information from the higher layer protocol to the frame payload. Note that the payload again is sent most significant bit first. The framer codes the logical channel type and the payload size in the header according to the HSCT header format (see **Figure 20-47**). Then a complete frame consisting of 16-bit synchronization pattern (see **Figure 20-44**), 8-bit header and payload field is put together.

The following logical channels are used for transmissions between master interface and slave interface:

- Data from the transmit Unit: The frame will be sent to the receiving interface side as soon as the transmit FIFO contains enough data for the required payload size. The appropriate values will be signaled with the payload size signal and in the logical channel type field in the header. For data transfer, only the logical channel types Data Channel A to D are be used! Receiving a header type reflecting the type Data Channel E to H generates an error.
- Slave interface control (at TX link) and Slave interface read (at RX link), identified by logical channel type encoding of Hex 2, is not supported.
- Unsolicited status information can be send by master interface and slave interface based on a 32-bit payload size. An unsolicited status can be used to send an unexpected and urgent message to the other side. Receiving an unsolicited message results in an interrupt at the receiving side.

Note: The Slave interface (RX link) can send out a control command (channel type encoding Hex 0), which is the predefined PING answer having a defined 32-bit payload. All other control commands are not available for the RX link to send. Slave interface solicited read (RX link, channel type encoding Hex 2) and Master interface control (TX link, channel type encoding Hex 2) are not supported by the HSCT automotive module. Receiving a header type reflecting these types on the RX link or TX link generates an error.

The handling of all frame parts is done by the framer. For determining the end of a frame, the framer shall count the number of payload bits sent to the receiver side. In between frames bits 0 shall be transmitted.

Clear to Send (CTS)

The HSCT interface is able to use “data pull” in both directions (master interface to slave interface and slave interface to master interface) to perform flow control on the transmission FIFO’s. Therefore the CTS bit in the header is asserted, when the other side is allowed to send more data, and it is negated when the other side should stop transferring data.

A CTS deactivation can be send out in a “normal” transmit frame, indicated by the header bit. The following payload is not discarded at receiving interface side and processed normally. CTS deactivation can be send out in a CTS type transmit frame, if no actual transmit data is available. The clear to send information is indicated by the header CTS bit deactivation. Following payload is discarded at receiving side. A received clear to send deactivation requires to stop the transmission immediately after the actual frame being in transmission or prevent to send a new frame, if currently no transmission is active. Control frames can still be send.

The clear to send is independent of the channel having caused the back pressure. It simply stops the data channel transfer. As soon as the traffic jam is resolved the CTS bit in the next transmitted frame is activated again, or a separate CTS frame is send with the CTS bit activated.

Higher Layer software must analyze which channel caused the traffic jam and can send the information to the other side.

The usage of the CTS signaling is optional. CTS signaling can be disabled by disabling the CTS_FRAME **CTSCTRL**.

Per default the CTS bit in the header is set to 1. When the threshold value in the receive FIFO is reached, the CTS bit shall be reset to 0 in the header of the next frame sent. If there are currently no data in the higher layer module transmission FIFO to be sent in a new frame, a dedicated CTS transfer according to the logical channel type in **Table 20-11** is generated. This transfer always uses the 8-bit payload size containing dummy bits. The payload in a CTS transfer will be discarded by the receiving side.

Generation of dedicated CTS frames can be disabled by resetting bit **CTS_FRAME** in register **CTSCTRL** to 0.

The CTS bit is set to 1 again when the receive FIFO fill level in the higher layer module is below the threshold value. This is reflected by activating the CTS signal again.

The CTS signals are full duplex signals and are side information in the transferred data frame. The deframer filters the TXCTS information from the received frame header. The TXCTS is presented to the higher layer TX interface frame based. Changes within a frame is not intended. At the higher layer receiver side the higher layer does activate the RXCTS signal, if no more data can be received. The Framer sends the RXCTS information with the header of the next frame.

Sleep Mode for line driver path

The HSCT interface offers an optional transmission sleep mode in between frames. Whether the move to the transmission sleep mode can be performed, depends on the actual symbol rate, as well as the protocol payload size, because it takes the LVDS line driver about 60 ns to wake up from sleep mode. In sleep mode, the transmitting line suggests sleep mode to the other side by sending an 1 immediately after the last bit in a frame. Setting the SLPEN bitfield to 1 enables Transmission sleep mode.

If enabled, Transmission sleep mode shall be triggered after every frame, in case there is no data or CTS frame due to be sent. When Transmission sleep mode shall be triggered to the opposite receiving side, the P/S converter inserts a 1 after the last bit in a frame, and asserts the sleep signal to the transmission LVDS driver.

The sleep signal is reset as soon as the transmission FIFO wake-up threshold value is reached, or when control information shall be sent to the slave interface from the master interface. These events trigger the wake-up counter which ensures that the LVDS line driver becomes ready for operation within 60 ns. After the wake-up time the framer starts sending eight bits 0 for signalling the start of a new frame to the receiving side. Subsequently the framer generates the new frame to be sent to the receiving side.

The transmission FIFO threshold value at the higher level protocol module can be programmed depending on the payload size and data rate in order to ensure that no additional latency in the data stream is generated due to the wake-up time for the LVDS line driver.

Interface Control

The master interface is configured via a CPU based configuration. The Slave interface can be configured by sending an interface control command from the master interface. The interface control command is used to configure the slave interface into the defined mode. The receiving slave interface shall take no action, if a reserved payload value is received. Instead it generates an error interrupt. HW reacts on the received control command.

After startup the interface is enabled to work at low speed (**SysClk**/4 or SysClk/2) and the PLL is off, no matter of the mode it had been before. Therefore shutting down the interface by chip internal control mechanism causes the interface to leave loopback-mode, clock test mode and sleep mode, if it was previously in any of these modes, and forces the receiver and transmitter to power down mode.

The interface transmitter path is disabled per default. It shall be enabled by using the appropriate interface control, which is a payload command for the slave interface and a control via SW for the master interface.

Note: No data can be transferred to the other side as long as the transmitter is disabled. In this case all data in TX direction are discarded!

The Interface Control Logical Channel transfer command always uses the 8-bit payload size and is send by the master interface only. Payload is send MSb first. The interface control payload values are shown in **Table 20-12**. All other payload values are reserved for future use. Whenever a reserved payload value is received it shall be ignored and reported by an error.

Table 20-12 Interface Control Payload Values

Value (hex)	Function
00_H	“ping” (send by master interface. Slave interface sends back a fixed 32-bit payload result.)
01_H	Reserved
02_H	Slave interface clock multiplier start (in preparation for high speed mode)
04_H	Slave interface clock multiplier stop (after fallback from high speed mode)
08_H	Select low speed mode for transfers from the Master interface to the Slave interface
10_H	Select high speed mode for transfers from the Master interface to the Slave interface
20_H	Select low speed mode for transfers from the Slave interface to the Master interface
40_H	Select medium speed mode for transfers from the Slave interface to the master interface *Note:* Not allowed, if SysClk = Crystal/2 (10 MHz) at Slave interface.
80_H	Select high speed mode for transfers from the Slave interface to the master interface
31_H	Enable Slave interface transmitter
32_H	Disable Slave interface transmitter

Table 20-12 Interface Control Payload Values (cont'd)

Value (hex)	Function
34_H	Turn on clock test mode (Send 101010... on Rx line continuously using currently configured Rx line rate; cancelled by issuing the "test mode off" command. Internal transmit and receive path is disabled. Received data is discarded. The only exception to this is the "test mode off" function, which in should not loop back and re-initialize itself for normal operation, retaining whichever interface clock rate are currently configured.)
38_H	Turn off test mode (cancel clock test mode and payload loopback)
FF_H	Turn on payload loopback (incoming frames at Slave interface are looped back until cancelled by a Frame containing "test mode off".) *Note: Requires same speed configuration for RX- and TX-link.*

Note: Before changing the speed mode SW has to take care that data Transmission on both links is stopped and the interface remains quiet.

As a general principle, after a mode change the master interface should request a data transfer from the slave interface to stimulate a frame, which confirms the correct reception and the mode change was successful. The PING function, available in the interface control logical channel shall be used to verify a successful speed change. The master interface generated PING has to be send in system defined time intervals, to verify the link is still alive. Sending out a ping requires system SW to activate a system timer. Not receiving the PING answer within the system defined time, the link cannot be considered as stable and a new initialization is required. The Slave interface sends back a fixed, known response based on a control command, at the currently configured link rate on RxData line.

Slow to Fast:

The slow to fast interface speed change can apply to only one of the interfaces data transfer directions or to both at the same time. At both sides Clock multipliers are needed, when either interface is to run at high speed. If the RXData link is not enabled, but needs to be, the master interface sends "Enable Slave Interface transmitter". If the slave interface clock multiplier is not already running the master interface sends "Slave interface clock multiplier start" to the slave interface at low speed. The master interface enables its own clock multiplier, if it is not already running. After the proper settling time, the master interface sends "select high speed" to the slave interface at the currently configured speed for the TXData link. The slave interface switches the requested interface to high speed. The master interface switches the requested interface to high speed. The master interface sends a frame to the slave interface requiring a response at the currently configured speed for the TxData Link. The slave interface responds with a frame to confirm the mode change has worked. In order to select high speed for both

RXData and TXData links the master interface sends “select high speed” for the RxData link first and then for the TxData link. As described before it is suggested to send the PING for verifying a successful speed change.

Fast to Slow:

The fast to slow interface speed change is the converse of the slow-to-fast transition. Both clock multipliers must be running for either interface to operate in high-speed mode. Once both interfaces no longer require the clock multipliers they can be turned off, using the appropriate interface control payload values to command the switch in the slave interface.

Before entering high speed mode it shall be assured that the high speed clock is available by sending the interface control value 0x02.

Figure 20-48 shows the TX transmission state machine, which controls transfers from the master interface to slave interface. The interface control value int_ctrl represents the received interface control payload value according to **Table 20-12**.

Note: Application Software has to ensure, that no data communication is active on RX-link or TX-link during the time the interface speed is changed. Otherwise a save speed change without data loss can not be guaranteed interface.

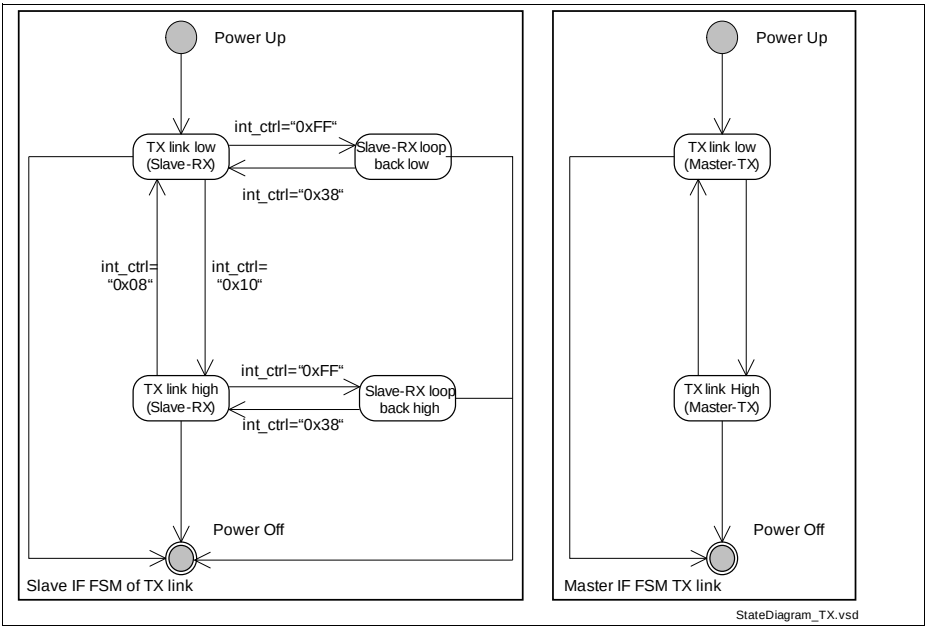

Figure 20-48 TX link State Machine

The loopback mode is used for test and verification to identify BER. When the master interface demands loopback mode, the slave interface internally loops back all received payload values in the following frames using the currently configured clock speed on the receive data link, without applying further processing internally. (Transmit and receive chains internally shall be disabled.) The header configuration is the same as in the incoming frame and the CTS bit in the header shall be asserted. Payload contents are ignored at slave interface in loopback mode, except for the “turn off test mode” interface control value, which ends loopback mode. The “turn off test mode” frame shall not be looped back to the master interface. After leaving loopback mode, the interface is prepared for normal operation at the previously used clock speed.

Note: The “loopback on” function has been intentionally coded at a large Hamming distance from the other codes (minimum of 5, usually 7, thus requiring at least five bit-errors in the Header field for another function to be corrupted into “loopback on”.

The RX link state machine, which is responsible for controlling transfers from slave interface to the master interface, can be seen in **Figure 20-49**. The state machine is implemented on slave interface at transmitting path. The interface control value int_ctrl represents the received interface control payload value according to **Table 20-12**.

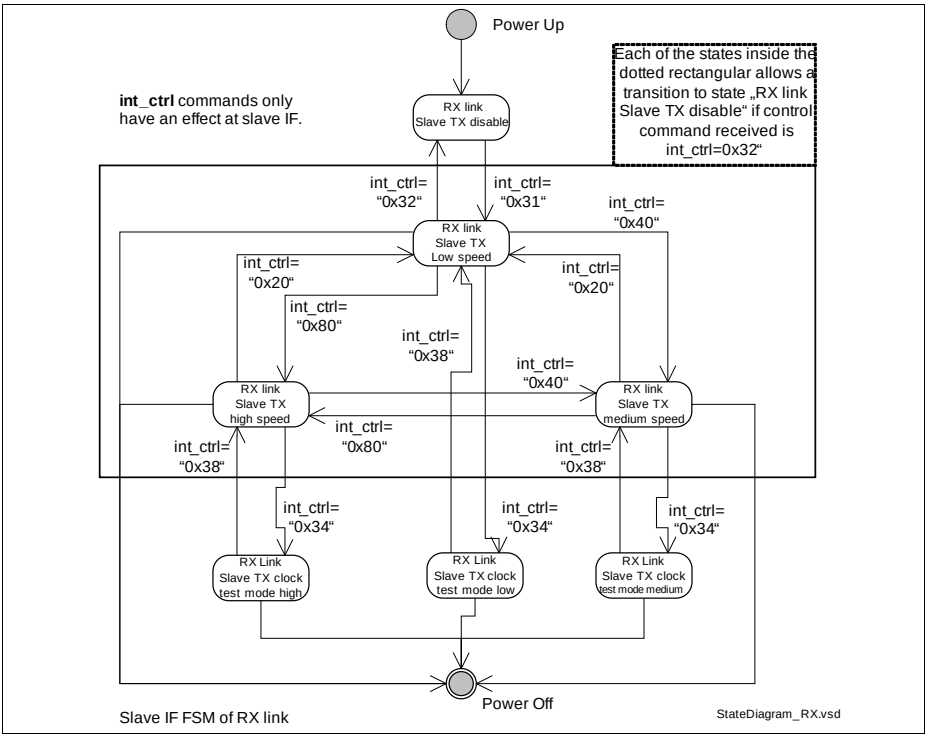

Figure 20-49 RX link State Machine

*Note: The **Medium speed mode is only available**, if the reference clock (SysClk) is running **at Crystal speed (20 MHz)**. For Crystal/2 medium speed mode is not available. A configuration of medium speed at Crystal/2 = SysClk causes low speed mode.*

In clock test mode the transmitter sends ‘101010 …’ continuously using the currently configured clock speed. Clock test mode can be left by sending the interface control value “turn off test mode”.

The ping function in the slave interface always uses the 32-bit payload size sending back the value 0xABCDEF01 (see **Figure 20-50**) using the logical channel type Hex 0 (PING Status - on RX link).

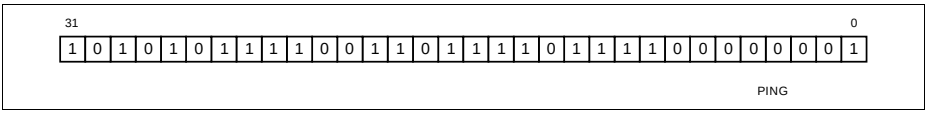

Figure 20-50 The Slave interface “ping” Response

The Interface control commands to configure the slave interface have to be written into the master interface register **IFCTRL**.IFCVS. For sending the control frame a logic 1 needs to be written to the **IFCTRL**.SIFCV register to trigger the frame transfer. The 8 register bits **IFCTRL**.IFCVS represent the same functionality as defined for the interface control payload values. Coding is as shown in **Table 20-12**. The register field **IFCTRL**.IFCVS shall be written with the appropriate interface control payload value for every state transition shown in **Figure 20-48** and **Figure 20-49**. The interface control in the slave interface can alternatively be performed by programming the **IFCTRL**.IFCVS. This allows controllability of the Slave interface besides the frame based configuration. The Master interface is controlled by register configuration of physical layer only.

In **Table 20-13** the processing times for the time consuming interface control transitions (defined in **Table 20-12**) are listed.

Table 20-13 Processing Times for Interface Control

IFCVS (hex)	Transition Description	Processing Time
02_H	Slave interface clock multiplier off to Slave interface high speed clock avail.	80 µs
04_H	Slave interface clock multiplier on to Slave interface clock multiplier off	2 µs
08_H	TX high speed mode to TX low speed mode	600 ns
10_H	TX low speed mode to TX high speed mode	400 ns
20_H	RX high or medium speed to RX low speed mode	400 ns
40_H	RX high or low speed to RX medium speed mode	400 ns
80_H	RX low or medium speed to RX high speed mode	400 ns
31_H	RX disabled to RX low speed mode	500 ns

Note: The physical layer requires about 20 µs to power up, including bandgap. Afterwards the PLL Reset is allowed to be release. After PLL reset removal it takes about 50 µs to get the PLL into a locked state.

Power up sequence

The power up sequence of the HSCT Physical Layer and the LVDS IO requires to have the BandGap enabled and stable before the Bias distributor and LVDS power can be enabled. Bias distributor and LVDS power on are enabled in Master interface mode by disabling the TX_PD at LVDS PAD Control register. The required time to power up is about 500 ns. In Slave interface mode the TX_PD at LVDS PAD Control register needs to be enabled by startup software during initialization process.

20.15.3 Use Cases

The following section describes the chip to chip communication requirements based on a HSCT interface connection. The Micro Controller (MC) is from a system point of view intended to be the master interface of the chip to chip communication. Application SW has to consider power up time of companion chip during the bringup of the link.

20.15.3.1 MC to ASIC

The MC (master) is connected to the ASIC (slave) which allows to perform data streaming in both directions and register control (read/write) by the MC, which allows to use ASIC defined ASIC functions.

20.15.3.2 MC to FPGA

The MC (master) is connected to the FPGA (slave), which allows to perform data streaming in both directions.

20.15.3.3 MC to MC

This use case allows to connect two MC’s together, whereas one of them gets, from the Interface point of view, the master function and the other the slave function. Potential application would be register control or data streaming. After the interface role (master or slave) definition, the role is not allowed to change. In this case only the master interface does have the crystal connected. The slave interface does use the SysClk as reference clock for the existing PLL’s. The reference clock at the slave interface is used to clock the HSCT PLL and additionally as clock source for the system PLL.

The HSCT analog part is per default in power down mode. Application SW is required to enable power supply for the analog part. Only after the power is on for the analog part, communication via the HSCT interface is possible.

20.15.4 HSCT Register Description

20.15.4.1 Registers Definition

This section describes the kernel registers of the HSCT module and the System related register in single kernel configuration. All HSCT kernel register will be referenced in other parts of the TC27x User's Manual by the module name prefix "HSCT_".

HSCT Kernel Register Overview

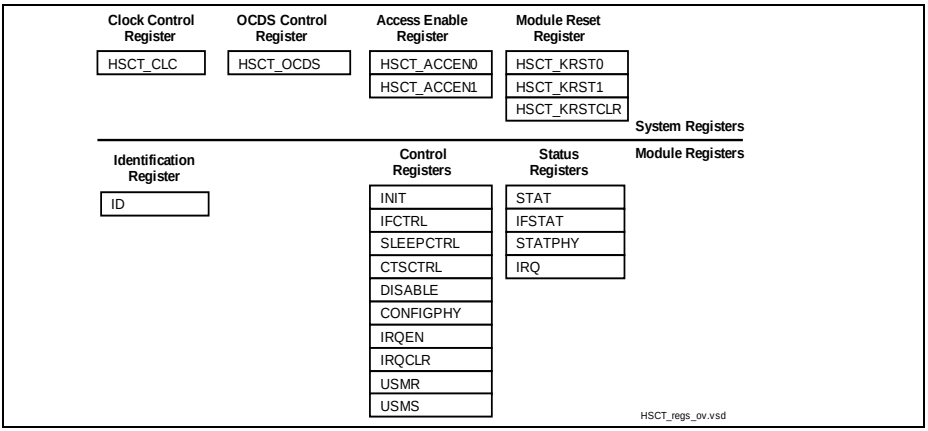

Figure 20-51 HSCT Register Overview

The complete and detailed address map of the HSCT modules is described in the next chapter.

Address Map

Table 20-14 Registers Address Space

Module	Base Address	End Address	Note
HSCT	$F0090000_H$	$F009FFFF_H$	-

Table 20-15 Registers Overview

Short Name	Description	Offset Addr.	Access Mode		Reset Class	Description See
			Read	Write		
CLC	Clock Control Register	00_H	U, SV	SV,E,P	3	Page 20-158
ID	Identification Register	08_H	U, SV	BE	3	Page 20-132
INIT	Initialization Register	10_H	U, SV	U,SV,P	3	Page 20-133
IFCTRL	Interface Control Register	14_H	U, SV	U,SV,P	3	Page 20-135
SLEEPCTRL	Sleep Control Register	18_H	U, SV	U,SV,P	3	Page 20-138
CTSCTRL	Clear To Send Register	$1C_H$	U, SV	U,SV,P	3	Page 20-139
DISABLE	Transmission Disable Register	20_H	U, SV	U,SV,P	3	Page 20-141
STAT	Status Register	24_H	U, SV	U,SV,P	3	Page 20-143
IFSTAT	Interface Status Register	28_H	U, SV	U,SV,P	3	Page 20-145
CONFIGPHY	Physical Layer Configuration Register	30_H	U, SV	U,SV,P	3	Page 20-146
STATPHY	Physical Layer Status Register	34_H	U, SV	U,SV,P	3	Page 20-148
IRQ	Interrupt Registers	40_H	U, SV	U,SV,P	3	Page 20-149
IRQEN	Interrupt Enable Registers	44_H	U, SV	U,SV,P	3	Page 20-153

Table 20-15 Registers Overview

Short Name	Description	Offset Addr.	Access Mode		Reset Class	Description See
			Read	Write		
IRQCLR	Clear Interrupt Registers	48_H	U, SV	U,SV,P	3	Page 20-155
USMR	Unsolicited Message Received Registers	50_H	U, SV	U,SV,P	3	Page 20-156
USMS	Unsolicited Message Send Registers	54_H	U, SV	U,SV,P	3	Page 20-157
OCS	OCDS Control and Status Register	$FFE8_H$	U, SV	SV,P	1	Page 20-159
KRSTCLR	Reset Status Clear Register	$FFEC_H$	U, SV	SV, E,P	3	Page 20-165
KRST1	Reset Control Register 1	$FFF0_H$	U, SV	SV, E,P	3	Page 20-164
KRST0	Reset Control Register 0	$FFF4_H$	U, SV	SV, E,P	3	Page 20-163
ACCEN1	Access Enable Register 1	$FFF8_H$	U, SV	SV, SE	3	Page 20-162
ACCEN0	Access Enable Register 0	$FFFC_H$	U, SV	SV, SE	3	Page 20-161

*Note: The absolute register address is calculated as follows: Module Base Address (**Table 20-14**) + Offset Address*

A register is addressed word wise.

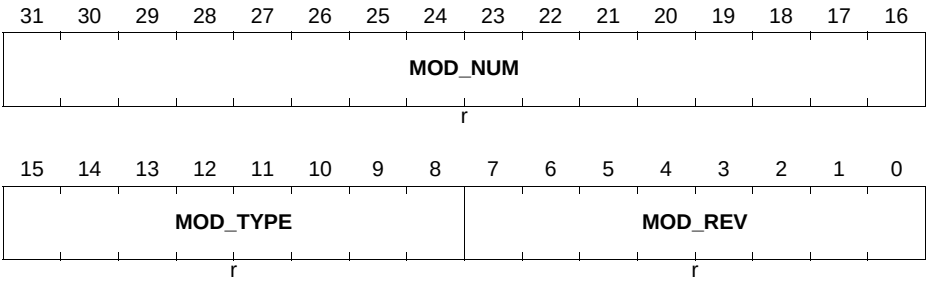
Note: Register bits marked reserved in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

HSCT Kernel Register Definitions

ID

The Module Identification Register ID contains read-only information about the module version. For a register overview, see the **Table 20-15**.

ID
Module Identification Register (08_H) Reset Value: $00B4\ C001_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** 01_H The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Number Type** $C0_H$ 32 bit peripheral
MOD_NUM	[31:16]	r	**Module Number for module identification** $00B4_H$ Is the module identification number for the HSCT interface.

INIT

INIT

Initialization register **(10_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0										RXHD			TXHD		
r										rw			rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					LHLR	0						IFM	SRCF	SYS_CLK_EN	0
r					rw	r						rw	rw	rw	r

Field	Bits	Type	Description
SYS_CLK_EN	1	rw	**Enable SysClk in Master interface** SysClk enable activates the SysClk. 0_B disable (default) 1_B enabled *Note: This feature is only available in the master interface. In slave interface mode the register setting does not have an effect.*
SRCF	2	rw	**Select SysClk / Reference Clock Frequency rate** For master interface defines Reference frequency. For slave interface frequency defines SysClk frequency. Has an effect for Low Speed only. 0_B SysClk; RefClk is 20 MHz (Divider 1/1) 1_B SysClk; RefClk is 10 MHz (Divider 1/2)
IFM	3	rw	**Select Interface Mode** Select the Interface Mode (master IF or slave IF). 0_B master IF 1_B slave IF

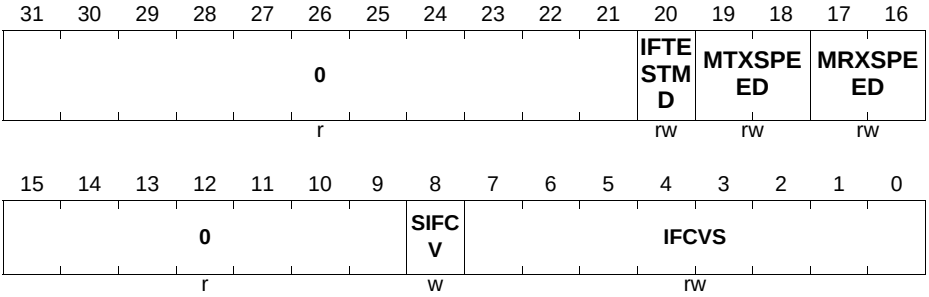
Field	Bits	Type	Description
LHLR	10	rw	**Loopback path at Slave interface side at higher layer system RAM.** Disable of the LVDS IO loopback when the bit is set. The function allows to loop back data at a higher layer in HW or by SW using a RAM area. 0_B Loopback path performed at LVDS IO 1_B Loopback path at higher layer RAM area
TXHD	[18:16]	rw	**Transmit High Speed Divider.** The Transmit High Speed data rate can be reduced by dividing factors. The Transmit High Speed data rate is separated from the Receive High Speed data rate. 000_B Divider 1/1 001_B Divider 1/2 010_B Divider 1/4 011_B Divider 1/8 100_B Divider 1/16 101_B For future use. 110_B For future use. 111_B For future use.
RXHD	[21:19]	rw	**Receive High Speed Divider.** The Receive High Speed data rate can be reduced by dividing factors. The Receive High Speed data rate is separated from the Transmit High Speed data rate. 000_B Divider 1/1 001_B Divider 1/2 010_B Divider 1/4 011_B Divider 1/8 100_B Divider 1/16 101_B For future use. 110_B For future use. 111_B For future use. *Note: For future use configuration leads to no output clock delivered to the correlator.*
0	[31:22], [15:11], [9:4], 0	r	**Reserved**

IFCTRL

This register allows to configure the transfer Speed of the Master Interface and is also used to send the command frame to the slave.

Note: The Master interface link speed configuration immediately takes place. Therefore the Master interface speed transition must not be changed with a Slave interface command send activity.

IFCTRL
CPU transfer control register (14_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
IFCVS	[7:0]	rw	**Master Mode - Interface Control Value to be send to Slave interface** See **Table 20-12**. *Note:* *7. Master IF: The value is taken as control frame value send as payload to the slave IF.* *8. Slave IF: The value is a new configuration of the slave IF.*

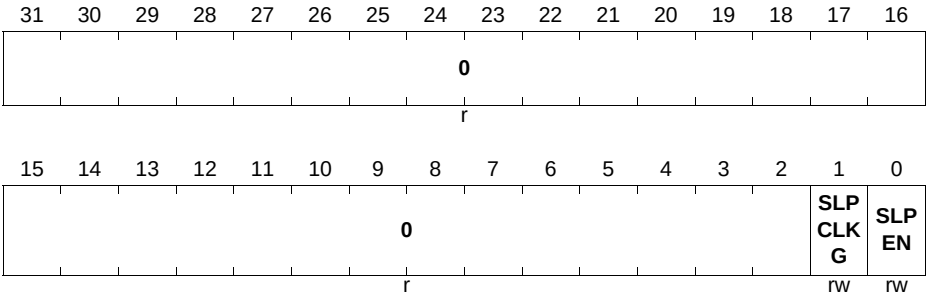
Field	Bits	Type	Description
SIFCV	8	w	**Master Mode - Slave IF control frame trigger** 0_B The IFCVS field configured value does not have an effect (default). 1_B Writing a one to the register bit sends the control frame configured in register field IFCVS, if the interface is configured as master. In slave interface configuration the trigger has an effect and takes the IFCTRL.IFCVS value. In slave mode this is not the usual control flow. A frame based configuration shall be used instead. A control frame has higher priority then a register control. At a simultaneous occurrence of both configuration source the register configuration in slave mode is lost. *Note: Changing the interface configuration, software must guarantee not having transfers active on the interface.* *Note: The register bit reads back a zero always.*
MRXSPEED	[17:16]	rw	**Master Mode RX speed** 00_B Low Speed 01_B Medium Speed 10_B High Speed 11_B for future use *Note: Register setting only valid in interface master mode.*
MTXSPEED	[19:18]	rw	**Master Mode TX speed** 00_B Low Speed 01_B for future use 10_B High Speed 11_B for future use *Note: Register setting only valid in interface master mode.*

Field	Bits	Type	Description
IFTESTMD	20	rw	**Master Mode Interface Test Mode** 0_B Test Mode disabled 1_B Test Mode enabled - send out 101010101.. test pattern continuously. *Note: Register setting only valid in interface master mode. Slave interface does send out the 101010101.. sequence on RX link by receiving the Turn clock test mode on interface Control logical channel command.*
0	[15:9],[31:21]	r	**Reserved**

SLEEPCTRL

SLEEPCTRL

Sleep Control Register **(18_H)** **Reset Value: 0000 0000$_H$**

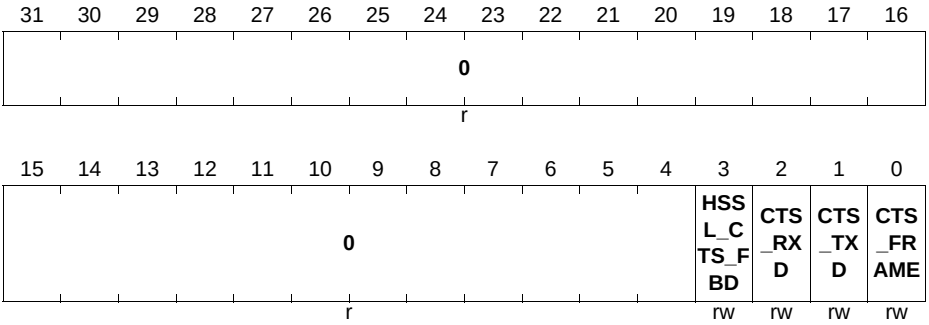


Field	Bits	Type	Description
SLPEN	0	rw	**Sleep mode enabled** Sleep mode is enabled and performed after receiving a 1 at the end of a received frame or in transmission direction, if a empty is received from HSSL FIFO. 0_B Sleep mode disabled. 1_B Sleep mode enabled.
SLPCLKG	1	rw	**Clock Gating in Sleep Mode** During transmission in sleep mode the clock for HSCT (framer, deframer) can be gated in order to minimize power consumption. *Note: Clock gating: Receiving path and transmitting path is separated.* 0_B Clock gating in transmission sleep mode disabled. 1_B Clock gating in transmission sleep mode enabled.
0	[31:2]	r	**Reserved**

CTSCTRL

CTSCTRL

Clear To Send Control Register (1C$_H$) Reset Value: 0000 0001$_H$



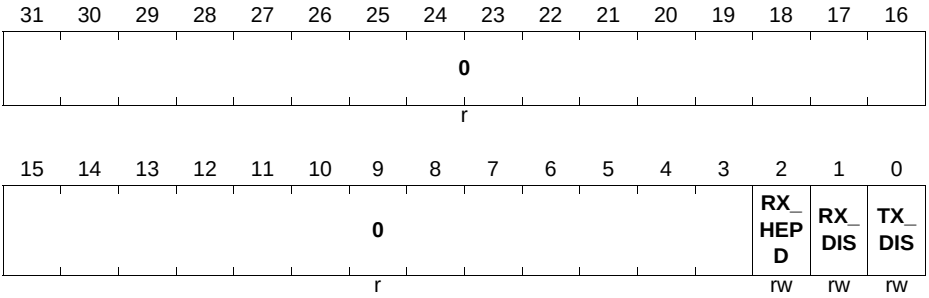
Field	Bits	Type	Description
CTS_FRAME	0	rw	**Transmit CTS Frame Generation** Dedicated CTS frames are generated after the receive FIFO threshold value is reached, indicated by the CTS header bit in case there is currently no data to be transferred. 0_B Generation of dedicated CTS frames disabled. 1_B Generation of dedicated CTS frames enabled.
CTS_TXD	1	rw	**Disable TX CTS signaling** If this bit is set to 1, CTS signaling is not performed at the interface and the status remains at the clear to send for every frame send. 0_B Enable CTS signaling (default). 1_B Disable CTS signaling.
CTS_RXD	2	rw	**Disable RX CTS detection** If this bit is set to 1, CTS detection is not performed at the receiver and the status remains internally at clear to send for every frame received. 0_B Enable CTS detection (default). 1_B Disable CTS detection.

Field	Bits	Type	Description
HSSL_CTS_FBD	3	rw	**Disable HSSL interface CTS Frame Blocking** If this bit is set to 1, CTS signaling is not performed at the interface and the status remains at the clear to send for every frame send. 0_B Enable CTS frame blocking (default). 1_B Disable CTS frame blocking.
0	[31:4]	r	**Reserved**

DISABLE

DISABLE

Transmission Disable Register (20_H) Reset Value: 0000 0003$_H$



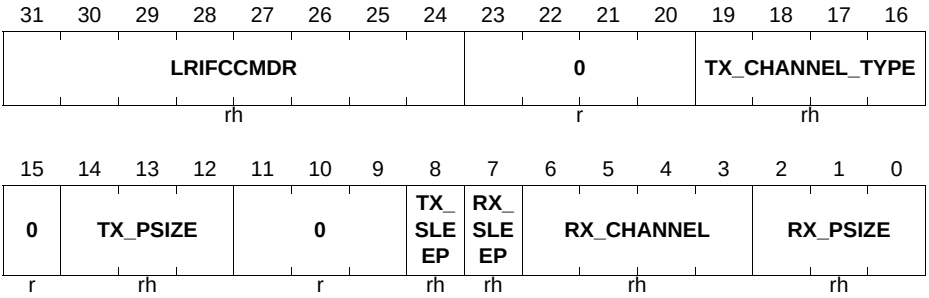
Field	Bits	Type	Description
TX_DIS	0	rw	**Disable HSCT Transmit path in Master interface** Disable the transmit path of the HSCT interface. If this bit is set to 1 - no transfer can be initiated and the LVDS driver is disabled. 0_B enable 1_B disable
RX_DIS	1	rw	**Disable HSCT Receive path in Master interface** Disable the receive line path of the HSCT interface. If this bit is set to 1 - no transfer from the other side can be received and the Master RX path is in a low power state. 0_B enable 1_B disable *Note: This feature is only available in the master interface. Slave interface RX path can not be disabled and a write to the register has no effect.*
RX_HEPD	2	rw	**Disable RX Header Error Discard Payload data.** Instead of discarding the Payload data at a header error the payload data is passed to the higher layer (HSSL). Only channel data to HSSL is affected. 0_B Header error received data is discarded 1_B Header error received data is passed to the higher hardware layer.

Field	Bits	Type	Description
0	[31:3]	r	**Reserved**

STAT

STAT

Status Register **(24_H)** **Reset Value: $0000\ 0000_H$**



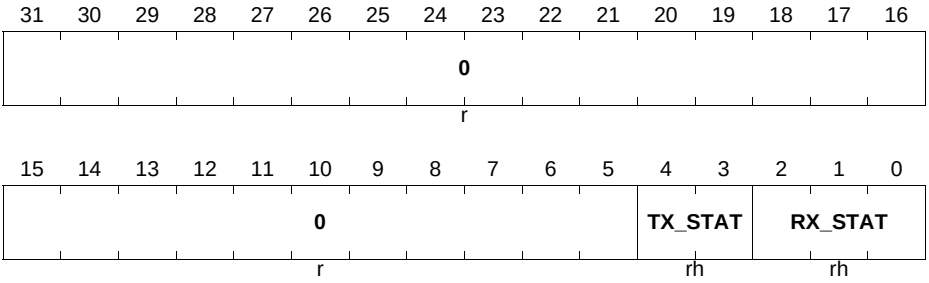
Field	Bits	Type	Description
RX_PSIZE	[2:0]	rh	**RX (receiving) Payload Size** Contains the payload size of the last received frame.
RX_CHANNEL	[6:3]	rh	**RX (receiving) Logical Channel Type** Contains the logical channel type of the last received frame. See **Logical Channel Type Coding**.
RX_SLEEP	7	rh	**RX (receiving) Sleep Mode Status** 0_B HSCT is in receive direction **active** 1_B HSCT is in receive direction in **sleep** mode
TX_SLEEP	8	rh	**TX (transmitting) Sleep Mode Status** 0_B HSCT is in transmit direction **active** 1_B HSCT is in transmit direction in **sleep** mode
TX_PSIZE	[14:12]	rh	**Transmission Payload Size** Coding of the logical channel type is according to the Table: **Payload Size Coding**. This value was used in the logical channel type field in the header for the actual transfer in transmit direction.
TX_CHANNEL_TYPE	[19:16]	rh	**Transmission Logical Channel Type** Coding of the logical channel type is according to the Table: **Logical Channel Type Coding**. This value was used in the logical channel type field in the header for the actual transfer in transmit direction.

Field	Bits	Type	Description
LIFCCMDR	[31:24]	rh	**Last Interface Control Command Received** The bit value reflects the last control command received. The bit is active in Slave interface mode only. In master mode it reflects logic 0 always. (See **Table 20-12**)
0	[23:20], 15,[11:9]	r	**Reserved**

IFSTAT

IFSTAT

Interface Status Register **(28_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RX_STAT	[2:0]	rh	**HSCT slave interface Status for RX link** 000_B Interface is disabled in RX link direction. 001_B Interface runs at low speed on RX link. 010_B Interface runs at medium speed on RX ink. 011_B Interface runs at high speed on RX link direction. 100_B Clock test mode and RX link disabled 101_B Clock test mode and low speed on RX ink 110_B Clock test mode and medium speed on RX link 111_B Clock test mode and high speed on RX link. *Note: slave interface transmitter only*
TX_STAT	[4:3]	rh	**HSCT slave interface Status for TX link** 00_B Interface runs at low speed on TX link. 01_B Interface runs at high speed on TX link. 10_B Loopback mode low speed. 11_B Loopback mode high speed. *Note: slave interface receiver only*
0	[31:5]	r	**Reserved**

CONFIGPHY

CONFIGPHY

Configuration physical layer register (30_H) **Reset Value: 0000 80FC$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0			OSC CLK EN	0		PLLIVR				PLLKI			PLLKP		
r			rw	r		rw				rw			rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PHY RST	PLL PKI	PLLWMF						PLLPE						PLL PON	0
rw	rw	rw						rw						rw	r

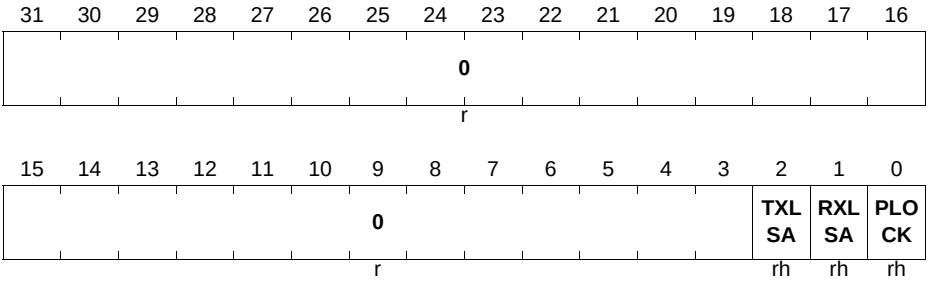
Field	Bits	Type	Description
PLLPON	1	rw	**PLL Power On (Master Mode only)** Power on the PLL. Additionally the PLL logic receives an reset going from power of in power on state. 0_B PLL power off. (default) 1_B PLL power on. *Note: A deactivation during an active High Speed Mode has no effect.*
PLLPE	[7:2]	rw	**PLL phase enable - allows to enable/disable each of the 6 Phase outputs.**
PLLWMF	[13:8]	rw	**PLL frequency control word multiplication factor** Output frequency of PLL can be configured following the formula: fpll = fref * PLLWMF 000000_Bword multiplication factor disabled **other**, word multiplication factor enabled using the configured value

Field	Bits	Type	Description
PLLKPKI	14	rw	**KP/KI Setting** Enable of KP/KI setting by register programming 0_B use default alpha, beta 1_B use pll_alpha_i and pll_beta_i values supplied at macro pins
PHYRST	15	rw	**Physical Layer Reset** Reset of Physical layer digital logic. 0_B Reset not enabled 1_B Reset active (default) *Note: For SysClk generation and interface control deactivate this bit.* *Note: A new Physical Layer Reset (changing the PHYRST bit value from 0 to 1) shall only be done by a complete HSCT module kernel reset using a class 3 reset or the kernel reset register KSRT0 and KRST1 to avoid communication issues.*
PLLKP	[18:16]	rw	**KP of PLL - Configuration of PLL beta coefficients of proportional part of loop filter**
PLLKI	[21:19]	rw	**KI of PLL - Configuration of PLL alpha coefficients of integral part of loop filter**
PLLIVR	[25:22]	rw	**Adjustment for integrated voltage regulator**
OSCCLKEN	28	rw	**Enable Oscillator Clock as PLL reference clock** 0_B PLL reference clock is HSCT SysClk_i 1_B PLL reference clock is Oscillator input *Note: Reference clock path needs to be configured correctly, if the interface is configured as Master or Slave.*
0	31,30, 29, 27, 26, 0	r	**Reserved**

STATPHY

STATPHY

STATPHY **(34_H)** **Reset Value: 0000 0006$_H$**



Field	Bits	Type	Description
PLOCK	0	rh	**PLL locked** 0_B PLL out of lock (default) 1_B PLL locked
RXLSA	1	rh	**Receiver in Low speed** 0_B Receiver in High speed 1_B Receiver in Low speed
TXLSA	2	rh	**Transmitter in Low speed** 0_B Transmitter in High speed 1_B Transmitter in Low speed
0	[31:3]	r	**Reserved**

IRQ

Interrupt status register. Read only and updated by HW. The bit's remain active until cleared. The clear pulse is coming from the IRQCLR register. Only an interrupt source not being already active in the interrupt status register does generate an interrupt pulse to the SoC interrupt controller.

IRQ
Interrupt register **(40_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r			rh	rh	rh	rh	rh	rh	r	rh	r	rh	rh	rh	r

Field	Bits	Type	Description
HER	1	rh	**Header error detected** Not supported size: • Received command at slave interface 8-bit size only - other command sizes generate an error. • Received command ping answer at master interface 32-bit size only - other command sizes generate an error • unsolicited data 32-bit only • logical data channel size 8-bit Not supported logical channel type Logical channel type **not** supported: • 0b1xxx • 0010 (Slave interface control and Slave interface read) 0_B Header OK 1_B Header issue detected.

Field	Bits	Type	Description
PYER	2	rh	**Payload error detected** Payload does not fit the header size 0_B Payload size OK 1_B Received payload size wrong
CER	3	rh	**HSCT command error** Control command not valid or control payload size bigger than 8-bit. 0_B No command error 1_B HSCT command error
IFCFS	4	rh	**HSCT interface control frame send** The scheduled interface control command is send. 0_B No interface control command send 1_B Interface control command send.
SMER	5	rh	**Speed Mode Switch Error (Master Mode only)** Speed mode change did not work. Received PING payload not valid. 0_B Interfaces runs at defined speed 1_B Ping payload error
USMSF	6	rh	**Unsolicited message frame send finished** Interrupt is indicated after the unsolicited message send is finished. 0_B No unsolicited message send. 1_B Unsolicited message send finished.
PLER	7	rh	**PLL lost lock error** After the PLL locked, the PLL may loose lock, which is reflected by the error 0_B PLL lock 1_B PLL lock loss
USM	8	rh	**Unsolicited Message Received** Unsolicited message received indication. Unsolicited message indicates a system event to the other interface side. 0_B no unsolicited message available 1_B unsolicited message available

Field	Bits	Type	Description
PAR	9	rh	**PING Answer Received** The received message was identified as PING. 0_B no PING message available 1_B PING message received
TXTE	10	rh	**TX transfer error occurred on a disabled TX channel.** A disabled TX triggers an error interrupt, if: • TX disabled on a pending or active data transfer. • TX CTS configuration change on a active CTS frame. 0_B no error situation occurred 1_B error situation occurred
SFO	11	rh	**Synchronization FIFO overflow (in RX direction)** Physical layer to Controller data synchronization FIFO in RX transfer direction hit an overflow situation. 0_B RX synchronization is running well. 1_B RX FIFO overflow *Note: This interrupt is an indication about a to slow SRI clock compared to Physical layer clock, which results in a overflow situation. (Minimum SRI frequency 40 MHz.)*
SFU	12	rh	**Synchronization FIFO underflow (in TX direction)** Controller to Physical layer data synchronization FIFO in TX transfer direction hit an underflow situation. 0_B TX synchronization is running well. 1_B TX FIFO underflow *Note: This interrupt is an indication about a to slow SRI clock compared to Physical layer clock, which results in a underflow situation. (Minimum SRI frequency 40 MHz.)*

Field	Bits	Type	Description
0	[31:13], 0	r	**Reserved**

IRQEN

Interrupt enable register. An enabled register generates an pulsed interrupt. On a disabled interrupt the interrupt pulse does not come through on the interrupt line.

IRQEN
Interrupt enable register **(44_H)** **Reset Value: 0000 0000$_H$**

0	[31:13], 0	r	**Reserved**

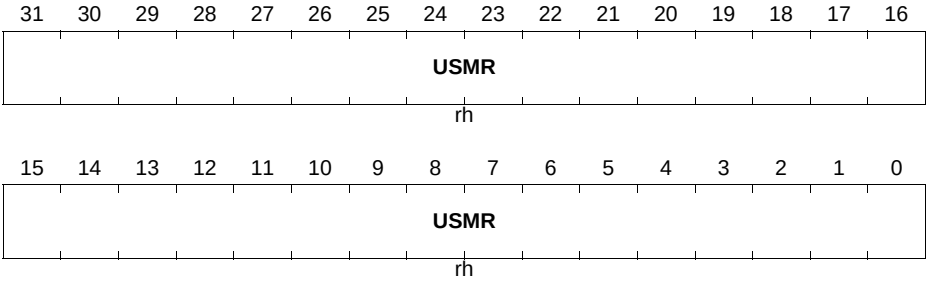
USMR

The Unsolicited Status message register is available to capture unsolicited messages received with the logical channel command encoding in the header of the frame (Logical Channel Type Hex 1).

USMR
Unsolicited Status Message Received (50_H) **Reset Value: $0000\ 0000_H$**



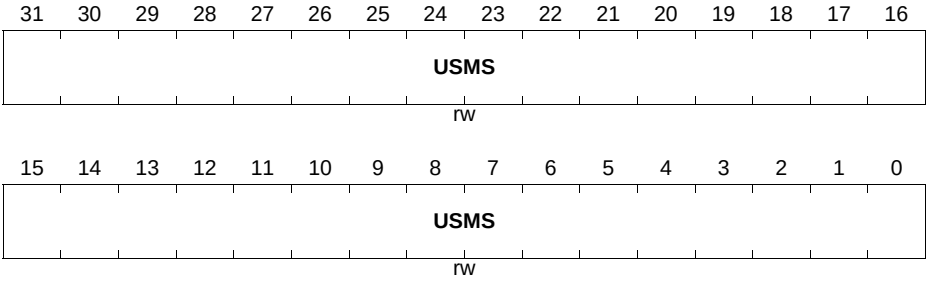
Field	Bits	Type	Description
USMR	[31:0]	rh	**Unsolicited status message received** The register contains the last received unsolicited status message.

USMS

A write to the register does activate the interface to send out an unsolicited status message to the other interface side. The Logical Channel Type reflected in the header is Hex 1 and the Payload is 32-bit always. An unsolicited frame has a higher priority then a Frame based on a data channel. In between frames the USMS gets higher priority then the data transfer requested by the HSSL.

USMS

Unsolicited Status Message Send (54_H) **Reset Value: 0000 0000$_H$**



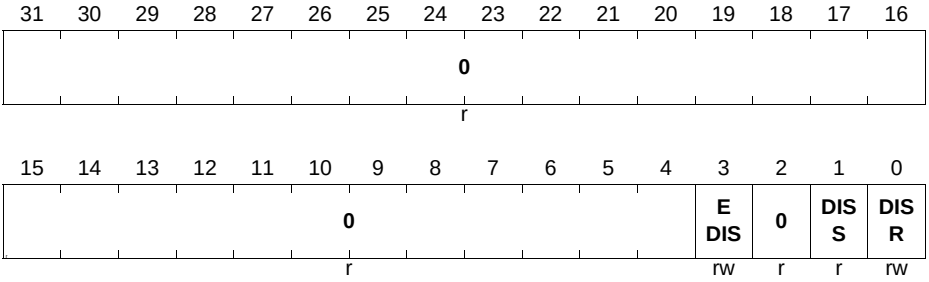
Field	Bits	Type	Description
USMS	[31:0]	rw	**Unsolicited status message send** Writing to the register triggers a unsolicited status message to be send to the other interface side.

BPI_FPI Module Registers (Single Kernel Configuration)

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the HSCT module. Where a module kernel is connected to the CLC clock control interface, CLC register controls the module clock, sleep mode and disable mode for the module.

CLC
Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control (clock and local access) of the module. The disable is performed after an acknowledge signal from the core logic is received.
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the module and is set after the requested disable is active.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode. A system sleep mode request only becomes active, if enabled by this bit. If sleep request is active, no writes to the module kernel are possible anymore.

Field	Bits	Type	Description
0	[31:4], 2	r	**Reserved** Read as 0; should be written with 0.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

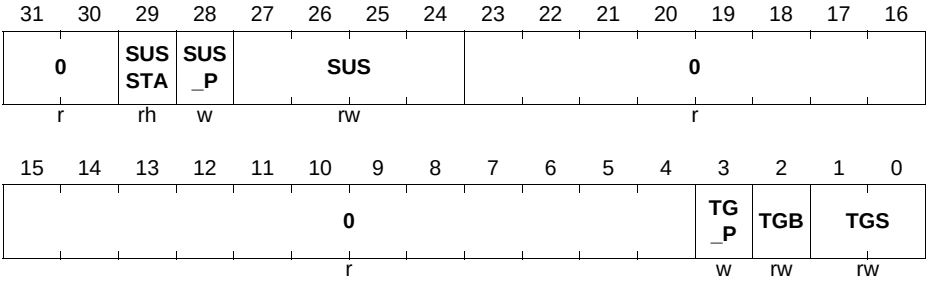
The OCS register can only be written when the OCDS is enabled.

If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32

The OCS register includes the module related control bits for the OCDS Trigger Bus (OTGB).

The register can only be written and the OCS control register bits are only effective while the OCDS is enabled (OCDS enable = ´1´). While OCDS is not enabled, OCS reset values/modes are effective.

OCS
OCDS Control and Status **(FFE8$_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
TGS	[1:0]	rw	**Trigger Set for OTGB0/1** 0_H No Trigger Set output 1_H TS16_HSCT **others**, reserved (no Trigger Set selected)
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1
TG_P	3	w	**TGS, TGB Write Protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.

Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately (read from registers still possible). *Note: After a Hard suspend the HSCT and higher layer protocol module must be reset. A a new initialization sequence is required afterwards* **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:4], [31:30]	r	**Reserved** Read as 0; must be written with 0.

The HSCT has one OCDS Trigger set available which gives a maximum of 16 triggers. The next table describes the available triggers.

Table 20-16 TS16_HSCT OCDS Trigger Set

Bits	Name	Description
0	HRXRQ	HSSL Interface RX transfer direction request
1	HRXCTS	HSSL Interface RX transfer direction CTS
2	HTXCTS	HSSL Interface TX transfer direction CTS
3	HTXRQ	HSSL Interface TX transfer direction request
4	TXF	First Byte transfer of transfer frame in TX transfer direction at Controller to Physical Layer interface
5	TXL	Last Byte transfer of transfer frame tin TX transfer direction at Controller to Physical Layer interface
6	TXW	Transmit direction wake-up at controller to physical layer interface
7	TXS	Transmit direction sleep indication at controller to physical layer interface

Table 20-16 TS16_HSCT OCDS Trigger Set

Bits	Name	Description
8	RXFS	Receive direction frame start at physical layer to controller interface.
9	DFSMI	Deframer state machine not in idle.
10	IFCT	Interface frame command trigger.
[15:11]		Reserved (value is 0)

Access Enable Register 0 (ACCEN0)

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... ,EN31 -> TAG ID 011111B.

ACCEN0

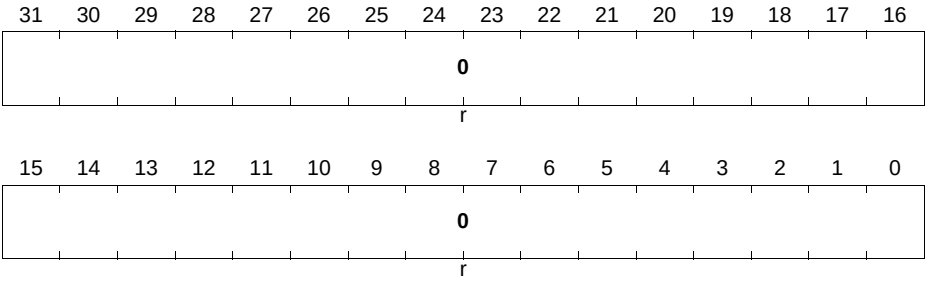
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables read/write access to the protected resources for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register 1 (ACCEN1)

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID master peripheral mapping). The BPI_FBI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ..., EN31 -> TAG ID 111111B.

ACCEN1
Access Enable Register 1 **(FFF8$_H$)** **Reset Value: 0000 0000$_H$**



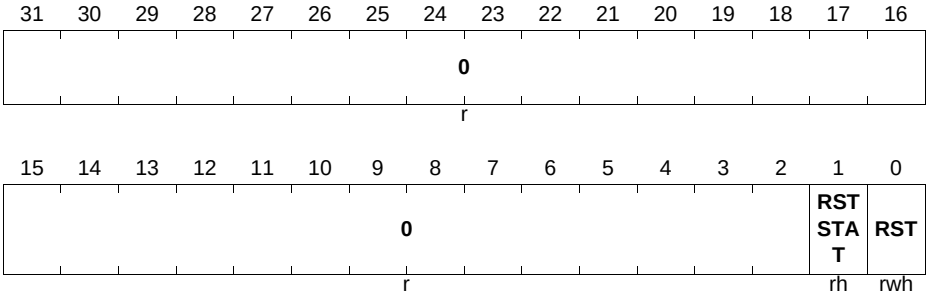
Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

KRST0
Reset Register 0 **(FFF4$_H$)** **Reset Value: 0000 0000$_H$**

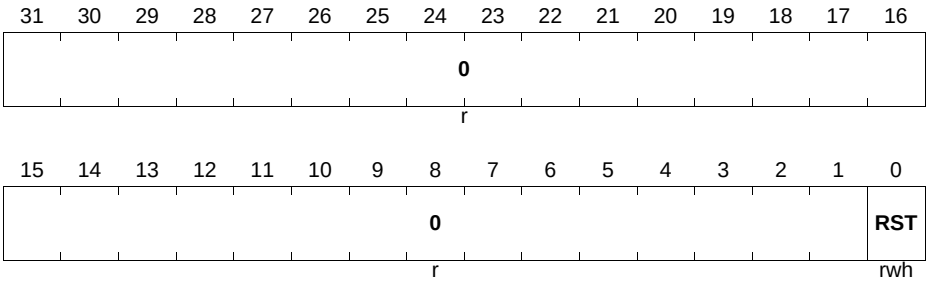


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. *Note: It is strongly recommended to reset the HSCT and HSSL in sequence to avoid communication issues.*
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1(KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Reset Register 1 **($FFF0_H$)** **Reset Value: $0000\ 0000_H$**

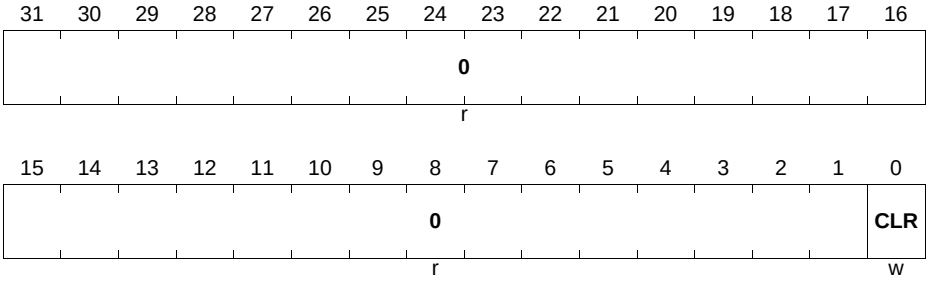


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. *Note: It is strongly recommended to reset the HSCT and HSSL in sequence to avoid communication issues.*
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR
Reset Status Clear Register **($FFEC_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

20.15.5 Suspend, Sleep and Power-Off Behavior

Generally, the HSCT module transmits and receives data and control information via the differential signal interface.

A power down of the module can be done in any situation of the transmission. After Power up the interfaces is in low speed mode, again. It is strongly recommended to have the transfers stopped from the higher layer protocol before sending the HSCT layer into power off state. In order to power down the module in a well defined way, the user software must take care that the power down request is issued after ongoing transfers or stop the transfers before. Issuing an power down within a transfer - all data is lost.

20.15.5.1 OCDS Suspend

OCDS suspend request, for debugging purposes, simply freezes the HSCT module in the current state. This corresponds to the hard suspend of the whole module, that is both the transmitter and the receiver. After the end of the suspend state, the receive data will be most probably corrupted. Therefore, the whole interface must be reset, re initialized and reactivated.

20.15.5.2 Sleep Mode

Going into sleep mode implies that the HSCT module has finished all activities and that the HSSL TX FIFOs are empty and the last data of the frame are send. It is responsibility of the user software to enable sleep mode SLEEPCTRL.**SLPEN**.

20.15.5.3 Disable Request (Power-Off)

Going into power off implies that the HSCT module has finished all activities.

21 Micro Second Channel (MSC)

This chapter describes the Micro Second Channel Interfaces , MSC0 and MSC1 of the TC27x. It contains the following sections:

- Functional description of the MSC kernel (see **Page 21-3**)
- MSC kernel register descriptions (see **Page 21-50**)
- TC27x implementation-specific details and registers of the MSC module (port connections and control, interrupt control, address decoding, and clock control, see **Page 21-92**)
- >> **Registers Overview**

*Note: The MSC kernel register names described in **Section 21.3** are also referenced in the TC27x User's Manual by the module name prefix "MSC0_" for the MSC0 module and by "MSC1_" for the MSC1 module.*

MSC Applications

The MSC is a serial interface that is especially designed to connect external power devices to the TC27x. The serial data transmission capability minimizes the number of pins required to connect such external power devices. Parallel data information (coming from the timer units) or command information is sent out to the power device via a high-speed synchronous serial data stream (downstream channel). The MSC receives data and status back from the power device via a low-speed asynchronous serial data stream (upstream channel).

Parallel requests from on chip bus masters to a module will be executed sequentially via the on chip bus system. Read-modify-write feature provides an atomic read/write sequence where no other master can access the module in between. Module hardware semaphores are not supported.

Figure 21-1 shows a typical TC27x application in which an MSC interface controls two power devices. Output data is provided by the module.

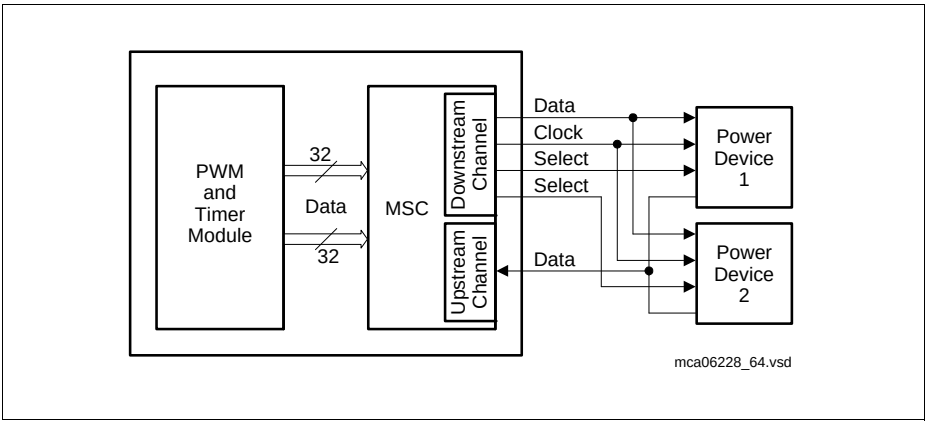

Figure 21-1 MSC to External Power Device Connection

Some applications are:

- Control of the external power switching unit via the downstream channel
- Receiving information back from power switching unit
- Serial connections of the TC27x to other peripheral devices

21.1 MSC Kernel Description

This section describes the functionality of the MSC kernel.

21.1.1 Overview

The MSC interface provides a serial communication link typically used to connect power switches or other peripheral devices. The serial communication link includes a fast synchronous downstream channel and a slow asynchronous upstream channel. **Figure 21-2** shows a global view of the MSC interface signals.

The MSC module features functional extensions, but is compatible to the MSC interface of the TC17xx devices.

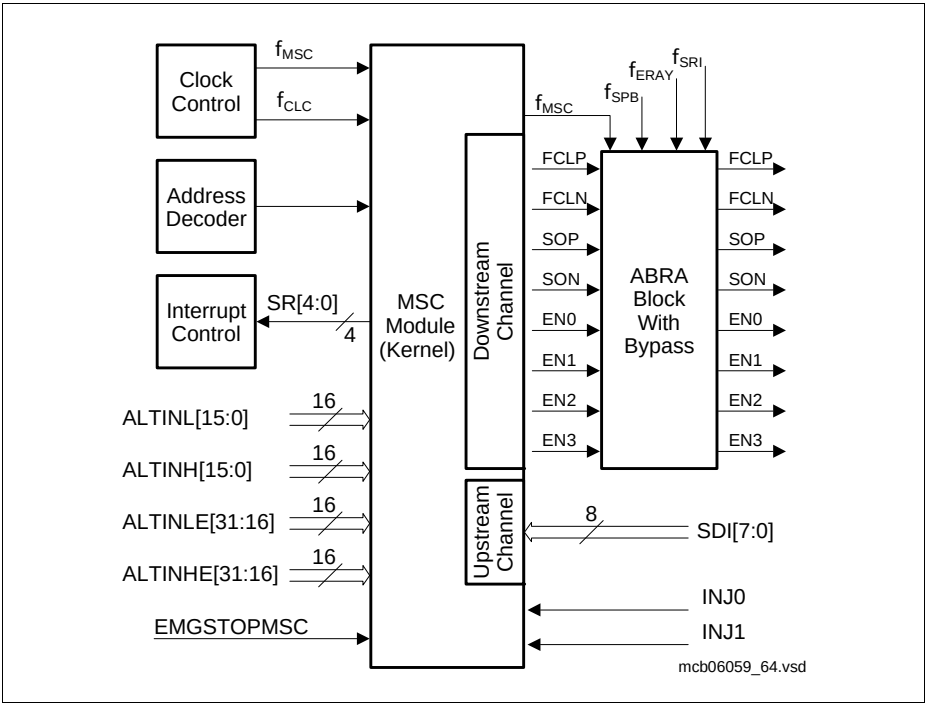

Figure 21-2 General Block Diagram of the MSC Interface

The downstream and upstream channels of the MSC module communicate with the external world via nine I/O lines. Eight output lines are required for the serial communication of the downstream channel (clock, data, and enable signals). One out of eight input lines SDI[7:0] is used as serial data input signal for the upstream channel. The source of the serial data to be transmitted by the downstream channel can be MSC

register contents or data that is provided at the ALTINL/ALTINH input lines. These input lines are typically connected to other on-chip peripheral units (for example with a timer unit like the GTM). An emergency stop input signal makes it possible to set bits of the serial data stream to dedicated values in emergency case.

Clock control, address decoding, and interrupt service request control are managed outside the MSC module kernel. Service request outputs are able to trigger an interrupt or a DMA request.

Features

- Fast synchronous serial interface to connect power switches in particular, or other peripheral devices via serial buses
- High-speed synchronous serial transmission on downstream channel
  - Serial output clock frequency: $f_{FCL} = f_{MSC}/2$ (f_{MSCmax} = 100 MHz)
  - Fractional clock divider for precise frequency control of serial clock f_{MSC}
  - Command, data, and passive frame types
  - Start of serial frame: Software-controlled, timer-controlled, or free-running
  - Transmission with or without SEL bit
  - Flexible chip select generation indicates status during serial frame transmission
  - Emergency stop without CPU intervention
- Low-speed asynchronous serial reception on upstream channel
  - Baud rate: f_{MSC} divided by 4, 8, 16, 32, 64, 128, or 256 (f_{MSCmax} = 100 MHz)
  - Standard asynchronous serial frames
  - Programmable upstream data frame length (16 or 12 bits)
  - Parity error checker
  - 8-to-1 input multiplexer for SDI lines
  - Built-in spike filter on SDI lines
  - Programmable delay of the receive interrupt after the last stop bit (0 or 1 bit time)
- Selectable pin types of downstream channel interface:
  four LVDS differential output drivers or four digital GPIO pins
- Module reset available
- Advanced features:
  - Asynchronous Baud Rate Adjustment Block
  - one extra interrupt
  - 64-bit data frames extension
  - fully compatible with the 32-bit data frames module version

21.1.2 Downstream Channel

The downstream channel performs a high-speed synchronous serial transmission of data to external devices. Its 64-bit shift register is divided into two 32-bit parts, SRL and SRH. Each bit of SRL and SRH can be selected to be delivered by the downstream data register DD, by the Downstream Command Register DC, or by two 16-bit wide input signal buses ALTINL and ALTINH.

Figure 21-3 is a diagram of the MSC downstream channel.

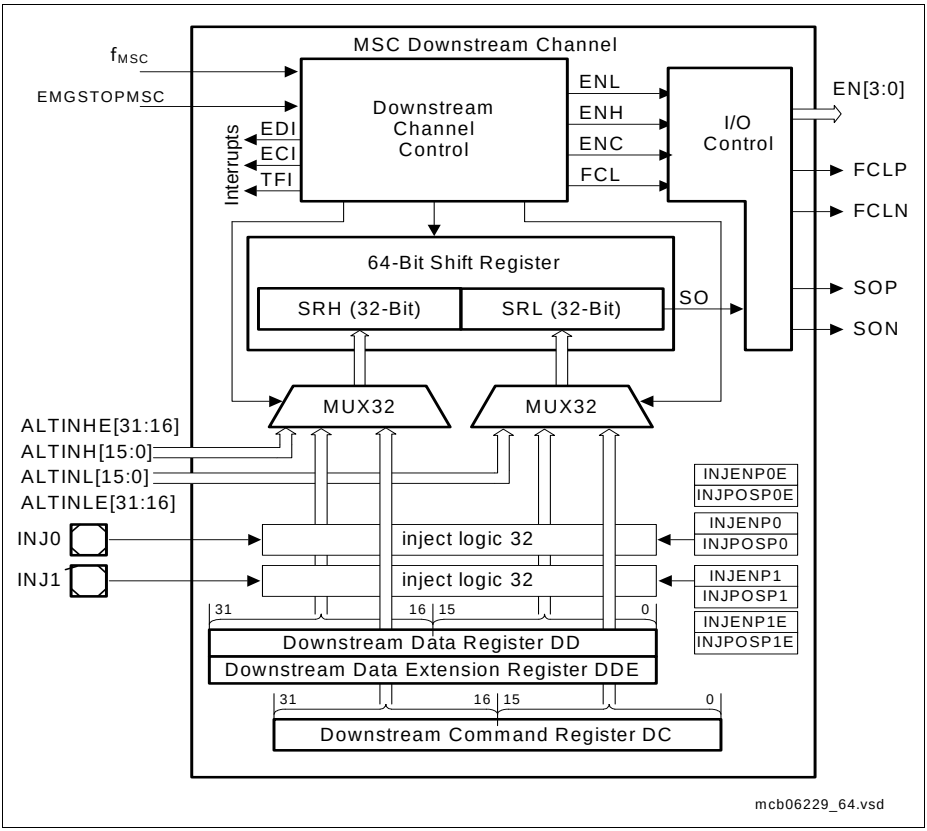

Figure 21-3 Downstream Channel Block Diagram

The enable signals ENL, ENH, and ENC indicate certain phases of the serial transmission in relation to the serial clock FCL. In the I/O control logic, these signals can be combined to four enable/select outputs EN[3:0]. For supporting differential output

drivers, the serial clock output FCL and the serial data output SO are available in both polarities, indicated by the signal name suffix “P” and “N”.

The emergency stop input line EMGSTOPMSC is used to indicate an emergency stop condition of a power device. In emergency case, shift register bits can be loaded bit-wise from the downstream data register instead from the ALTINL and ALTINH buses.

21.1.2.1 Frame Formats and Definitions

This section describes the frame formats and definitions of the MSC.

Basic Definitions

Figure 21-4 shows the layout and definitions of a downstream frame. A downstream frame is composed of an active phase and a passive phase. During the active phase, data transmission takes place and during the passive phase no data is transmitted at SO. The active phase is split into two parts: The SRL active phase in which the content of the shift register low part SRL is transmitted, and the SRH active phase in which the content of the shift register high part SRH is transmitted. At the beginning of the SRL and SRH active phase, a selection bit (SELL) can be optionally inserted into the serial data stream. In the frame shown in **Figure 21-4**, SELL is generated at the beginning of the SRL active phase (not for the SRH active phase). The least significant bits of SRL and SRH are sent out first.

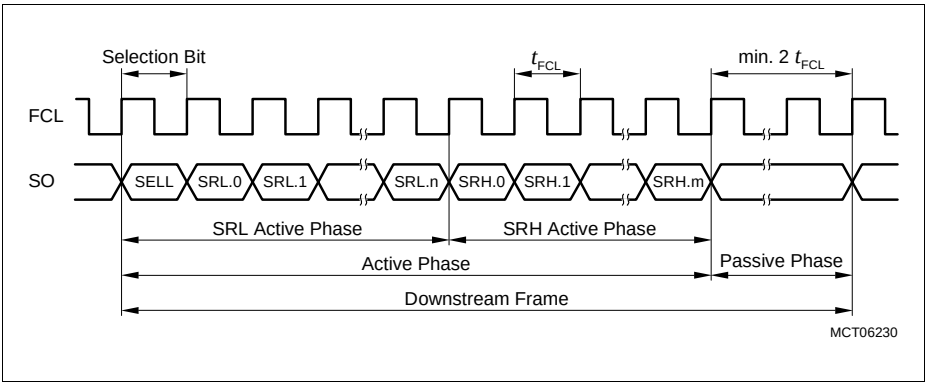

Figure 21-4 Downstream Channel Frame

The MSC downstream channel uses three types of frame formats for operation:

- Command frames, indicated by SELL = 1
- Data frames, indicated by SELL = 0 or SELL bit insertion disabled
- Passive time frame, indicated by ENL = ENH = 0

Command Frames

A command frame has two active phase parts, SRL active phase and SRH active phase. The command frame always starts with a high-level selection bit, independently whether the selection bit insertion (as defined by bit DSC.ENSELL) is enabled or not. The number of the bits transmitted during SRL and SRH active phases (except the selection bit) is defined by bit field DSC.NBC. SRL and SRH are combined to a value up to 64-bit whose length can be selected from 0 up to 32 bits. In other words, whenever bits of SRH are transmitted, they are always preceded by the transmission of the complete SRL content.

During the active phase of a command frame, the enable output signal ENC becomes active. The enable output signals ENL and ENH remain inactive.

The passive phase of a command frame always has a fixed length of $2 \times t_{FCL}$. The diagram shown in **Figure 21-5** assumes that the FCL clock is only generated during the active phase of the command frame (OCR.CLKCTRL = 0).

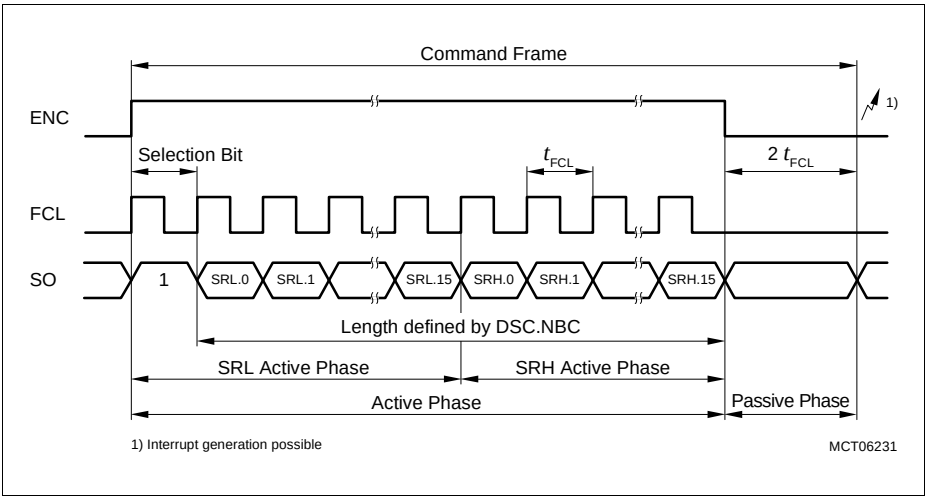

Figure 21-5 Command Frame Layout

Table 21-1 shows the programming of the bits to be transmitted and the resulting length of the complete command frame.

Table 21-1 Command Frame Length

DSC.NBC	SRL/SRH Bits that are Transmitted in Active Phase	Command Frame Length in t_{FCL} Periods
000000_B	No bit shifted out	1 + 0 + 2 = 3
000001_B	SRL[0] shifted out	1 + 1 + 2 = 4
000010_B	SRL[1:0] shifted out	1 + 2 + 2 = 5
000011_B	SRL[2:0] shifted out	1 + 3 + 2 = 6
…	…	…
001111_B	SRL[14:0] shifted out	1 + 15 + 2 = 18
010000_B	SRL[15:0] shifted out	1 + 16 + 2 = 19
010001_B	SRL[15:0] and SRH[0] shifted out	1 + 17 + 2 = 20
010010_B	SRL[15:0] and SRH[1:0] shifted out	1 + 18 + 2 = 21
010011_B	SRL[15:0] and SRH[2:0] shifted out	1 + 19 + 2 = 22
…	…	…
011111_B	SRL[15:0] and SRH[14:0] shifted out	1 + 31 + 2 = 34
100000_B	SRL[15:0] and SRH[15:0] shifted out	1 + 32 + 2 = 35
Other NBC combinations	Reserved; do not use these bit combinations.	

Data Frames

A data frame has two active phase parts, SRL active phase and SRH active phase. The number of bits that are transmitted can be programmed separately for each of these two phases. Bit field DSC.NDBL determines the number of SRL bits that are transmitted during the SRL active phase and DSC.NDBH determines the number of SRH bits that are transmitted during the SRH active phase.

SRL and SRH active phases can start with a low-level selection bit when enabled by bits DSC.ENSELL or DSC.ENSELH.

During the SRL active phase of a data frame, the enable output signal ENL becomes active and during the SRH active phase of a data frame, the enable output signal ENH becomes active. The enable output signal ENC remains inactive.

The length of the data frame's passive phase is variable and is defined by bit field DSC.PPD. It can be within a range of $2 \times t_{FCL}$ up to $31 \times t_{FCL}$. The diagram shown in **Figure 21-6** assumes that the FCL clock is only generated during the active phase of the data frame (OCR.CLKCTRL = 0).

Table 21-2, **Table 21-3**, and **Table 21-5** show the definitions of the five data frame parameters that determine the layout of the data frame.

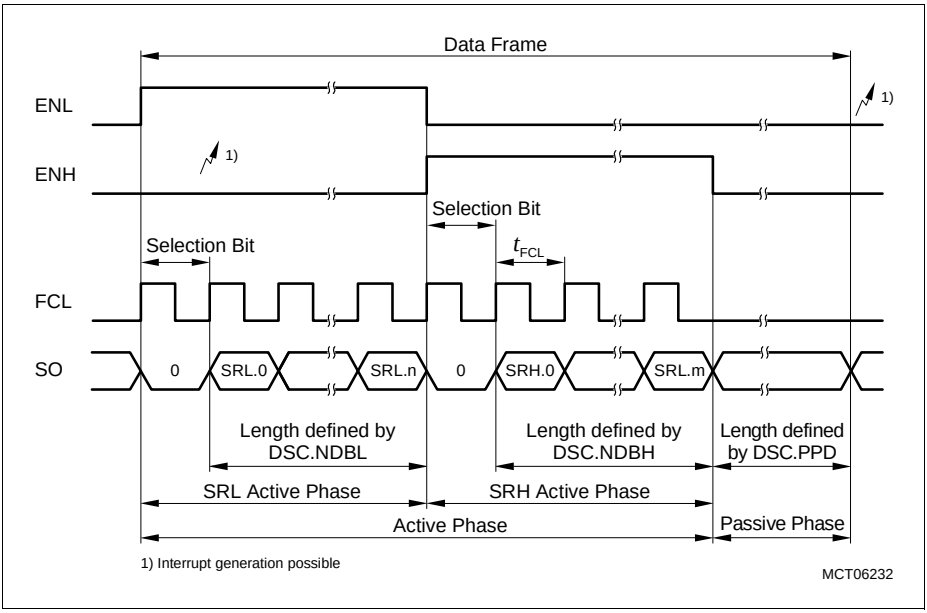

Figure 21-6 Data Frame Layout

Table 21-2 Data Frame Selection Bit Parameters

DSC.ENSELL	Selection Bit	DSC.ENSELH	Selection Bit
0	No selection bit inserted at the beginning of the SRL active phase	0	No selection bit inserted at the beginning of the SRH active phase
1	A low level selection bit is inserted at the beginning of the SRL active phase	1	A low level selection bit is inserted at the beginning of the SRH active phase

*Note: The MSC module can ooperate in two modes: standard (up to 32 data bits) or extended (up to 64 data bits). The mode is selected by using the bit **DSCE**.EXEN.*

Table 21-3 Data Frame SRL/SRH Length Parameters, Standard Mode

DSCE.NDBLE=0 and DSC.NDBL	SRL Bits Transmitted in SRL Active Phase	DSCE.NDBHE=0 and DSC.NDBH	SRH Bits Transmitted in SRH Active Phase
$0\ 00000_B$	No SRL bit transmitted	$0\ 00000_B$	No SRH bit transmitted
$0\ 00001_B$	SRL[0]	$0\ 00001_B$	SRH[0]

DSCE.NDBLE=1 and DSC.NDBL	SRL Bits Transmitted in SRL Active Phase	DSCE.NDBHE=1 and DSC.NDBH	SRH Bits Transmitted in SRH Active Phase
$1\ 10000_B$	SRL[31:0]	$1\ 10000_B$	SRH[31:0]
Other bit combinations	Reserved; do not use these bit combinations.	Other bit combinations	Reserved; do not use these bit combinations.

Table 21-5 Data Frame Passive Phase Length

DSC.PPD	Passive Phase Length
00000_B	$2 \times t_{FCL}$
00001_B	$2 \times t_{FCL}$
00010_B	$2 \times t_{FCL}$
00011_B	$3 \times t_{FCL}$
…	…
11110_B	$30 \times t_{FCL}$
11111_B	$31 \times t_{FCL}$

The following formula determines the number of t_{FCL} cycles of an up to 32-bit data frame: All parameters (bits and bit fields) are located in register DSC.

$$Ncycles = ENSELL + NDBL + ENSELH + NDBH + PPD \quad (21.1)$$

Note that in the formula above, PPD must be set to 2 when DSC.PPD $\leq 00010_B$.

The following formula determines the number of t_{FCL} cycles of an extended, up to 64-bit data frame, in case DSC.NDBL and DSC.NDBH are not equal to zero:

$$Ncycles = ENSELL + NDBL + NDBLE \cdot EXEN \cdot 16 + ENSELH + NDBH + NDBHE \cdot EXEN \cdot 16 + PPD + PPDE \cdot 32 \quad (21.2)$$

Otherwise, the corresponding factor NDBLE*EXEN*16 or NDBHE*EXEN*16 must be taken as zero (see **Table 21-4**).

Note that in the formula above, PPD must be set to 2 when DSC.PPD ≤ 00010_B.

The parameters (bits and bit fields) are located in registers DSC and DSCE.

Attention: In order to calculate the time between two consecutive TRPs, always use ENSELL=1 in the formulas above. ENSELL does not influence the time between two consecutive TRPs, but only the length of a data

frame. The difference in the starting point of a frame with ENSELL=0 and 1 is shown in the Figure 21-13 and Figure 21-14.

Passive Time Frames

A passive time frame has the length defined by the five data frame parameters according **Equation (21.1)**. They are generated only in Data Repetition Mode. Under special conditions (command frame insertion), passive time frames can be shortened (see **Figure 21-10**).

During passive time frames, the data output SO have to be considered as invalid at the receiving device and the clock output FCL may toggle or not (as selected by bit OCR.CLKCTRL). The ENL and ENH enable signals remain at low level during a passive time frame.

21.1.2.2 Shift Register Operation

This section describes the SRL and SRH shift register loading.

SRL Shift Register Loading

During the SRL/SRH shift register load operation at the beginning of each downstream frame transmission, several parameters determine which information is loaded into the bits of the shift register. **Figure 21-7** shows the logic that is implemented for the SRL shift register loading operation. The logic for the SRH shift register loading operation is equivalent to the one for the SRL register. Its differences in data sources and register controls are described later in this section.

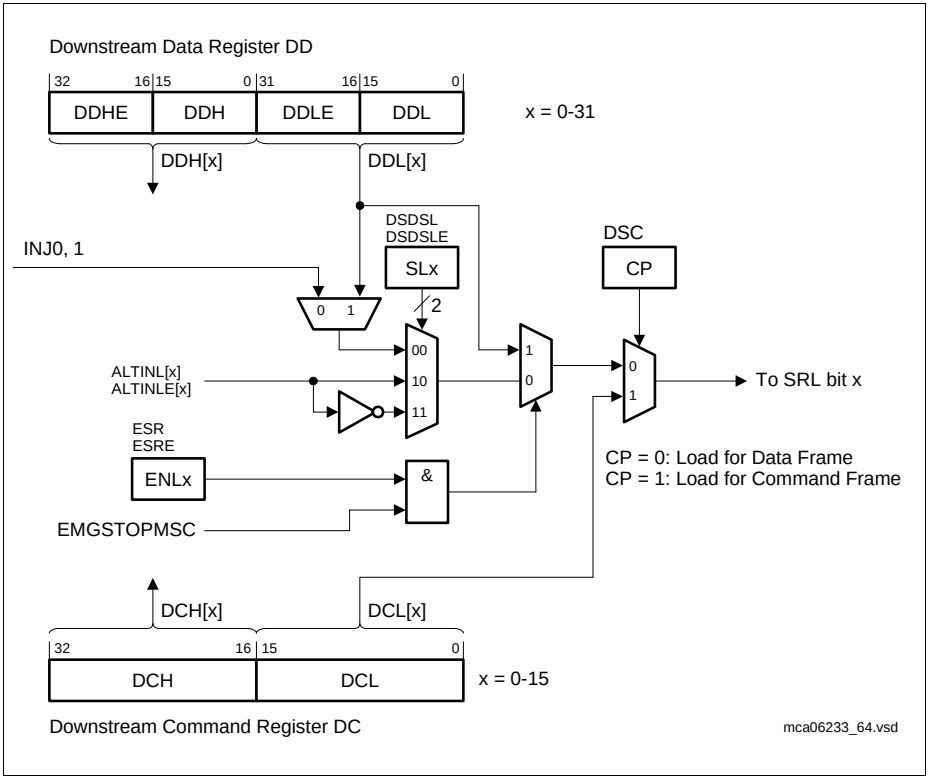

Figure 21-7 SRL Shift Register Data Loading Control

Four data sources can be selected for each SRL bit by using several control bits and one control signal:

- ALTINL input line (non-inverted)
- ALTINL input line (inverted)
- Bit of DD.DDL (downstream data register)
- Bit of DC.DCL (downstream control register)

When SRL is loaded for data frame transmission (DSC.CP = 0), bit fields DSDSL.SLx determine bit-wise which data is loaded into SRL bit x. The data source selection as controlled by DSDSL.SLx will only be effective when EMGSTOPMSC is inactive (at low level). When EMGSTOPMSC = 1 (active) during the load operation, all SRL[x] bits that are enabled for the emergency stop feature (bit ESR.ENLx = 1) are loaded directly with the corresponding bit DDL[x] of the downstream data register DD.

When SRL is loaded for command frame transmission (DSC.CP = 1), always the lower 16-bit part DCL of the downstream control register is loaded completely into SRL.

Table 21-6 summarizes all SRL data source selection capabilities (x = 0-31):

- in standard mode, **DSCE**.EXEN = 0, the selection configuration of up to 16 bits (x = 0-15) is taken into account
- in extended mode, , **DSCE**.EXEN = 1, the selection configuration of up to 32 bits (x = 0-31) is taken into account

Table 21-6 SRL Data Source Selection Capabilities

DSC.CP	DSDSL. SLx DSDSLE.SLx	ESR.ENLx	EMGSTOPMSC	Selection
0	00_B	0	–	Bit DD.DDL[x] is loaded into SRL[x].
	01_B			Reserved.
	10_B			State of ALTINL[x] input is loaded into SRL[x].
	11_B			Inverted state of ALTINL[x] input is loaded into SRL[x].
	XX_B	1	1	Bit DD.DDL[x] is loaded into SRL[x].
1	XX_B	X	X	Bit fields DCL and DCH are completely loaded into SRL and SRH, respectively.

*Note: The data signals can be overrulled by injected pin signals INJ0 and INJ1. See **DSCE** register.*

SRH Shift Register Loading

The SRH shift register load operation is equivalent to the SRL shift register load operation. The following differences must be taken into account for SRH shift register loading:

- Input lines ALTINH are connected instead of ALTINL input lines.
- DSDSH register bits control data source selection instead of DSDSL register.
- Emergency stop is enabled by ESR.ENHx bits instead of ESR.ENLx bits.
- Bits of the downstream data register high part DDH are selected instead of DDL.
- Downstream control register high part DCH is selected instead of DCL.

21.1.2.3 External Signal Injection

Input signals from two pins can be independently injected at two data bit positions in a data frame. The injection takes place both in normal and in extended mode. The external signals are always injected at the defined position, and if the data frame is shorter than this position, than these signals remain unused. For example, if **DSCE**.INJPOS0 defines injection the position 14 of the SRL, and the **DSC**.NBDL=12, then all the data bits from position 12 and up remain unused, including the injected signal.

In normal mode the bits are counted from 0 to 31 from LSB to MSB, and in extended mode the bits are counted from 0 to 63 from LSB to MSB, see **Figure 21-8**. The injection position is always counted as if the frame has the maximal length. In the first step of the preparation for a transmission the injection takes place, and then in the second step, if some fields are configured to be shorter or omitted (for example DDLE or DDH or any other), the unused bits are discarded and only the remaining valid bits are shifted out.

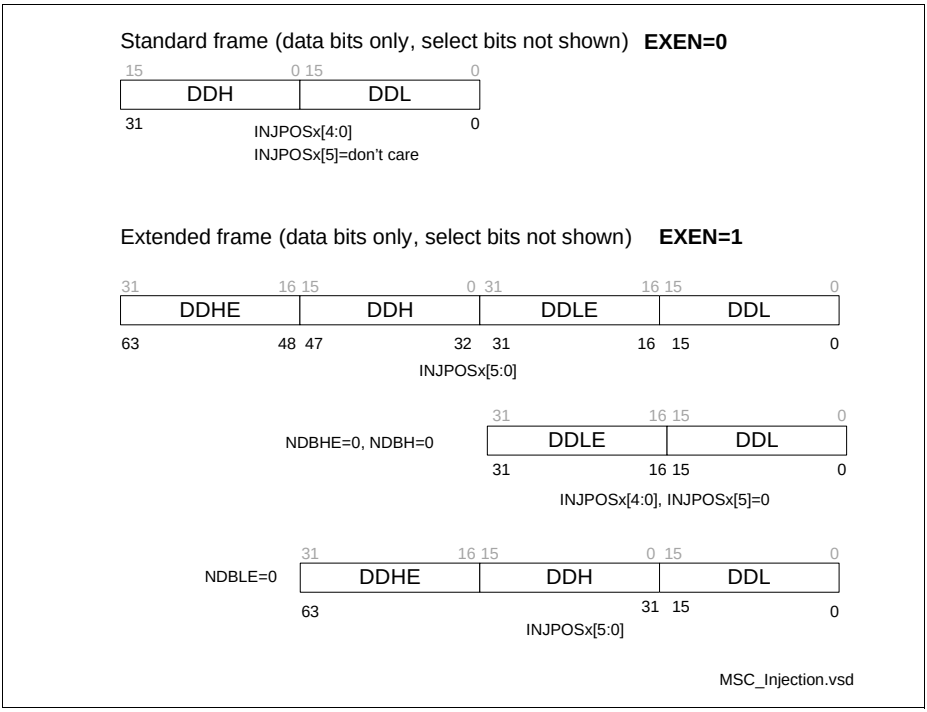

Figure 21-8 External Signal Injection

21.1.2.4 Transmission Modes

The downstream channel of the MSC makes it possible to select between two transmission modes:

- Triggered Mode, selected by DSC.TM = 0, or
- Data Repetition Mode, selected by DSC.TM = 1

Triggered Mode

In Triggered Mode, command frames or data frames are sent out as a result of a software event. When a frame transmission has been finished and no further frame transmission has been requested, the downstream channel returns to idle state and waits for the next frame transmission to be triggered by software.

Setting the DSC.TM bit triggers immediately a frame transmission using the values exisiting at that moment.

When the Downstream Command Register DC is written, the command pending bit DSC.CP becomes set and a command frame will be immediately started and sent out if the downstream channel is idle. If a data or command frame is currently processed and output, the command frame transmission is delayed, and started when the active downstream frame has been finished. The command pending bit DSC.CP becomes cleared by hardware when the first bit of the command frame is sent out.

If the downstream channel is idle and the data pending bit DSC.DP is set by writing bit ISC.SDP with 1, a data frame will be immediately started and sent out if the downstream channel is idle. If a data frame or a command frame is currently processed and output, the data frame transmission is delayed and started when the active downstream frame has been finished. The data pending bit DSC.DP becomes cleared by hardware when the first bit of the data frame is sent out.

A command frame always has priority over the data frame. This means that if both frame pending bits are set (DSC.DP = DSC.CP = 1), the command frame will always be sent first. Therefore, a pending data frame transmission will be delayed as long as no further command frame transmission is running or requested.

Figure 21-9 is a flow diagram of the Triggered Mode. This diagram especially shows the behavior of the data and command pending bits DSC.DP and DSC.CP. If both frame pending bits are set (DSC.DP = DSC.CP = 1), the command frame will always be sent first, followed by the data frame (assuming no further command frame has been requested).

The type of the active frame that is currently processed and output is indicated by two status flags: DSS.DFA is set during a data frame transmission and DSS.CFA is set during a command frame transmission. Further, the downstream counter DSS.DC indicates the number of shift clock periods that have been elapsed since the start of the current frame.

In Triggered Mode, the shift register loading event as described in **Section 21.1.2.2** occurs just before a command or data frame transmission is started.

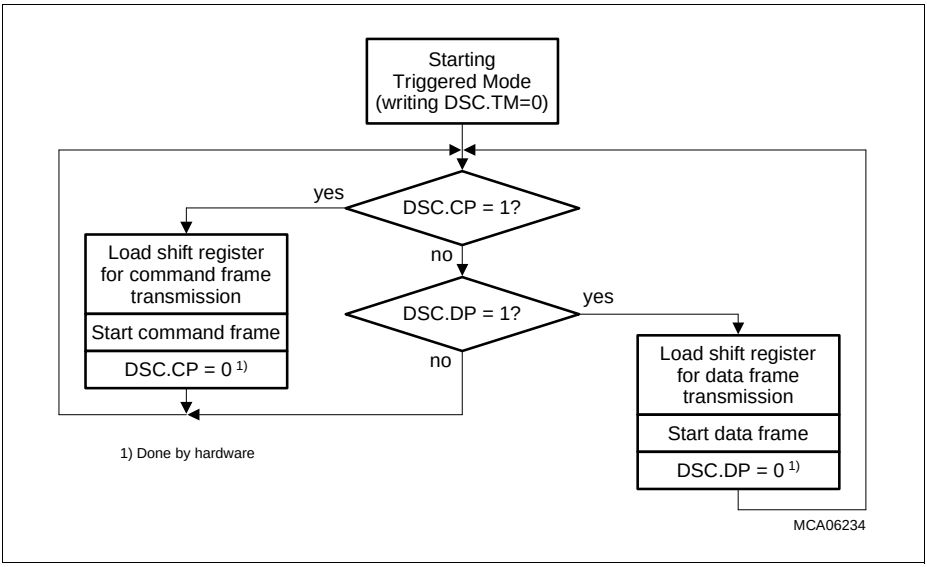

Figure 21-9 Triggered Mode Flow Diagram

Data Repetition Mode

In Data Repetition Mode, data frames are sent out continuously without any software interaction. In the time gap between two consecutive data frames, passive time frames can be inserted. The number of passive time frames to be inserted (0 to 15) is defined by bit field DSS.NPTF. The duration of data frame (t_{DF}) and passive time frames (t_{PTF}) is determined by the five data frame parameters (see **Equation (21.1)**). These parameters determine the time reference points (TRP) at which a data, command or passive time frames is started (see diagram A in **Figure 21-10**).

The automatic data frame generation is controlled by the data pending bit DSC.DP. This bit is set at the end of the last passive data frame if a command frame is running or starts at this TRP, overruling a data frame. DSC.DP is cleared by hardware when the pending data frame starts with transmission at the next TRP. Data Frames are always aligned to time reference points. This means they always start at a TRP. Passive time frames can be shortened. This is especially the case when command frames are inserted.

Continuous data frame transmission can be interrupted by insertion of command frames. Command frames are initiated by software. When the downstream command register DC is written, the command pending bit DSC.CP is set by hardware. CP = 1 indicates that the MSC starts a command frame at the next TRP, independently of whether a data

frame (indicated by DSC.DP = 1) or passive time frame should be started with the next TRP. This means also that command frames are always aligned to time reference points.

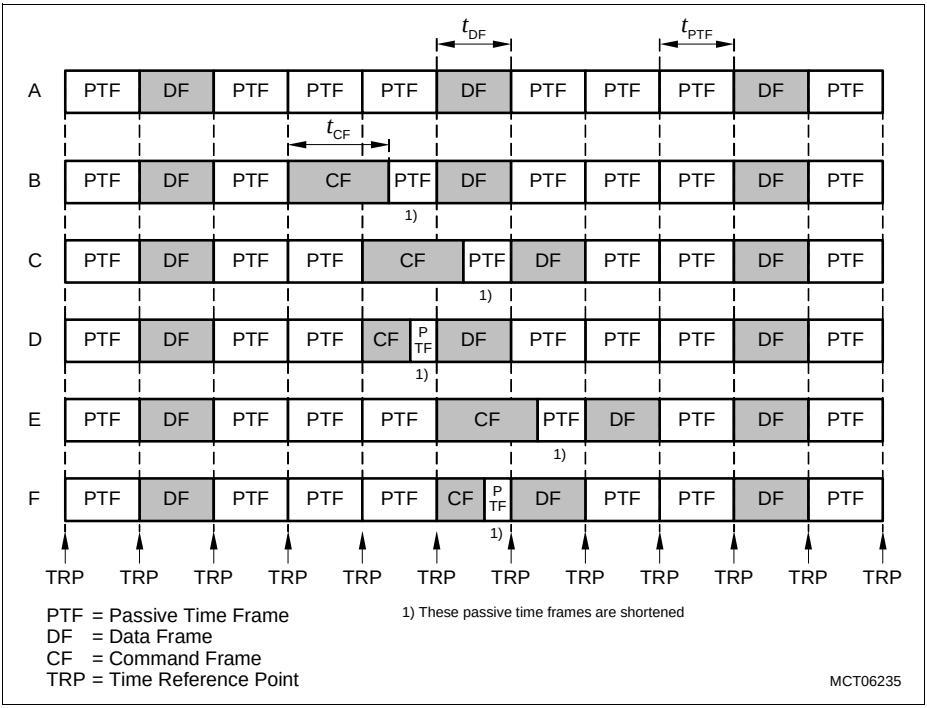

Figure 21-10 Data Repetition Mode Frame Examples with DSS.NPTF = 0011_B

Diagrams B to F in **Figure 21-10** show the command frame insertion in Data Repetition Mode.

In diagram B, a command frame has been requested during the first passive time frame after the data frame, and is inserted at the next TRP. In diagrams C and D, a command frame has been requested during the second passive time frame, and is inserted at the time reference point of the last nominal passive time frame.

When the command frame and data frame is not of the same length (this is the case in diagram B to F), a shortened passive time frame is inserted until the next TRP is reached. This ensures that the next data or normal passive time frame is again aligned to a TRP.

Figure 21-11 is a flow diagram of the Data Repetition Mode. This diagram especially shows the behavior of the data and command pending bits DSC.DP and DSC.CP. If both frame pending bits are set (DSC.DP = DSC.CP = 1), the command frame will always be

sent first, followed by the data frame when the next TRP is reached (assuming no further command frame has been requested).

When the last passive frame is transmitted, DSC.DP becomes set by hardware. This triggers the start of a data frame when the next TRP is reached.

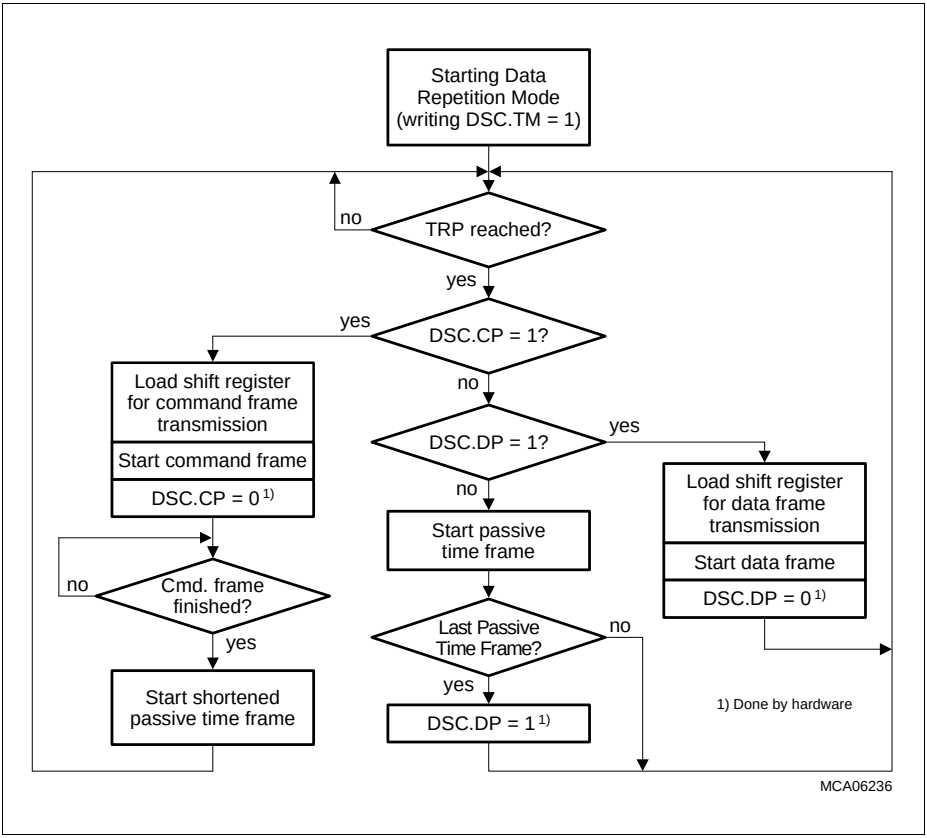

Figure 21-11 Data Repetition Mode Flow Diagram

The type of the active frame (data or command frame) that is currently processed and output is indicated by two status flags: DSS.DFA is set during a data frame transmission and DSS.CFA is set during a command frame transmission. Further, the downstream counter DSS.DC indicates the number of shift clock periods that have been elapsed since the start of the current data, command, or passive time frame.

As in Triggered Mode, the shift register loading event as described in **Section 21.1.2.2** occurs in Data Repetition Mode just before a TRP, this means shortly before a command or data frame transmission is started.

Passive Frame Counter in Data Repetition Mode

In Data Repetition Mode, a passive time frame counter DSS.PFC indicates how many time frames have been already transmitted after the last regular data frame occurrence. The passive time frame counter counts up from 0000_B to the value which has been written into bit field DSS.NPTF (number of passive time frames). DSS.PFC = 0000_B indicates that a data frame is requested for transmission.

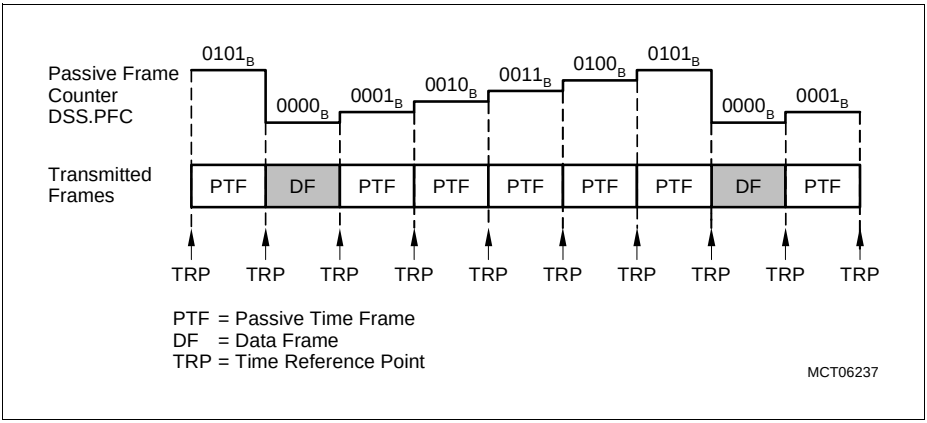

Figure 21-12 Passive Frame Counter Operation (with DSS.NPTF = 0101_B)

21.1.2.5 Downstream Counter and Enable Signals

During downstream channel operation, a 8-bit downstream counter DSS.DC is counting FCL shift clock periods. With the loading of the shift register, the downstream counter is reset to 00_H and started for counting up to the end of the downstream frame (end of passive phase).

In Triggered Mode, the downstream counter stops counting at the end of the passive phase and waits until a new downstream frame is started.

In Repetition Mode, the downstream counter does not stop at the end of the passive phase but is reset and starts counting up again with the next frame, independently whether a data frame, command frame, or passive time frame is started as next frame.

Figure 21-13 shows an example of downstream channel data frame transmission. In this example, the selection bit for the SRL active frame is enabled (ENSELL = 1), and the selection bit for the SRH active frame is disabled (ENSELH = 0). With loading of the shift register SRL/SRH, the downstream counter is reset and then starts counting up with each FCL clock until the end of the passive phase. ENL is set to high level at the beginning of the SRL active frame selection bit.

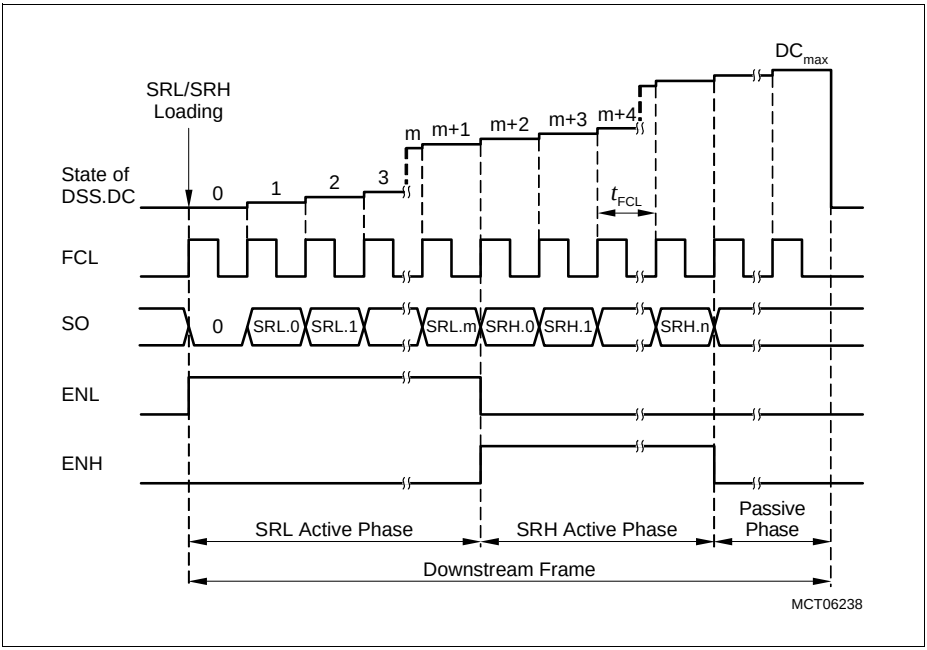

Figure 21-13 Shift Clock Counting: Data Frame with ENSELL = 1 and ENSELH = 0

When the selection bit for the SRL active frame is disabled (ENSELL = 0, see **Figure 21-14**), the loading of the shift register SRL/SRH (and reset of the downstream counter) occurs one FCL clock cycle before the first data bit SRL.0 is output. ENL is set to high level with the beginning of the first data bit SRL.0.

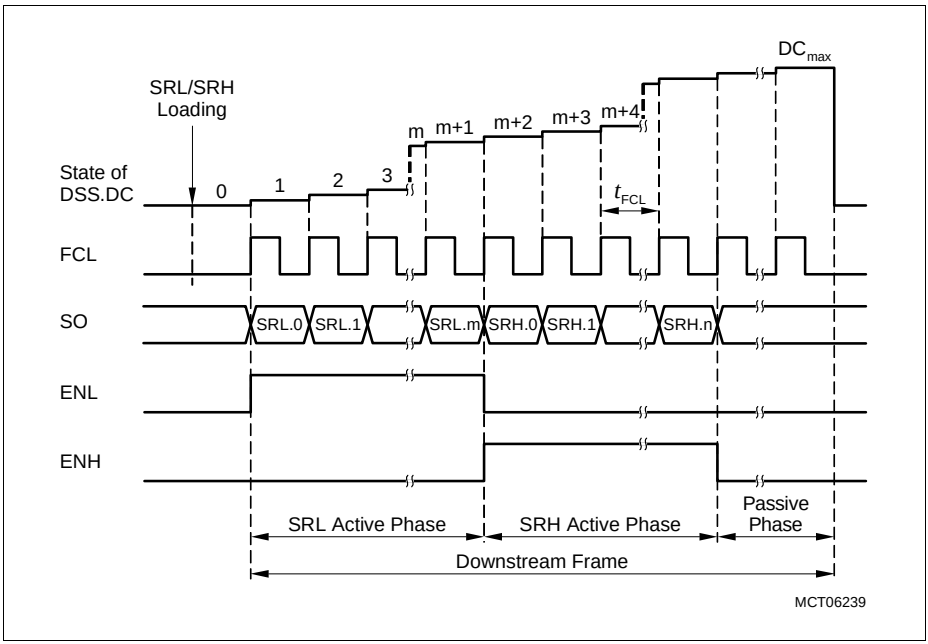

Figure 21-14 Shift Clock Counting: Data Frame with ENSELL = 0 and ENSELH = 0

21.1.2.6 Baud Rate

The baud rate of the downstream channel's serial transmission is defined by the frequency of the serial clock FCL, and is always $f_{MSC}/2$. The f_{MSC} generation is device specific and depends on the implementation of the MSC module. The TC27x specific clock generation is described on **Page 21-103**.

21.1.2.7 Abort of Frames

Only a reset condition of the device can abort a current transmission. The MSC module does not start a new frame transmission when the downstream channel becomes disabled, the suspend mode is requested, or the sleep mode is entered. If one of these three conditions becomes active during a running frame transmission, the frame transmission is completely finished before the requested abort state is entered. Note that in this case no time frame finished interrupt is generated any more.

21.1.3 Upstream Channel

The MSC upstream channel is an asynchronous serial receiver based on the standard asynchronous data transfer protocol. It is dedicated to receive a serial data stream from a peripheral device via its serial data input SDI, using two specific data frame formats.

Figure 21-15 is a block diagram of the MSC upstream channel.

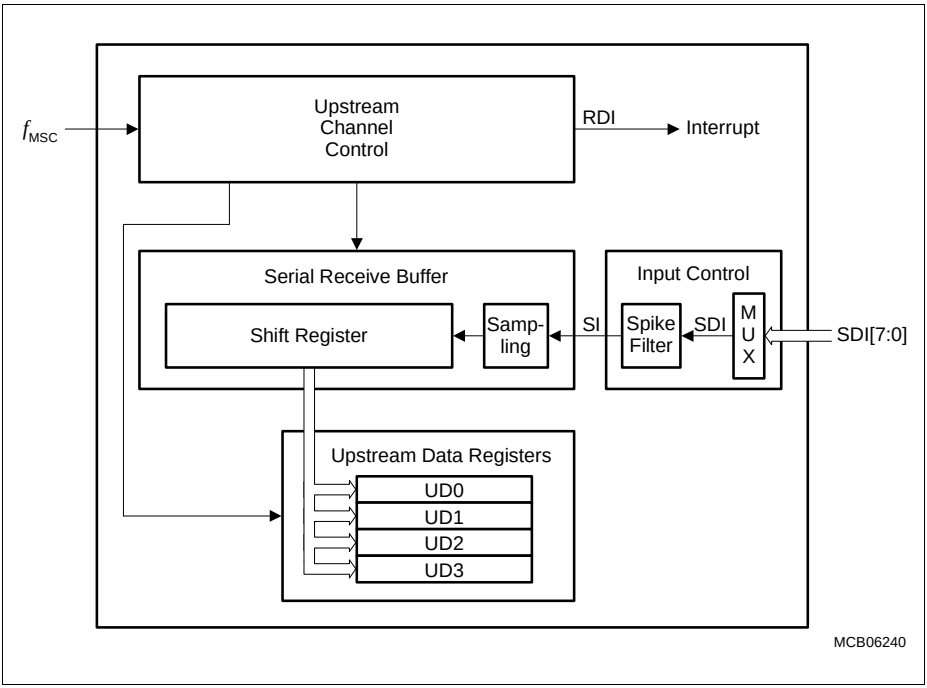

Figure 21-15 Upstream Channel Block Diagram

The incoming data at SI is sampled after it has been filtered for spikes. The detected logic states of the serial input are clocked into a shift register. After the complete reception of the serial data frame, the content of the shift register is transferred into one of the four data registers, and an interrupt can be generated optionally.

The reception baud rate is directly coupled to the module clock f_{MSC}, and can be within a range of $f_{MSC}/4$ up to $f_{MSC}/256$.

Note: If the ABRA block is used with a fractional divider with a fractional ratio generating the upstream baud rate, and in order to compensate the additional fractional divider jitter, the reception baud rate must be less than $f_{MSC}/10$, or $f_{MSC}/(8 \text{ to} 256)* n/1024 < f_{MSC}/10$.

21.1.3.1 Data Frames

The asynchronous data frames used by the upstream channel include four basic parts:

1. One start bit, always at low level
2. An 8-bit data field D[7:0] with LSB first
3. An optional 4-bit address field A[3:0] with LSB first
4. One parity bit and two stop bits, that are always at high level

As shown in **Figure 21-16**, the 16-bit upstream data frame includes an additional 4-bit address field. The upstream frame type is selected by bit USR.UFT.

- USR.UFT = 0: 12-bit upstream data frame selected
- USR.UFT = 1: 16-bit upstream data frame with 4-bit address field selected

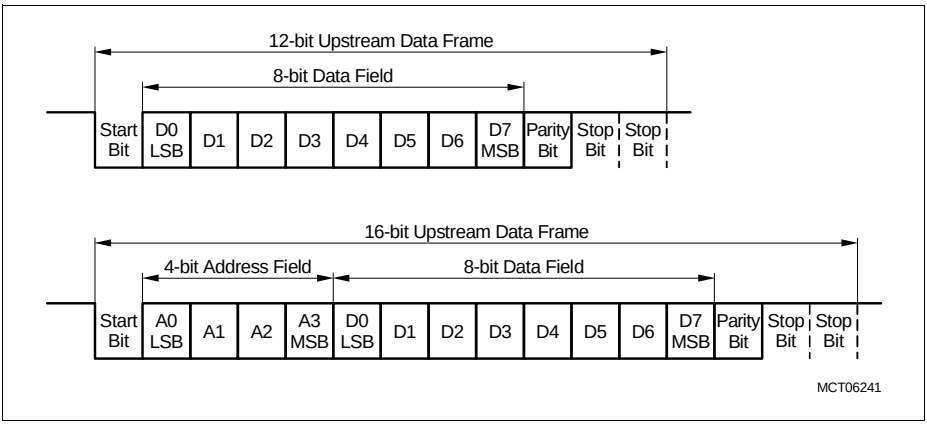

Figure 21-16 Upstream Channel Frame Types

21.1.3.2 Parity Checking

The incoming parity bit of the data frames can be checked by the upstream channel. When a parity error is detected, the parity error flag PERR in the related Upstream Data Register UDx is set. Note that a setting of the parity error flag PERR does not generate an interrupt. The PERR bits must be checked by software. The UDx registers also store the parity bit of the incoming data frame (UDx.P) and the parity bit that is generated internally (UDx.IPF).

Bit USR.PCTR determines the parity mode, even or odd, that is selected for parity checking. With USR.PCTR = 0, even parity mode is selected. Even parity means that the parity bit is set on an odd number of 1s in the data field (12-bit upstream data frame) or in the address plus data field (16-bit upstream data frame). With USR.PCTR = 1, odd parity mode is selected. In odd parity mode, the parity bit is set on an even number of 1s of the related data.

The parity checking logic in the upstream channel also controls whether start bit and the two stop bits of the upstream data frame are at correct logic level. If the start bit is not at low level and the two stop bits are not at high level at the end of the frame reception, the parity error flag UDx.PERR is set, too.

21.1.3.3 Data Reception

The reception of the upstream frame is started with a falling edge (1-to-0 transition) on the SI line. When the start bit is detected, serial reception is enabled and the receive circuit begins to sample the incoming serial data and to buffer it in the receive buffer. After the second stop bit has been detected, the content of the receive buffer is transferred to one of four upstream data registers UDx. The receive circuit then waits for the next start bit (1-to-0 transition) at the SI line. When the content of the receive buffer has been transferred to UDx, the valid bit UDx.V is set by hardware, and a receive interrupt can be generated.

The data reception mechanism does not involve destructive read mechanisms.

Note: The SI input line is the filtered non-inverted (OCR.ILP = 0) or inverted (OCR.ILP = 1) SDI input signal. The SI input signal selection is described on ***Page 21-34****).*

Frame Reception with Address Field

Frame reception for a 16-bit data frame (see **Figure 21-17**) is selected by USR.UFT = 1. When the content of the receive buffer has been received completely, it is transferred to one of the four UDx registers. The two most significant address bits A[3:2] of the received 4-bit address field select the number x of register UDx in which the received frame content is stored. Register UDx is loaded with the two least significant address bits A0 and A1 (UDx.LABF), the 8-bit data (UDx.DATA), the received parity bit (UDx.P), the calculated parity bit (UDx.IPF), and the parity checking result (UDx.PERR). Finally, the valid bit UDx.V is set to indicate that the UDx register contains valid data.

The current state of the frame reception is indicated by the content of an upstream counter that is readable via bit field USR.UC. The upstream counter is a 5-bit counter that counts the upstream frame bits during reception. As shown in **Figure 21-17**, the upstream counter is loaded with 10000_B at the detection of a start bit. It counts down and is again at 00000_B when the second stop bit has been detected and the frame reception is finished.

The state of the serial input data line SI is sampled in the middle of a bit cell and shifted into the receive buffer at the end of the bit cell. The frequency of the shift clock f_{SHIFT} depends the selected baud rate (see **Page 21-28**).

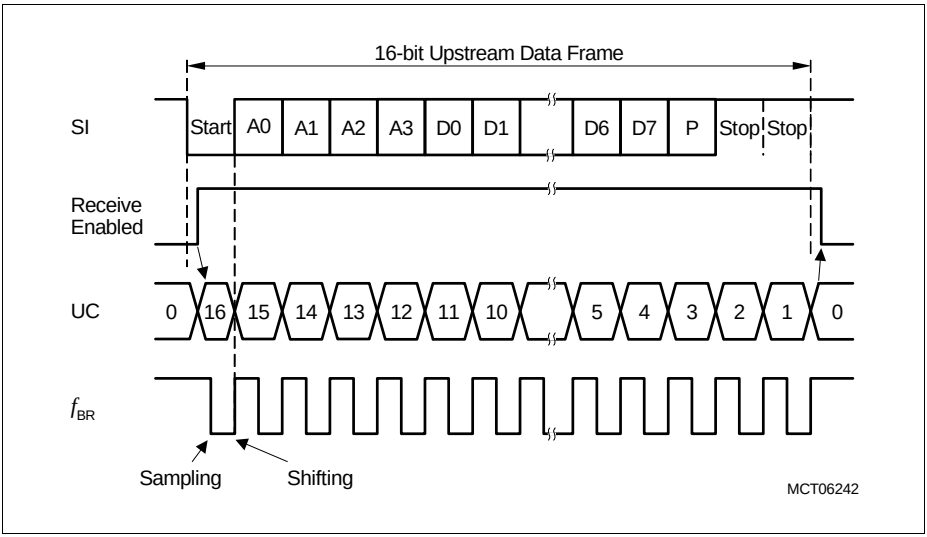

Figure 21-17 16-bit Upstream Reception

Data Reception without Address Field

Frame reception for a 12-bit data frame is selected by USR.UFT = 0. The reception scheme is comparable with that of the 16-bit data frame reception but there are a few differences:

- The upstream counter is initially loaded with 01100_B.
- The received frame content is always stored in register UD0.
- Bit field UD0.LABF is always loaded with 00_B when the frame is stored.

21.1.3.4 Baud Rate

The baud rate of the upstream channel is derived from the MSC module clock f_{MSC}. **Figure 21-18** shows the configuration of the upstream channel clock circuitry.

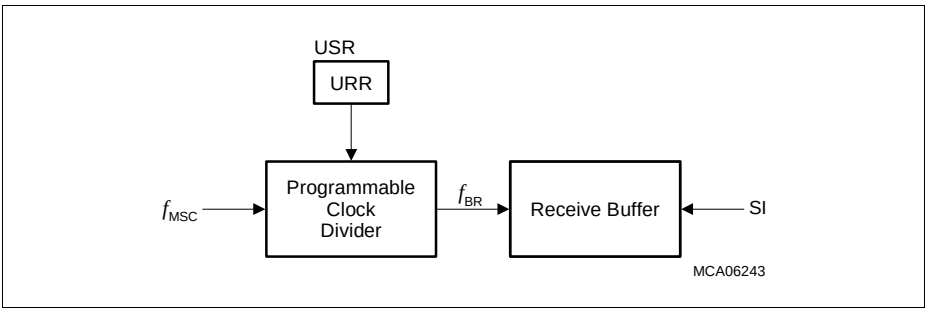

Figure 21-18 Upstream Channel Clock Circuitry

The serial data input SI is evaluated with the baud rate clock f_{BR} in the middle of each bit cell, and latched in case of a data bit. The baud rate clock f_{BR} is derived from f_{MSC} by a programmable clock divider. The frequency of f_{BR} determines the width of a received bit cell and therefore the baud rate for the received data. The content of bit field USR.URR selects the baud rate according **Table 21-7**. The resulting baud rate formula is:

$$\text{Baud rate}_{\text{MSC Upstream Channel}} = \frac{f_{MSC}}{DF} \quad (21.3)$$

Table 21-7 Upstream Channel Divide Factor DF Selection & Baud Rate

USR.URR	Divide Factor DF	Baud Rate
000_B	reception disabled	–
001_B	4	$f_{MSC}/4$
010_B	8	$f_{MSC}/8$
011_B	16	$f_{MSC}/16$
100_B	32	$f_{MSC}/32$
101_B	64	$f_{MSC}/64$
110_B	128	$f_{MSC}/128$
111_B	256	$f_{MSC}/256$

Note: With the USR.URR = 000_B the upstream channel is disabled and data reception is not possible.

The content of bit field USR.URR determines the operation of an internal sampling reload counter that is clocked with f_{MSC}. **Figure 21-19** shows the operation of the sampling counter at the beginning of an upstream frame with a divide factor DF of 8 (USR.URR = 010_B is equal to DF = 8) which means eight sampling clocks per each frame bit cell.

When the upstream channel is in idle state, it waits for a falling edge (1-to-0 transition) at SI. Therefore, the sample counter starts counting up and is reset when the selected divide factor DF as shown in **Table 21-7** is reached. In the middle of the sampling counter's count range, the logic state at SI is evaluated and, in case of a data bit, latched in the receive buffer's shift register. With the reload of the sampling counter, the shift register is shifted by one bit position.

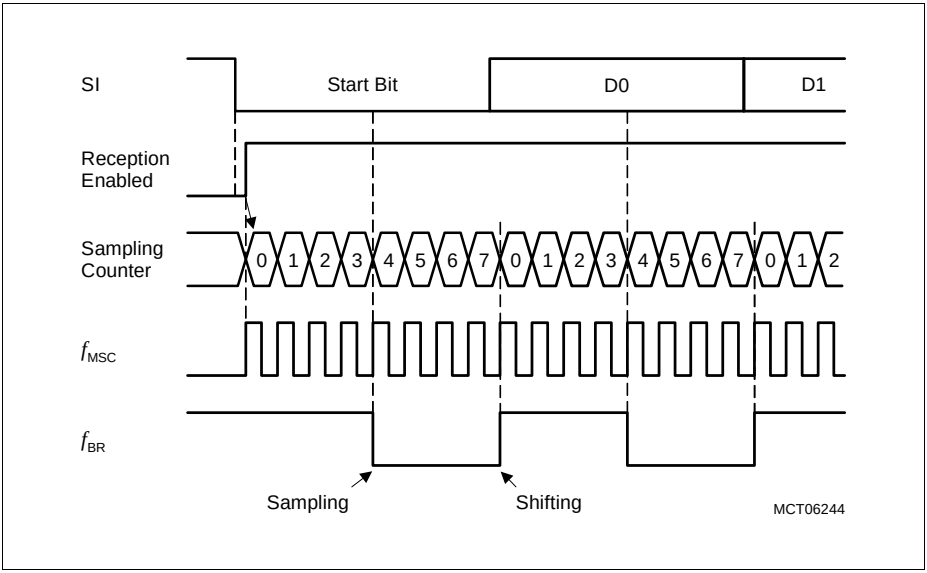

Figure 21-19 Upstream Channel Sampling with URR = 010_B

21.1.3.5 Spike Filter

The upstream channel input line SDI is sampled using a built-in spike filter with synchronization stage, both clocked with f_{MSC}. The spike filter is a chain of flip-flops with a majority decision logic (2 out of 3). A sampled value that is found at least twice in three samples is taken as data input value for SI.

21.1.3.6 Upstream Timer

The upstream timer monitors the time interval between two subsequent upstream frames. The timer reloads its starting values from the register **USCE** and starts counting downwards. If the time interval between two frames is longer than allowed, the counter reaches the value of zero, raises an upstream timer interrupt and stops counting. The counter reloads and starts counting on four events:

- Enabling of the MSC module after reset via **CLC**.DISR
- Reseting the module
- Writing the bit fileds **USCE**.USTOPRE or **USCE**.USTOVAL per software
- Detecting the falling edge of the start bit of a frame

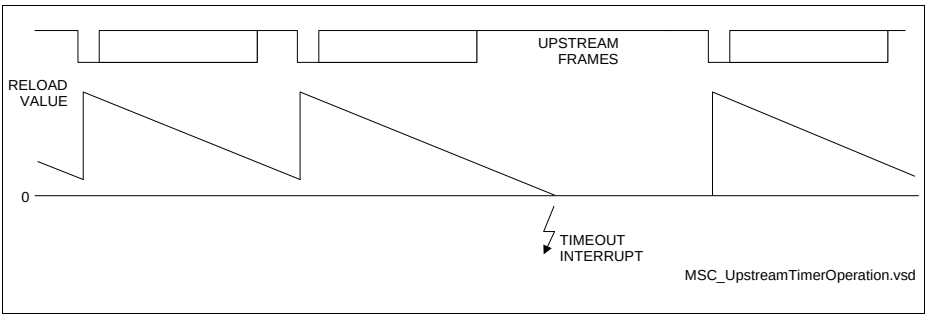

Figure 21-20 Upstream Timer Operation

The upstream watchdog timer counts bit times. The time window in which the next upstream frame must occur can be calculated according to the formula:

$TimeOut = BitTime * 2^{(USTOPRE+1)} * (USTOVAL+1)$

21.1.4 I/O Control

The types of I/O control logic for the MSC module I/O lines are shown in **Figure 21-21**. The downstream channel generates five output signals that control eight MSC module outputs, split into four chip select outputs, two clock outputs, and two serial data outputs. The upstream channel has one input signal.

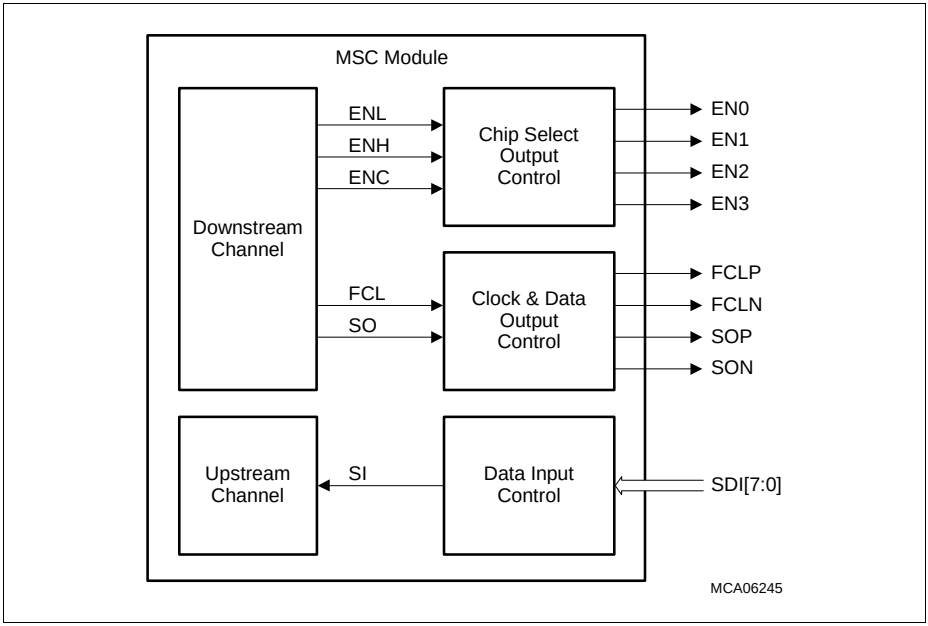

Figure 21-21 I/O Control

The MSC module I/O signals is controlled by bit fields that are located in the Output Control Register OCR.

21.1.4.1 Downstream Channel Output Control

As shown in **Figure 21-5** and **Figure 21-6**, the active phases during downstream channel operation are indicated by three enable signals:

- ENL indicates the SRL active phase of a data frame
- ENH indicates the SRH active phase of a data frame
- ENC indicates the active phase of a command frame

The chip select output control logic of the MSC uses a signal compressing scheme (similar to the interrupt request compressing scheme in **Figure 21-29**) that allows each of the three enable signals to be directed via a 2-bit selector to one of the four chip enable

outputs EN[3:0]. This also makes it possible to connect more than one internal enable signal (ENL, ENH, ENC) to one chip enable output ENx. Three bit fields in register OCR (CSL, CSH, and CSC) determine which chip enable output becomes active on a valid internal enable signal.

In the MSC, enable signals are high-level active signals. If required in a specific application, all chip enable outputs ENx can be assigned for low-level active polarity by setting bit OCR.CSLP.

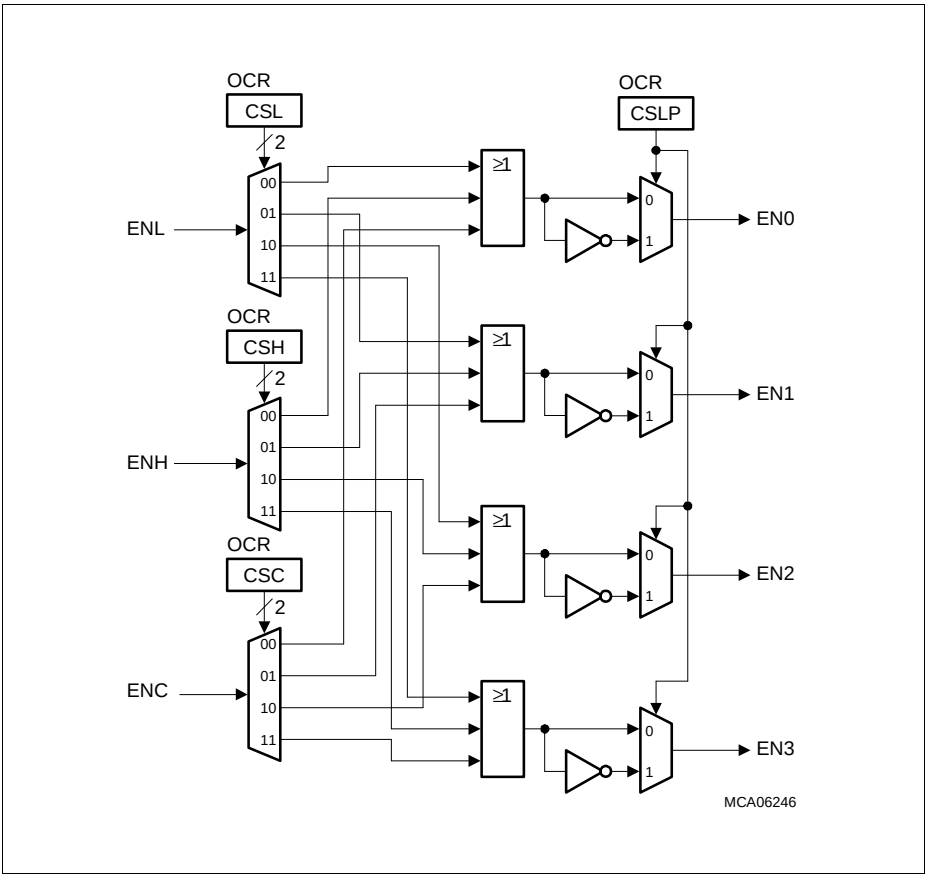

Figure 21-22 Downstream Channel: Chip Enable Output Control

At the MSC downstream channel, the internal serial clock output FCL and data output line SO are available outside the MSC module as two signal pairs with inverted signal polarity, FCLP/FCLN and SOP/SON. Both, clock and data outputs, are generated from the module internal signals FCL and SO according to **Figure 21-23**.

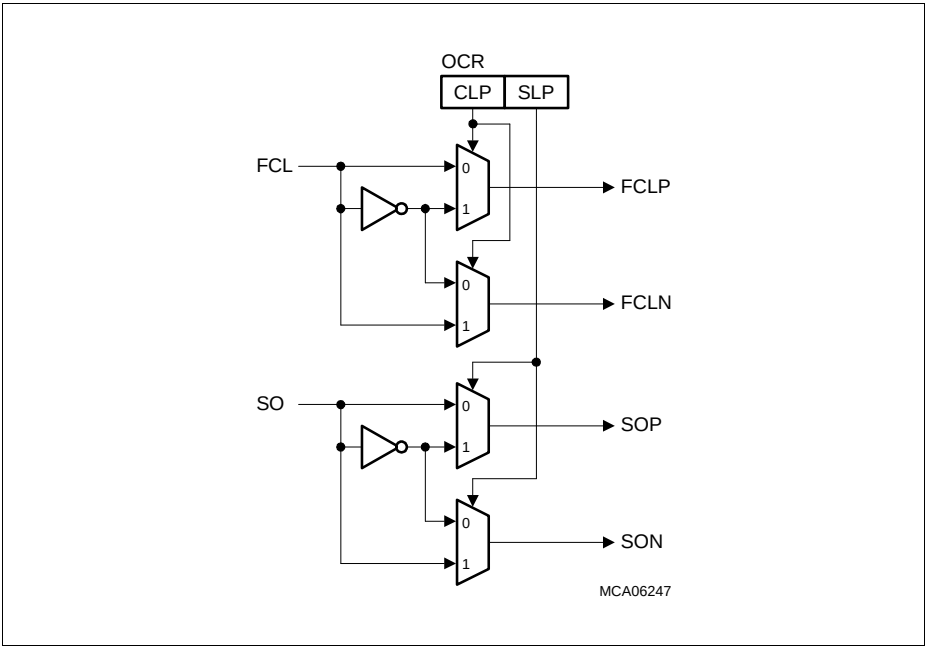

Figure 21-23 Downstream Channel: Clock and Data Output Control

With OCR.CLP = 0, FCLP has identical and FCLN has inverted polarity compared to FCL. Setting OCR.CLP, exchanges the signal polarities of FCLP and FCLN. An equivalent control capability is available for the SOP and SON data outputs (controlled by OCR.SLP).

One additional control capability not shown in **Figure 21-23** is available for the FCL signal. With OCR.CLKCTRL = 1, the FCL clock signal will always be generated, independently whether a downstream frame is currently transmitted or not. If OCR.CLKCTRL = 0, FCL becomes only active during the active phases of data or command frames (not during passive time frames).

21.1.4.2 Upstream Channel

As shown in **Figure 21-24**, the MSC upstream channel can be connected to up to eight SDI[7:0] serial inputs. Bit field OCR.SDISEL selects one out of these input lines (input signal SDI). If OCR.ILP = 0, SDI is directly connected to the serial receive buffer input SI. If OCR.ILP = 1, SDI is connected to input SI via an inverter.

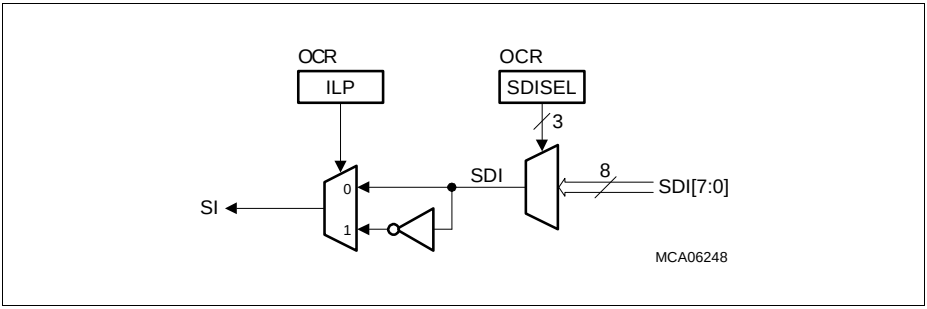

Figure 21-24 Upstream Channel Serial Data Input Control

21.1.5 MSC Interrupts

The MSC module has seven interrupt sources and five service request outputs. A service request output is able to generate interrupts (controlled by a service request control register) or DMA requests. The service request output assignment, interrupt or DMA request, is specific for each microcontroller that is using the MSC. In this section, the term “interrupt request” has the meaning of “service request” that is able to handle interrupt or DMA requests.

Each interrupt source is provided with a status flag, enable bit(s) with software set/clear capability, and an interrupt node pointer. An interrupt event, internally generated as a request pulse, is always stored in an interrupt status flag that is located in the Interrupt Status Register ISR. All interrupt status flag can be set or cleared individually by software via the interrupt Set Clear Register ISC. Software-controlled interrupt generation can be initiated by setting the interrupt status flag of the corresponding interrupt. Each interrupt source can be enabled or disabled individually. When an interrupt event is enabled, a 2-bit interrupt node pointer determines which of the service request outputs will be activated. See **Figure 21-29**.

Table 21-8 shows the seven MSC interrupt sources.

Table 21-8 MSC Interrupt Sources

Interrupt Type	Generated by
Data frame interrupt	Downstream Channel
Command frame interrupt	
Time frame finished interrupt	
Receive data interrupt	Upstream Channel
Upstream Timeout Interrupt	
Sync FIFO overflow	ABRA Block
Sync FIFO underflow	

21.1.5.1 Data Frame Interrupt

A data frame interrupt can be generated when either the first or the last data bit of the downstream channel is shifted out and becomes available at the SO output line (see also **Figure 21-6**). Bit ICR.EDIEI selects which case is selected.

Note: If ICR.EDIE = 10_B, an interrupt at the first data bit is only generated if DSC.NDBL is not equal 00000_B. This means, at least one SRL bit must be shifted out for the first data bit shifted interrupt to become active.

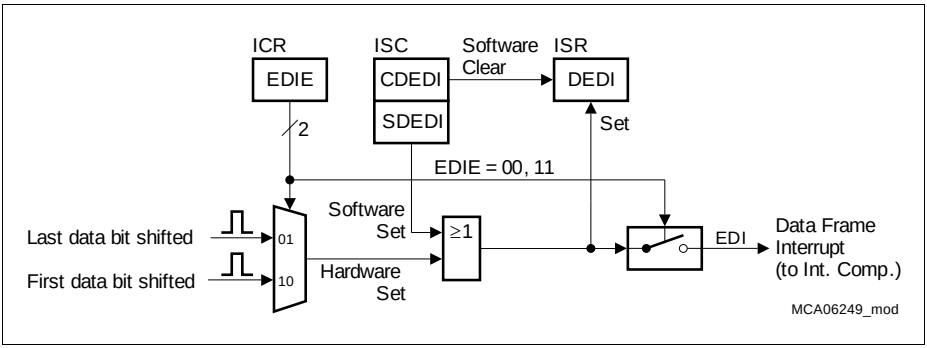

Figure 21-25 Data Frame Interrupt Control

21.1.5.2 Command Frame Interrupt

A command frame interrupt can be generated at the end of a downstream channel command frame (see also **Figure 21-5**).

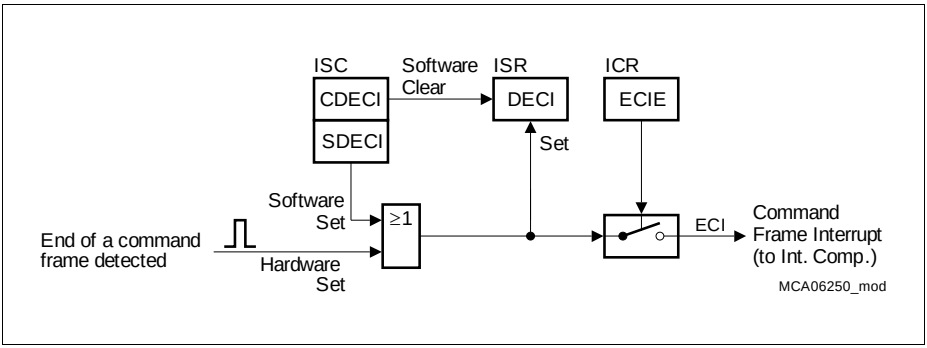

Figure 21-26 Command Frame Interrupt Control

21.1.5.3 Time Frame Finished Interrupt

A time frame finished interrupt can be generated at the end of a downstream channel passive time phase.

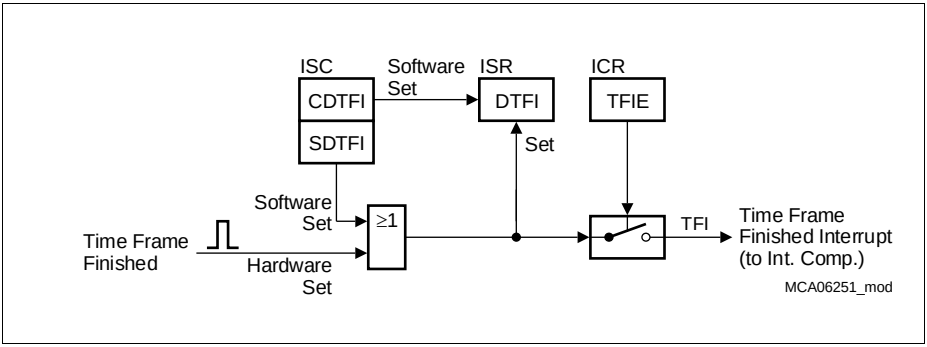

Figure 21-27 Time Frame Interrupt Control

21.1.5.4 Receive Data Interrupt

Whenever the upstream channel receives data in registers UDx (x = 0-3), the MSC is able to generate an interrupt. Three interrupt generation conditions can be selected for the receive data interrupt:

- Each update of UDx (x = 0-3) generates a receive data interrupt.
- Each update of UDx (x = 0-3) generates a receive data interrupt when the updated value is not equal 00_H.
- Only an update of register UD3 generates a receive data interrupt.

The selection of the interrupt generation condition is controlled by bit field ICR.RDIE. Setting ICR.RDIE = 0 disables the receive data interrupt in general. ISR.URDI is the interrupt status flag that can be set or clear when writing bits ISC.SURDI or ISC.CURDI with a 1. If the fractional divider is used, then the software should clear the URDI flag by using ISC.CURDI with a delay of one bit time after the interrupt signal has been generated. The same applies to clearing the UDx.V flag via UDx.C. Otherwise, due to the latencies introduced by the fractional divider, the clear may fail.

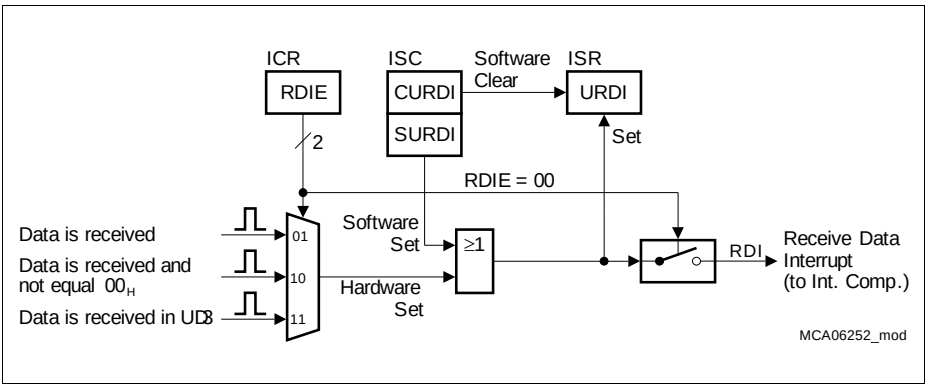

Figure 21-28 Receive Data Interrupt Control

The upstream receive interrupt can be optionally delayed for 1 bit time by setting the **USR**.SRDC bit.

21.1.5.5 Interrupt Request Compressor

The interrupt control logic of the MSC uses a flexible interrupt compressing scheme. Seven interrupt sources can be directed via a 2-bit interrupt node pointer to one of the four service request outputs SR[3:0], and three of them additionally to SR4. This makes it possible to connect more than one interrupt source to one interrupt output SRx.

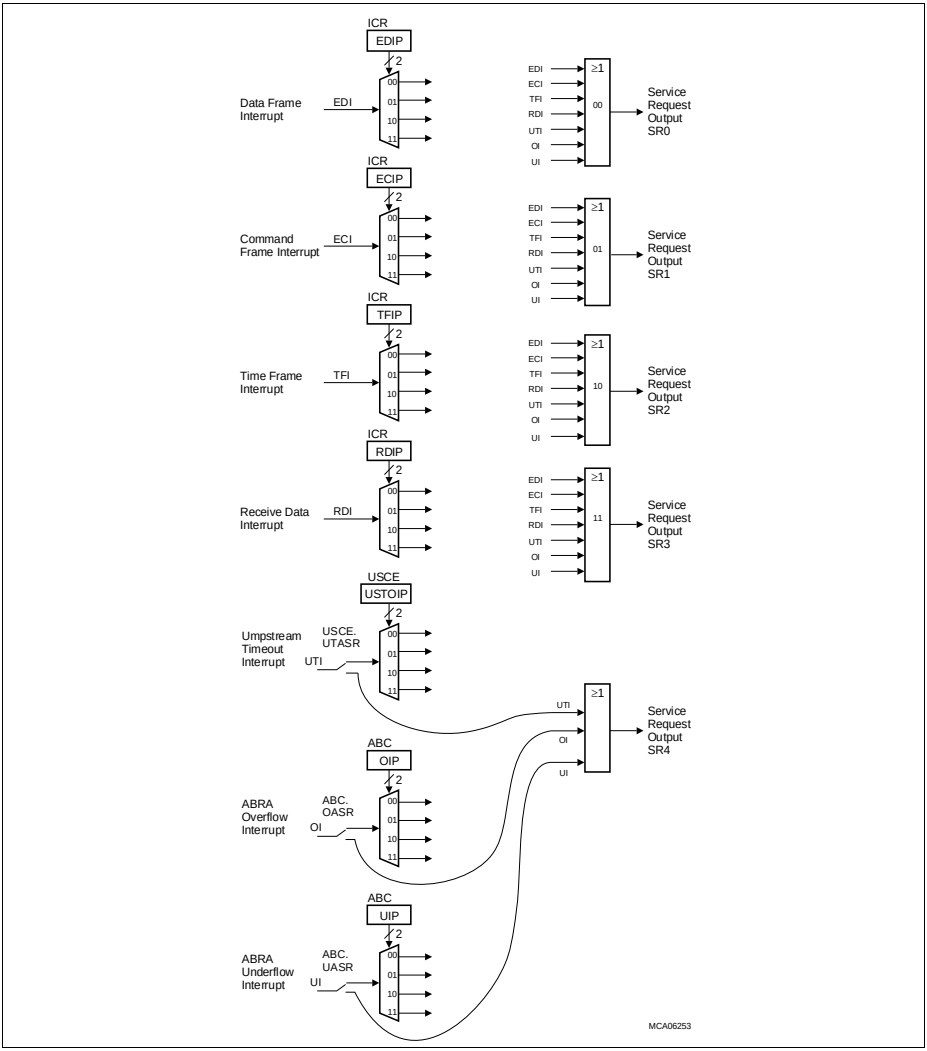

Figure 21-29 MSC Interrupt Request Compressor

21.2 ABRA (Asynchronous Baud Rate Adjustment Block)

The Asynchronous Baud Rate Adjustment Block (ABRA) takes as an input a serial MSC stream with one baud rate and outputs the same serial stream with another baud rate, asynchronous to the input one. The input signal bundle consists of serial clock, data and select signal, and the output signal bundle consists of the same signals.

Additionally, the output clock of an MSC without ABRA can be only set to 50% duty cycle, while with the ABRA block, other duty cycles are also possible.

21.2.1 Overview

The ABRA block is located between the MSC kernel and the output pins.

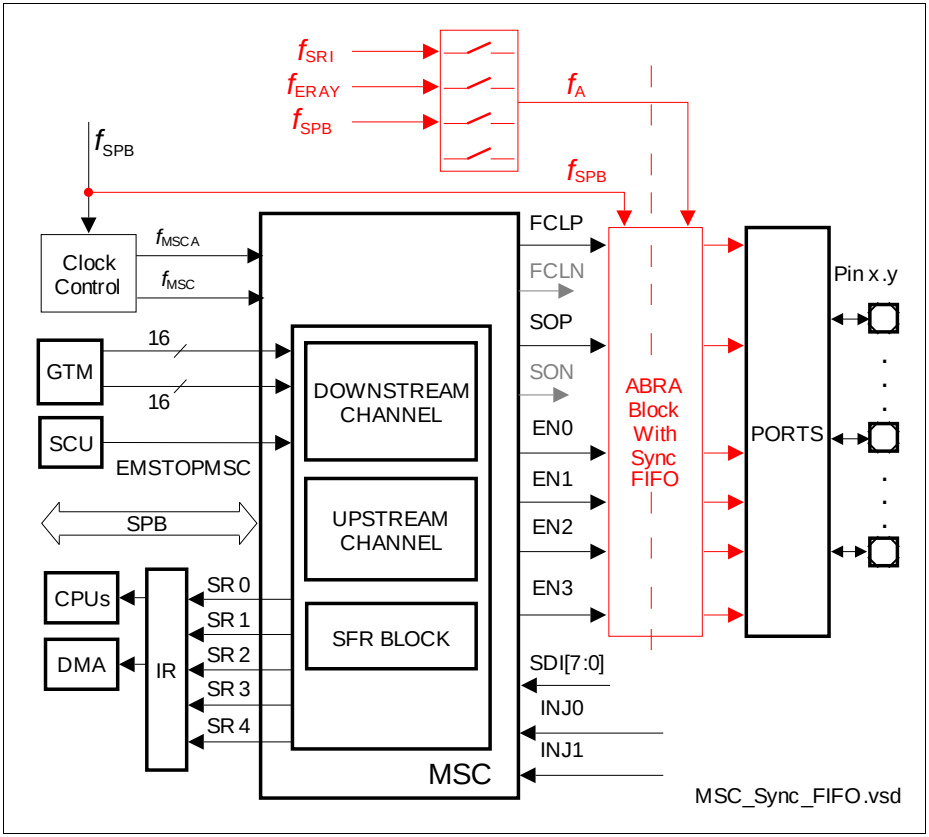

Figure 21-30 ABRA Overview

The user has two possibilities: either to use the ABRA block, or to bypass it. In case of using ABRA, additional delay in the signal path between the module and the pins of up to three f_A periods is to be taken into account. Additionally, some margin between the input frame length and the output frame length must be guarranteed by the customer, in order to avoid overflow of the ABRA block.

If the ABRA is not used, the behavior of the MSC module is identical with the previous implementations. The user can also choose between using the 64-bit extension or not, which makes 4 combinations in total, as shown in **Figure 21-31**

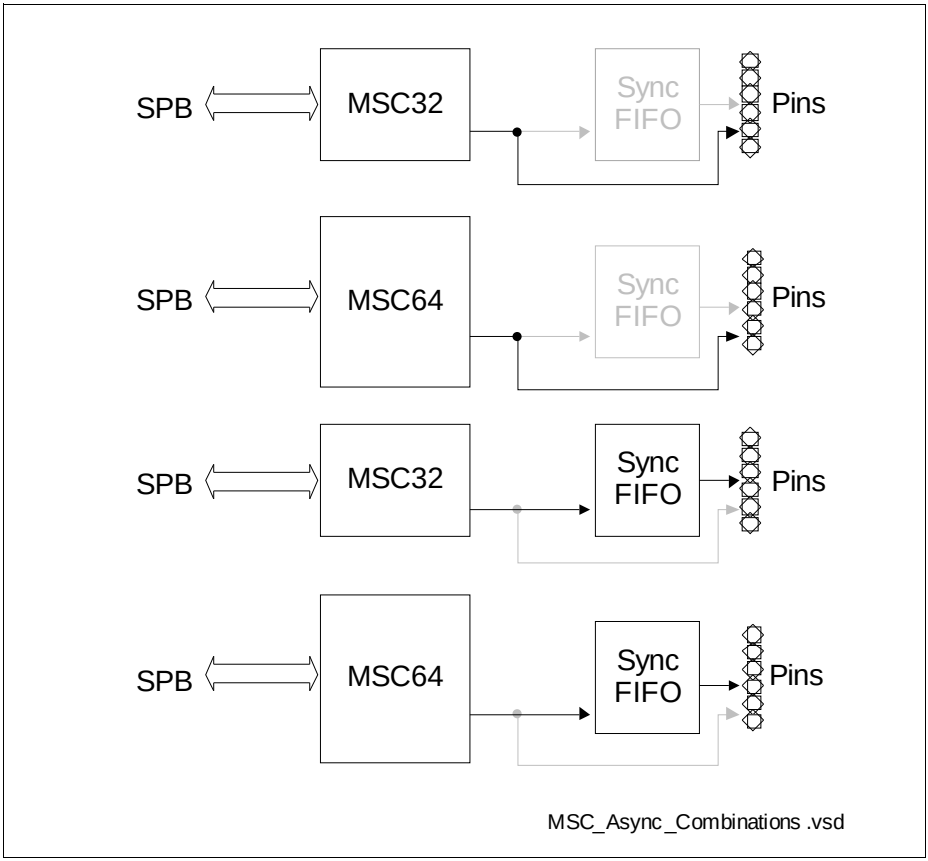

Figure 21-31 Use-Case Combinations

All configuration parameters related to the ABRA block are located in the ABC (Asynchronous Block Configuration) register.

21.2.2 Timings Issues

The ABRA block introduces a delay in the signal path from the MSC module to the pins. However it does not influence significantly the timings between the signals themselves. The output delays between the shift clock, data and enable signals remain approximately the same as if the ABRA block is not used, except for small differences that may appear due to the different routes that the signals take inside the chip, but these differences are included in the one common timing of the MSC module.

21.2.3 Adjusting the Passive Phase of a Frame

The main purpose of the Asynchronous Baud Rate Adjustment block is to transform a frame going in with a higher baud rate (for example 50Mbaud), to a frame going out with a lower baud rate (for example 40MBaud). Therefore, the duration of the outgoing frame is longer then the duration of the incoming frame. In order not to overflow the ABRA block with too many incoming frames, there must be a pause between them, which is adjusted by configuring the passive phase of the frames. This pause plus the incoming frame duration must be longer or equal to the outgoing frame duration plus some margin.

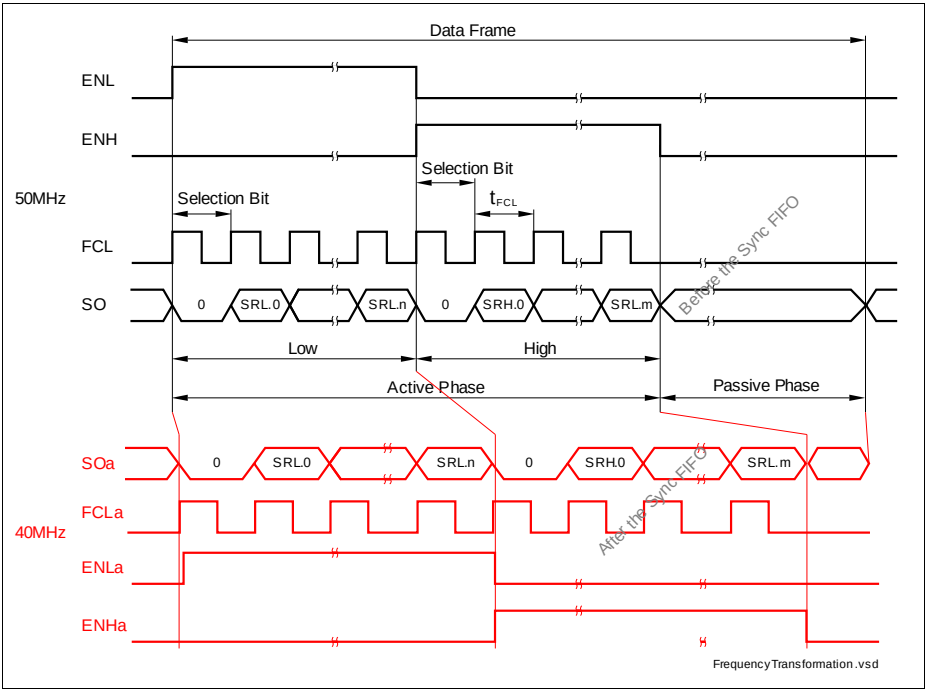

Figure 21-32 Passive Phase Adjustment

In order to allow for frame length adjustments:

- for command frames, the bit field **DSTE**.PPCE defines a programmable passive phase in a range of 2 to 65 input frequency cycles, and
- for data fames, the bit field **DSTE**.PPDE extends the passive phase from 0 to 32 to 0 to 128 bit times.

The length of the frame in the MSC domain (data and passive bits) must be longer than the length of the frame in the asynchronous domain, in order to prevent overload in case of back to back transmission:

$(N_D + N_P) * T_{FCL} > (N_D + N_{PA}) * T_{FCLA}$

which results to the the following inequality for setting the length of the passive phase in the MSC domain:

$N_P > [N_D * (T_{FCLA} - T_{FCL}) + N_{PA} * T_{FCLA}] / T_{FCL}$

Where:

T_{FCL}:
serial clock period in the MSC domain with activated ABRA: $T_{FCL} = 1 / BaudRate_{MSCA}$, $BaudRate_{MSCA} = f_{SPB} / (2*m)$, see **Intermedate Downstream Channel Baud Rate** with ABRA block.

T_{FCLA}:
serial clock period of the ABRA block $T_{FCLA} = 1 / BaudRate_{ABRA}$,
$BaudRate_{ABRA} = f_A / (\textbf{ABC}.NDA * (\textbf{ABC}.LOW+1 + \textbf{ABC}.HIGH+1))$

N_P: number of the passive bits in the MSC domain (see **DSTE**.PPDE and **DSC**.PPD)

N_{PA}:number of the targeted passive bits in the asynchronous domain

N_D:number of data bits **DSC**.NDBH+NDBL+SELH+SELL+**DSCE**.NDBLE+NDBHE in both domains.

Note: If the passive phase settings in the MSC module are not correctly configured in such a way that two frames merge, that is, there is no passive phase on the pins at all, an overflow interrupt is triggered. If the passive phase is wrongly shorter, no error signal is generated.

Input/Output Baud Rate Ratio

The ABRA output baud rate going to the pins must be lower than the input baud rate comming from the MSC module and higher then roughly half of the input baud rate (more precisely higher than 57% of the input baud rate in worst-case, due to the fact that in worst-case MSC data frame can contain 64 data bits plus additionally two select bits).

21.2.4 Jitter of the Downstream Frames

This section describes the jitter effects affecting the starting point of the downstream frames, depending on the setting of the serial clock - serial clock only during the active phase of a frame, or continuous clock.

Note: If the asynchronous frequency f_A is a multiple of f_{SPB}, derived from the same PLL, there is no jitter of the downstream frames, only delay. This applies to the cases where f_A is f_{SPB} or f_{SRI} (for example 200MHz or 300MHz).

21.2.4.1 Jitter in Active Phase Clock Mode

The active phase clock mode is set when **OCR**.CLKCTRL = 0. In this mode the serial clock is generated only during the transmission of the data bits. The ABRA outgoing frame is delayed relative to the incoming frame for three to four f_A cycles. This implies passive phase duration jitter of +- one f_A cycle. The example in the **Figure 21-33** assumes 50MBaud input and 40MBaud output baud rate, f_A = 80MHz, back to back frames.

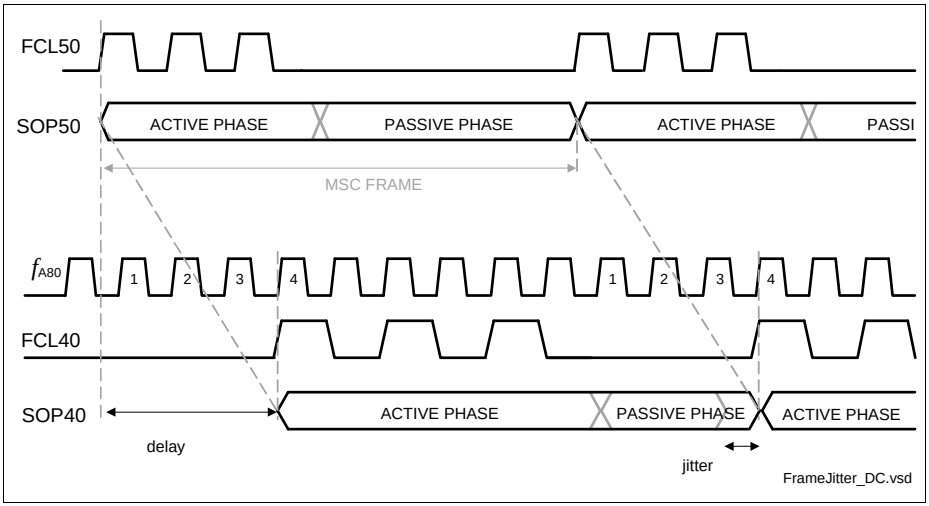

Figure 21-33 Frame Jitter in Active Phase Clock Mode

21.2.4.2 Jitter in Continuous Clock Mode

Continuous clock mode is set when **OCR**.CLKCTRL = 1. In this mode the serial clock is always on. The ABRA output frame is delayed relative to the input frame first for two to three f_A cycles, and then it is shifted out with the first available outgoing rising edge of the serial clock. This implies total delay of three to four f_A cycles plus zero to one half output bit time, and a jitter of one output bit time.

The average length of the output frames is equal to the length of the input frames. The ABRA block generates an averaging effect similar to that of a fractional divider. It introduces occasionally jitter of one bit time in the output frame length, in the passive phase of the frame, in order to adjust the average output time raster to the ideal input time raster. The granularity of the input time raster is one input bit time (for example 20ns at 50MBaud), the granularity of the output time raster is one output bit time (for example 25ns at 40MBaud).

The example in the **Figure 21-34** assumes 50MBaud input baud rate and 40MBaud output baud rate, f_A = 80MHz, back to back frames.

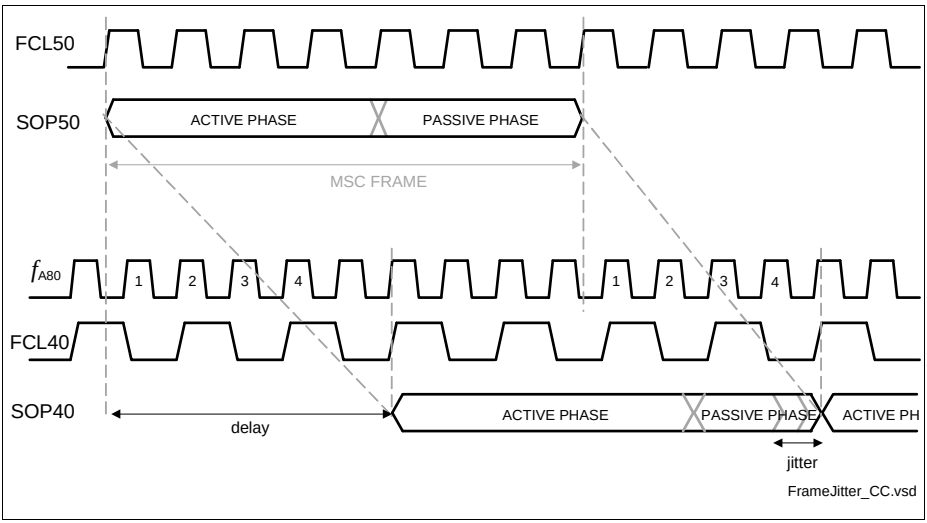

Figure 21-34 Frame Jitter in Continuous Clock Mode

21.2.5 Interrupt Position with the ABRA Block

The position of the MSC interrupts within a frame depends only on the internal time schedule of the MSC module in both use cases with and without ABRA block. Therefore the interrupt position in the internal time raster is constant and is the same as in the previous versions of the MSC module, and does not depend on the asyncronous baud rate which is seen on the pins. This behavior affects only the downstream interrupts, which are:

- Data Frame Interrupt
- Command Frame Interrupt
- Time Frame Finished Interrupt

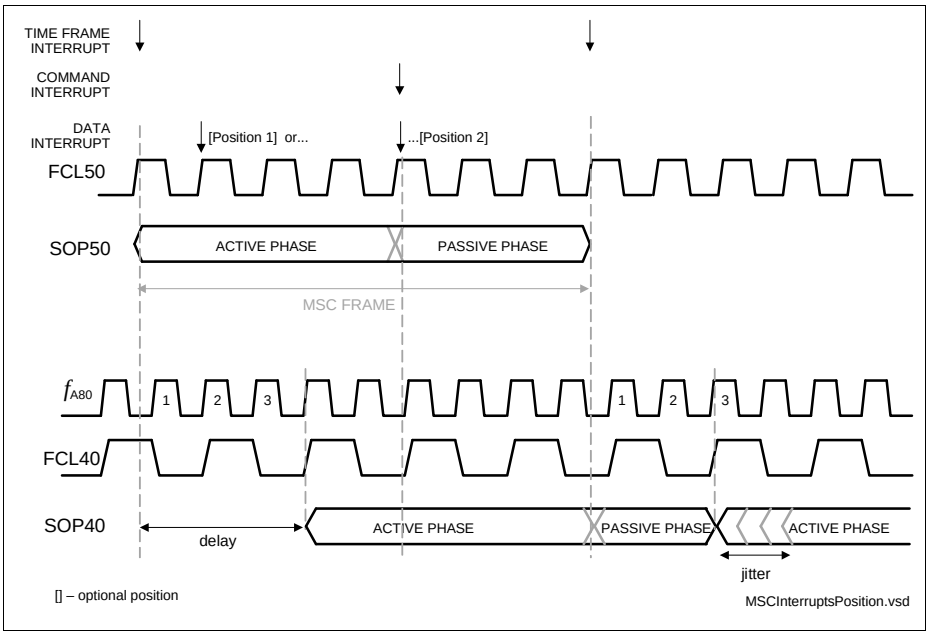

Figure 21-35 Interrupt Position with the ABRA Block

The downstream interrupts can be used for updates of the shadowed rw bit fields for the next frame transmission. Such bit fields are located in the Data Register **DD**, Command Register **DC**, Data Control **DSC** and Data Status **DSS**. Due to the next-frame-update effect, the small jitter and delay effects of the frames as seen on the pins is not relevant, as well as the position of the interrupt in the asynchronous frame.

21.2.6 Configuring the ABRA block

This section describes all the configurable parameters of the ABRA block. They are located in the **ABC** (Asynchronous Block Configuration) register.

Output Baud Rate

The ABRA block shifts out the data with a baud rate generated by dividing the clock f_A in the range of 2 to 32.

The high and the low time of the shift clock are generated by a separate 4-bit n-divider, each operating in the range of 1 to 16. Therefore the duty cycle can be finely configured to be 50% or any other ratio. This may provide some advantages when the communicating devices have asymmetrical timings (output delays or set-up/hold times). See the description of the bit-fields **ABC**.HIGH and **ABC**.LOW

The output baud rate of the ABRA block is defined with the formula:

Baud Rate = f_A / (**ABC**. NDA * (**ABC**.LOW+1 + **ABC**.HIGH+1))

Continuous Shift Clock

As defined in the bit field **ABC**.CC, the shift clock signal can be active either:

- only during the data transmission time
- continuously

Overflow and Underflow Interrupts

If the input and the output timings of the ABRA block are not adjusted to each other, an overflow of the ABRA block will occur and an error interrupt will be triggered on line X.

Overflow occures either if the input data rate is too high or the output data rate is too low.

The corresponding bit fields are **ABC**.OF, OFM, OIE.

Underflow occures either if the input data rate is too low or the output data rate is too high.

The corresponding bit fields are **ABC**.UF, UFM, UIE

See also **Interrupt Request Compressor**.

This feature can not guarantee protection against software errors like reconfiguring the baud rates in the middle of a frame.

The configuration of the ABRA block and the MSC kernel is static and the time behavior is deterministic and calculable. Therefore, an overflow/underflow event always signals some configuration error resulting in unadjusted input/output baud rate ratio (see **Input/Output Baud Rate Ratio**). In normal operation and with correctly configured baud rates (clocks and clock dividers) these events do not occur.

In case of underflow/overflow event the output frame will be corrupt. The simplest solution to a sporadic event caused by a transient (noise, alpha particle) is to reset the module, reconfigure and restart the communication.

Bypass Mode

If the ABRA block is not used, it is disabled and bypassed via the bit field **ABC**.ABB.

21.2.7 Implementation Issues

The ABRA block operates using synchronization FIFO. The MSC module writes its serial stream to the synchronization FIFO with its serial shift clock, and the same data is read out of the FIFO by using the ABRA serial shift clock, generating out of the f_A.

Three signals are being transformed: the serial shift clock, the serial data stream and the enable (chip select) signals.

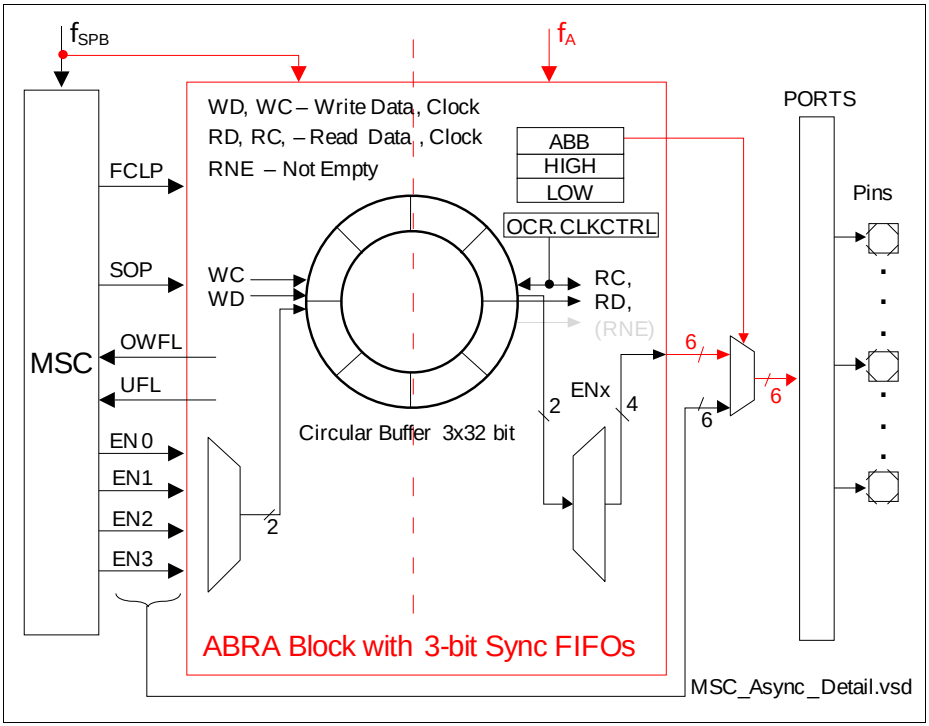

Figure 21-36 Implementation Details of the ABRA Block

21.2.8 ABRA Disable, Sleep and Suspend Behavior

This section describes the behavior of the MSC module in case of:

- switching the module on/off - disable behavior
- power saving - sleep mode
- debugging - OCDS suspend mode

The main concept is to provide as similar behavior as the behavior of the MSC module without the ABRA block, as much as possible.

21.2.8.1 Disable and Sleep Behavior

There is no difference in the behavior of the module in case of entering / leaving the disable and sleep state. Disable state is controlled by a bit set / cleared by software, sleep state is controlled by a hardware signal which can be disabled or enabeled.

On disable/sleep state request, the module finishes the possibly ongoing frames (downstream or upstream), then acknowledges the request and the module clock is switched off.

On leaving the disable/sleep state, the module continues with the operation at the same point where it entered the corresponding state.

21.2.8.2 OCDS Suspend Behavior

In case of Hard Suspend, the clock is switched off immediately. A running frame will not be finished.

In case of Soft Suspend, the state is entered after the following two conditions are met:

- any ongoing upstream reception is completed, and
- any ongoing downstream frame transmission is completed, both from the MSC kernel and the ABRA block side

21.3 MSC Kernel Registers

This section describes the kernel registers of the MSC module. All MSC kernel register names described in this section will be referenced in other parts of the TC27x User's Manual by the module name prefix "MSCx_".

All registers in the MSC address spaces are reset with the application reset (definition see SCU section "Reset Operation").

1) The absolute register address is calculated as follows:
Module Base Address (**Table 21-9**) + Offset Address (shown in this column)

2) All registers have read access mode U, SV. Read access to reserved addresses delivers bus error (BE) except 50H and 54H.
All registers belong to reset class 3 except OCS, which belongs to reset class 1.

21.3.1 Module Identification Register

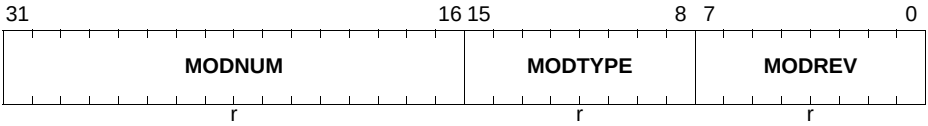
ID

The MSC Module Identification Register ID contains read-only information about the module version.

>> **Registers Overview**

ID

Module Identification Register **(08_H)** **Reset Value: 0028 C01X$_H$**



Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$
MODNUM	[31:16]	r	**Module Number Value** This bit field defines the module identification number for the MSC: 0028_H

21.3.2 Status and Control Registers

USR

The Upstream Status Register is used to configure the upstream channel data format, baud rate, and parity type. It also provides the status information of the upstream counter (UC).

>> **Registers Overview**

USR

Upstream Status Register **(10_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0											UC				
r											rh				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0										SRDC	PCTR	URR			UFT
r										rw	rw	rw			rw

Field	Bits	Type	Description
UFT	0	rw	**Upstream Channel Frame Type** This bit determines the frame type used by the upstream channel for data reception. 0_B 12-bit upstream frame selected 1_B 16-bit upstream frame selected (with 4-bit address field)
URR	[3:1]	rw	**Upstream Channel Receiving Rate** This bit field determines the baud rate for the upstream channel. 000_B Upstream channel disabled; no reception is possible 001_B Baud rate = $f_{MSC}/4$ 010_B Baud rate = $f_{MSC}/8$ 011_B Baud rate = $f_{MSC}/16$ 100_B Baud rate = $f_{MSC}/32$ 101_B Baud rate = $f_{MSC}/64$ 110_B Baud rate = $f_{MSC}/128$ 111_B Baud rate = $f_{MSC}/256$

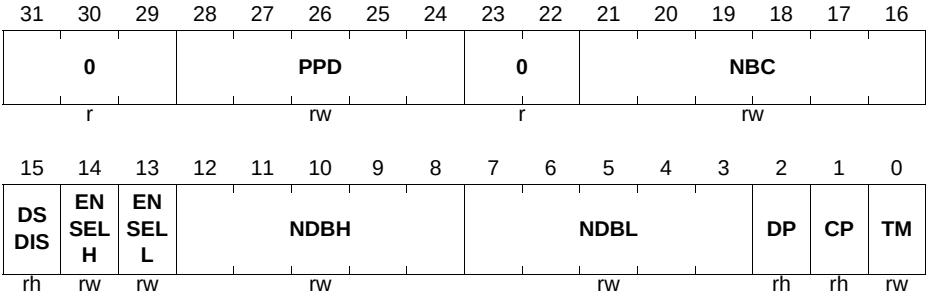
Field	Bits	Type	Description
PCTR	4	rw	**Parity Control** This bit determines the parity mode used by the upstream channel for data reception. 0_B Even parity mode is selected. A parity bit is set on an odd number of 1s in the serial address/data stream. 1_B Odd parity mode is selected. A parity bit is set on an even number of 1s in the serial address/data stream.
SRDC	5	rw	**Service Request Delay Control** This bit determines the additional delay inserted by the upstream channel when triggering the receive interrupt. Only the hardware generated interrupt can be delayed. The software generated interrupt by writing the ISC.SURDI bit is never delayed. 0_B No delay 1_B Delay of 1 bit time
UC	[20:16]	rh	**Upstream Counter** This bit field indicates the content of the upstream counter that counts the bits during upstream channel reception.
0	[15:6], [31:21]	r	**Reserved** Read as 0; shall be written with 0.

DSC

The Downstream Control Register is used to control the operation mode and frame layout of the downstream channel transmission. It also contains the two pending status bits.

>> **Registers Overview**

DSC
Downstream Control Register (14_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
TM	0	rw	**Transmission Mode** This bit selects the transmission mode of the downstream channel. 0_B Triggered Mode selected 1_B Data Repetition Mode selected
CP	1	rh	**Command Pending** This bit is set when the downstream command register DC is written. CP is cleared when the first bit of the related command frame is sent out.
DP	2	rh	**Data Pending** In Triggered Mode, this bit is set when the set data pending bit ISC.SDP is set by software. In Data Repetition Mode, this bit is set by hardware at the last passive time frame. At the start of the data frame, DP is cleared by hardware.

Field	Bits	Type	Description
NDBL	[7:3]	rw	**Number of SRL Bits Shifted at Data Frames** NDBL determines the number of shift register low part (SRL) bits that are shifted out on SO during a data frame. 00000_B No SRL bit shifted 00001_B SRL[0] shifted 00010_B SRL[1:0] shifted $...{}_B$ ... 01111_B SRL[14:0] shifted 10000_B SRL[15:0] shifted Other bit combinations are reserved; do not use these bit combinations.
NDBH	[12:8]	rw	**Number of SRH Bits Shifted at Data Frames** NDBH determines the number of shift register high part (SRH) bits that are shifted out on SO during a data frame. 00000_B No SRH bit shifted; no selection bit is generated, the SRH active phase is completely skipped. 00001_B SRH[0] shifted 00010_B SRH[1:0] shifted $...{}_B$ ... 01111_B SRH[14:0] shifted 10000_B SRH[15:0] shifted Other bit combinations are reserved; do not use these bit combinations.
ENSELL	13	rw	**Enable SRL Active Phase Selection Bit** This bit determines whether a low level selection bit is inserted at the beginning of a data frame's SRL active phase. 0_B No selection bit inserted. 1_B Low level selection bit inserted.
ENSELH	14	rw	**Enable SRH Active Phase Selection Bit** This bit determines whether a low level selection bit is inserted at the beginning of a data frame's SRH active phase. 0_B No selection bit inserted. 1_B Low level selection bit inserted.

Field	Bits	Type	Description
DSDIS	15	rh	**Downstream Disable** This bit indicates the state of the downstream channel operation. 0_B The downstream channel is enabled. A frame transmission can take place (Triggered Mode) or takes place (Data Repetition Mode). 1_B Downstream Counter becomes disabled. No new frame transmission is started. A running frame transmission is always completed.
NBC	[21:16]	rw	**Number of Bits Shifted at Command Frames** This bit field determines how many bits of the SRL/SRH shift registers are shifted out during transmission of a command frame. 000000_B No bit shifted 000001_B SRL[0] shifted 000010_B SRL[1:0] shifted 000011_B SRL[2:0] shifted $\ldots_B$ ... 010000_B SRL[15:0] shifted 010001_B SRL[15:0] and SRH[0] shifted 010010_B SRL[15:0] and SRH[1:0] shifted $\ldots_B$ ... 011111_B SRL[15:0] and SRH[14:0] shifted 100000_B SRL[15:0] and SRH[15:0] shifted Other bit combinations are reserved; do not use these bit combinations
PPD	[28:24]	rw	**Passive Phase Length at Data Frames** This bit field determines the length of the passive phase of a data frame. 00000_B Passive phase length is $2 \times t_{FCL}$ 00001_B Passive phase length is $2 \times t_{FCL}$ 00010_B Passive phase length is $2 \times t_{FCL}$ 00011_B Passive phase length is $3 \times t_{FCL}$ $\ldots_B$ ... 11111_B Passive phase length is $31 \times t_{FCL}$
0	[23:22], [31:29]	r	**Reserved** Read as 0; shall be written with 0.

Note: The "rw" bits in the DSC register are buffered in a shadow buffer at the start of a corresponding frame transmission.

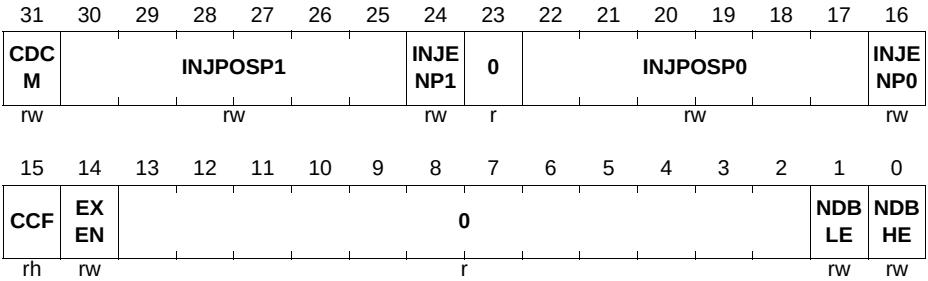
DSCE

The Downstream Control Enhanced Register is used to control the enhanced operation mode and frame layout of the downstream channel transmission.

>> **Registers Overview**

DSCE

Downstream Control Enhanced Register 1(58_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
NDBHE	0	rw	**Number of SRH Bits Shifted at Data Frames Extension** Additional MSB bit extension of the NDBH bit field.
NDBLE	1	rw	**Number of SRH Bits Shifted at Data Frames Extension** Additional MSB bit extension of the NDBL bit field.
EXEN	14	rw	**Extension Enable** Enables the extension bit fields.
CCF	15	rh	**Command-Comand Flag** This bit flags that a second command frame has been written without data frame to be sent in between. It is active only if CTCM=1. Otherwise it is always low. 0_B no second command 1_B second command frame pending
INJENP0	16	rw	**Injection Enable of the Pin 0 Signal** This bit selects if an external signal is injected in a data frame. 0_B Disabled 1_B Enabled

Field	Bits	Type	Description
INJPOSP0	[22:17]	rw	**Injection Position of the Pin 0 Signal** This bit selects the position of the injected external one bit signal, at the bit position in range of 0 to 63 in the data frame. If both PIN0POS and PIN1POS point to a same bit, PIN0POS has the higher priority, that is PIN0 level will be visible in the data frame.
INJENP1	24	rw	**Injection Enable of the Pin 1 Signal** This bit selects if an external signal is injected in a data frame. 0_B Disabled 1_B Enabled
INJPOSP1	[30:25]	rw	**Injection Position of the Pin 1 Signal** This bit selects the position of the injected external one bit signal, at the bit position in range of 0 to 63 in the data frame.
CDCM	31	rw	**Command-Data-Comand in Data Repetition Mode** This bit selects if a data frame is autmatically inserted between two consecutive command frame requests. 0_B Automatic data insertion disabled 1_B Automatic data insertion enabled
0	23, [13:2]	r	**Reserved** Read as 0; shall be written with 0.

USCE

The Upstream Control Enhanced Register is used to control the upstream channel timeout feature.

>> **Registers Overview**

USCE

Upstream Control Enhanced Register 1($5C_H$) **Reset Value: 0000 00FF_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USTOIP		UTASR	0	UTS	UTC	UTF	UTOEN	USTOVAL				USTOPRE			
rw		rw	r	w	w	rh	rw	rw				rw			

Field	Bits	Type	Description
USTOPRE	[3:0]	rw	**Upstream Timeout Prescaler** Prescaler for the upstream time-out limit. Expressed in upstream bit times. 2^N divider in the range of 1 to 32768. Write to this bit field triggers new start of the watchdog timer. 0000_B 1 0001_B 2 0010_B 4 $\cdots_B$ ... 1110_B 32768 1111_B reserved
USTOVAL	[7:4]	rw	**Upstream Timeout Value** Upstream timeout value for the N-divider in the range of 1 to 16, expressed in number of upstream bit time lengths (the upstream bit time is the reciprocal value of the upstream baud rate). TimeOut = BitTime * $2^{(USTOPRE+1)}$ * (USTOVAL+1). Write to this bit field triggers new start of the watchdog timer.

Field	Bits	Type	Description
USTOEN	8	rw	**Upstream Timeout Interrupt Enable** Enable bit for the upstream timeout interrupt. The timout counter runs continuously independently of the USTOEN bit. The USTOEN enables only the interrupt generation. 0_B Disabled 1_B Enabled
USTF	9	rh	**Upstream Timeout Flag** Signals an upstream timer event. If set by software, the interupt is also triggered, if enabled. The watchdog timer runs continuously and sets the USTF flag at overflow, independtly from the enable bit. Therefore this bit must be cleared with the same write access which enables the interrupt. 0_B Disabled 1_B Enabled
USTC	10	w	**Upstream Timout Clear** Clears the USTF flag. Write only bit, reads as 0. 0_B No actioni 1_B Clear
USTS	11	w	**Upstream Timout Set** Sets the USTF flag. Write only bit, reads as 0. 0_B No action 1_B Set
UTASR	13	rw	**Upstream Timout Alternate Service Request** Selects if the interrupt signal is routed to the alternate service request node. See **Figure 21-29**. 0_B SR Multiplexer selected 1_B Alternate Service Request Node (SR4) selected
USTOIP	[15:14]	rw	**Upstream Timout Interrupt Node Pointer** USTOIP selects the service request output line SRn (n = 0-3) for the data frame interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
0	[31:16], 12	r	**Reserved** Read as 0; shall be written with 0.

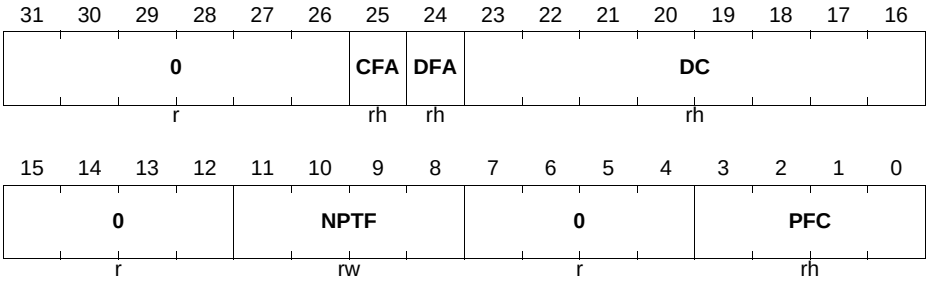
DSS

The Downstream Status Register DSS contains counter bit fields, status bits, and indicates the number of passive time frames.

>> **Registers Overview**

DSS

Downstream Status Register **(18_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
PFC	[3:0]	rh	**Passive Time Frame Counter** In Data Repetition Mode, this bit field indicates the count of passive time frames that are currently transmitted. In Triggered Mode PFC remains at 0000_B. 0000_B Data frame is transmitted. 0001_B First passive time frame is transmitted. 0010_B Second passive time frame is transmitted. $\ldots_B$ ... 1111_B Fifteenth passive time frame is transmitted.
NPTF	[11:8]	rw	**Number Of Passive Time Frames** This bit field indicates the number of passive time frames that are inserted in Data Repetition Mode between two data frames. 0000_B No passive time frame inserted. 0001_B One passive time frame inserted. 0010_B Two passive time frames inserted. $\ldots_B$ ... 1111_B Fifteen passive time frames inserted. *Note: NPTF is buffered in a shadow buffer at the start of each data frame.*

Field	Bits	Type	Description
DC	[23:16]	rh	**Downstream Counter** This bit field indicates the number of downstream shift clock periods that have been elapsed since the start of the current frame. 00_H No shift clock elapsed (after counter reset). 01_H 1 shift clock elapsed. $\ldots_H$ … $7F_H$ 127 shift clocks elapsed. DC is reset at the end of a downstream frame.
DFA	24	rh	**Data Frame Active** This bit indicates if a data frame is currently sent out. 0_B No data frame is currently sent out. 1_B A data frame is currently sent out.
CFA	25	rh	**Command Frame Active** This bit indicates if a command frame is currently sent out. 0_B No command frame is currently sent out. 1_B A command frame is currently sent out.
0	[7:4], [15:12], [31:26]	r	**Reserved** Read as 0; shall be written with 0.

DSDSL

The bit fields of the Downstream Select Data Low Register DSDSL determine the data source for each bit in shift register SRL.

>> **Registers Overview**

DSDSL
Downstream Select Data Source Low Register

Field	Bits	Type	Description
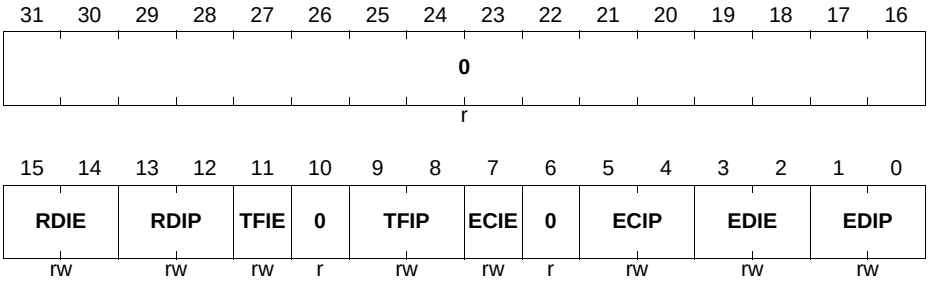
ENLx (x = 0-15)	x	rw	**Emergency Stop Enable for Bit x in SRL** This bit enables the emergency stop feature selectively for each SRL bit. If the emergency stop condition is met and enabled (ENLx = 1), the SRL[x] bit is of the data register DD.DDL[x] is used for the shift register load operation. 0_B Emergency stop feature for bit SRL[x] is disabled. 1_B The emergency stop feature for bit SRL[x] is enabled.
ENHx (x = 0-15)	x+16	rw	**Emergency Stop Enable for Bit x in SRH** This bit enables the emergency stop feature selectively for each SRH bit. If the emergency stop condition is met and enabled (ENHx = 1), the SRH[x] bit of the data register DD.DDH[x] is used for the shift register load operation. 0_B Emergency stop feature for bit SRH[x] is disabled. 1_B The emergency stop feature for bit SRH[x] is enabled.

ICR

The Interrupt Control Register ICR holds the interrupt enable bits and interrupt pointers of four MSC interrupts.

>> **Registers Overview**

ICR
Interrupt Control Register **(40_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
EDIP	[1:0]	rw	**Data Frame Interrupt Node Pointer** EDIP selects the service request output line SRn (n = 0-3) for the data frame interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
EDIE	[3:2]	rw	**Data Frame Interrupt Enable** This bit field determines the enable conditions for the data frame interrupt. 00_B Interrupt generation disabled 01_B An interrupt is generated when the last data bit has been shifted out. 10_B An interrupt is generated when the first data bit has been shifted out, but only if DSC.NDBL is not equal 00000_B. This means, at least one SRL bit must be shifted out for the first data bit shifted interrupt to become active. 11_B Interrupt generation disabled

Field	Bits	Type	Description
ECIP	[5:4]	rw	**Command Frame Interrupt Node Pointer** ECIP selects the service request output line SRn (n = 0-3) for the command frame interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
ECIE	7	rw	**Command Frame Interrupt Enable** This bit enables the command frame interrupt. 0_B Interrupt generation disabled. 1_B Interrupt generation enabled.
TFIP	[9:8]	rw	**Time Frame Interrupt Pointer** TFIP selects the service request output line SRn (n = 3-0) for the time frame interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
TFIE	11	rw	**Time Frame Interrupt Enable** This bit enables the time frame interrupt. 0_B Interrupt generation disabled. 1_B Interrupt generation enabled.
RDIP	[13:12]	rw	**Receive Data Interrupt Pointer** RDIP selects the service request output line SRn (n = 3-0) for the receive data interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected

Field	Bits	Type	Description
RDIE	[15:14]	rw	**Receive Data Interrupt Enable** This bit field determines the enable conditions for the receive data interrupt. 00_B Interrupt generation disabled. 01_B An interrupt is generated when data is received and written into the upstream data registers UDx (x = 0-3). 10_B An interrupt is generated as with RDIE = 01_B but only if the received data is not equal to 00_H. 11_B An interrupt is generated when data is received and written into register UD3.
0	6, 10, [31:16]	r	**Reserved** Read as 0; shall be written with 0.

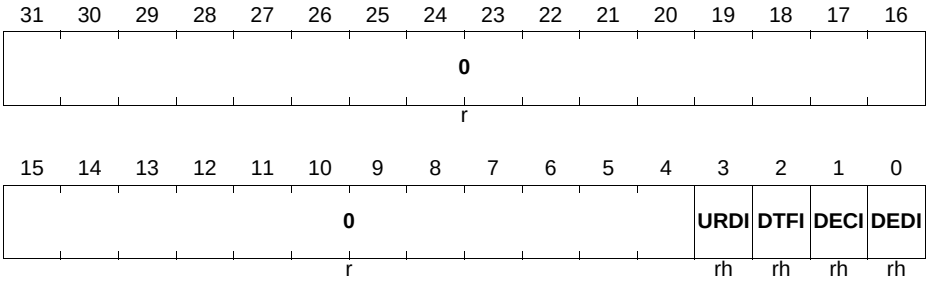
ISR

The Interrupt Status Register ISR holds the interrupt status flags that indicate an interrupt occurrence in downstream and upstream channels.

>> **Registers Overview**

ISR

Interrupt Status Register **(44_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DEDI	0	rh	**Data Frame Interrupt Flag** This flag is always set by hardware when a downstream channel data frame interrupt is generated. DEDI can be set or cleared by software when writing to register ISC with the appropriate bits ISC.SDEDI or ISC.CDEDI set.
DECI	1	rh	**Command Frame Interrupt Flag** This flag is always set by hardware when a downstream channel command frame interrupt is generated, whether or not it is enabled. DECI can be set or cleared by software when writing to register ISC with the appropriate bits SDECI or CDECI set.
DTFI	2	rh	**Time Frame Interrupt Flag** This flag is always set by hardware when a downstream channel time frame interrupt is generated, whether or not it is enabled. DTFI can be set or cleared by software when writing to register ISC with the appropriate bits SDTFI or CDTFI set.

Field	Bits	Type	Description
URDI	3	rh	**Receive Data Interrupt Flag** This flag is always set by hardware when an upstream channel receive data interrupt is generated, whether or not it is enabled. URDI can be set or cleared by software when writing to register ISC with the appropriate bits SURDI or CURDI set.
0	[31:4]	r	**Reserved** Read as 0; shall be written with 0.

ISC

The Interrupt Set Clear Register ISC is used to set or clear the MSC interrupt flags located in the Interrupt Status Register ISR. Reading ISC always returns 0000 0000$_H$.

>> **Registers Overview**

ISC
Interrupt Set Clear Register (48$_H$) Reset Value: 0000 0000$_H$

SURDI	19	w	**Set URDI Flag** 0_B No operation 1_B Bit ISR.URDI is set.
SDP	20	w	**Set DP Bit** 0_B No effect 1_B Bit DSC.DP is set.
SCP	21	w	**Set CP Flag** 0_B No operation 1_B Bit DSC.CP is set.
SDDIS	22	w	**Set DSDIS Flag** 0_B No operation 1_B Bit DSC.DSDIS is set.
0	[15:7], [31:23]	r	**Reserved** Read as 0; shall be written with 0.

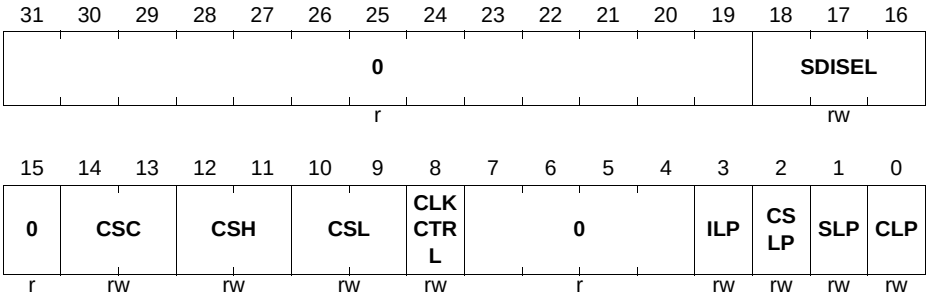
Note: When the ISC register is written with both bits (set and reset bit) for a specific interrupt flag, the clear operation takes place and the set operation is ignored.

OCR

The Output Control Register OCR determines the MSC input/output signal polarities, the chip select output signal assignment, and the serial output clock generation.

>> **Registers Overview**

OCR
Output Control Register **($4C_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CLP	0	rw	**FCLP Line Polarity** 0_B FCLP and FCL signal polarity is identical. FCLN signal has inverted FCL signal polarity. 1_B FCLP signal has inverted FCL signal polarity. FCLN and FCL signal polarities are identical.
SLP	1	rw	**SOP Line Polarity** 0_B SOP and SO signal polarity is identical. SON signal has inverted SO signal polarity. 1_B SOP signal has inverted SO signal polarity. SON and SO signal polarities are identical.
CSLP	2	rw	**Chip Selection Lines Polarity** 0_B EN[3:0] and ENL, ENH, ENC signal polarities are identical (high active). 1_B EN[3:0] signal polarities are inverted (low active) to the ENL, ENH, ENC signal polarities. Bit CSLP is buffered during a frame transmission. This means that any change of CSLP becomes valid first with the start of the next frame transmission.

Field	Bits	Type	Description
ILP	3	rw	**SDI Line Polarity** 0_B SDI and SI signal polarities are identical. 1_B SDI and SI signal polarities are inverted.
CLKCTRL	8	rw	**Clock Control** This bit determines the activation of clock output FCL. 0_B FCL is activated only during the active phases of data or command frames (not during passive time frames). 1_B FCL is always active whether or not a downstream frame is currently transmitted.
CSL	[10:9]	rw	**Chip Enable Selection for ENL** This bit field selects the chip enable output ENx that becomes active during the SRL active phase (ENL = 1) of a data frame. The active level of ENx is defined by bit CSLP. 00_B EN0 line is selected for ENL. 01_B EN1 line is selected for ENL. 10_B EN2 line is selected for ENL. 11_B EN3 line is selected for ENL.
CSH	[12:11]	rw	**Chip Enable Selection for ENH** This bit field selects the chip enable output ENx that becomes active during the SRH active phase (ENH = 1) of a data frame. The active level of ENx is defined by bit CSLP. 00_B EN0 line is selected for ENH. 01_B EN1 line is selected for ENH. 10_B EN2 line is selected for ENH. 11_B EN3 line is selected for ENH.
CSC	[14:13]	rw	**Chip Enable Selection for ENC** This bit field selects the chip enable output ENx that becomes active during the active phase (ENC = 1) of a command frame. The active level of ENx is defined by bit CSLP. 00_B EN0 line is selected for ENC. 01_B EN1 line is selected for ENC. 10_B EN2 line is selected for ENC. 11_B EN3 line is selected for ENC.

Field	Bits	Type	Description
SDISEL	[18:16]	rw	**Serial Data Input Selection** This bit field selects the source for the serial data input SDI of the upstream channel. 000_B SDI0 input is selected for SDI. 001_B SDI1 input is selected for SDI. 010_B SDI2 input is selected for SDI. 011_B SDI3 input is selected for SDI. 100_B SDI4 input is selected for SDI. 101_B SDI5 input is selected for SDI. 110_B SDI6 input is selected for SDI. 111_B SDI7 input is selected for SDI.
0	[7:4], 15, [31:19]	r	**Reserved** Read as 0; shall be written with 0.

DSDSLE

The bit fields of the Downstream Select Data Low Register DSDSL determine the data source for the upper 16 bits in the shift register SRL.

>> **Registers Overview**

DSDSLE

Downstream Select Data Source Low Extension Register

(60_H) **Reset Value: $0000\ 0000_H$**

SHx (x = 16-31)	[2*x-31 : 2*x-32]	rw	**Select Source for SRH** SHx determines which data source is used for the shift register bit SRH[x] during data frame transmission. 00_B SRH[x] is taken from data register DD.DDH[x]. 01_B Reserved. 10_B SRH[x] is taken from the ALTINH input line x. 11_B SRH[x] is taken from the ALTINH input line x in inverted state.

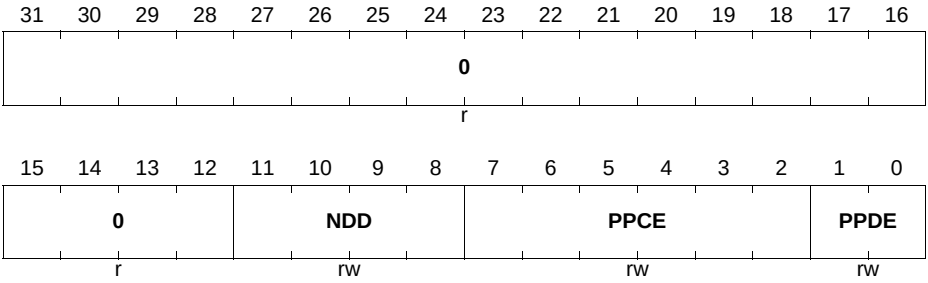
DSTE

The Downstream Control Enhanced Register is used to control the enhanced operation mode and frame layout of the downstream channel transmission.

>> **Registers Overview**

DSTE

Downstream Timing Extension Register (74_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
PPDE	[1:0]	rw	**Passive Phase Length at Data Frames Extension** Additional MSB bits extension of the PPD bit field.
PPCE	[7:2]	rw	**Passive Phase Length at Control Frames Extension** Additional MSB bits extension of the fixed length of 2 of the command frames passive phase. The final length is 2 + PPCE resulting in a range of 2 to 65. 000000_B 2 000001_B 3 $...{}_B$ ... 111111_B 65
NDD	[11:8]	rw	**N Divider Downstream** Defines the division ratio in the range of 1 to 16. 0000_B 1 0001_B 2 $...{}_B$ ... 1111_B 16
0	[31:12]	r	**Reserved** Read as 0; shall be written with 0.

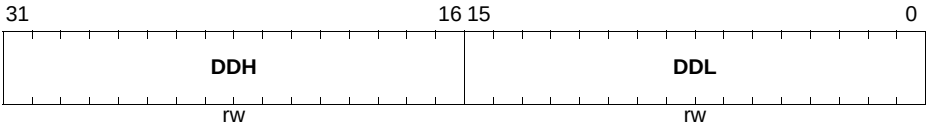
21.3.3 Data Registers

DD

The Downstream Data Register DD contains data to be transmitted during data frames.

>> **Registers Overview**

DD
Downstream Data Register **($1C_H$)** **Reset Value: 0000 0000_H**



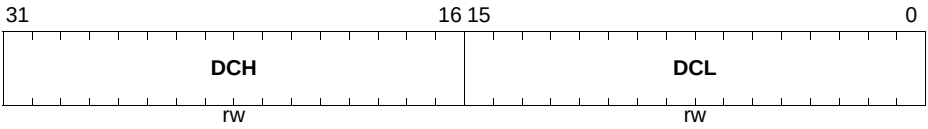
Field	Bits	Type	Description
DDL	[15:0]	rw	**Downstream Data for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a data frame.
DDH	[31:16]	rw	**Downstream Data for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a data frame.

DC

The Downstream Command Register DC contains command information to be transmitted during command frames.

>> **Registers Overview**

DC
Downstream Command Register **(20_H)** **Reset Value: 0000 0000_H**



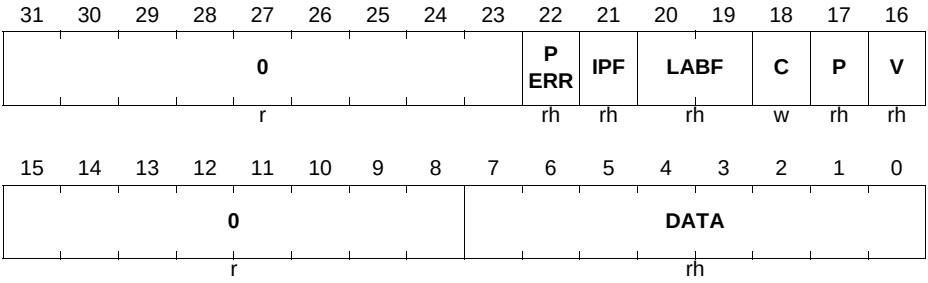
Field	Bits	Type	Description
DCL	[15:0]	rw	**Downstream Command for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a command frame.
DCH	[31:16]	rw	**Downstream Command for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a command frame.

UDx

The four Upstream Data Registers UDx store the content (data, addresses, received and calculated parity bit, parity error bit) of a received upstream channel data frame.

>> **Registers Overview**

UDx (x = 0-3)
Upstream Data Register x **(30_H+x*4_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DATA	[7:0]	rh	**Received Data** This bit field contains the 8-bit receive data.
V	16	rh	**Valid Bit** This bit is set by hardware when the received data is written to UDx. Writing bit C = 1 clears V. If hardware setting and software clearing of the valid bit occur simultaneously, bit V will be cleared.
P	17	rh	**Parity Bit** This flag contains the parity bit that has been received with the data frame.
C	18	w	**Clear Bit** 0_B No operation. 1_B Bit V is cleared. C is always read as 0.
LABF	[20:19]	rh	**Lower Address Bit Field** This bit field contains the two address bits A[1:0] of the 4-bit address field (16-bit data frame). If 12-bit data frame is selected, LABF is always set to 00_B.

Field	Bits	Type	Description
IPF	21	rh	**Internal Parity Flag** This bit contains the parity bit that has been calculated in the MSC during data frame reception.
PERR	22	rh	**Parity Error** This bit indicates if a start bit error, parity error, or stop bit error occurred during frame reception. 0_B No error detected. 1_B Error detected.
0	[15:8], [31:23]	r	**Reserved** Read as 0; shall be written with 0.

21.3.4 Extension Registers

This sub-chapter describes the registers related to 64-bit extension of the MSC module.

ESRE

The Emergency Stop Extension Register ESRE determines which bits of SRL and SRH are enabled for emergency operation.

>> **Registers Overview**

ESRE
Emergency Stop Extension Register (68_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

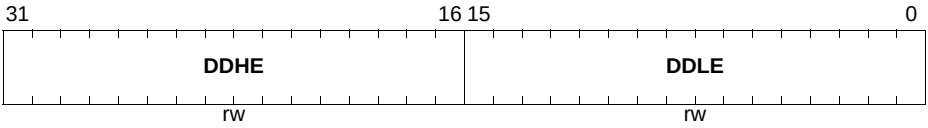
Field	Bits	Type	Description
ENLx (x = 16-31)	x-16	rw	**Emergency Stop Enable for Bit x in SRL** This bit enables the emergency stop feature selectively for each SRL bit. If the emergency stop condition is met and enabled (ENLx = 1), the SRL[x] bit is of the data register DD.DDL[x] is used for the shift register load operation. 0_B Emergency stop feature for bit SRL[x] is disabled. 1_B The emergency stop feature for bit SRL[x] is enabled.
ENHx (x = 16-31)	x	rw	**Emergency Stop Enable for Bit x in SRH** This bit enables the emergency stop feature selectively for each SRH bit. If the emergency stop condition is met and enabled (ENHx = 1), the SRH[x] bit of the data register DD.DDH[x] is used for the shift register load operation. 0_B Emergency stop feature for bit SRH[x] is disabled. 1_B The emergency stop feature for bit SRH[x] is enabled.

DDE

The Downstream Data Extension Register DDE contains data to be transmitted during data frames.

>> **Registers Overview**

DDE
Downstream Data Extension Register ($6C_H$) **Reset Value: $0000\ 0000_H$**



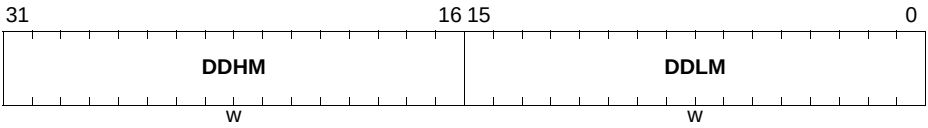
Field	Bits	Type	Description
DDLE	[15:0]	rw	**Downstream Data Extension for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a data frame.
DDHE	[31:16]	rw	**Downstream Data Extension for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a data frame.

DDM

The Downstream Data Mirror Register DDM provides alternative address for the DD register. The purpose of this alternative address is to provide convenient way to write up to 64 bit data blocks to the MSC module by using DMA with automatic address increment and wrap arround. The DMA writes first to the DDE register, and then to the DDM register, which trigers the data transfer in the same way as a write to the DD register.

>> **Registers Overview**

DDM
Downstream Data Mirror Register (70_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
DDLM	[15:0]	w	**Downstream Data Mirror for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a data frame.
DDHM	[31:16]	w	**Downstream Data Mirror for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a data frame.

21.3.5 Asynchronous Block Registers

ABC

The Asynchronous Block Configuration register ABC contains all the bit fields related to the ABRA block.

>> **Registers Overview**

>> **Configuring the ABRA block**

ABC

Asynchronous Block Configuration Register (80_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ABB	**0**	**CLKSEL**			**UIE**	**UFM**		**UNF**	**0**	**UASR**	**UIP**		**NDA**		
rw	r	rw			rw	w		r	r	rw	rw		rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OIE	**OFM**		**OVF**	**0**	**OASR**	**OIP**		**HIGH**				**LOW**			
rw	w		r	r	rw	rw		rw				rw			

Field	Bits	Type	Description
LOW	[3:0]	rw	**Duration of the Low Phase of the Shift Clock** Defines the duration of the low phase of the shift clock in periods of f_A in the range of 1 to 16. 0000_B 1 0001_B 2 …$_B$ … 1111_B 16
HIGH	[7:4]	rw	**Duration of the High Phase of the Shift Clock** Defines the duration of the high phase of the shift clock in periods of f_A in the range of 1 to 16. 0000_B 1 0001_B 2 …$_B$ … 1111_B 16

Field	Bits	Type	Description
OIP	[9:8]	rw	**Overflow Interrupt Node Pointer** OIP selects the service request output line SRn (n = 0-3) for the overflow interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
OASR	10	rw	**Overflow Alternate Service Request** Selects if the interrupt signal is routed to the alternate service request node. See **Figure 21-29**. 0_B SR Multiplexer selected 1_B Alternate Service Request Node (SR4) selected
OVF	12	r	**Overflow Flag** Indicates if overflow error has occured. 0_B No overflow error 1_B Overflow error
OFM	[14:13]	w	**Overflow Flag Modify** Sets or clears the overflow flag OF. 00_B No action 01_B Set (and triggers the overflow interrupt if enabled) 10_B Clear (additionally flushes the ABRA FIFO and resets the bit counter) 11_B No action
OIE	15	rw	**Overflow Interrupt Enable** Enables or disables the path of the interrupt signal towards the interrupt node. If enabled, an overflow event triggers an interrupt, and if disabled then not. The OF flag always indicates the occurence of an overflow event, independently of OIE. 0_B Overflow interrupt disabled 1_B Overflow interrupt enabled
NDA	[18:16]	rw	**N Divider ABRA** Defines the division ratio in the range of 1 to 8. 000_B 1 001_B 2 $\cdots_B$ ... 111_B 8

Field	Bits	Type	Description
UIP	[20:19]	rw	**Underflow Interrupt Node Pointer** UIP selects the service request output line SRn (n = 0-3) for the underflow interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
UASR	21	rw	**Underflow Alternate Service Request** Selects if the interrupt signal is routed to the alternate service request node. See **Figure 21-29**. 0_B SR Multiplexer selected 1_B Alternate Service Request Node (SR4) selected
UNF	23	r	**Underflow Flag** Indicates if overflow error has occured. 0_B No overflow error 1_B Overflow error
UFM	[25:24]	w	**Underflow Flag Modify** Sets or clears the overflow flag UF. 00_B No action 01_B Set (also triggers the underflow interrupt if enablede) 10_B Clear (additionally flushes the ABRA FIFO and resets the bit counter) 11_B No action
UIE	26	rw	**Underflow Interrupt Enable** Enables or disables the path of the interrupt signal towards the interrupt node. If enabled, an overflow event triggers an interrupt, and if disabled then not. The UF flag always indicates the occurence of an overflow event, independently of UIE. 0_B Overflow interrupt disabled 1_B Overflow interrupt enabled
CLKSEL	[29:27]	rw	**Clock Select** Selects the clock source for the ABRA block. 000_B no clock 001_B f_{SPB} 010_B f_{SRI} 100_B f_{ERAY} **others**, reserved (no clock)

Field	Bits	Type	Description
ABB	31	rw	**Asynchronous Block Bypass** Defines if the asynchronous block and the n-divider of the MSC downstream path (located parallel to the fractional divider) are used or not. If bypassed, then also disabled. 0_B Bypassed and disabled 1_B Not bypassed and active
0	11, 22, 30	r	**Reserved** Read as 0; shall be written with 0.

*Note: The reconfiguration of the clock source has to be done by using two writes: first a write of zero to the CLKSEL bitfield, and then a second write defining the new clock source. Between the first and the second write a delay of minimum 4 * (1/f_A) + 2 * (1/f_{CLC}) must be inserted by software, where f_A is the frequency being switched off with the first write. Exception: in case that the f_{CLC} is selected as f_A (CSR.CLKSEL = 1), no delay cycles between the writes are necessary. In both cases, simply using one write defining the new clock source is not allowed.*

21.4 MSC Module Implementation

This section describes the MSC module interface as implemented in the TC27x. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

21.4.1 Module Identification Registers

The reset value of the ID module identification register is 0028 C01X$_H$.

21.4.2 BPI_FPI Module Registers (Single Kernel Configuration)

21.4.2.1 System Registers

Figure 21-38 shows all registers associated with the BPI_FPI module, configured for one kernel.

BPI_FPI Registers Overview

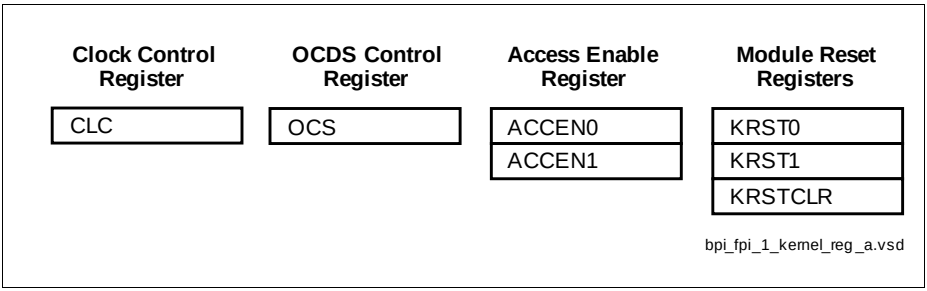


Figure 21-38 BPI_FPI Registers

The writes of the bus masters to the MSC module is controlled by Acces Protection regigisters ACCENx.

The MSC implements two ACCENx registers, ACCEN0 and ACCEN1.

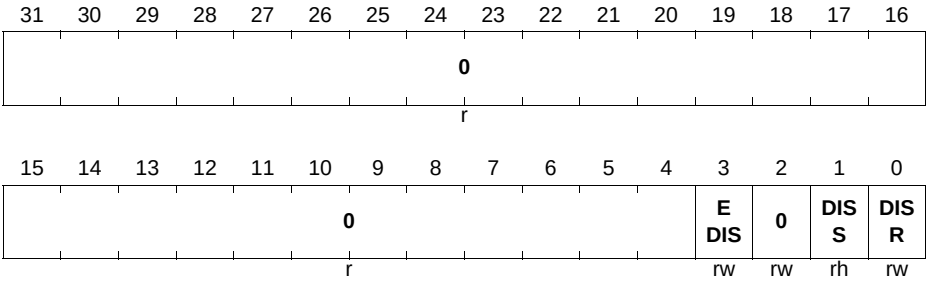
The ACCENx registers are protected by Safety Endinit mechanism.

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the $f_{<>}$ module clock signal, sleep mode and disable mode for the module.

>> **Registers Overview**

CLC
Clock Control Register **(00_H)** **Reset Value: $0000\ 0003_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
0	[31:4]	r	**Reserved** Read as 0; shall be written with 0.
0	2	rw	**Reserved** Read as 0; shall be written with 0.

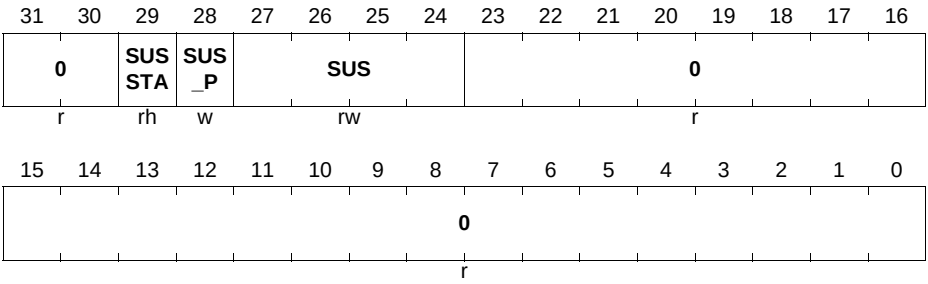
OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode

>> **Registers Overview**

OCS
OCDS Control and Status **($E8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. 2_H Soft suspend **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

>> **Registers Overview**

ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the

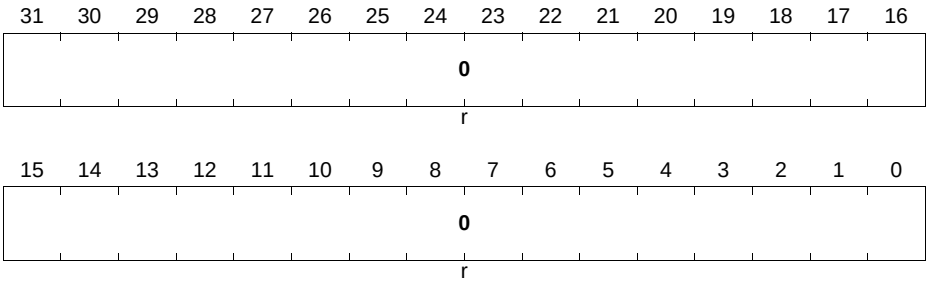
1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

>> **Registers Overview**

ACCEN1
Access Enable Register 1 **($F8_H$)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; shall be written with 0.

Kernel Reset Register 0 (KRST0)

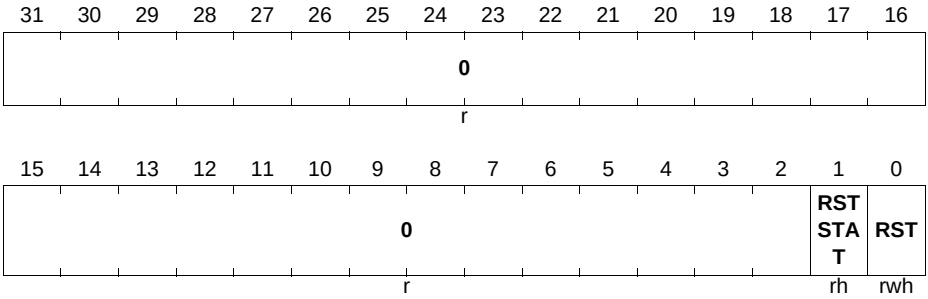
The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

>> **Registers Overview**

KRST0
Kernel Reset Register 0 **($F4_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.

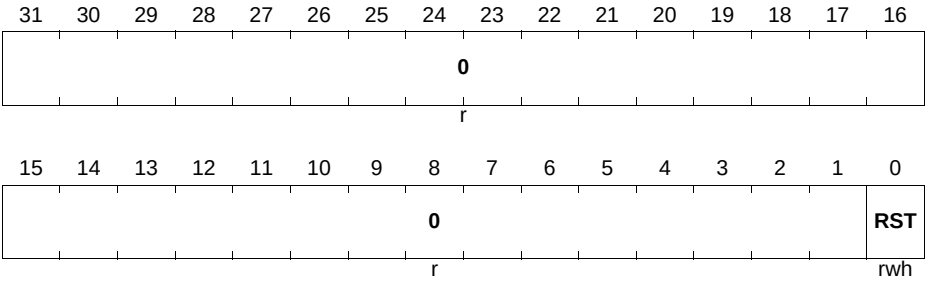
Field	Bits	Type	Description
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; shall be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

>> **Registers Overview**

KRST1
Kernel Reset Register 1 **($F0_H$)** **Reset Value: $0000\ 0000_H$**



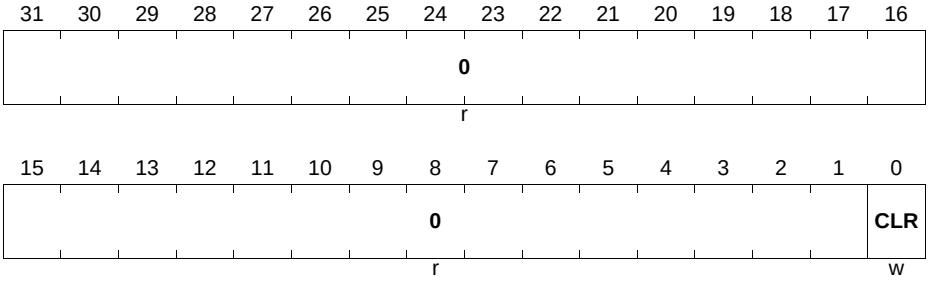
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; shall be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

>> **Registers Overview**

KRSTCLR
Kernel Reset Status Clear Register (EC_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; shall be written with 0.

21.4.3 Interface Connections of the MSC Module

The MSC module is supplied with a separate clock control, address decoding, and interrupt control logic. The service request outputs are connected with the interrupt nodes in the Interrupt Router module. Outputs of the GTM module are connected to the alternate input buses ALTINL/ALTINH. The emergency stop output from the SCU controls the corresponding inputs of MSC0 module.

The serial data and clock outputs of the downstream channels of the MSC module are connected to combined GPIO/LVDS differential output drivers. Details about these four pins are defined in the ports chapter.

21.4.4 MSC Module-Related External Registers

Figure 21-39 summarizes the module-related external registers which are required for MSC programming (see also **Figure 21-37** for the module kernel specific registers). Generally, additionally to programming the MSC kernel and BPI registers, the Fractional Divider, the ports registers located in the Ports module and interrupt registers located in the Interrupt Router module.

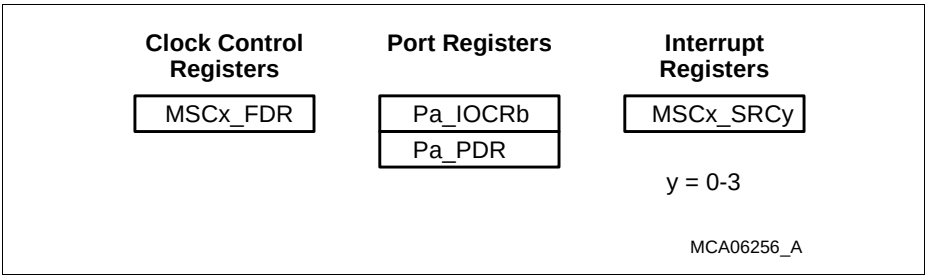


Figure 21-39 MSC Implementation-specific Special Function Registers

21.4.5 Clock Control

The following section describes the clock control and the baud rate generation of the MSC module.

The MSC module is provided with two independent clock signals (**Figure 21-40**):

- f_{CLC}
  This is the module clock that is used inside the MSC kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{CLC} is always identical to the system clock frequency f_{SPB}. The clock control register MSC_CLC makes it possible to enable/disable f_{CLC} under certain conditions.
- f_{MSC}
  This clock is the module clock that is used inside the MSC for baud rate generation of the serial upstream and downstream channel. The fractional divider register MSC_FDR controls the frequency of f_{MSC} and makes it possible to enable/disable it independent of f_{CLC}.
- f_{MSCA}
  This clock is the downstream clock which is used together with the ABRA block. In this case, the upstream baud rate can be fine-tuned with the fractional divider, and the downstream channel frequency is configured with an n-divider.

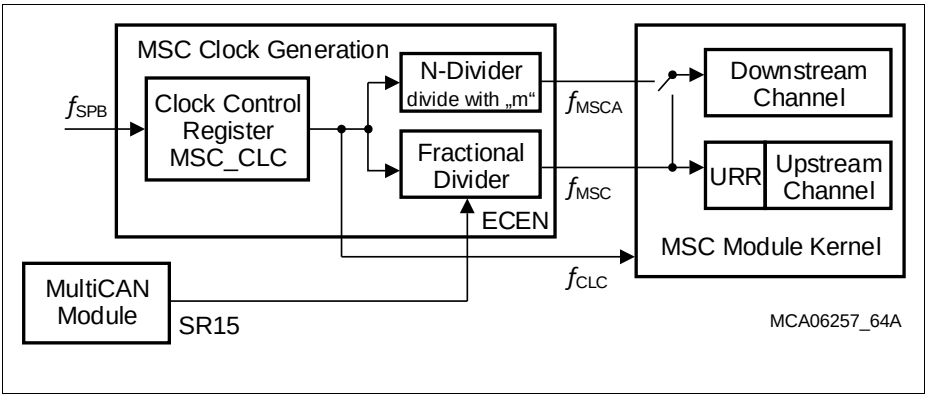

Figure 21-40 MSC Module Clock Generation

21.4.5.1 Clock Control Without the ABRA Block

Not using the ABRA block is the standard, compatibility use-case, which guarantees the full compatibility with the standard MSC module not containing the ABRA block. The clock generation is therefore identical with the standard MSC clock generation. The additional N-Divider (dividing with the division factor named “m”) is not used. Only the fractional divider is used (using the factor named “n” in the formulas below).

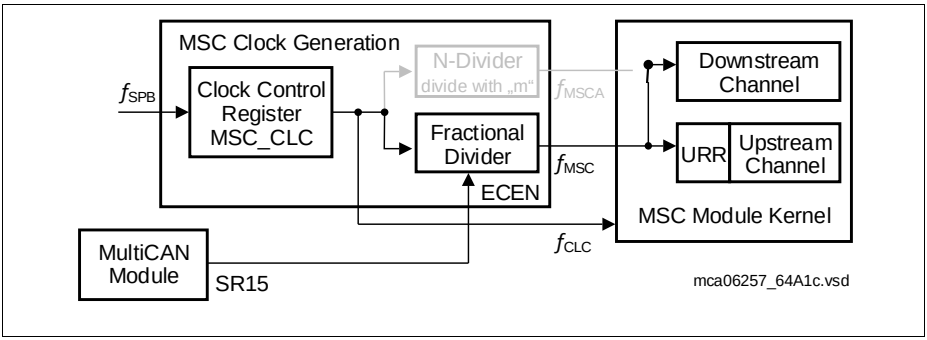

Figure 21-41 MSC Module Clock Generation

The following two formulas define the frequency of f_{MSC}:

$$f_{MSC} = f_{SPB} \times \frac{1}{n} \quad \text{with n = 1024 - MSC.FDR.STEP} \tag{21.4}$$

$$f_{MSC} = f_{SPB} \times \frac{n}{1024} \quad \text{with n = 0-1023} \tag{21.5}$$

Downstream Channel Baud Rate

As the clock signal FCL of the synchronous downstream channel is always half the frequency of f_{MSC}, the resulting downstream channel baud rate is defined by:

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{1}{2 \times (1024 - \text{MSC.FDR.STEP})} \quad (21.6)$$

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{\text{MSC.FDR.STEP}}{2 \times 1024} \quad (21.7)$$

Upstream Channel Baud Rate

The baud rate of the asynchronous upstream channel is derived from the module clock f_{MSC} by a programmable clock divider selected by bit field USR.URR (see also **Equation (21.3)** on **Page 21-28**). The divide factor DF can be at minimum 4 and at maximum 256.

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{1}{DF \times (1024 - \text{MSC.FDR.STEP})} \quad (21.8)$$

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{\text{MSC.FDR.STEP}}{DF \times 1024} \quad (21.9)$$

Equation (21.4), **Equation (21.6)**, and **Equation (21.8)** are valid for normal divider mode (FDR.DM = 01_B). **Equation (21.5)**, **Equation (21.7)**, and **Equation (21.9)** are valid for fractional divider mode (FDR.DM = 10_B).

21.4.5.2 Clock Control when using the ABRA Block

Using the ABRA block makes additional considerations regarding the baud-rate adjustments neccessary.

An additional N-Divider **DSTE**.NDD is used for configuring the intermediate downstream baud rate the MSC module is using for writing to the ABRA block (dividing the f_{SPB} with the integer division factor named “m” in the formulas below). The final output downstream baud rate is configured in the ABRA block itself. The following restriction applies: the ABRA output downstream baud rate is between half and whole intermediate baud rate.

When ABRA block is active, the fractional divider **FDR**.STEP is used only for adjusting the upstream baud rate (using the factor named “n” in the formulas below).

Attention: The following restriction applies: the upstream baud rate must be less than one tenth of the f_{SPB}. See also Upstream Channel.

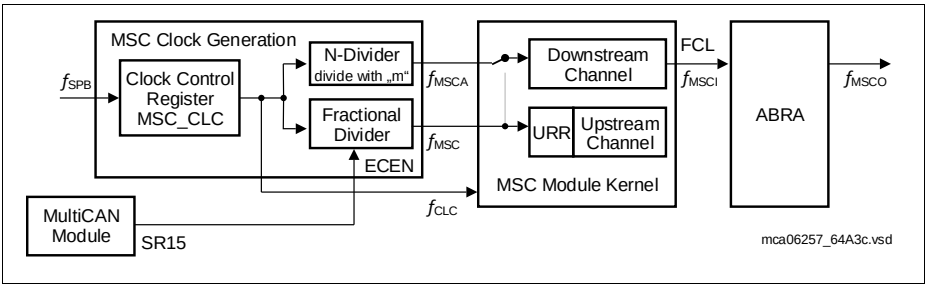

Figure 21-42 MSC Module Clock Generation

The following two formulas define the frequency of f_{MSC}:

$$f_{MSC} = f_{SPB} \times \frac{1}{n} \text{ with n = 1024 - MSC.FDR.STEP} \quad (21.10)$$

$$f_{MSC} = f_{SPB} \times \frac{n}{1024} \text{ with n = 0-1023} \quad (21.11)$$

The following formula defines the frequency of f_{MSCA}:

$$f_{MSCA} = f_{SPB} \times \frac{1}{m} \text{ with m = 1 - 16} \quad (21.12)$$

Intermedate Downstream Channel Baud Rate

When the ABRA block and the downstream N-divider are enabled with **ABC**.ABB, the intermediate clock signal FCL of the synchronous downstream channel going into the ABRA block is always half the frequency of f_{MSCA}:

$$\text{Baud rate}_{MSCA} = f_{SPB} \times \frac{1}{2 \times m} \quad (21.13)$$

The final output baud rate f_{MSCO} can be calculated as described in **Output Baud Rate**.

Upstream Channel Baud Rate

The baud rate of the asynchronous upstream channel is derived from the module clock f_{MSC} by a programmable clock divider selected by bit field USR.URR (see also **Equation (21.3)** on **Page 21-28**). The divide factor DF can be at minimum 4 and at maximum 256. Nevertheless, the minimum DF factor when using ABRA block should be 8. See the note on **Page 21-24**.

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{1}{DF \times (1024 - MSC.FDR.STEP)} \quad (21.14)$$

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{MSC.FDR.STEP}{DF \times 1024} \quad (21.15)$$

Equation (21.10), **Equation (21.11)**, and **Equation (21.14)** are valid for normal divider mode (FDR.DM = 01_B). **Equation (21.11)** and **Equation (21.15)** are valid for fractional divider mode (FDR.DM = 10_B).

Example for Setting the Fractional Divider

This example shows how to receive upstream frames generated from 40MHz downstream clock, when the module baud-rate fequency is 100MHz/2=50MHz. The fractional divider is used to adjust the FCL clock of 50MHz to FCL clock of 40MHz, that is, it multiplies with 4/5. The best approximation of 4/5 with x/1024 is for x=819, giving an error of 0.025%. So in this case, the optimal setting for FDR.STEP is 819. In the next stage of the divider cascade, the DF power-of-two-divder divides the clock further to the final baud rate, matching the baud rate generated by the MSC slave device.

21.4.5.3 Fractional Divider Register

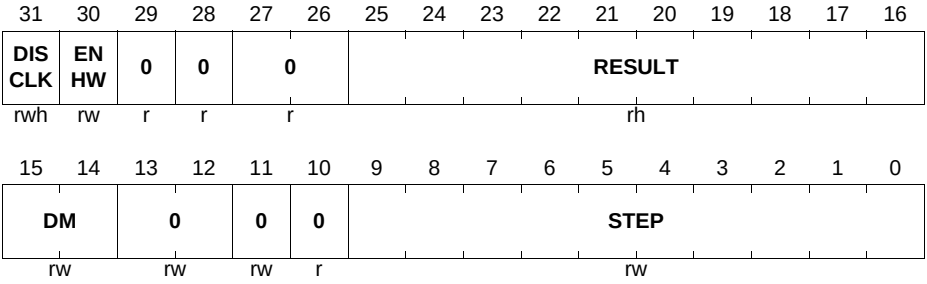
FDR

The Fractional Divider Register controls the clock rate of the shift clock f_{MSC}.

>> **Registers Overview**

FDR

Fractional Divider Register **($0C_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
DM	[15:14]	rw	**Divider Mode** DM selects normal or fractional divider mode.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.
ENHW	30	rw	**Enable Hardware Clock Control** Controls operation of ECEN input and DISCLK bit.
DISCLK	31	rwh	**Disable Clock** Hardware controlled disable for f_{MSC} signal.
0	10, [27:26], 28, 29	r	**Reserved** Read as 0; shall be written with 0.
0	11, [13:12]	rw	**Reserved** rw bit with no function. Read as 0; shall be written with 0.

21.4.6 Port Control

MSC clock and data output lines are connected to dedicated LVDS differential output drivers. Some of the MSC module I/O lines are connected to I/O ports and therefore controlled in the port logic.

The following port control operations selections must be executed for these I/O lines:

- Input/output function selection (IOCR registers)
- Pad driver characteristics selection for the outputs (PDR registers)

21.4.7 On-Chip Connections

This section describes the on-chip connections of the MSCx modules.

21.4.7.1 EMGSTOPMSC Signal (from SCU)

The emergency stop input signal EMGSTOPMSC of the MSCx modules is connected to the output signal of the emergency stop input control logic. This logic is located in the SCU. Its functionality is controlled by the SCU emergency stop register.

Note: If the emergency stop signal is used by the MSC module, setting the SCU.EMSR.MODE=0 is mandatory. MODE=1 is not allowed to be used with the MSC module.

21.4.7.2 Interrupt Service Requests

All four service request outputs SR[4:0] are connected to the Interrupt Router Module. There they are routed further to a CPU or a DMA. The MSCx_SRCy registers are also located in the IR (Interrrupt Router) Module.

21.4.7.3 Connections to Ports / Pins

These connections are described in the chapters regarding the ports and the pinning.

Unused SDI signal are tied high.

21.4.7.4 GTM Connections

Each MSC module is connected to up to 64 TOM or ATOM outputs of the GTM module. For more detailed description of the connections for each derivative, see the section “MSC Connections” in the GTM chapter.

Table 21-11 GTM to MSC Connections

MSC Input	GTM Output
MSC0_ALTINL[15:0]	GTM_MSC0ALTINL[15:0]
MSC0_ALTINLE[15:0]	GTM_MSC0ALTINH[15:0]
MSC0_ALTINH[15:0]	GTM_MSC0ALTINH[15:0]
MSC0_ALTINHE[15:0]	GTM_MSC0ALTINL[15:0]
MSC1_ALTINL[15:0]	GTM_MSC1ALTINL[15:0]
MSC1_ALTINLE[15:0]	GTM_MSC1ALTINH[15:0]
MSC1_ALTINH[15:0]	GTM_MSC1ALTINH[15:0]
MSC1_ALTINHE[15:0]	GTM_MSC1ALTINL[15:0]

21.5 Use Case Example Micro Second Channel (MSC)

This section provides a code example for the MSC module to give an overview about the core functionality. It describes how to send data frames continuously without any software interaction, called data repetition mode. The MSC module contains two MSC serial interfaces, MSC 0 and MSC 1, each is able to connect up to four external power devices. This examples uses interface MSC 0.

Each interface can send command and data frames (see also 25.1.2.1 Frame Formats and Definitions(LINK)) via downstream channel. Between each data frame one or more passive frames can be inserted (see also Figure 25-9, Data Repetitions Mode Frame Examples (LINK)). This example realizes sending out only data frames in repetition mode with one passive frame in between. The module has more features than the example shows. For further details please see user's manual.

The MSC module can also receive frames with the upstream channel. These frames are usually status frames from the external devices. The example keeps the focus on sending out via downstream channel so the upstream channel is not part of this chapter. The initialization process follows the following order:

1. Enable MSC 0
2. Initialize MSC 0 for down streaming
3. Start sending

Step description to initialize the MSC module:

(Line 1) reset ENDINIT to get access to ENDINIT protected registers. (see also ENDINIT protection chapter 8.9.3(LINK)).

(Line 2) enable control of the module, in clock control register CLC (LINK).

(Line 3) read back (dummy variable has to be defined). The reading process ensures that the write process from line 2 is done.

(Line 4) This line loads the fractional divider register FDR(LINK). DM=01 sets the module to normal divider mode while STEP defines the Baudrate.

Note: Assuming f_{clc}=100MHz and STEP=3FE --> Bautrate =25 Mbaud

(Line 5) set ENDINIT to lock the protected register again.

(Line 6) This line loads the downstream control register DSC (LINK). TM=1 sets the module to data repetition mode, NDBL and NDBH are defining the length of the SRL and SRH active phase, here set to 15 bit(see also Figure 25-6(LINK)). PPD=2 sets the length of the passive frame to 2 x t_{FCL} and DIDIS=1 disables sending. Sending will be enabled after initialization.

(Line 7) This line set the number of passive time frames in the downstream status register DSS (LINK). NPTF=1 --> one passive time frame gets inserted.

(Line 8) The data gets loaded in the downstream data register DD (LINK). The data itself is here just an example.

(Line 9) This line resets DIDIS, so the module starts sending out data and passive time frames.

Initialization of the MSC module:

```
// enable MSC 0
(1)  SCU_vResetENDINIT (0);     // enable ENDINIT reg
(2)  MSC0_CLC = 0x000;          // disable module control
(3)  dummy = MSC0_CLC;          // read to check the made changes
(4)  MSC0_FDR = (1 << 14) | 0x3FE;   // DM=01, STEP=3FE
(5)  SCU_vSetENDINIT (0);       // lock ENDINIT reg
// Initialize MSC 0 for down streaming
(6)  MSC0_DSC = 0x02009081; //PPD=2,DSDIS=1,NDBH=16,NDBL=16,TM=1
(7)  MSC0_DSS = (1 << 8);       // NPTF=1
(8)  MSC0_DD = 0x5555AAAA;      // downstream data (example)
// Start sending
(9)  MSC0_DSC |= (1 << 15);     // DIDIS=0
```

22 Controller Area Network Controller (MultiCAN+)

This chapter describes the MultiCAN+ controller of the TC27x. It contains the following sections:

- CAN basics (see **Page 22-2**)
- Overview of the CAN Module in the TC27x (see **Page 22-12**)
- CAN Flexible Data Rate in TC27x (see **Page 22-16**)
- Functional description of the MultiCAN+ Kernel (see **Page 22-18**)
- MultiCAN+ Kernel register description (see **Page 22-72**)
- TC27x implementation-specific details (port connections and control, interrupt control, address decoding, clock control, see **Page 22-150**).

Table 22-1 Fixed Module Constants

Constant	Description
n_objects	**Number of Message Objects available.**
n_interrupts	**Number of Interrupt Output Lines available.**
n_pendings **n_pendingregs**	**Number of Message Pending Bits available.** There are n_pendings/32 message pending registers.
n_lists	**Number of Lists available for allocation of Message Objects.**
n_nodes	**Number of CAN Nodes available** As each CAN node has its own list in addition to the list of un-allocated elements, the relation n_nodes < n_lists is true.

22.1 CAN Basics

CAN is an asynchronous serial bus system with one logical bus line. It has an open, linear bus structure with equal bus participants called nodes. A CAN bus consists of two or more nodes.

The bus logic corresponds to a “wired-AND” mechanism. Recessive bits (equivalent to the logic 1 level) are overwritten by dominant bits (logic 0 level). As long as no bus node is sending a dominant bit, the bus is in the recessive state. In this state, a dominant bit from any bus node generates a dominant bus state. The maximum CAN bus speed is, by definition, 1 Mbit/s. This speed limits the CAN bus to a length of up to 40 m. For bus lengths longer than 40 m, the bus speed must be reduced.

The binary data of a CAN frame is coded in NRZ code (Non-Return-to-Zero). To ensure re-synchronization of all bus nodes, bit stuffing is used. This means that during the transmission of a message, a maximum of five consecutive bits can have the same polarity. Whenever five consecutive bits of the same polarity have been transmitted, the transmitter will insert one additional bit (stuff bit) of the opposite polarity into the bit stream before transmitting further bits. The receiver also checks the number of bits with the same polarity and removes the stuff bits from the bit stream (= destuffing).

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC Sequence. The stuff bits will be inserted at fixed positions.

22.1.1 Addressing and Bus Arbitration

In the CAN protocol, address information is defined in the identifier field of a message. The identifier indicates the contents of the message and its priority. The lower the binary value of the identifier, the higher is the priority of the message.

For bus arbitration, CSMA/CD with NDA (Carrier Sense Multiple Access/Collision Detection with Non-Destructive Arbitration) is used. If bus node A attempts to transmit a message across the network, it first checks that the bus is in the idle state (“Carrier Sense”) i.e. no node is currently transmitting. If this is the case (and no other node wishes to start a transmission at the same moment), node A becomes the bus master and sends its message. All other nodes switch to receive mode during the first transmitted bit (Start-Of-Frame bit). After correct reception of the message (acknowledged by each node), each bus node checks the message identifier and stores the message, if required. Otherwise, the message is discarded.

If two or more bus nodes start their transmission at the same time (“Multiple Access”), bus collision of the messages is avoided by bit-wise arbitration (“Collision Detection / Non-Destructive Arbitration” together with the “Wired-AND” mechanism, dominant bits override recessive bits). Each node that sends also reads back the bus level. When a recessive bit is sent but a dominant one is read back, bus arbitration is lost and the transmitting node switches to receive mode. This condition occurs for example when the message identifier of a competing node has a lower binary value and therefore sends a

message with a higher priority. In this way, the bus node with the highest priority message wins arbitration without losing time by having to repeat the message. Other nodes that lost arbitration will automatically try to repeat their transmission once the bus returns to idle state. Therefore, the same identifier can be sent in a Data Frame only by one node in the system. There must not be more than one node programmed to send Data Frames with the same identifier.

Standard message identifier has a length of 11 bits. CAN specification 2.0B extends the message identifier lengths to 29 bits, i.e. the extended identifier.

22.1.2 CAN Frame Formats

Four different data frame formats are supported which differ in the length of the Arbitration Field and Control Field:

- Classical CAN Base format: 11-bit long identifier, constant bit rate
- Classical CAN Extended format: 29-bit long identifier, constant bit rate
- CAN FD Base format: 11-bit long identifier, dual bit rate
- CAN FD Extended format: 29-bit long identifier, dual bit rate

In addition for Classical CAN remote frames exist, for 11-bit and 29bit identifiers.

22.1.3 CAN Frame Types

There are three types of CAN frames:

- Data Frames
- Remote Frames
- Error Frames

A Data Frame contains a Data Field of 0 to 8 bytes in length. A Remote Frame contains no Data Field and is typically generated as a request for data (e.g. from a sensor). Data and Remote Frames can use an 11-bit “Standard” identifier or a 29-bit “Extended” identifier. An Error Frame can be generated by any node that detects a CAN bus error.

22.1.3.1 Data Frames

There are four types of Data Frames defined (see **Figure 22-1**):

- Standard Data Frame Classical CAN Format
- Extended Data Frame Classical CAN Format
- Standard Data Frame CAN FD Format
- Extended Data Frame CAN FD Format

11-bit Data Frame (CAN Format)

A Data Frame begins with the Start-Of-Frame bit (SOF = dominant level) for hard synchronization of all nodes. The SOF is followed by the Arbitration Field consisting of 12 bits, the 11-bit identifier (reflecting the contents and priority of the message), and the

RTR (Remote Transmission Request for Classical CAN) bit. With RTR at dominant level, the frame is marked as Data Frame. With RTR at recessive level, the frame is defined as a Remote Frame.

The next field is the Control Field consisting of 6 bits. The first bit of this field is the IDE (Identifier Extension) bit and is at dominant level for the Standard Data Frame. The following bit is reserved and defined as a dominant bit. The remaining 4 bits of the Control Field are the Data Length Code (DLC) that specifies the number of bytes in the Data Field. The Data Field can be 0 to 8 bytes wide. The Cyclic Redundancy (CRC) Field that follows the data bytes is used to detect possible transmission errors. It consists of a 15-bit CRC sequence completed by a recessive CRC delimiter bit.

The final field is the Acknowledge Field. During the ACK Slot, the transmitting node sends out a recessive bit. Any node that has received an error free frame acknowledges the correct reception of the frame by sending back a dominant bit, regardless of whether or not the node is configured to accept that specific message. This behavior assigns the CAN protocol to the “in-bit-response” group of protocols. The recessive ACK delimiter bit, which must not be overwritten by a dominant bit, completes the Acknowledge Field.

Seven recessive End-of-Frame (EOF) bits finish the Data Frame. Between any two consecutive frames, the bus must remain in the recessive state for at least 3 bit times (called Inter Frame Space). If after the Inter Frame Space, no other nodes attempt to transmit the bus remains in idle state with a recessive level.

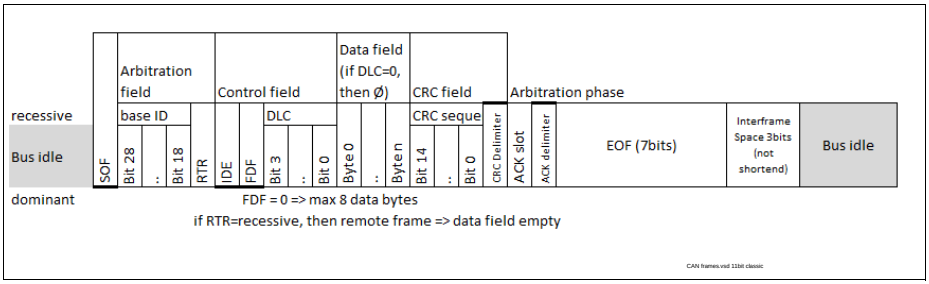


Figure 22-1 Classical 11bit ID CAN Data Frame

Extended Data Frame (Classical CAN Format)

In the Extended CAN Data Frame, the message identifier of the standard frame has been extended to 29-bit. A split of the extended identifier into two parts, an 11-bit least significant section (as in classical CAN frame) and an 18-bit most significant section, ensures that the Identifier Extension bit (IDE) can remain at the same bit position in both standard and extended frames.

In the Extended CAN Data Frame, the SOF bit is followed by the 32-bit Arbitration Field. The first 11 bits are the least significant bits of the 29-bit Identifier (“Base-ID”). These 11 bits are followed by the recessive Substitute Remote Request (SRR) bit. The SRR is

further followed by the recessive IDE bit, which indicates the frame to be an Extended CAN frame. If arbitration remains unresolved after transmission of the first 11 bits of the identifier, and if one of the nodes involved in arbitration is sending a classical CAN frame, then the CAN frame will win arbitration due to the assertion of its dominant IDE bit. Therefore, the SRR bit in an Extended CAN frame is recessive to allow the assertion of a dominant RTR bit by a node that is sending a CAN Remote Frame. The SRR and IDE bits are followed by the remaining 18 bits of the extended identifier and the RTR bit.

Control field and frame termination is identical to the Classical Data Frame.

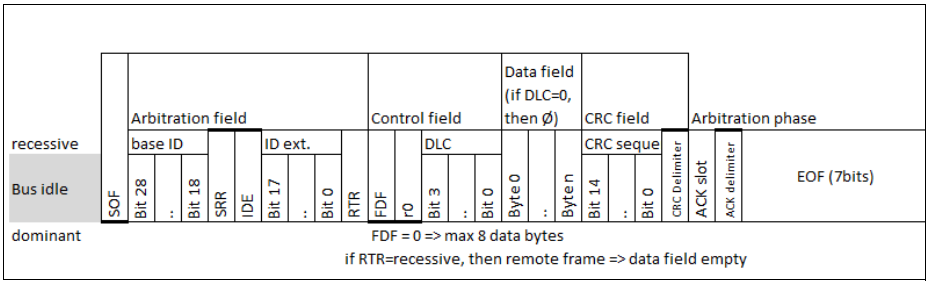

Figure 22-2 Classical 29 bit ID CAN Data Frame

Standard and Extended Data Frame (CAN FD Format)

Data frames for CAN FD with 11bit identifier are shown in **Figure 22-3**.

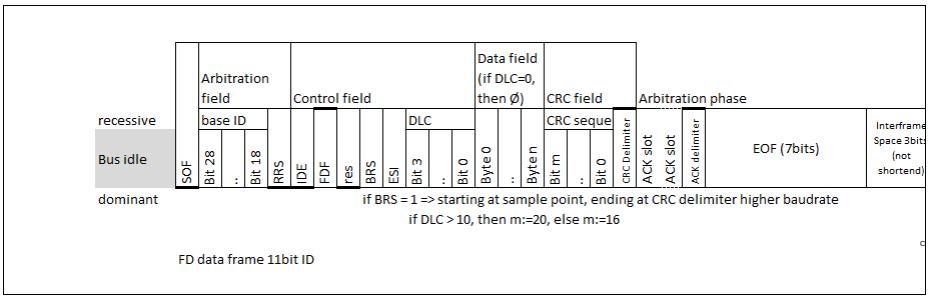

Figure 22-3 CAN FD 11bit ID Data Frames

Extended data frames for CAN FD are shown in **Figure 22-4**.

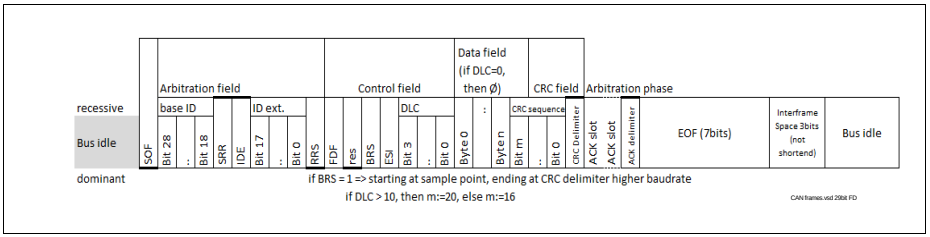

Figure 22-4 CAN FD 29bit ID Data Frames

The difference between Standard / Extended Data Frames in CAN and CAN FD format are highlighted below:

1. In the Arbitration Field:
   a) CAN Format Frames contain the RTR bit, where in CAN FD Format it is replaced with the dominant r1(reserved) bit.
   b) The reserved r0, r1 (bits) are sent dominant. Receivers accept dominant and recessive bits.
2. In the Control Field:
   a) CAN FD Format Frames consists of the additional (FDF) CAN FD format bit, (BRS) bit rate switch bit and (ESI) error state indicator bit.
   b) CAN FD format (FDF) bit comes after the IDE bit for frames with 11-bit identifier and it comes after the r1 (reserved) bit with 29-bit identifier. FDF is the new name for the previous r0 bit.
   c) Bit Rate Switch (BRS) bit switches the bit rate from standard bit rate of Arbitration Phase to preconfigured bit rate of the Data Phase when the bit is transmitted recessive. The bit rate is not switched when BRS bit is transmitted dominant.
   d) Error State Indicator (ESI) bit is transmitted dominant by error active nodes and recessive by error passive nodes.
   e) Data Length Code (DLC) bits indicates the number of bytes in the Data Field.
3. In the CRC Field:
   a) CRC sequence bits for CAN FD uses CRC_17 for data field up to sixteen bytes long and CRC_21 for data field longer than sixteen bytes. CRC calculation consists of the SOF, Arbitration Field, Control Field and (if present) Data field, supplemented with nCRC bits of ‘0’.
   Stuff-bits are included in CRC calculation. All CRC sequences (CRC_15, 17, 21) are calculated for all nodes, where the node that wins the arbitration send the CRC sequence selected by values of the FDF bit and DLC. Receivers only consider the selected CRC polynomial to check for CRC error
   b) CRC Delimiter for CAN FD consists of one or two recessive bits that has the function of switching the Data phase to Arbitration phase when the sample point reaches the first bit of the CRC Delimiter.
   Transmitter sends only one recessive bit as CRC delimiter, but accepts two

recessive bits before the edge from recessive to dominant of the Acknowledge slot. Receiver sends Acknowledge bit after the first CRC Delimiter.

c) Due to a weakness of the CRC in a certain situation, and additional checksum is needed. For example a software checksum inside the last data byte. This is a weakness in the standard and not of the module. Therefore with DIS2015 the CRC field of CAN FD will be changed.

4. In the ACK Field:
   a) For ACK slot, CAN FD nodes accept a two bit long dominant phase of overlapping ACK bits as a valid ACK, to compensate for phase shifts between Receivers.

22.1.3.2 Remote Frames

Normally, data transmission is performed on an autonomous basis with the data source node (e.g. a sensor) sending out a Data Frame. It is also possible, however, for a destination node (or nodes) to request the data from the source. For this purpose, the destination node sends a Remote Frame with an identifier that matches the identifier of the required Data Frame. The appropriate data source node will then send a Data Frame as a response to this remote request.

There are 2 differences between a Remote Frame and a Data Frame.

- The RTR bit is in the recessive state in a Remote Frame.
- There is no Data Field in a Remote Frame.

If a Data Frame and a Remote Frame with the same identifier are transmitted at the same time, the Data Frame wins arbitration due to the dominant RTR bit following the identifier. In this way, the node that transmitted the Remote Frame receives the requested data immediately.

Remote frames are only defined in Classical CAN format. Remote frames and the corresponding RTR bit do not exist for CAN FD format. Remote frame requests do not change the format of the preconfigured reply data frames (i.e FDF and BRS bits of preconfigured data frames are not changed on remote frame requests, reply data frames may be in CAN base/extended or CAN FD base/extended).

22.1.3.3 Error Frames

An Error Frame is generated by any node that detects a bus error. An Error Frame consists of two fields, an Error Flag field followed by an Error Delimiter field. The Error Delimiter Field consists of 8 recessive bits and allows the bus nodes to restart bus communications after an error. There are, however, two forms of Error Flag fields. The form of the Error Flag field depends on the error status of the node that detects the error.

When an error-active node detects a bus error, the node generates an Error Frame with an active-error flag. The error-active flag is composed of six consecutive dominant bits that actively violate the bit-stuffing rule. All other stations recognize a bit-stuffing error and generate Error Frames themselves. The resulting Error Flag field on the CAN bus

therefore consists of six to twelve consecutive dominant bits (generated by one or more nodes). The Error Delimiter field completes the Error Frame. After completion of the Error Frame, bus activity returns to normal and the interrupted node attempts to re-send the aborted message.

If an error-passive node detects a bus error, the node transmits an error-passive flag followed, again, by the Error Delimiter field. The error-passive flag consists of six consecutive recessive bits, and therefore the Error Frame (for an error-passive node) consists of 14 recessive bits (i.e. no dominant bits). Therefore, the transmission of an Error Frame by an error-passive node will not affect any other node on the network, unless the bus error is detected by the node that is actually transmitting (i.e. the bus master). If the bus master node generates an error-passive flag, this may cause other nodes to generate Error Frames due to the resulting bit-stuffing violation. After transmission of an Error Frame an error-passive node must wait for 6 consecutive recessive bits on the bus before attempting to rejoin bus communications.

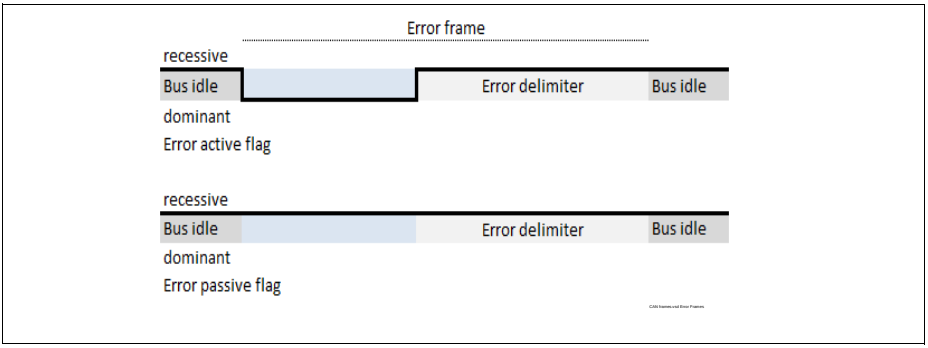

Figure 22-5 CAN Error Frames

A CAN FD node operating in the Data-Phase will switch back to the Arbitration Phase when starting an Error Flag.

22.1.3.4 Overload Frame

The Overload Frame consists of two bit fields which are Overload Flag and Overload Delimiter.

Overload conditions

If a CAN FD node samples a dominant bit at the eight bit (last bit) of an Error Delimiter or Overload Delimiter, or if a CAN FD Receiver samples a dominant bit at the last bit of End of Frame, it will start transmitting an Overload Frame (not an Error Frame). The Error Counters will not be incremented.

22.1.4 The Nominal Bit Time

One bit cell (this means one high or low pulse of the NRZ code) is composed by four segments. Each segment is an integer multiple of Time Quanta t_Q. The Time Quanta is the smallest discrete timing resolution used by a CAN node. The nominal bit time definition with its segments is shown in **Figure 22-6**.

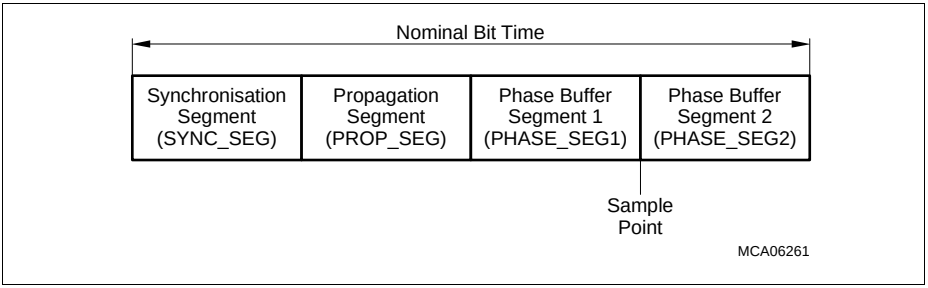

Figure 22-6 Partition of Nominal Bit Time

The Synchronization Segment (SYNC_SEG) is used to synchronize the various bus nodes. If there is a bit state change between the previous bit and the current bit, then the bus state change is expected to occur within this segment. The length of this segment is always 1 t_Q.

The Propagation Segment (PROP_SEG) is used to compensate for signal delays across the network. These delays are caused by signal propagation delay on the bus line and through the electronic interface circuits of the bus nodes.

The Phase Segments 1 and 2 (PHASE_SEG1, PHASE_SEG2) are used to compensate for edge phase errors. These segments can be lengthened or shortened by re-synchronization. PHASE_SEG2 is reserved for calculation of the subsequent bit level, and is ≥ 2 t_Q. At the sample point, the bus level is read and interpreted as the value of the bit cell. It occurs at the end of PHASE_SEG1.

The total number of t_Q in a bit time is between 8 and 25.

As a result of re-synchronization, PHASE_SEG1 can be lengthened or PHASE_SEG2 can be shortened. The amount of lengthening or shortening the phase buffer segments has an upper limit given by the re-synchronization jump width. The re-synchronization jump width may be between 1 and 4 t_Q, but it may not be longer than PHASE_SEG1.

22.1.4.1 CAN FD bit timing

The first part of a CAN FD frame until the BRS bit is transmitted with the Nominal Bit Rate. The bit rate is switched if the BRS bit is recessive, until the CRC Delimiter is reached or until the CAN FD controller sees an error condition that results in the starting

of an Error Frame. CAN FD Error Frames, as well as ACK Field, End of Frame, Overload Frames and all in CAN Format are transmitted with the Nominal Bit Rate

Synchronization Rules

Hard synchronization and Resynchronization are the two forms of synchronization. They obey the following rules,

- Hard synchronization is performed whenever there is a recessive to dominant edge during Bus Idle, Suspend Transmission, and second or third bits of Intermission. Hard synchronization is also performed at the recessive to the dominant edge from FDF to r0 in CAN FD format frames
- A transmitter shall not resynchronize while it transmits in the CAN FD data phase

22.1.5 Error Detection and Error Handling

The CAN protocol has sophisticated error detection mechanisms. The following errors can be detected:

- **Cyclic Redundancy Check (CRC) Error**
  With the CRC, the transmitter calculates special check bits for the bit sequence from the start of a frame until the end of the Data Field. This CRC sequence is transmitted in the CRC Field. The receiving node also calculates the CRC sequence using the same formula, and performs a comparison to the received sequence. If a mismatch is detected, a CRC error has occurred and an Error Frame is generated. The message is repeated.
- **Acknowledge Error**
  In the Acknowledge Field of a message, the transmitter checks whether a dominant bit is read during the Acknowledge Slot (that is sent out as a recessive bit). If not, no other node has received the frame correctly, an Acknowledge Error has occurred, and the message must be repeated. No Error Frame is generated.
- **Form Error**
  If a transmitter detects a dominant bit in one of the four segments End of Frame, Interframe Space, Acknowledge Delimiter, or CRC Delimiter, a Form Error has occurred, and an Error Frame is generated. The message is repeated.
- **Bit Error**
  A Bit Error occurs if a) a transmitter sends a dominant bit and detects a recessive bit or b) if the transmitter sends a recessive bit and detects a dominant bit when monitoring the actual bus level and comparing it to the just transmitted bit. In case b), no error occurs during the Arbitration Field (ID, RTR, IDE) and the Acknowledge Slot.
- **Stuff Error**
  If between Start of Frame and CRC Delimiter, six consecutive bits with the same polarity are detected, the bit-stuffing rule has been violated. A stuff error occurs and an Error Frame is generated. The message is repeated.

Detected errors are made public to all other nodes via Error Frames (except Acknowledge Errors). The transmission of the erroneous message is aborted and the frame is repeated as soon as possible. Furthermore, each CAN node is in one of the three error states (error-active, error-passive or bus-off) according to the value of the internal error counters. The error-active state is the usual state where the bus node can transmit messages and active-error frames (made of dominant bits) without any restrictions. In the error-passive state, messages and passive-error frames (made of recessive bits) may be transmitted. The bus-off state makes it temporarily impossible for the node to participate in the bus communication. During this state, messages can be neither received nor transmitted.

Basic CAN, Full CAN

There is one more CAN characteristic that is related to the interface of a CAN module (controller) and the host CPU: Basic-CAN and Full-CAN functionality.

In Basic-CAN devices, only basic functions of the protocol are implemented in hardware, such as the generation and the check of the bit stream. The decision, whether a received message has to be stored or not (acceptance filtering), and the complete message management must be done by software.

Full-CAN devices (this is the case for the MultiCAN+ controller as implemented in TC27x) manage the whole bus protocol in hardware, including the acceptance filtering and message management. Full-CAN devices contain message objects that handle autonomously the identifier, the data, the direction (receive or transmit) and the information of CAN operation. During the initialization of the device, the host CPU determines which messages are to be sent and which are to be received. The host CPU is informed by interrupt if the identifier of a received message matches with one of the programmed (receive-) message objects. The CPU load of Full-CAN devices is greatly reduced. When using Full-CAN devices, high baud rates and high bus loads with many messages can be handled.

22.2 Overview

The MultiCAN+ module provides a communication interface which is fully compliant with CAN specification V2.0B (active) and to CAN FD ISO11898-1 DIS version 2014, providing communications at up to 1 Mbit/s in Classical CAN (ISO 11898-1:2003(E) mode and/or CAN FD until 5 MBaud dataspeed (dependent on frequency and nodes)).

The MultiCAN+ module for the TC27x consists of 1 module (i.e MultiCAN with 4 CAN nodes), representing 4 serial communication interfaces. All nodes are CAN FD capable[1)] . Each CAN node communicates over two pins (TXD and RXD). The device ports which are used for TXD and RXD may be individually configured within the PORTS block. Several port configuration options are available to provide application-specific flexibility.

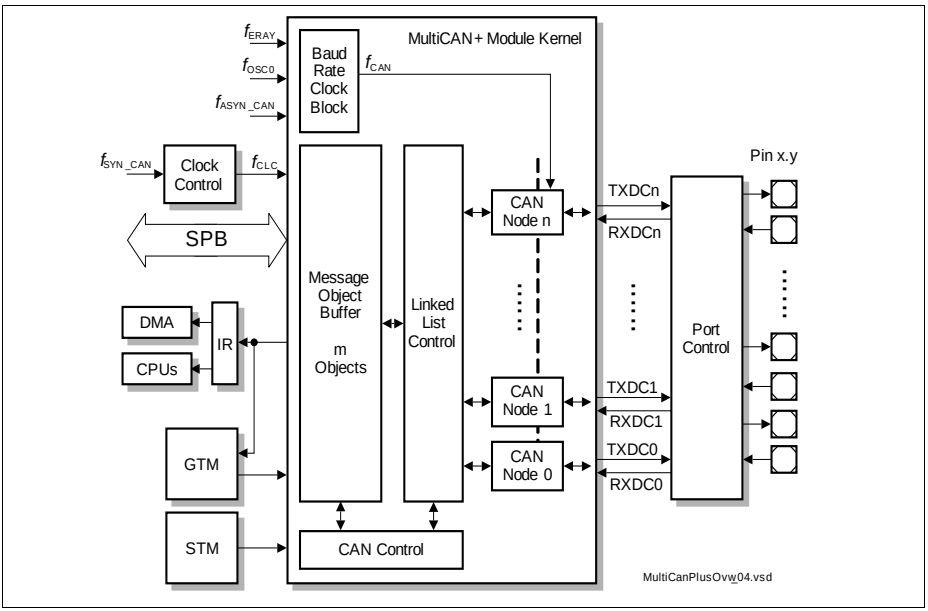

Figure 22-7 Overview of the MultiCAN+ Module with 4 nodes and 256 message objects in AURIX products.

The MultiCAN+ module contains 4 independently operating CAN nodes with Full-CAN functionality that are able to exchange Data and Remote Frames via a gateway function. Each CAN node can receive and transmit standard frames with 11-bit identifiers as well as extended frames with 29-bit identifiers.

1)

All CAN nodes share a common set of 256 message objects. Each message object can be individually allocated to one of the CAN nodes.Besides serving as a storage container for incoming and outgoing frames, message objects can be combined to build gateways between the CAN nodes or to setup a FIFO buffer.

The message objects are organized in double-chained linked lists, where each CAN node has its own list of message objects. A CAN node stores frames only into message objects that are allocated to the message object list of the CAN node, and it transmits only messages belonging to this message object list. A powerful, command-driven list controller performs all message object list operations.

The bit timings for the CAN nodes are derived from the module timer clock (f_{CAN}) and are programmable up to a data rate of 1 Mbit/s in Classical CAN (ISO 11898-1:2003(E) mode or up to 5 MBaud in CAN FD mode. External bus transceivers are connected to a CAN node via a pair of receive and transmit pins.

22.2.1 Features List

The MultiCAN+ module provides the following features:

- Compliant with ISO 11898 and SAE J 1939
- CAN functionality according to CAN specification V2.0 B active
- Supports CAN with Flexible Data-Rate Specification CAN FD DIS version ISO11898-1 2014 with max. 64 data bytes[1)]
- Dedicated control registers for each CAN node
- Data transfer rates up to 1 Mbit/swhen operating in Classical CAN mode per ISO 11898-1:2003(E)
- Supports up to 5MBaud, when operating in CAN FD mode.
- Support for asynchronous clock sources for baud rate generation by providing separate frequency domain and input:
  - System frequency clock f_{CLC}
  - Low-jitter E-Ray PLL clock
  - Direct oscillator clock (e.g. from ceramic resonator)
- Frequency jitter calibration based on external CAN messages during runtime
- Flexible and powerful message transfer control and error handling capabilities
- Advanced CAN bus bit timing analysis and baud rate detection for each CAN node via a frame counter
- Full-CAN functionality: A set of 256 message objects can be individually
  - Allocated (assigned) to any CAN node
  - Configured as transmit or receive object
  - Setup to handle frames with 11-bit or 29-bit identifier
  - Identified by a timestamp via a frame counter

1) At time of release of this document ISO 11898-1 (Classical CAN and CAN FD) is in working draft mode, an errata sheet will document differences when ISO 11898-1 has been finalized.

  - Configured to remote monitoring mode
- Advanced Acceptance Filtering
  - Each message object provides an individual acceptance mask to filter incoming frames
  - A message object can be configured to accept standard or extended frames or to accept both standard and extended frames
  - Message objects can be grouped into different priority classes for transmission and reception
  - The selection of the message to be transmitted first can be based on frame identifier, IDE bit and RTR bit according to CAN arbitration rules, or on its order in the list
- Advanced CAN node features
  - Analyzer Mode supports monitoring of bus traffic without actively participating on the bus
  - Internal Loop-Back Mode is available for test purposes
  - An internal timer is provided that can detect a receive or remote frame time-out; the message objects to be supervised are selectable
  - Data transmission from a node can be stopped without affecting reception
  - Programmable minimum delay between two consecutive messages
- Advanced message object functionality
  - Message objects can be combined to build FIFO message buffers of arbitrary size, limited only by the total number of message objects
  - Message objects can be linked to form a gateway that automatically transfers frames between 2 different CAN buses. A single gateway can link any two CAN nodes. An arbitrary number of gateways can be defined
- Advanced data management
  - The message objects are organized in double-chained lists
  - List reorganizations can be performed at any time, even during full operation of the CAN nodes
  - A powerful, command-driven list controller manages the organization of the list structure and ensures consistency of the list
  - Message FIFOs are based on the list structure and can easily be scaled in size during CAN operation
- Advanced interrupt handling
  - Message interrupts, node interrupts can be generated
  - Interrupt requests can be routed individually to one of the 16 interrupt output lines
  - Message post-processing notifications can be combined flexibly into a dedicated register field of 256 notification bits
- Module internal SRAM with ECC protection
- Pretended Networking Operation for energy saving purposes
  - If direct oscillator clock is selected for baud rate generation, CPU clock can be slowed down or CPU Idle Mode can be entered

- Three selectable message object can be transmitted periodically without CPU involvement, triggered by a CAN node timer or by STM or GTM modules.
- Message objects are received without CPU involvement and can wake up the system via receive interrupt

AUTOSAR optimized and backward compatible with existing MultiCAN software

22.3 CAN Flexible Data-Rate (CAN FD)

CAN Flexible Data-Rate (CAN FD) builds on existing CAN (ISO 11898-1) specifications allowing higher data rates and larger payloads. This is achieved with a new CAN FD frame format different from existing Classical CAN format, both frame formats can coexist within the same network. Classical CAN nodes and CAN FD nodes can communicate with each other as long as CAN FD frame format is not being used.

CAN FD functionality is available on all nodes of MultiCAN+ module.

Feature Lists

- Supports CAN Flexible Data-Rate Specification V1.0

22.3.1 Transmitter Delay Compensation

The CAN protocol requires that transmitted data be compared with the received data from its local CAN transceiver to determine if there are any transmit errors. In the case of CAN FD data phase when a faster bit rate is used, resulting in shorter bit timing, the delay caused by the local transmitting loop delay will be greater than TSEG1 (time segment before sample point) causing a bit error to be detected. The transmitter loop delay limits the bit rate in the data phase of a CAN FD frame.

Thus to overcome this limitation, a Transmitter Delay Compensation feature is introduced where a new sample point (Secondary Sample Point) shall be used by transmitters in the data phase of a CAN FD frame, the sample point which does not account for the transceiver loop delay is ignored.

The Secondary Sample Point consists of the transmitter loop delay and a configurable Transmitter Delay Compensation offset (NTDCRx.TDCO). (i.e The secondary sample point is reached by counting the total delay consisting of the compensation offset and measured transceiver loop delay.)

The Transmitter loop delay is measured in each transmitted frame at the edge from the FDF bit to the following bit r0, between the edge of the transmitted bit and the edge of the received bit. (see **Figure 22-8**) The count down is started with the begin of the bit time (transmit point).

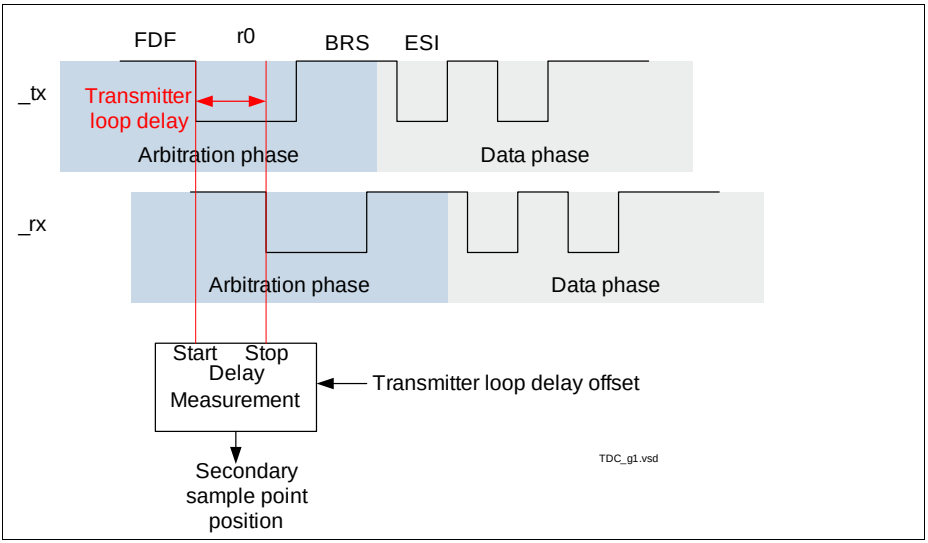

Figure 22-8 Transmitter Delay Loop measurement

Transmitter Delay compensation offset (NTDCRx.TDCO) is used to adjust the secondary sample point inside the bit time (e.g half of the bit time in the data phase). Finally the resulting Secondary Sample Point is rounded down to the next integer number of time quanta t_q and placed after the end of the transmitted bit. If a bit error is detected at the Secondary Sample Point, the transmitter will react to this bit error at the next sample point.

(i.e When a bit error is detected by the Transmitter Delay compensation unit, the error is reported at the next sample point and becomes visible (in error active case) at the transmit point that follows the regular sample point.)

Secondary Sample Point is used in the Data Phase of CAN FD and Sample Point is used in the Arbitration Phase of CAN FD. The Transmitter Delay compensation which determines the secondary sample point is able to handle a total delay (measured transceiver loop delay + compensation offset) which goes beyond the current bit time.

MultiCAN+ module allows the secondary sample point to be placed anywhere within the current and next 3 bit times (i.e covers up to 4 data phase bit rate). The maximum delay which can be compensated by MultiCAN+ delay compensation during the data phase is 4 bit times.

Note:

9. CAN receive input line contributes to the measured loop delay.
10. Measurement granularity of the Transmitter Delay compensation is the fast time quantum given by the fast baud rate prescaler.

22.4 MultiCAN+ Kernel Functional Description

This section describes the functionality of the MultiCAN+ module.

22.4.1 Module Structure

Figure 22-9 shows the general structure of the MultiCAN+ module.

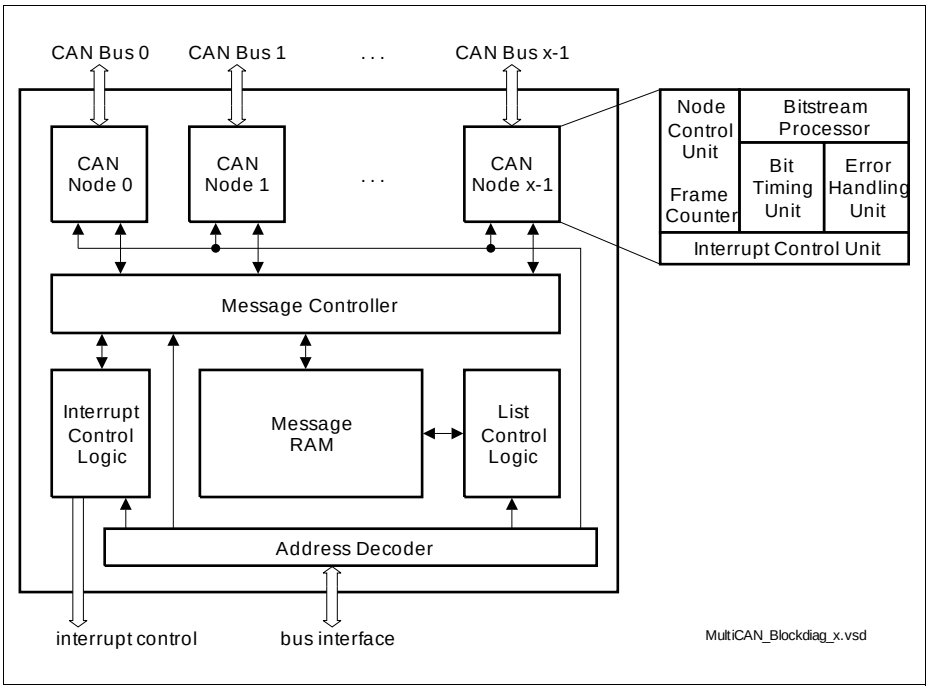

Figure 22-9 MultiCAN+ Block Diagram

CAN Nodes

Each CAN node consists of several sub-units.

- **Bitstream Processor**
  The Bitstream Processor performs data, remote, error and overload frame processing according to the ISO 11898 standard. This includes conversion between the serial data stream and the input/output registers.
- **Bit Timing Unit**
  The Bit Timing Unit determines the length of a bit time and the location of the sample point according to the user settings, taking into account propagation delays and phase shift errors. The Bit Timing Unit also performs resynchronization.

- **Error Handling Unit**
  The Error Handling Unit manages the receive and transmit error counter. Depending on the contents of both counters, the CAN node is set into an error-active, error passive or bus-off state.
- **Node Control Unit**
  The Node Control Unit coordinates the operation of the CAN node:
  – Enable/disable CAN transfer of the node
  – Enable/disable and generate node-specific events that lead to an interrupt request (CAN bus errors, successful frame transfers etc.)
  – Administration of the frame counter and of the node timers
- **Interrupt Control Unit**
  The Interrupt Control Unit in the CAN node controls the interrupt generation for the different conditions that can occur in the CAN node.

Message Controller

The Message Controller handles the exchange of CAN frames between the CAN nodes and the message objects that are stored in the Message RAM. The Message Controller performs several functions:

- Receive acceptance filtering to determine the correct message object for storing of a received CAN frame
- Transmit acceptance filtering to determine the message object to be transmitted first, individually for each CAN node
- Transfer contents between message objects and the CAN nodes, taking into account the status/control bits of the message objects
- Handling of the FIFO buffering and gateway functionality
- Aggregation of message-pending notification bits

List Controller

The List Controller performs all operations that lead to a modification of the double-chained message object lists. Only the list controller is allowed to modify the list structure. The allocation/deallocation or reallocation of a message object can be requested via a user command interface (command panel). The list controller state machine then performs the requested command autonomously.

Interrupt Control

The general interrupt structure is shown in **Figure 22-10**. The interrupt event can trigger the interrupt generation. The interrupt pulse is generated independently of the interrupt flag in the interrupt status register. The interrupt flag can be reset by software by writing a 0 to it.

If enabled by the related interrupt enable bit in the interrupt enable register, an interrupt pulse can be generated at one of the 16 interrupt output lines INT_Om of the MultiCAN+ module. If more than one interrupt source is connected to the same interrupt node pointer (in the interrupt node pointer register), the requests are combined to one common line.

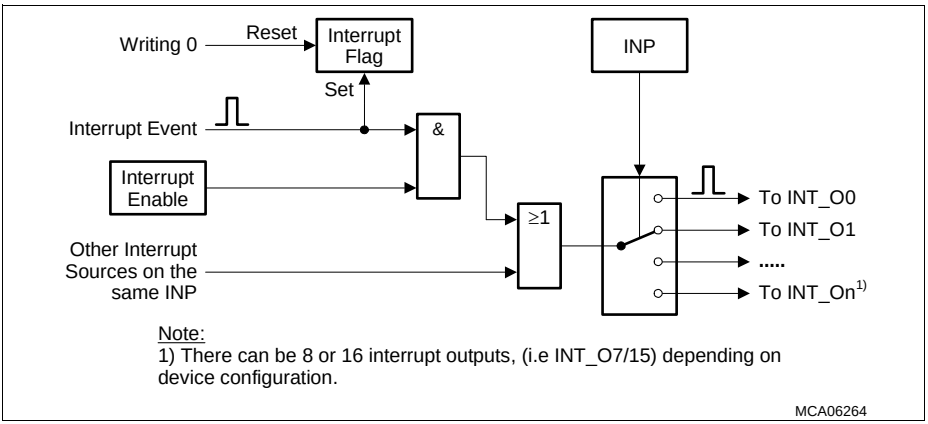

Figure 22-10 General Interrupt Structure

22.4.2 Clock Control

The CAN module timer clock f_{CAN} of the functional blocks of the MultiCAN+ module is derived from the asynchronous, higher precision clock f_A or from the synchronous clock source. The Fractional Divider is used to generate f_{CAN} used for bit timing calculation, The frequency of f_{CAN} is identical for all CAN nodes. The register file operate with the module control clock f_{CLC}. See also **“MultiCAN+ Clock Generation” on Page 22-21**.

The output clock f_{CAN} of the Fractional Divider is based on the clock f_A, but only every nth clock pulse is taken. The suspend signal (coming as acknowledge from the MultiCAN+ module in response to a OCDS suspend request) freezes or resets the Fractional Divider. The clock select and fractional divider are reset together with the CAN module kernel when the module kernel reset is triggered.

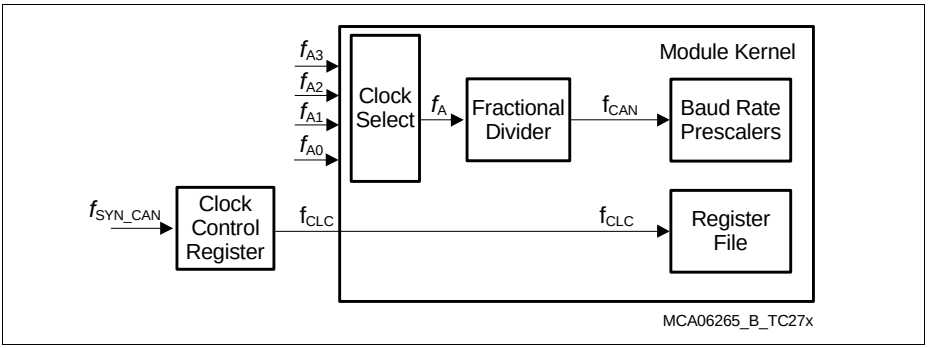

Figure 22-11 MultiCAN+ Clock Generation

The f_{SYN_CAN} is identical to f_{SPB}. f_{Ai} is the asynchronous clock input.

Table 22-2 indicates the minimum operating frequencies in MHz for f_{CLC} that are required for a baud rate of 1 Mbit/s for the active CAN nodes. If a lower baud rate is desired, the values can be scaled linearly (e.g. for a maximum of 500 kbit/s, 50% of the indicated value are required).

For CAN FD operations, please refer to **Table 22-3** for the minimum operating frequency in MHz for f_{CLC} that are required.

The values imply that the CPU (or DMA) executes maximum accesses to the MultiCAN+ module. The values may contain rounding effects.

Table 22-2 Minimum Operating Frequencies[1)2)] [MHz]

Number of allocated message objects MO[3)],	Number of Active CAN Nodes				
	1	**2**	**3**	**4**	**5**
16 MO	12	19	26	33	40
32 MO	15	23	30	37	44
64 MO	21	28	37	46	53
128 MO	40	45	50	55	61
256 MO	72	77	82	88	93

1) In the case of 15 time quanta, the minimum operating frequency required is 15MHz.

2) To guarantee the minimum operating frequencies when low power mode (pretended networking mode) is enabled (i.e when frequency of f_{SPB} is reduced), f_{SYN_CAN} and f_{CLC} are switched from f_{SPB} to f_{CAN} when SCU register CCUCON.LPDIV>0.

3) Only those message objects have to be taken into account that are allocated to a CAN node. The unallocated message objects have no influence on the minimum operating frequency.

Table 22-3 Minimum Operating Frequencies for CAN FD [MHz]

No. of allocated MO[1)]	No. of Active CAN Nodes	Acceleration Factor[2)3)]				
		1	2	3	4	5
16 MO	1	20	40	60	80	100
	2	39	48	72	96	-
	3	58	58	84	-	-
	4	77	77	96	-	-
	5	96	96	-	-	-
32 MO	1	20	40	60	80	100
	2	39	48	72	96	-
	3	58	58	84	-	-
	4	77	77	96	-	-
	5	96	96	-	-	-
64 MO	1	27	40	60	80	100
	2	39	51	72	96	-
	3	58	65	84	-	-
	4	77	79	96	-	-
	5	96	96	-	-	-
128 MO	1	47	65	75	81	100
	2	57	79	91	99	-
	3	67	93	-	-	-
	4	77	-	-	-	-
	5	96	-	-	-	-

1) Only those message objects have to be taken into account that are allocated to a CAN node. The unallocated message objects have no influence on the minimum operating frequency.
When message objects are configured as transmit or receive FIFO structures i.e MOFCRn.MMC = 0001/0010, only the base object of 1 is counted towards the minimum frequency requirement, all other slave objects on the FIFO do not count towards the minimum frequency requirement. See **Section 22.4.12.5**

2) Acceleration Factor is the ratio of the Data Bit Rate to Nominal Bit Rate. The Nominal Bit Rate is taken as 1Mbit/s in table above. As an example, an acceleration factor(A.F) of 4 refers to a Data Bit Rate of 4Mbit/s and Nominal Bit Rate is 1Mbit/s.
Only the node operating with the highest baudrate need to be considered when several nodes operate at different acceleration factor. e.g When 1node operate at A.Fof 3 and 3 nodes operate at A.F of 2, the minimum operating frequency required is determined by the node operate at A.F of 3.

3) Please note that other combinations of acceleration factor are possible, values here are for illustrative purposes only. Values with dash '-' indicates required f_{CLC} exceeding the maximum frequency capability off product SCU typically at 100MHz.

The baud rate generation of the MultiCAN+ being based on f_A, this frequency has to be chosen carefully to allow correct CAN bit timing. The required value of f_A is given by an integer multiple (n) of the CAN baud rate multiplied by the number of time quanta per CAN bit time. For example, to reach 1 Mbit/s with 20 tq per bit time, possible values of f_A are given by formula [n × 20] MHz, with n being an integer value, starting at 1.

In order to minimize jitter, it is not recommended to use the fractional divider mode for high baud rates.

Additionally, for correct operation of the MultiCAN, the following conditions have to be fulfilled,

$$\text{Baudrate}_{max} = [(8 \times T_{CAN}) + (8 \times T_{CLC}) + (4 \times \text{No. of active CAN nodes} \times T_{CLC})] \quad (22.1)$$

also

$$\text{NBTR.SJW} < \text{NBTR.TSEG1}$$

As an example, when f_{CLC} = 10MHz, f_{CAN} = 20MHz, No of active CAN nodes =2,

Baudrate_{max}=[(8x50ns) + (8x100ns) + (4x2x100ns)] = 2000ns = 500 KBaud

Table 22-4 below illustrates the minimum CAN module timer clock f_{CAN} and Module Control Clock f_{CLC} that's required to support a baudrate generation of 500KBaud. If a higher baudrate is desired, the values need to be calculated as per **Equation (22.1)**.

Table 22-4 Minimum Operating Frequencies [MHz] required for 500KBaud

No. of active CAN nodes	$f_{CAN} = f_{CLC}$ (MHz)	$f_{CAN} \neq f_{CLC}$ (MHz)[1]	
		f_{CAN}	f_{CLC}
1	10	16	8
		20	8
		24	8
		80	7
2	12	16	11
		20	10
		24	10
		80	9
3	14	16	14
		20	13
		24	12
		80	11

Table 22-4 Minimum Operating Frequencies [MHz] required for 500KBaud

4	16	16	16
		20	15
		24	15
		80	13

1) To guarantee the minimum operating frequencies when low power mode (pretended networking mode) is enabled (i.e when frequency of f_{SPB} is reduced), f_{SYN_CAN} and f_{CLC} are switched from f_{SPB} to f_{CAN} when SCU register CCUCON.LPDIV>0.

22.4.3 Port Input Control

It is possible to select the input lines for the RXDCANx inputs for the CAN nodes. The selected input is connected to the CAN node and is also available to wake-up the system. More details are defined in **Section 22.7.5.2** on **Page 22-168**.

22.4.4 OCDS Suspend

The OCDS suspend of MultiCAN+ is controlled with the **OCS** register. MultiCAN+ module provides the following Suspend Modes:

Hard Suspend Mode (VERSION: RW ACCESS NEEDS KERNEL CLOCKING) (All actions are immediately stopped)

The Hard Suspend mode is not to be used in normal CAN applications, this mode is meant for debugging the peripheral IP within a controlled environment.

In Hard Suspend Mode, the MultiCAN+ module clocks f_{CLC} and f_{CAN} are switched off. Reading and writing of registers is possible but will enable the kernel clock for a few cycles. In this mode, there is a very high probability that the communication with other CAN devices is made impossible and that the CAN bus is blocked (e.g. if the suspended CAN module just sends a dominant level). A reset operation must be executed to leave Hard Suspend Mode.

Attention: Register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a MultiCAN+ kernel reset might not be sufficient to bring the system into a defined state.

Soft Suspend Mode (The current action is finished)

In Soft Suspend Mode, the MultiCAN+ module clock f_{CLC} is kept running. Module functions are stopped automatically after internal actions have been finished before it enters the suspended state with **OCS**.SUSSTA set (for example, after a CAN frame has been sent out). Due to this behavior, the communication network is not blocked. All registers are accessible for read and write actions. As a result, the debugger can stop

the module actions and modify registers. These modifications are taken into account after the Suspend Mode is left. Soft Suspend mode does not influence the kernel clock.

The Hard Suspend Mode can be enabled/disabled only for the complete MultiCAN+ module. The Soft Suspend Mode can be individually enabled for each CAN node.

The user has to be aware that the Soft Suspend Mode can corrupt the TTCAN timing values, because the counter clock can be disabled. In order to guarantee correct TTCAN behavior, a TTCAN node should not enter any Suspend Mode if the consistency of the timing data must be ensured.

Note: During suspend mode, kernel registers may be accessed only when the kernel clock is running.

22.4.5 OCDS Trigger Bus (OTGB) Interface

The MultiCAN Trigger Set is shown in **Table 22-5**. Its output is on OTGB0 or OTGB1 controlled by the **OCS** register.

Table 22-5 TS16_CAN Trigger Set MultiCAN

Bits	Name	Description
[7:0]	MON	Message Object Number for transmit and receive direction. Only valid when TT or RT is active and FMI is inactive.
[11:8]	NN	Node Number for transmit and receive direction. Only valid when TT or RT is active and FMI is inactive.
12	TT	Transmit Trigger. Active for one clock cycle when the transmit message is setup.
13	RT	Receive Trigger. Active for one clock cycle after End-of-Frame (EOF) processing for a receive message.
14	FMI	Foreign Message Indicator. The received message will not be copied to any message object. Only valid when RT is active.
15		Reserved

MCDS Trigger Setup

Table 22-6 lists the qualification methods for TC16_CAN with MCDS. The methods are not exclusive and can be combined.

Table 22-6 TS16_CAN MCDS Trigger Setup

Qualification	Method
Transmit and/or receive messages	Positive edge sensitivity on TS16_CAN.TT and/or RT. Configured in the OTGM MCDS I/F.
No foreign messages.	MCDS data value condition TS16_CAN < 4000_H
Specific message object	MCDS masked data value comparison. TS16_CAN & $00FF_H$ == message object number
Specific node	MCDS masked data value comparison. TS16_CAN & $0F00_H$ == (node number) << 8

22.4.6 CAN Node Control

Each CAN node may be configured and run independently of the other CAN node. Each CAN node is equipped with its own node control logic to configure the global behavior and to provide status information.

Note: In the following descriptions, index “x” stands for the node number and index “n” represents the message object number.

Configuration Mode is activated when bit NCRx.CCE is set to 1. This mode allows CAN bit timing parameters and the error counter registers to be modified.

CAN Analyzer Mode

CAN Analyzer Mode is activated when bit NCRx.CALM is set to 1. In this operation mode, Data And Remote Frames are monitored without active participation in any CAN transfer (CAN transmit pin is held on recessive level). Incoming Remote Frames are stored in a corresponding transmit message object, while arriving data frames are saved in a matching receive message object.

In CAN Analyzer Mode, the entire configuration information of the received frame is stored in the corresponding message object, and can be evaluated by the CPU to determine their identifier, IDE bit information and data length code (ID and DLC optionally if the Remote Monitoring Mode is active, bit MOFCRn.RMM = 1). Incoming frames are not acknowledged, and no Error Frames are generated. If CAN Analyzer Mode is enabled, Remote Frames are not responded to by the corresponding Data Frame, and Data Frames cannot be transmitted by setting the transmit request bit MOSTATn.TXRQ. Receive interrupts are generated in CAN Analyzer Mode (if enabled) for all error free received frames.

The node-specific interrupt configuration is also defined by the Node Control Logic via the NCRx register bits TRIE, ALIE and LECIE:

- If control bit TRIE is set to 1, a transfer interrupt is generated when the NSRx register has been updated (after each successfully completed message transfer).
- If control bit ALIE is set to 1, an alert interrupt is generated when a “bus-off” condition has been recognized or the Error Warning Level has been exceeded or under-run. Additionally, list or object errors lead to this type of interrupt.
- If control bit LECIE is set to 1, a last error code interrupt is generated when an error code > 0 is written into bit field NSRx.LEC by hardware.

Setting bit TXDIS in register NCRx stops the transmit activity of this node without affecting reception; bit CANDIS disables the node completely.

The Node x Status Register NSRx provides an overview about the current state of the respective CAN node x, comprising information about CAN transfers, CAN node status, and error conditions.

The CAN frame counter can be used to check the transfer sequence of message objects or to obtain information about the instant a frame has been transmitted or received from the associated CAN bus. CAN frame counting is performed by a 16-bit counter, controlled by register NFCRx. Bit fields NFCRx.CFMOD and NFCRx.CFSEL determine the operation mode and the trigger event incrementing the frame counter.

22.4.6.1 Bit Timing Unit

According to the ISO 11898 standard, a CAN bit time is subdivided into different segments (**Figure 22-12**). Each segment consists of multiples of a time quantum t_q. The magnitude of t_q is adjusted by Node x Bit Timing Register bit fields NBTRx.BRP and NBTRx.DIV8, both controlling the baud rate prescaler (register NBTRx is described on **Page 22-106**). The baud rate prescaler is driven by the module timer clock f_{CAN} (generation and control of f_{CAN} is described on **Page 22-163**).

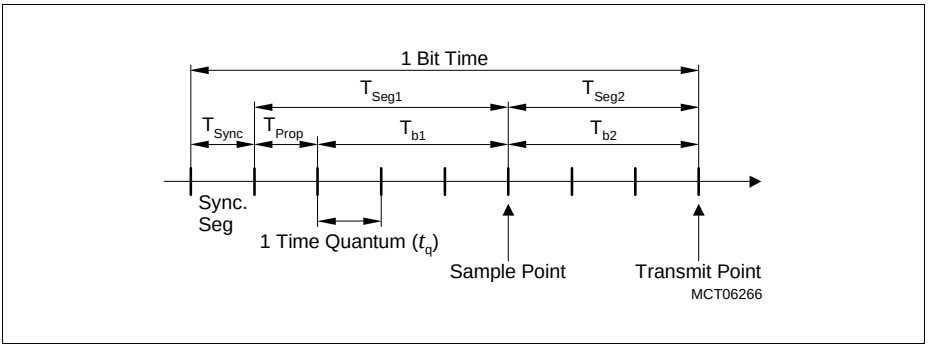

Figure 22-12 CAN Bus Bit Timing Standard

The Synchronization Segment (T_{Sync}) allows a phase synchronization between transmitter and receiver time base. The Synchronization Segment length is always one t_q. The Propagation Time Segment (T_{Prop}) takes into account the physical propagation delay in the transmitter output driver on the CAN bus line and in the transceiver circuit. For a working collision detection mechanism, T_{Prop} must be two times the sum of all propagation delay quantities rounded up to a multiple of t_q. The phase buffer segments 1 and 2 (T_{b1}, T_{b2}) before and after the signal sample point are used to compensate for a mismatch between transmitter and receiver clock phases detected in the synchronization segment.

The maximum number of time quanta allowed for re-synchronization is defined by bit field NBTRx.SJW. The Propagation Time Segment and the Phase Buffer Segment 1 are combined to parameter T_{Seg1}, which is defined by the value NBTRx.TSEG1. A minimum of 3 time quanta is demanded by the ISO standard. Parameter T_{Seg2}, which is defined by the value of NBTRx.TSEG2, covers the Phase Buffer Segment 2. A minimum of 2 time

quanta is demanded by the ISO standard. According to ISO standard, a CAN bit time, calculated as the sum of T_{Sync}, T_{Seg1} and T_{Seg2}, must not fall below 8 time quanta.

Calculation of the bit time:

t_q	$= (BRP + 1) / f_{CAN}$	if DIV8 = 0
	$= 8 \times (BRP + 1) / f_{CAN}$	if DIV8 = 1
T_{Sync}	$= 1 \times t_q$	
T_{Seg1}	$= (TSEG1 + 1) \times t_q$	(min. 3 t_q)
T_{Seg2}	$= (TSEG2 + 1) \times t_q$	(min. 2 t_q)
bit time	$= T_{Sync} + T_{Seg1} + T_{Seg2}$	(min. 8 t_q)

To compensate phase shifts between clocks of different CAN controllers, the CAN controller must synchronize on any edge from the recessive to the dominant bus level. The hard synchronization is enabled (at the start of frame), the bit time is restarted at the synchronization segment. Otherwise, the re-synchronization jump width T_{SJW} defines the maximum number of time quanta, a bit time may be shortened or lengthened by one re-synchronization. The value of SJW is defined by bit field NBTRx.SJW.

T_{SJW}	$= (SJW + 1) \times t_q$
T_{Seg1}	$\geq T_{SJW} + T_{prop}$
T_{Seg2}	$\geq T_{SJW}$

The maximum relative tolerance for f_{CAN} in classical CAN format and CAN FD format depends on the Phase Buffer Segments, re-synchronization jump width and the bit time.

Classical CAN Format

df_{CAN}	$\leq \min (T_{b1}, T_{b2}) / [2 \times (13 \times \text{bit time} - T_{b2})]$	AND
df_{CAN}	$\leq T_{SJW} / 20 \times \text{bit time}$	

CAN FD Format

df_{CAN}	$\leq \min (T_{b1(N)}, T_{b2(N)}) / [2 \times (13 \times \text{bit time}_{(N)} - T_{b2(N)})]$	AND
df_{CAN}	$\leq T_{SJW(N)} / 20 \times \text{bit time}_{(N)}$	AND
df_{CAN}	$\leq T_{SJW(D)} / 20 \times \text{bit time}_{(D)}$	AND

$df_{CAN} \leq \min (T_{b1(D)}, T_{b2(D)}) / (2 \times [(6 \times \text{bit time}_{(D)} - T_{b2(D)}) \times BRP_{(D)} / BRP_{(N)} + (7 \times \text{bit time}_{(N)})] ($ AND

$df_{CAN} \leq [T_{SJW(D)} - (BRP_{(N)} / BRP_{(D)} - 1)] / (2 \times [(2 \times \text{bit time}_{(N)} - T_{b2(N)}) \times BRP_{(N)} / BRP_{(D)} + T_{b2(D)} + 4 \times \text{bit time}_{(D)}])$

A valid CAN bit timing must be written to the CAN Node Bit Timing Register NBTR and Fast Node Bit Timing Register before resetting the INIT bit in the Node Control Register, i.e. before enabling the operation of the CAN node.

The Node Bit Timing Register may be written only if bit CCE (Configuration Change Enable) is set in the corresponding Node Control Register.

22.4.6.2 Bitstream Processor

Based on the message objects in the message buffer, the Bitstream Processor generates the remote and Data Frames to be transmitted via the CAN bus. It controls the CRC generator and adds the checksum information to the new remote or Data Frame. After including the SOF bit and the EOF field, the Bitstream Processor starts the CAN bus arbitration procedure and continues with the frame transmission when the bus was found in idle state. While the data transmission is running, the Bitstream Processor continuously monitors the I/O line. If (outside the CAN bus arbitration phase or the acknowledge slot) a mismatch is detected between the voltage level on the I/O line and the logic state of the bit currently sent out by the transmit shift register, a CAN LEC error interrupt request is generated, and the error code is indicated by the Node x Status Register bit field NSRx.LEC.

The data consistency of an incoming frame is verified by checking the associated CRC field. When an error has been detected, a CAN LEC error interrupt request is generated and the associated error code is presented in the Node x Status Register NSRx. Furthermore, an Error Frame is generated and transmitted on the CAN bus. After decomposing a faultless frame into identifier and data portion, the received information is transferred to the message buffer executing remote and Data Frame handling, interrupt generation and status processing.

22.4.6.3 Error Handling Unit

The Error Handling Unit of a CAN node x is responsible for the fault confinement of the CAN device. Its two counters, the Receive Error Counter REC and the Transmit Error Counter TEC (bit fields of the Node x Error Counter Register NECNTx, see **Page 22-113**) are incremented and decremented by commands from the Bitstream Processor. If the Bitstream Processor itself detects an error while a transmit operation is running, the Transmit Error Counter is incremented by 8. An increment of 1 is used when the error condition was reported by an external CAN node via an Error Frame generation. For error analysis, the transfer direction of the disturbed message and the

node that recognizes the transfer error are indicated for the respective CAN node x in register NECNTx. Depending on the values of the error counters, the CAN node is set into error- active, error-passive, or bus-off state.

The CAN node is in error-active state if both error counters are below the error-passive limit of 128. The CAN node is in error-passive state, if at least one of the error counters is equal to or greater than 128.

The bus-off state is activated if the Transmit Error Counter is equal to or greater than the bus-off limit of 256. This state is reported for CAN node x by the Node x Status Register flag NSRx.BOFF. The device remains in this state, until the “bus-off” recovery sequence is finished. Additionally, Node x Status Register flag NSRx.EWRN is set when at least one of the error counters is equal to or greater than the error warning limit defined by the Node x Error Count Register bit field NECNTx.EWRNLVL. Bit NSRx.EWRN is reset if both error counters fall below the error warning limit again (see **Page 22-96**).

22.4.6.4 CAN Frame Counter

Each CAN node is equipped with a frame counter that counts transmitted/received CAN frames or obtains information about the time when a frame has been started to transmit or be received by the CAN node. CAN frame counting/bit time counting is performed by a 16-bit counter that is controlled by Node x Frame Counter Register NFCRx (see **Page 22-114**). Bit field NFCRx.CFSEL determines the operation mode of the frame counter:

- **Frame Count Mode:**
  After the successful transmission and/or reception of a CAN frame, the frame counter is copied into the CFCVAL bit field of the MOIPRn register of the message object involved in the transfer. Afterwards, the frame counter is incremented.
- **Time Stamp Mode:**
  The frame counter is incremented with the beginning of a new bit time. When the transmission/reception of a frame starts, the value of the frame counter is captured and stored to the CFC bit field of the NFCRx register. After the successful transfer of the frame the captured value is copied to the CFCVAL bit field of the MOIPRn register of the message object involved in the transfer.
- **Bit Timing Mode:**
  Used for baud rate detection and analysis of the bit timing (**Chapter 22.4.8.3**).
- **Error Count Mode:**
  The frame counter is incremented when an error frame is received or an error is detected by the node (010_B to 110_B) (see **Table 22-12** for **Encoding of the LEC Bit field**). If the NFCRx.CFCIE interrupt bit is enabled, the NFCRx.CFCOV overflow flag will be set when the frame counter overflows.

22.4.6.5 Node Timing Functions

A CAN node offers the following timing functions:

- A receive time-out mode that can detect reception of message objects; the message objects to be supervised are selectable.
- Without CPU involvement, a selectable message object can be transmitted periodically, triggered by a timer, a System Timer (STM) or General Timer Module (GTM).

The clocking options for the node timer is controlled by Node Timer Clock Control Register, **CAN_NTCCRx (x = 0-3)**, the node timing functions for Receive Timeout Mode is controlled by Node x Timer Receive Timeout Register, **CAN_NTRTRx (x = 0-3)** and for Transmit Trigger Mode is controlled by Node x Timer A/B/C Transmit Trigger Registers, **CAN_NTATTRx (x = 0-3)**, **CAN_NTBTTRx (x = 0-3)**, **CAN_NTCTTRx (x = 0-3)**.

Modes with Timer Usage

A CAN node timer is driven by the CAN bit time clock, divided by a prescaler selected via bit field TPSC in the corresponding timer control register. The timers are enabled by writing to the RELOAD bits in the relevant node timer registers; then it decrements from its initial value. The further behavior depends on the selected timer mode:

- **Receive Timeout Mode:**
  By setting bit MOFCRn.RXTOE, a receive time-out check is enabled for message object n, which may be a receive or remote data object. If any of the participating message objects is received before the timer is 0, the timer will be reloaded. When the timer reaches 0, it will stop. Bit TE in NTRTRx register will be set. With bit TEIE = 1, a node interrupt will be generated.
- **Transmit Trigger Mode:**
  When the timer reaches 0, Bit MOSTATn.TXRQ of the message object n selected by bit field TXMO in the timer control register will be set.

Transmit Trigger by System Timer or General Timer Module

For Node x Timer the trigger for transmission of a message can also be set by a System Timer (STM) trigger event or General Timer Module (GTM) trigger event. See **Figure 22-13**.
Bit NTCCRx.TRIGSRC in the timer clock control register enables this feature and the timer is started once values are written to the RELOAD bits of the relevant NTATTx, NTBTTx, or NTCTTx registers. In transmit trigger mode, when a trigger event occurs (STM or GTM), the node timer will be decremented per trigger event timing prescaled by (TPSC+1) till it reaches zero where Bit MOSTATn.TXRQ of the message object n selected by bit field TXMO in the timer control register will be set.

Note: The transmit request bits (i.e NTATTx.TXMO / NTBTTx.TXMO / NTCTTx.TXMO) in the timer control register of a node is able to trigger transmit request (MOSTATn.TXRQ) of message object in a list belonging to any other CAN nodes.

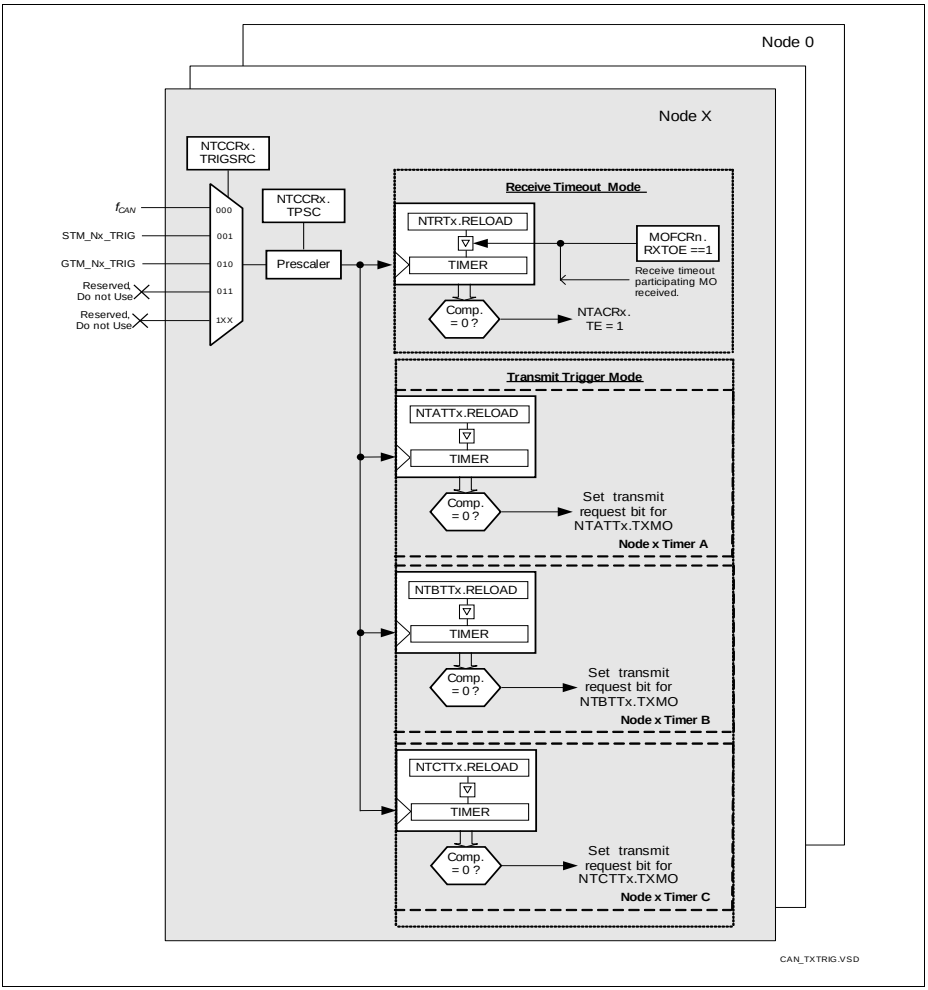

Figure 22-13 CAN Node Timing Modes

22.4.6.6 CAN Node Interrupts

Each CAN node has five hardware triggered interrupt request types that are able to generate an interrupt request upon:

- The successful transmission or reception of a frame
- A CAN protocol error with a last error code
- An alert condition: Transmit/receive error counters reach the warning limit, bus-off state changes, a List Length Error occurs, or a List Object Error occurs
- An overflow of the frame counter
- A node timer A, C or D event

Besides the hardware generated interrupts, software initiated interrupts can be generated using the Module Interrupt Trigger Register MITR. Writing a 1 to bit n of bit field MITR.IT generates an interrupt request signal on the corresponding interrupt output line INT_On. When writing MITR.IT more than one bit can be set resulting in activation of multiple INT_On interrupt output lines at the same time. See also **“Interrupt Control” on Page 22-171** for further processing of the CAN node interrupts.

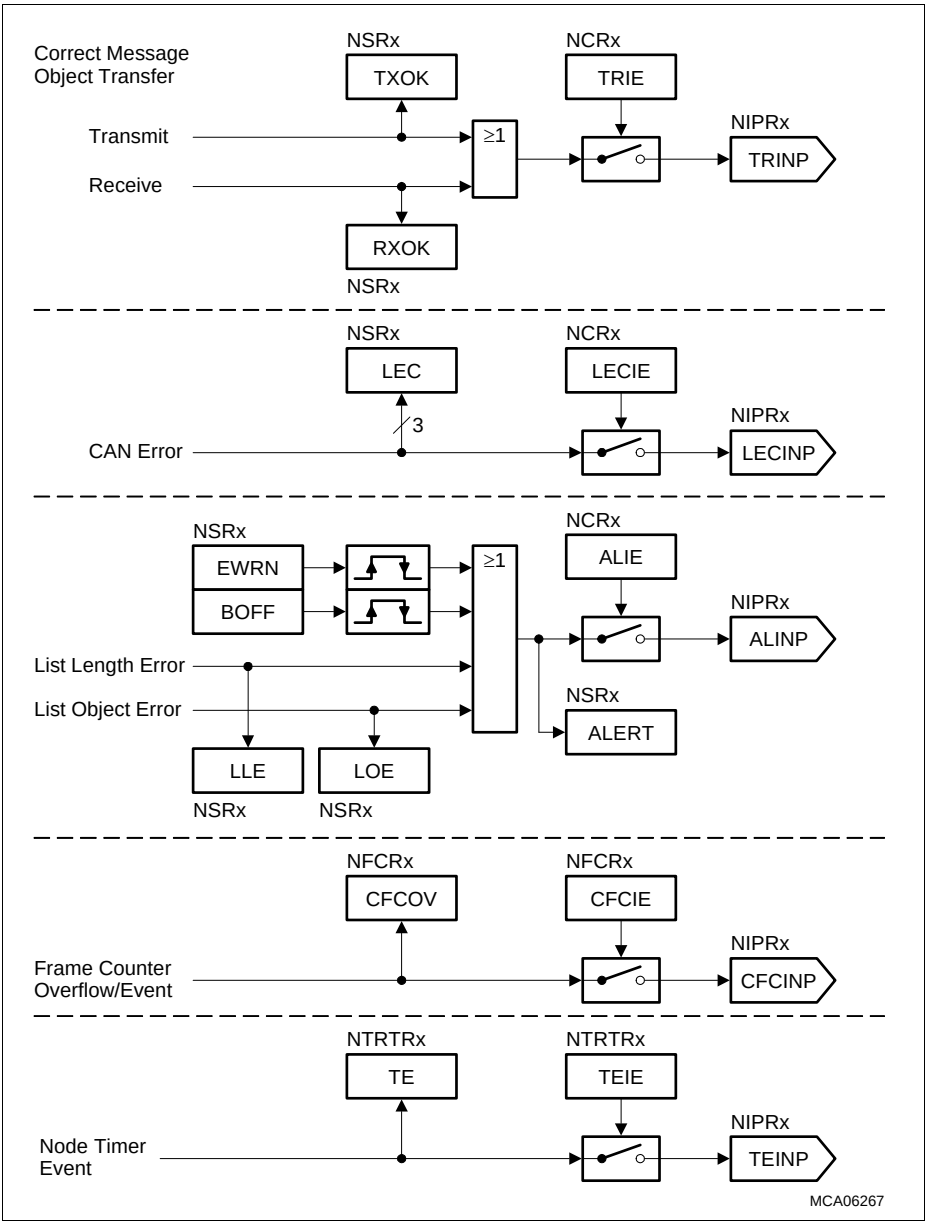

Figure 22-14 CAN Node Interrupts

22.4.7 Message Object List Structure

This section describes the structure of the message object lists in the MultiCAN+ module.

22.4.7.1 Basics

The message objects of the MultiCAN+ module are organized in double-chained lists, where each message object has a pointer to the previous message object in the list as well as a pointer to the next message object in the list. The MultiCAN+ module provides 16 lists. Each message object is allocated to one of these lists. In the example in **Figure 22-15**, the three message objects (3, 5, and 16) are allocated to the list with index 2 (List Register LIST2).

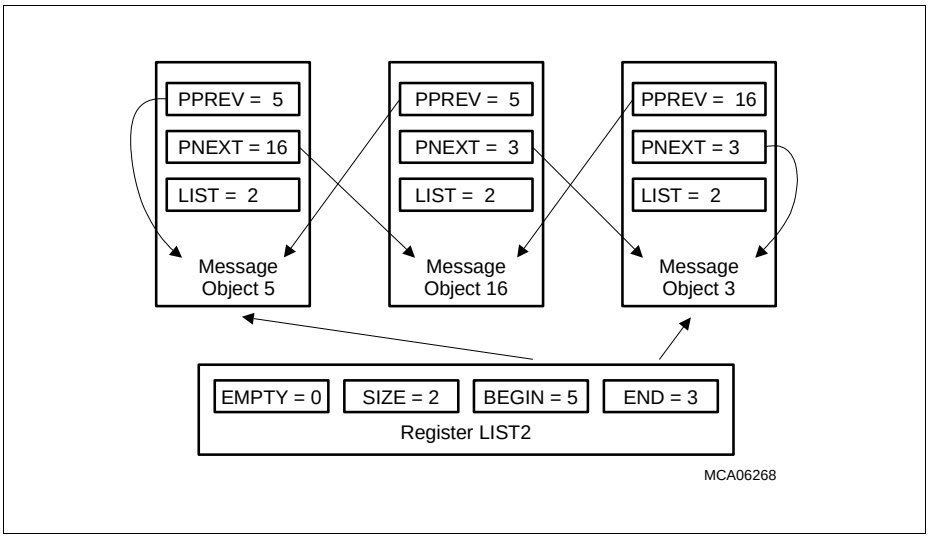

Figure 22-15 Example Allocation of Message Objects to a List

Bit field BEGIN in the List Register (for definition, see **Page 22-87**) points to the first element in the list (object 5 in the example), and bit field END points to the last element in the list (object 3 in the example). The number of elements in the list is indicated by bit field SIZE of the List Register (SIZE = number of list elements - 1, thus SIZE = 2 for the 3 elements in the example). The EMPTY bit of the List Register indicates whether or not a list is empty (EMPTY = 0 in the example, because list 2 is not empty).

Each message object n has a pointer PNEXT in its Message Object n Status Register MOSTATn (see **Page 22-127**) that points to the next message object in the list, and a pointer PPREV that points to the previous message object in the list. PPREV of the first message object points to the message object itself because the first message object has

no predecessor (in the example message object 5 is the first message object in the list, indicated by PPREV = 5). PNEXT of the last message object also points to the message object itself because the last message object has no successor (in the example, object 3 is the last message object in the list, indicated by PNEXT = 3).

Bit field MOSTATn.LIST indicates the list index number to which the message object is currently allocated. The message object of the example are allocated to list 2. Therefore, all LIST bit fields for the message objects assigned to list 2 are set to LIST = 2.

22.4.7.2 List of Unallocated Elements

The list with list index 0 has a special meaning: it is the list of all unallocated elements. An element is called unallocated if it belongs to list 0 (MOSTATn.LIST = 0). It is called allocated if it belongs to a list with an index not equal to 0 (MOSTATn.LIST > 0).

After reset, all message objects are unallocated. This means that they are assigned to the list of unallocated elements with MOSTATn.LIST = 0. After this initial allocation of the message objects caused by reset, the list of all unallocated message objects is ordered by message number (predecessor of message object n is object n-1, successor of object n is object n+1).

22.4.7.3 Connection to the CAN Nodes

Each CAN node is linked to one unique list of message objects. A CAN node performs message transfer only with the message objects that are allocated to the list of the CAN node. This is illustrated in **Figure 22-16**. Frames that are received on a CAN node may only be stored in one of the message objects that belongs to the CAN node; frames to be transmitted on a CAN node are selected only from the message objects that are allocated to that node, as indicated by the vertical arrows.

There are more lists (16) than CAN nodes (4). This means that some lists are not linked to one of the CAN nodes. A message object that is allocated to one of these unlinked lists cannot receive messages directly from a CAN node and it may not transmit messages.

FIFO and gateway mechanisms refer to message numbers and not directly to a specific list. The user must take care that the message objects targeted by FIFO/gateway belong to the desired list. The mechanisms make it possible to work with lists that do not belong to the CAN node.

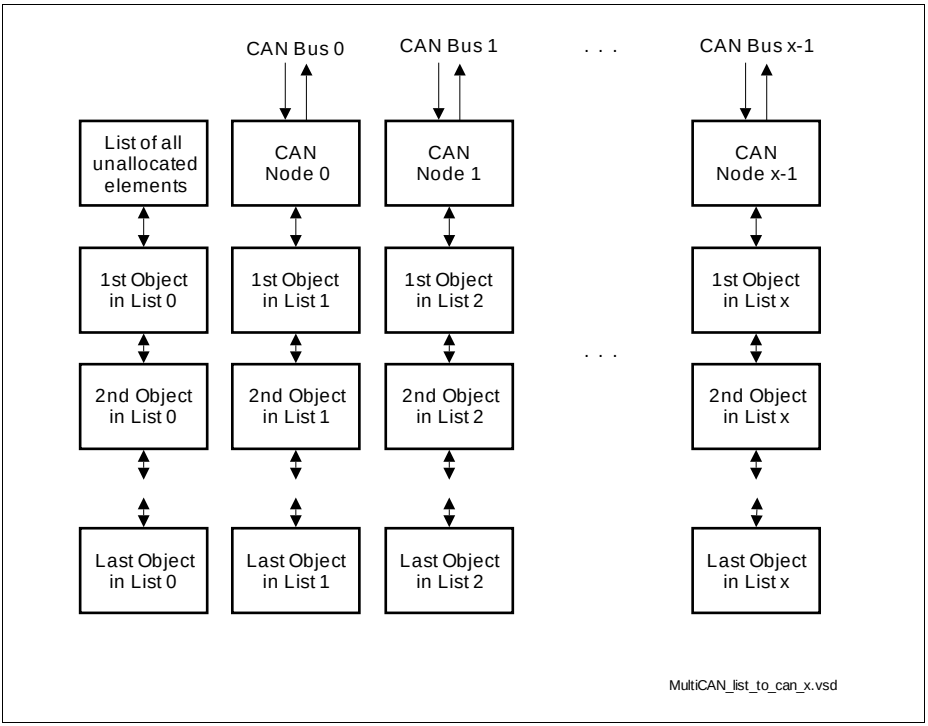

Figure 22-16 Message Objects Linked to CAN Nodes

22.4.7.4 List Command Panel

The list structure cannot be modified directly by write accesses to the LIST registers and the PPREV, PNEXT and LIST bit fields in the Message Object Status Registers, as they are read only. The list structure is managed by and limited to the list controller inside the MultiCAN+ module. The list controller is controlled via a command panel allowing the user to issue list allocation commands to the list controller. The list controller has two main purposes:

1. Ensure that all operations that modify the list structure result in a consistent list structure.
2. Present maximum ease of use and flexibility to the user.

The list controller and the associated command panel allows the programmer to concentrate on the final properties of the list, which are characterized by the allocation of message objects to a CAN node, and the ordering relation between objects that are allocated to the same list. The process of list (re-)building is done in the list controller.

Table 22-7 gives an overview on the available panel commands while Table 22-11 on Page 22-81 describes the panel commands in more detail.

Table 22-7 Panel Commands Overview

Command Name	Description
No Operation	No new command is started.
Initialize Lists	Run the initialization sequence to reset the CTRL and LIST field of all message objects.
Static Allocate	Allocate message object to a list.
Dynamic Allocate	Allocate the first message object of the list of unallocated objects to the selected list.
Static Insert Before	Remove a message object (source object) from the list that it currently belongs to, and insert it before a given destination object into the list structure of the destination object.
Dynamic Insert Before	Insert a new message object before a given destination object.
Static Insert Behind	Remove a message object (source object) from the list that it currently belongs to, and insert it behind a given destination object into the list structure of the destination object.
Dynamic Insert Behind	Insert a new message object behind a given destination object.

A panel command is started by writing the respective command code into the Panel Control Register bit field PANCTR.PANCMD (see Page 22-80). The corresponding command arguments must be written into bit fields PANCTR.PANAR1 and PANCTR.PANAR2 before writing the command code, or latest along with the command code in a single 32-bit write access to the Panel Control Register.

With the write operation of a valid command code, the PANCTR.BUSY flag is set and further write accesses to the Panel Control Register are ignored. The BUSY flag remains active and the control panel remains locked until the execution of the requested command has been completed. After a reset and resetting the CLC.DISR (see Page 22-165) register, the list controller builds up list 0. Afterwards the BUSY bit is set, dependent on core speed this might be visible. During list controller initialization, BUSY is set and other accesses to the CAN RAM are forbidden. The CAN RAM can be accessed again when BUSY becomes inactive.

Note: The CAN RAM is automatically initialized after reset by the list controller in order to ensure correct list pointers in each message object. The end of this CAN RAM initialization is indicated by bit PANCTR.BUSY becoming inactive.

In case of a dynamic allocation command that takes an element from the list of unallocated objects, the PANCTR.RBUSY bit is also set along with the BUSY bit (RBUSY = BUSY = 1). This indicates that bit fields PANAR1 and PANAR2 are going to be updated by the list controller in the following way:

1. The message number of the message object taken from the list of unallocated elements is written to PANAR1.
2. If ERR (bit 7 of PANAR2) is set to 1, the list of unallocated elements was empty and the command is aborted. If ERR is 0, the list was not empty and the command will be performed successfully.

The results of a dynamic allocation command are written before the list controller starts the actual allocation process. As soon as the results are available, RBUSY becomes inactive (RBUSY = 0) again, while BUSY still remains active until completion of the command. This allows the user to set up the new message object while it is still in the process of list allocation. The access to message objects is not limited during ongoing list operations. However, any access to a register resource located inside the RAM delays the ongoing allocation process by one access cycle.

As soon as the command is finished, the BUSY flag becomes inactive (BUSY = 0) and write accesses to the Panel Control Register are enabled again. Also, the “No Operation” command code is automatically written to the PANCTR.PANCMD field. A new command may be started any time when BUSY = 0.

All fields of the Panel Control Register PANCTR except BUSY and RBUSY may be written by the user. This makes it possible to save and restore the Panel Control Register if the Command Panel is used within independent (mutually interruptible) interrupt service routines. If this is the case, any task that uses the Command Panel and that may interrupt another task that also uses the Command Panel should poll the BUSY flag until it becomes inactive and save the whole PANCTR register to a memory location before issuing a command. At the end of the interrupt service routine, the task should restore PANCTR from the memory location.

Before a message object that is allocated to the list of an active CAN node shall be moved to another list or to another position within the same list, bit MOSTATn.MSGVAL (“Message Valid”) of message object n must be cleared.

22.4.8 CAN Node Analyzer Mode

The chapter describes the CAN node analyzer capabilities of the MultiCAN+ module.

22.4.8.1 Analyzer Mode

The CAN Analyzer Mode makes it possible to monitor the CAN traffic for each CAN node individually without affecting the logical state of the CAN bus. The CAN Analyzer Mode for CAN node x is selected by setting Node x Control Register bit NCRx.CALM.

In CAN Analyzer Mode, the transmit pin of a CAN node is held at a recessive level permanently. The CAN node may receive frames (Data, Remote, and Error Frames) but is not allowed to transmit. Received Data/Remote Frames are not acknowledged (i.e. acknowledge slot is sent recessive) but will be received and stored in matching message objects as long as there is any other node that acknowledges the frame. The complete message object functionality is available, but no transmit request will be executed. CAN Analyzer mode works for both Classical CAN format and CAN FD format.

22.4.8.2 Loop-Back Mode

The MultiCAN+ module provides a Loop-Back Mode to enable an in-system test of the MultiCAN+ module as well as the development of CAN driver software without access to an external CAN bus.

The loop-back feature consists of an internal CAN bus (inside the MultiCAN+ module) and a bus select switch for each CAN node (see **Figure 22-17**). With the switch, each CAN node can be connected either to the internal CAN bus (Loop-Back Mode activated) or the external CAN bus, respectively to transmit and receive pins (normal operation). The CAN bus that is not currently selected is driven recessive; this means the transmit pin is held at 1, and the receive pin is ignored by the CAN nodes that are in Loop-Back Mode.

The Loop-Back Mode is selected for CAN node x by setting the Node x Port Control Register bit NPCRx.LBM. All CAN nodes that are in Loop-Back Mode may communicate together via the internal CAN bus without affecting the normal operation of the other CAN nodes that are not in Loop-Back Mode.

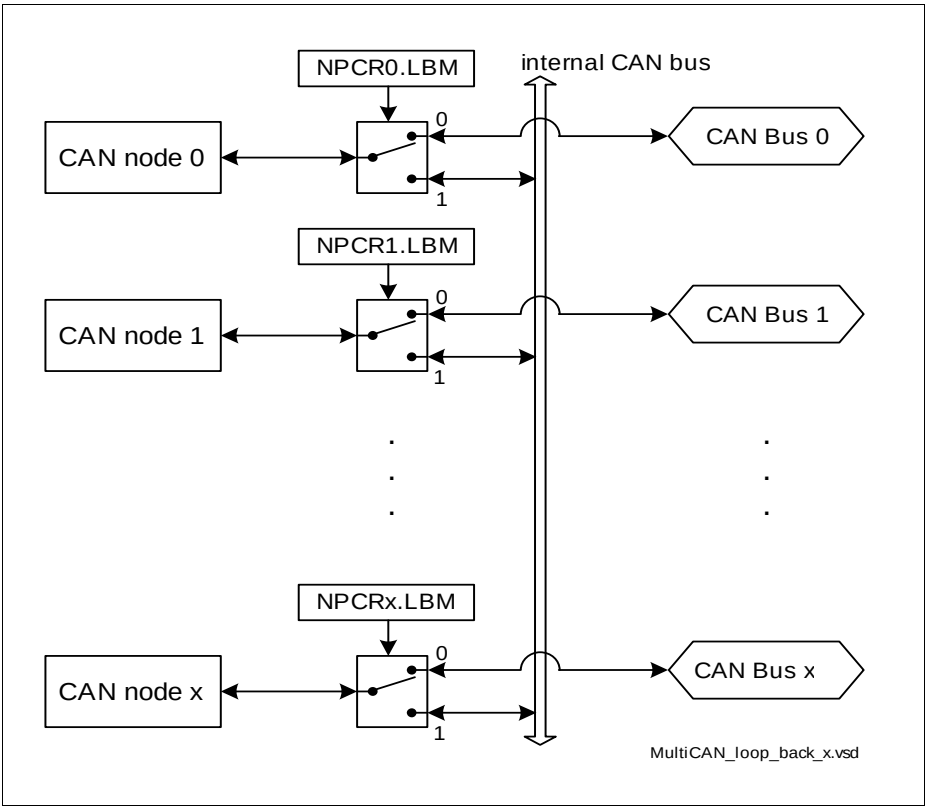

Figure 22-17 Loop-Back Mode

22.4.8.3 Bit Timing Analysis

Detailed analysis of the bit timing can be performed for each CAN node using the analysis modes of the CAN frame counter. The bit timing analysis functionality of the frame counter may be used for automatic detection of the CAN baud rate, as well as to analyze the timing of the CAN network.

Bit timing analysis for CAN node x is selected when bit field NFCRx.CFMOD = 10_B. Bit timing analysis does not affect the operation of the CAN node.

The bit timing measurement results are written into the NFCRx.CFC bit field. Whenever NFCRx.CFC is updated in bit timing analysis mode, bit NFCRx.CFCOV is also set to indicate the CFC update event. The value of NFCRx.CFC is valid one module cycle later when NFCRx.CFCOV is set. If NFCRx.CFCIE is set, an interrupt request can be generated (see **Figure 22-14**).

Automatic Baud Rate Detection

For automatic baud rate detection, the time between the observation of subsequent dominant edges on the CAN bus must be measured. This measurement is automatically performed if bit field NFCRx.CFSEL = 000_B. With each dominant edge monitored on the CAN receive input line, the time (measured in f_{CAN} clock cycles) between this edge and the most recent dominant edge is stored in the NFCRx.CFC bit field.

Synchronization Analysis

The bit time synchronization is monitored if NFCRx.CFSEL = 010_B. The time between the first dominant edge and the sample point is measured and stored in the NFCRx.CFC bit field. The bit timing synchronization offset may be derived from this time as the first edge after the sample point triggers synchronization and there is only one synchronization between consecutive sample points.

Synchronization analysis can be used, for example, for fine tuning of the baud rate during reception of the first CAN frame with the measured baud rate.

Driver Delay Measurement

The delay between a transmitted edge and the corresponding received edge is measured when NFCRx.CFSEL = 011_B (dominant to dominant) and NFCRx.CFSEL = 100_B (recessive to recessive). These delays indicate the time needed to represent a new bit value on the physical implementation of the CAN bus.

22.4.9 Message Acceptance Filtering

The chapter describes the Message Acceptance Filtering capabilities of the MultiCAN+ module.

22.4.9.1 Receive Acceptance Filtering

When a CAN frame is received by a CAN node, a unique message object is determined in which the received frame is stored after successful frame reception. A message object is qualified for reception of a frame if the following six conditions are met.

- The message object is allocated to the message object list of the CAN node by which the frame is received.
- Bit MOSTATn.MSGVAL in the Message Object Status Register (see **Page 22-127**) is set.
- Bit MOSTATn.RXEN is set.
- Bit MOSTATn.DIR is equal to bit RTR of the received frame.
  If bit MOSTATn.DIR = 1 (transmit object), the message object accepts only Remote Frames. If bit MOSTATn.DIR = 0 (receive object), the message object accepts only Data Frames.

- If bit MOAMRn.MIDE = 1, the IDE bit of the received frame becomes evaluated in the following way: If MOARn.IDE = 1, the IDE bit of the received frame must be set (indicates extended identifier). If MOARn.IDE = 0, the IDE bit of the received frame must be cleared (indicates standard identifier).
  If bit MOAMRn.MIDE = 0, the IDE bit of the received frame is “don’t care”. In this case, message objects with standard and extended frames are accepted.
- The identifier of the received frame matches the identifier stored in the Arbitration Register of the message object as qualified by the acceptance mask in the MOAMRn register. This means that each bit of the received message object identifier is equal to the bit field MOARn.ID, except those bits for which the corresponding acceptance mask bits in bit field MOAMRn.AM are cleared. These identifier bits are “don’t care” for reception. **Figure 22-18** illustrates this receive message identifier check.

Among all messages that fulfill all six qualifying criteria the message object with the highest receive priority wins receive acceptance filtering and becomes selected to store the received frame. All other message objects lose receive acceptance filtering.
The following priority scheme is defined for the message objects:
A message object a (MOa) has higher receive priority than a message object b (MOb) if the following two conditions are fulfilled (see **Page 22-144**):

1. MOa has a higher priority class than MOb. This means, the 2-bit priority bit field MOARa.PRI must be equal or less than bit field MOARb.PRI.
2. If both message objects have the same priority class (MOARa.PRI = MOARb.PRI), MOb is a list successor of MOa. This means that MOb can be reached by means of successively stepping forward in the list, starting from a.

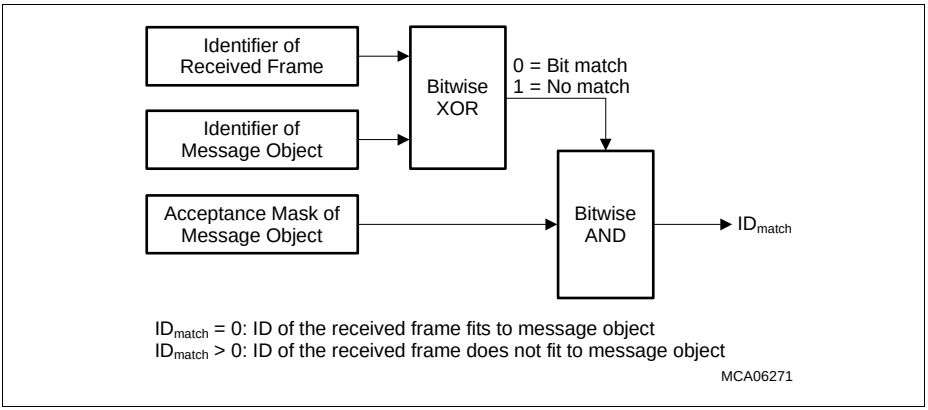

Figure 22-18 Received Message Identifier Acceptance Check

22.4.9.2 Transmit Acceptance Filtering

A message is requested for transmission by setting a transmit request in the message object that holds the message. If more than one message object have a valid transmit request for the same CAN node, one of these message objects is chosen for transmission, because only a single message object can be transmitted at one time on a CAN bus.

A message object is qualified for transmission on a CAN node if the following four conditions are met (see also **Figure 22-19**).

1. The message object is allocated to the message object list of the CAN node.
2. Bit MOSTATn.MSGVAL is set.
3. Bit MOSTATn.TXRQ is set.
4. Bit MOSTATn.TXEN0 and MOSTATn.TXEN1 are set.

A priority scheme determines which one of all qualifying message objects is transmitted first. It is assumed that message object a (MOa) and message object b (MOb) are two message objects qualified for transmission. MOb is a list successor of MOa. For both message objects, CAN messages CANa and CANb are defined (identifier, IDE, and RTR are taken from the message-specific bit fields and bits MOARn.ID, MOARn.IDE and MOSTATn.DIR).
If both message objects belong to the same priority class (identical PRI bit field in register MOARn), MOa has a higher transmit priority than MOb if one of the following conditions is fulfilled.

- PRI = 10_B and CAN message MOa has higher or equal priority than CAN message MOb with respect to CAN arbitration rules (see **Table 22-19** on **Page 22-145**).
- PRI = 01_B or PRI = 11_B (priority by list order).

The message object that is qualified for transmission and has highest transmit priority wins the transmit acceptance filtering, and will be transmitted first. All other message objects lose the current transmit acceptance filtering round. They get a new chance in subsequent acceptance filtering rounds.

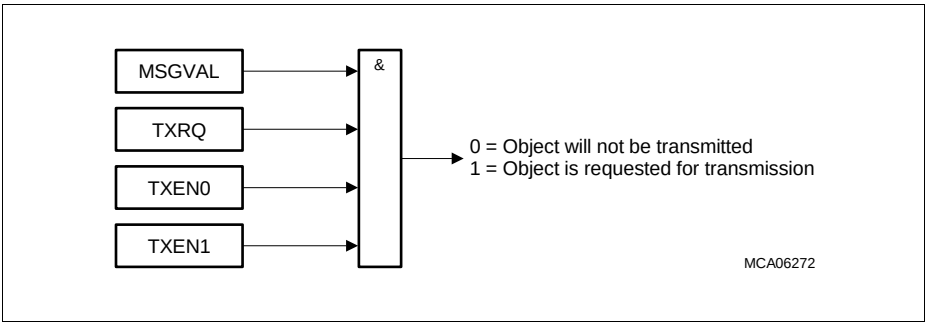

Figure 22-19 Effective Transmit Request of Message Object

22.4.10 Message Postprocessing

After a message object has successfully received or transmitted a frame, the CPU can be notified to perform a postprocessing on the message object. The postprocessing of the MultiCAN+ module consists of two elements:

1. Message interrupts to trigger postprocessing.
2. Message pending registers to collect pending message interrupts into a common structure for postprocessing.

22.4.10.1 Message Object Interrupts

When the storage of a received frame into a message object or the successful transmission of a frame is completed, a message interrupt can be issued. For each message object, a transmit and a receive interrupt can be generated and routed to one of the sixteen CAN interrupt output lines (see **Figure 22-20**). A receive interrupt occurs also after a frame storage event that has been induced by a FIFO or a gateway action. The status bits TXPND and RXPND in the Message Object n Status Register are always set after a successful transmission/reception, whether or not the respective message interrupt is enabled.

A third FIFO full interrupt condition of a message object is provided. If bit field MOFCRn.OVIE (Overflow Interrupt Enable) is set, the FIFO full interrupt will be activated depending on the actual message object type.

In case of a Receive FIFO Base Object (MOFCRn.MMC = 0001_B), the FIFO full interrupt is routed to the interrupt output line INT_Om as defined by the transmit interrupt node pointer MOIPRn.TXINP.

In case of a Transmit FIFO Base Object (MOFCRn.MMC = 0010_B), the FIFO full interrupt becomes routed to the interrupt output line INT_Om as defined by the receive interrupt node pointer MOIPRn.RXINP.

See also **“Interrupt Control” on Page 22-171** for further processing of the message object interrupts.

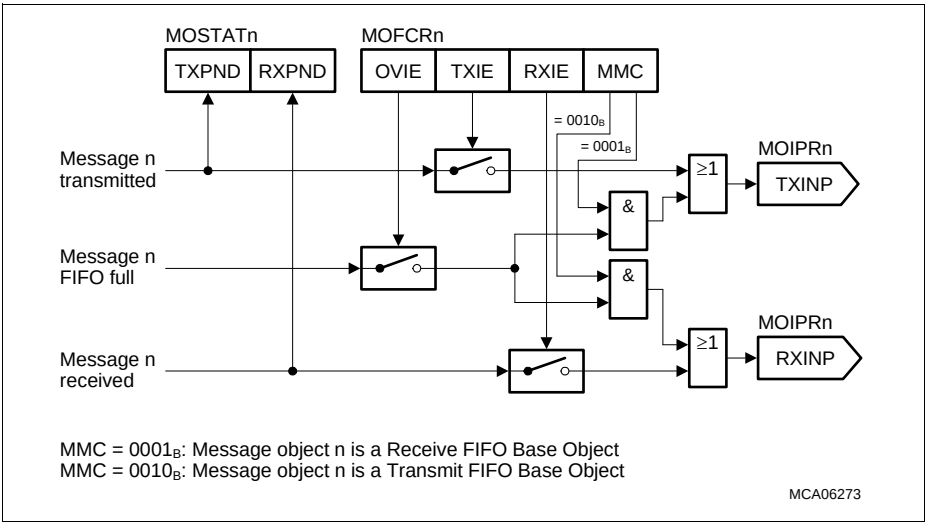

Figure 22-20 Message Interrupt Request Routing

22.4.10.2 Pending Messages

When a message interrupt request is generated, a message pending bit is set in one of the Message Pending Registers. There are 8 Message Pending Registers, MSPNDk (k = 0-7) with 32 pending bits available each. The general **Figure 22-21** shows the allocation of the message pending bits in case that the maximum possible number of eight Message Pending Registers are implemented and available on the chip.

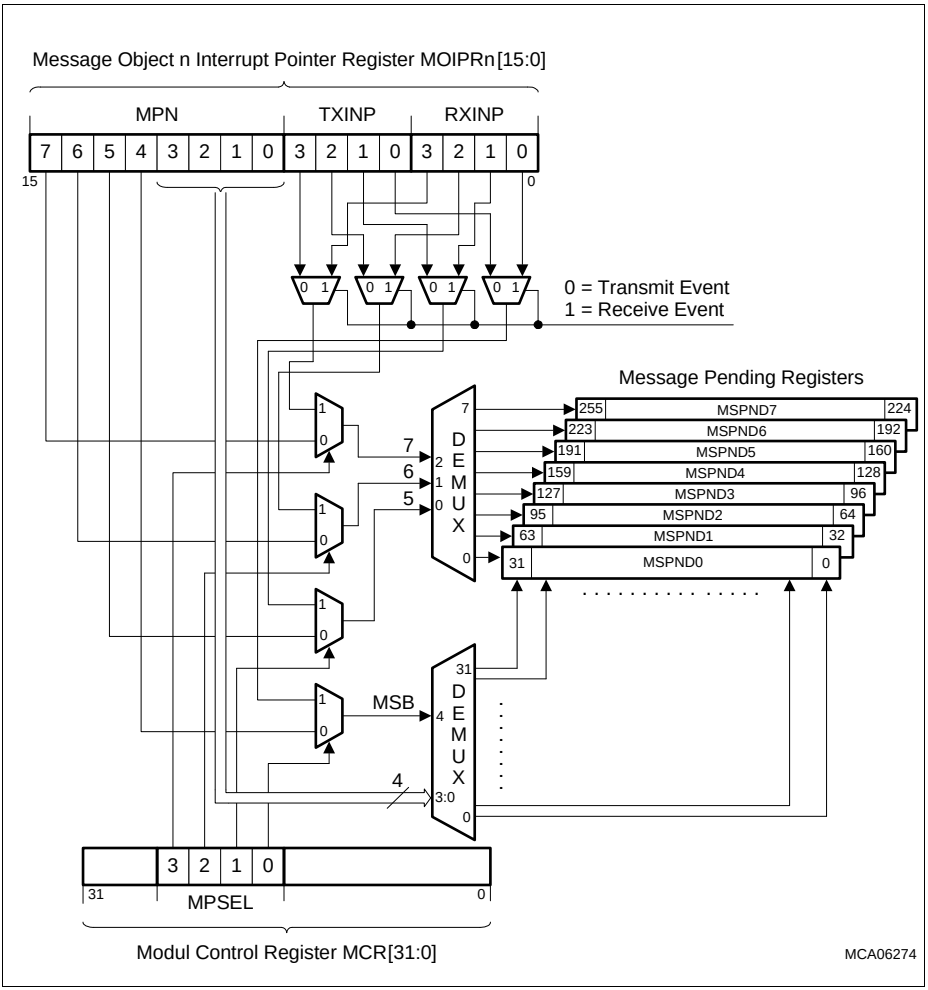

Figure 22-21 Message Pending Bit Allocation

The location of a pending bit is defined by two demultiplexers selecting the number k of the MSPNDk registers (3-bit demux), and the bit location within the corresponding MSPNDk register (5-bit demux).

Allocation Case 1

In this allocation case, bit field MCR.MPSEL = 0000_B (see **Page 22-84**). The location selection consists of 2 parts:

- The upper three bits of MOIPRn.MPN (MPN[7:5]) select the number k of a Message Pending Register MSPNDk in which the pending bit will be set.
- The lower five bits of MOIPRn.MPN (MPN[4:0]) select the bit position (0-31) in MSPNDk for the pending bit to be set.

Allocation Case 2

In this allocation case, bit field MCR.MPSEL is taken into account for pending bit allocation. Bit field MCR.MPSEL makes it possible to include the interrupt request node pointer for reception (MOIPRn.RXINP) or transmission (MOIPRn.TXINP) for pending bit allocation in such a way that different target locations for the pending bits are used in receive and transmit case. If MPSEL = 1111_B, the location selection operates in the following way:

- At a transmit event, the upper 3 bits of TXINP determine the number k of a Message Pending Register MSPNDk in which the pending bit will be set. At a receive event, the upper 3 bits of RXINP determine the number k.
- The bit position (0-31) in MSPNDk for the pending bit to be set is selected by the lowest bit of TXINP or RXINP (selects between low and high half-word of MSPNDk) and the four least significant bits of MPN.

General Hints

The Message Pending Registers MSPNDk can be written by software. Bits that are written with 1 are left unchanged, and bits which are written with 0 are cleared. This makes it possible to clear individual MSPNDk bits with a single register write access. Therefore, access conflicts are avoided when the MultiCAN+ module (hardware) sets another pending bit at the same time when software writes to the register.

Each Message Pending Register MSPNDk is associated with a Message Index Register MSIDk (see **Page 22-90**) which indicates the lowest bit position of all set (1) bits in Message Pending Register k. The MSIDk register is a read-only register that is updated immediately when a value in the corresponding Message Pending Register k is changed by software or hardware.

22.4.11 Message Object Data Handling

This chapter describes the handling capabilities for the Message Object Data of the MultiCAN+ module.

22.4.11.1 Frame Reception

After the reception of a message, it is stored in a message object according to the scheme shown in **Figure 22-22**. The MultiCAN+ module not only copies the received data into the message object, and it provides advanced features to enable consistent data exchange between MultiCAN+ and CPU.

MSGVAL

Bit MSGVAL (Message Valid) in the Message Object n Status Register MOSTATn is the main switch of the message object. During the frame reception, information is stored in the message object only when MSGVAL = 1. If bit MSGVAL is reset by the CPU, the MultiCAN+ module stops all ongoing write accesses to the message object. Now the message object can be re-configured by the CPU with subsequent write accesses to it without being disturbed by the MultiCAN+.

RTSEL

When the CPU re-configures a message object during CAN operation (for example, clears MSGVAL, modifies the message object and sets MSGVAL again), the following scenario can occur:

1. The message object wins receive acceptance filtering.
2. The CPU clears MSGVAL to re-configure the message object.
3. The CPU sets MSGVAL again after re-configuration.
4. The end of the received frame is reached. As MSGVAL is set, the received data is stored in the message object, a message interrupt request is generated, gateway and FIFO actions are processed, etc.

After the re-configuration of the message object (after step 3 above) the storage of further received data may be undesirable. This can be achieved through bit MOSTATn.RTSEL (Receive/Transmit Selected) that makes it possible to disconnect a message object from an ongoing frame reception.

When a message object wins the receive acceptance filtering, its RTSEL bit is set by the MultiCAN+ module to indicate an upcoming frame delivery. The MultiCAN+ module checks RTSEL whether it is set on successful frame reception to verify that the object is still ready for receiving the frame. The received frame is then stored in the message object (along with all subsequent actions such as message interrupts, FIFO & gateway actions, flag updates) only if RTSEL = 1.

When a message object is invalidated during CAN operation (resetting bit MSGVAL), RTSEL should be cleared before setting MSGVAL again (latest with the same write

access that sets MSGVAL) to prevent the storage of a frame that belongs to the old context of the message object. Therefore, a message object re-configuration should consist of the following steps:

1. Clear MSGVAL bit
2. Re-configure the message object while MSGVAL = 0
3. Clear RTSEL bit and set MSGVAL again

RXEN

Bit MOSTATn.RXEN enables a message object for frame reception. A message object can receive CAN messages from the CAN bus only if RXEN = 1. The MultiCAN+ module evaluates RXEN only during receive acceptance filtering. After receive acceptance filtering, RXEN is ignored and has no further influence on the actual storage of a received message in a message object.

Bit RXEN enables the “soft phase out” of a message object: after clearing RXEN, a currently received CAN message for which the message object has won acceptance filtering is still stored in the message object but for subsequent messages the message object no longer wins receive acceptance filtering.

RXUPD, NEWDAT and MSGLST

An ongoing frame storage process is indicated by the RXUPD (Receive Updating) flag in the MOSTATn register. RXUPD is set with the start and cleared with the end of a message object update, which consists of frame storage as well as flag updates.

After storing the received frame (identifier, IDE bit, DLC; including the Data Field for Data Frames), the NEWDAT (New Data) bit of the message object is set. If NEWDAT was already set before it becomes set again, bit MSGLST (Message Lost) is set to indicate a data loss condition.

The RXUPD and NEWDAT flags can help to read consistent frame data from the message object during an ongoing CAN operation. The following steps are recommended to be executed:

1. Clear NEWDAT bit.
2. Read message content (identifier, data etc.) from the message object.
3. Check that both, NEWDAT and RXUPD, are cleared. If this is not the case, go back to step 1.
4. When step 3 was successful, the message object contents are consistent and has not been updated by the MultiCAN+ module while reading.

Bits RXUPD, NEWDAT and MSGLST have the same behavior for the reception of Data as well as Remote Frames.

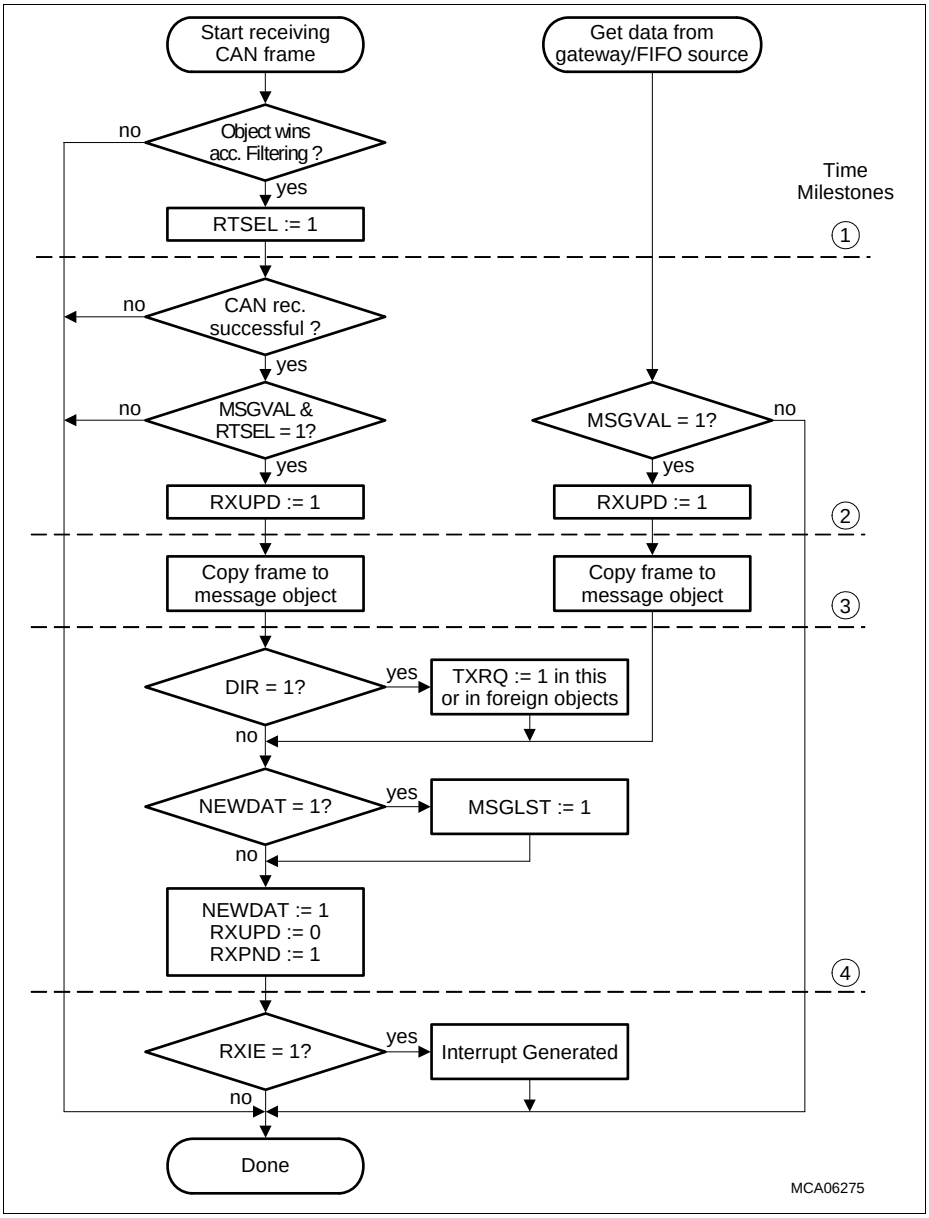

Figure 22-22 Reception of a Message Object

22.4.11.2 Frame Transmission

The process of a message object transmission is shown in **Figure 22-23**. Along with the copy of the message object content to be transmitted (identifier, IDE bit, RTR = DIR bit, DLC, including the Data Field for Data Frames) into the internal transmit buffer of the assigned CAN node, several status flags are also served and monitored to control consistent data handling.

The transmission process of a message object starting after the transmit acceptance filtering is identical for Remote and Data Frames.

MSGVAL, TXRQ, TXEN0, TXEN1

A message can only be transmitted if all four bits in registers MOSTATn, MSGVAL (Message Valid), TXRQ (Transmit Request), TXEN0 (Transmit Enable 0), TXEN1 (Transmit Enable 1) are set as shown in **Figure 22-19**. Although these bits are equivalent with respect to the transmission process, they have different semantics:

Table 22-8 Message Transmission Bit Definitions

Bit	Description
MSGVAL	**Message Valid** This is the main switch bit of the message object.
TXRQ	**Transmit Request** This is the standard transmit request bit. This bit must be set whenever a message object should be transmitted. TXRQ is cleared by hardware at the end of a successful transmission, except when there is new data (indicated by NEWDAT = 1) to be transmitted. When bit MOFCRn.STT (“Single Transmit Trial”) is set, TXRQ becomes already cleared when the contents of the message object are copied into the transmit frame buffer of the CAN node. A received remote request (after a Remote Frame reception) sets bit TXRQ to request the transmission of the requested data frame.
TXEN0	**Transmit Enable 0** This bit can be temporarily cleared by software to suppress the transmission of this message object when it writes new content to the Data Field. This avoids transmission of inconsistent frames that consist of a mixture of old and new data. Remote requests are still accepted when TXEN0 = 0, but transmission of the Data Frame is suspended until transmission is re-enabled by software (setting TXEN0).

Table 22-8 Message Transmission Bit Definitions (cont'd)

Bit	Description
TXEN1	**Transmit Enable 1** This bit is used in transmit FIFOs to select the message object that is transmit active within the FIFO structure. For message objects that are not transmit FIFO elements, TXEN1 can either be set permanently to 1 or can be used as a second independent transmission enable bit.

RTSEL

When a message object has been identified to be transmitted next after transmission acceptance filtering, bit MOSTATn.RTSEL (Receive/Transmit Selected) is set.

When the message object is copied into the internal transmit buffer, bit RTSEL is checked, and the message is transmitted only if RTSEL = 1. After the successful transmission of the message, bit RTSEL is checked again and the message postprocessing is only executed if RTSEL = 1.

For a complete re-configuration of a valid message object, the following steps should be executed:

1. Clear MSGVAL bit
2. Re-configure the message object while MSGVAL = 0
3. Clear RTSEL and set MSGVAL

Clearing of RTSEL ensures that the message object is disconnected from an ongoing/scheduled transmission and no message object processing (copying message to transmit buffer including clearing NEWDAT, clearing TXRQ, time stamp update, message interrupt, etc.) within the old context of the object can occur after the message object becomes valid again, but within a new context.

NEWDAT

When the contents of a message object have been transferred to the internal transmit buffer of the CAN node, bit MOSTATn.NEWDAT (New Data) is cleared by hardware to indicate that the transmit message object data is no longer new.

When the transmission of the frame is successful and NEWDAT is still cleared (if no new data has been copied into the message object meanwhile), TXRQ (Transmit Request) is cleared automatically by hardware.

If, however, the NEWDAT bit has been set again by the software (because a new frame should be transmitted), TXRQ is not cleared to enable the transmission of the new data.

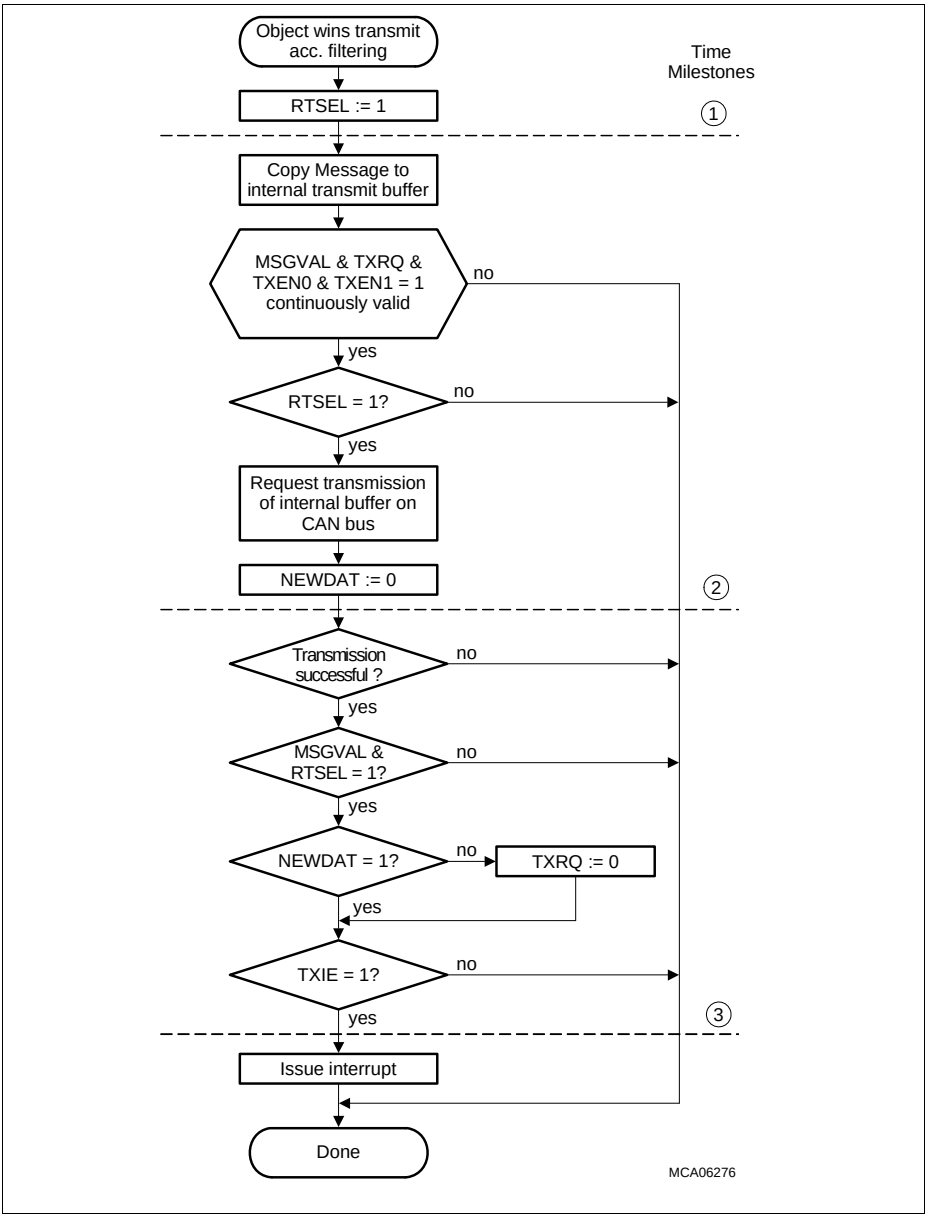

Figure 22-23 Transmission of a Message Object

22.4.12 Message Object Functionality

This chapter describes the functionality of the Message Objects in the MultiCAN+ module.

22.4.12.1 Standard Message Object

A message object is selected as standard message object when bit field MOFCRn.MMC = 0000_B (see **Page 22-114**). The standard message object can transmit and receive CAN frames according to the basic rules described in the previous sections. Additional services such as Single Data Transfer Mode or Single Transmit Trial (see following sections) are available and can be individually selected.

22.4.12.2 Single Data Transfer Mode

Single Data Transfer Mode is a useful feature in order to broadcast data over the CAN bus without unintended duplication of information. Single Data Transfer Mode is selected via bit MOFCRn.SDT.

Message Reception

When a received message stored in a message object is overwritten by a new received message, the contents of the first message are lost and replaced with the contents of the new received message (indicated by MSGLST = 1).

If SDT is set (Single Data Transfer Mode activated), bit MSGVAL of the message object is automatically cleared by hardware after the storage of a received Data or Remote Frame. This prevents the reception of further messages.

Message Transmission

When a message object receives a series of multiple remote requests, it transmits several Data Frames in response to the remote requests. If the data within the message object has not been updated in the time between the transmissions, the same data can be sent more than once on the CAN bus.

In Single Data Transfer Mode (SDT = 1), this is avoided because MSGVAL is automatically cleared after the successful transmission of a Data or Remote Frame.

22.4.12.3 Single Transmit Trial

If the bit STT in the message object function register is set (STT = 1), the transmission request is cleared (TXRQ = 0) when the frame contents of the message object have been copied to the internal transmit buffer of the CAN node. Thus, the transmission of the message object is not tried again when it fails due to CAN bus errors.

22.4.12.4 Message Object Format (Classical CAN & CAN FD)

Message objects are used for transmission or reception of CAN data frames. The transmit and receive behavior of a Classical CAN node in Classical CAN (ISO 11898-1:2003(E)) or CAN FD (ISO11898-1 DIS version 2014) are determined by a node control register bit (i.e NCRx.FDEN) and two message object function control register bits (i.e MOFCRn.FDF and MOFCRn.BRS) as shown in **Table 22-18**.

A CAN node which has been set to work in Classical CAN mode i.e (NCRx.FDEN = 0) would be able to transmit message objects programmed for Classical CAN Frames (i.e MOFCRn.FDF = 0, MOFCRn.BRS = 0/1) only. When receiving Classical CAN data frames in a node that works in Classical CAN mode the message object function control register bits (i.e MOFCRn.FDF and MODFCRn.BRS) are not used and not updated.

In the case when a CAN node set to work in a particular mode (e.g Classical CAN mode) and receives a message object request for transmission or reception that does not correspond with the CAN mode (i.e MOFCRn.FDF = 1, MOFCRn.BRS = 0/1), the transmission would be cancelled (i.e corresponding MOSTATn.TXRQ cleared) and CAN frame not received in message object. The CAN node is not blocked and able to transmit or receive other message objects.

However a CAN node that has been set to work in CAN FD mode i.e (NCRx.FDEN = 1) is able to transmit and receive Classical CAN Data Frames, Long Data Frames or Long + Fast Data Frames. For message object transmission, message object function control bits (i.e MOFCRn.FDF & MOFCRn.BRS) determines the CAN frame format to be used and functions as status register bits during message reception.

Note: Remote Frame Requests do not change MOFCRn.FDF and MOFCRn.BRS bits.

22.4.12.5 Message Object FIFO Structure

In case of high CPU load it may be difficult to process a series of CAN frames in time. This may happen if multiple messages are received or must be transmitted in short time.

Therefore, a FIFO buffer structure is available to avoid loss of incoming messages and to minimize the setup time for outgoing messages. The FIFO structure can also be used to automate the reception or transmission of a series of CAN messages and to generate a single message interrupt when the whole CAN frame series is done.

There can be several FIFOs in parallel. The number of FIFOs and their size are limited only by the number of available message objects. A FIFO can be installed, resized and de-installed at any time, even during CAN operation.

The basic structure of a FIFO is shown in **Figure 22-24**. A FIFO consists of one base object and n slave objects. The slave objects are chained together in a list structure (similar as in message object lists). The base object may be allocated to any list. Although **Figure 22-24** shows the base object as a separate part beside the slave objects, it is also possible to integrate the base object at any place into the chain of slave objects. This means that the base object is slave object, too (not possible for gateways).

The absolute object numbers of the message objects have no impact on the operation of the FIFO.

The base object does not need to be allocated to the same list as the slave objects. Only the slave object must be allocated to a common list (as they are chained together). Several pointers (BOT, CUR and TOP) that are located in the Message Object n FIFO/Gateway Pointer Register MOFGPRn link the base object to the slave objects, regardless whether the base object is allocated to the same or to another **list** than the slave objects.

The smallest FIFO would be a single message object which is both, FIFO base and FIFO slave (not very useful). The biggest possible FIFO structure would include all message objects of the MultiCAN+ module. Any FIFO sizes between these limits are possible.

In the FIFO base object, the FIFO boundaries are defined. Bit field MOFGPRn.BOT of the base object points to (includes the number of) the bottom slave object in the FIFO structure. The MOFGPRn.TOP bit field points to (includes the number of) the top slave object in the FIFO structure. The MOFGPRn.CUR bit field points to (includes the number of) the slave object that is actually selected by the MultiCAN+ module for message transfer. When a message transfer takes place with this object, CUR is set to the next message object in the list structure of the slave objects (CUR = PNEXT of current object). If CUR was equal to TOP (top of the FIFO reached), the next update of CUR will result in CUR = BOT (wrap-around from the top to the bottom of the FIFO). This scheme represents a circular FIFO structure where the bit fields BOT and TOP establish the link from the last to the first element.

Bit field MOFGPRn.SEL of the base object can be used for monitoring purposes. It makes it possible to define a slave object within the list at which a message interrupt is generated whenever the CUR pointer reaches the value of the SEL pointer. Thus SEL makes it possible to detect the end of a predefined message transfer series or to issue a warning interrupt when the FIFO becomes full.

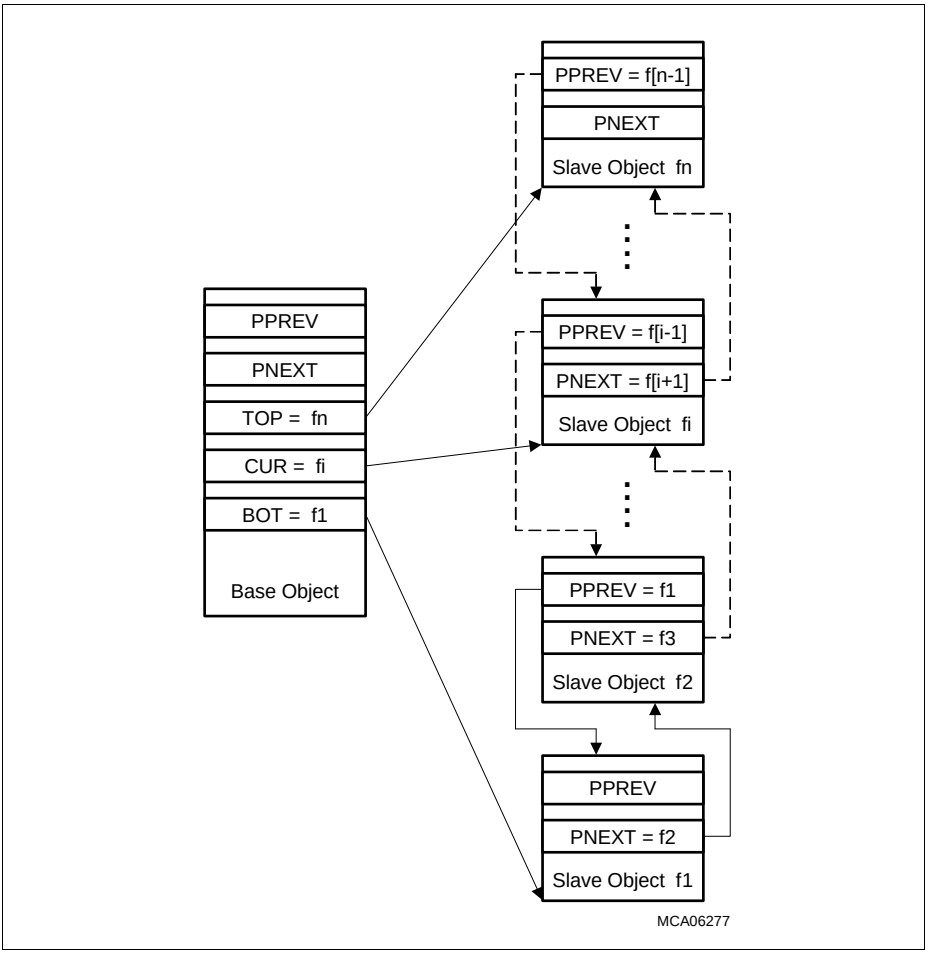

Figure 22-24 FIFO Structure with FIFO Base Object and n FIFO Slave Objects

22.4.12.6 Receive FIFO

The Receive FIFO structure is used to buffer incoming (received) Remote or Data Frames.

A Receive FIFO is selected by setting MOFCRn.MMC = 0001_B in the FIFO base object. This MMC code automatically designates a message object as FIFO base object. The message modes of the FIFO slave objects are not relevant for the operation of the Receive FIFO.

When the FIFO base object receives a frame from the CAN node it belongs to, the frame is not stored in the base object itself but in the message object that is selected by the base object's MOFGPRn.CUR pointer. This message object receives the CAN message as if it is the direct receiver of the message. However, MOFCRn.MMC = 0000_B is implicitly assumed for the FIFO slave object, and a standard message delivery is performed. The actual message mode (MMC setting) of the FIFO slave object is ignored. For the slave object, no acceptance filtering takes place that checks the received frame for a match with the identifier, IDE bit, and DIR bit.

With the reception of a CAN frame, the current pointer CUR of the base object is set to the number of the next message object in the FIFO structure. This message object will then be used to store the next incoming message.

If bit field MOFCRn.OVIE ("Overflow Interrupt Enable") of the FIFO base object is set and the current pointer MOFGPRn.CUR becomes equal to MOFGPRn.SEL, a FIFO overflow interrupt request is generated. This interrupt request is generated on interrupt node TXINP of the base object immediately after the storage of the received frame in the slave object. Transmit interrupts are still generated if TXIE is set.

A CAN message is stored in FIFO base and slave object only if MSGVAL = 1.

In order to avoid direct reception of a message by a slave message object, as if it was an independent message object and not a part of a FIFO, the bit RXEN of each slave object must be cleared. The setting of the bit RXEN is "don't care" only if the slave object is located in a list not assigned to a CAN node.

22.4.12.7 Transmit FIFO

The Transmit FIFO structure is used to buffer a series of Data or Remote Frames that must be transmitted. A transmit FIFO consists of one base message object and one or more slave message objects.

A Transmit FIFO is selected by setting MOFCRn.MMC = 0010_B in the FIFO base object. Unlike the Receive FIFO, slave objects assigned to the Transmit FIFO must explicitly set their bit fields MOFCRn.MMC = 0011_B. The CUR pointer in all slave objects must point back to the Transmit FIFO Base Object (to be initialized by software).

The MOSTATn.TXEN1 bits (Transmit Enable 1) of all message objects except the one which is selected by the CUR pointer of the base object must be cleared by software. TXEN1 of the message (slave) object selected by CUR must be set. CUR (of the base object) may be initialized to any FIFO slave object.

When tagging the message objects of the FIFO as valid to start the operation of the FIFO, then the base object must be tagged valid (MSGVAL = 1) first.

Before a Transmit FIFO becomes de-installed during operation, its slave objects must be tagged invalid (MSGVAL = 0).

The Transmit FIFO uses the TXEN1 bit in the Message Object Status Register of all FIFO elements to select the actual message for transmission. Transmit acceptance filtering evaluates TXEN1 for each message object and a message object can win transmit acceptance filtering only if its TXEN1 bit is set. When a FIFO object has transmitted a message, the hardware clears its TXEN1 bit in addition to standard transmit postprocessing (clear TXRQ, transmit interrupt etc.), and moves the CUR pointer in the next FIFO base object to be transmitted. TXEN1 is set automatically (by hardware) in the next message object. Thus, TXEN1 moves along the Transmit FIFO structure as a token that selects the active element.

If bit field MOFCRn.OVIE (“Overflow Interrupt Enable”) of the FIFO base object is set and the current pointer CUR becomes equal to MOFGPRn.SEL, a FIFO overflow interrupt request is generated. The interrupt request is generated on interrupt node RXINP of the base object after postprocessing of the received frame. Receive interrupts are still generated for the Transmit FIFO base object if bit RXIE is set.

22.4.12.8 Gateway Mode

The Gateway Mode makes it possible to establish an automatic information transfer between two independent CAN buses without CPU interaction.

The Gateway Mode operates on message object level. In Gateway mode, information is transferred between two message objects, resulting in an information transfer between the two CAN nodes to which the message objects are allocated. A gateway may be established with any pair of CAN nodes, and there can be as many gateways as there are message objects available to build the gateway structure.

Gateway Mode is selected by setting MOFCRs.MMC = 0100_B for the gateway source object s. The gateway destination object d is selected by the MOFGPRd.CUR pointer of the source object. The gateway destination object only needs to be valid (its MSGVAL = 1). All other settings are not relevant for the information transfer from the source object to the destination object.

Gateway source object behaves as a standard message object with the difference that some additional actions are performed by the MultiCAN+ module when a CAN frame has been received and stored in the source object (see **Figure 22-25**):

1. If bit MOFCRs.DLCC is set, the data length code MOFCRs.DLC is copied from the gateway source object to the gateway destination object.
2. If bit MOFCRs.IDC is set, the identifier MOARs.ID and the identifier extension MOARs.IDE are copied from the gateway source object to the gateway destination object.
3. If bit MOFCRs.DATC is set, the data bytes stored in the two data registers MODATALs and MODATAHs are copied from the gateway source object to the gateway destination object. All 8 data bytes are copied, even if MOFCRs.DLC indicates less than 8 data bytes.
4. If bit MOFCRs.GDFS is set, the transmit request flag MOSTATd.TXRQ is set in the gateway destination object.
5. The receive pending bit MOSTATd.RXPND and the new data bit MOSTATd.NEWDAT are set in the gateway destination object.
6. A message interrupt request is generated for the gateway destination object if its MOSTATd.RXIE is set.
7. The current object pointer MOFGPRs.CUR of the gateway source object is moved to the next destination object according to the FIFO rules as described on **Page 22-58**. A gateway with a single (static) destination object is obtained by setting MOFGPRs.TOP = MOFGPRs.BOT = MOFGPRs.CUR = destination object.

The link from the gateway source object to the gateway destination object works in the same way as the link from a FIFO base to a FIFO slave. This means that a gateway with an integrated destination FIFO may be created; in **Figure 22-24**, the object on the left is the gateway source object and the message object on the right side is the gateway destination objects.

The gateway operates equivalent for the reception of data frames (source object is receive object, i.e. DIR = 0) as well as for the reception of Remote Frames (source object is transmit object).

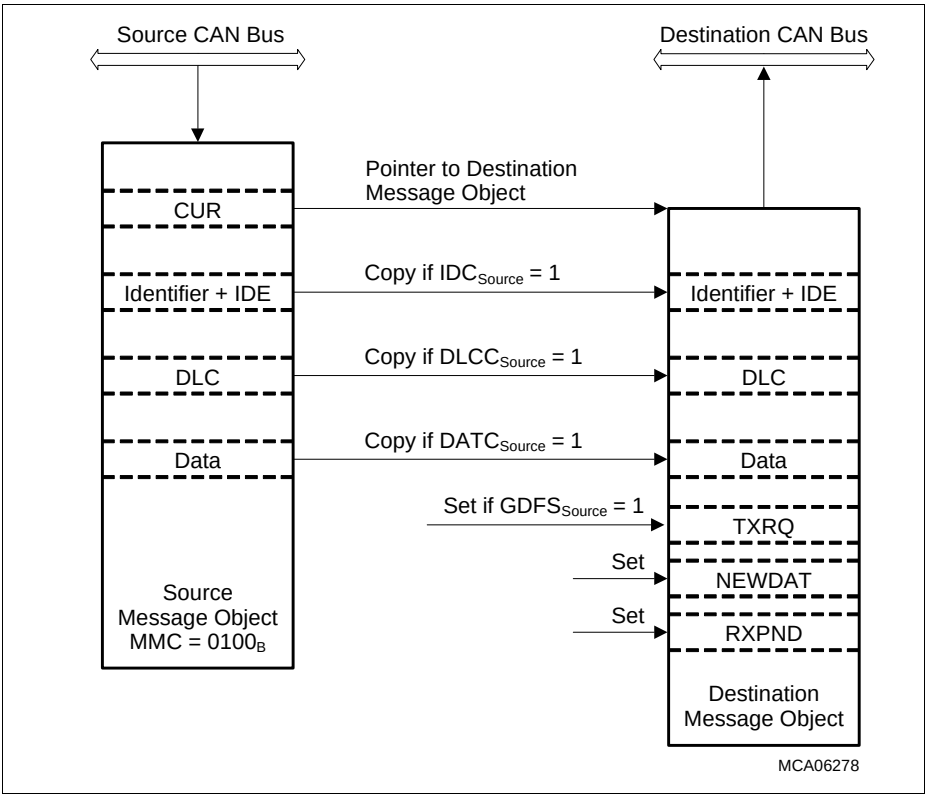

Figure 22-25 Gateway Transfer from Source to Destination

22.4.12.9 Foreign Remote Requests

When a Remote Frame has been received on a CAN node and is stored in a message object, a transmit request is set to trigger the answer (transmission of a Data Frame) to the request or to automatically issue a secondary request. If the Foreign Remote Request Enable bit MOFCRn.FRREN is cleared in the message object in which the remote request is stored, MOSTATn.TXRQ is set in the same message object.

If bit FRREN is set (FRREN = 1: foreign remote request enabled), TXRQ is set in the message object that is referenced by pointer MOFGPRn.CUR. The value of CUR is, however, not changed by this feature.

Although the foreign remote request feature works independently of the selected message mode, it is especially useful for gateways to issue a remote request on the source bus of a gateway after the reception of a remote request on the gateway destination bus. According to the setting of FRREN in the gateway destination object, there are two capabilities to handle remote requests that appear on the destination side (assuming that the source object is a receive object and the destination is a transmit object, i.e. DIR_{source} = 0 and $DIR_{destination}$ = 1):

FRREN = 0 in the Gateway Destination Object

1. A Remote Frame is received by gateway destination object.
2. TXRQ is set automatically in the gateway destination object.
3. A Data Frame with the current data stored in the destination object is transmitted on the destination bus.

FRREN = 1 in the Gateway Destination Object

1. A Remote Frame is received by gateway destination object.
2. TXRQ is set automatically in the gateway source object (must be referenced by CUR pointer of the destination object).
3. A remote request is transmitted by the source object (which is a receive object) on the source CAN bus.
4. The receiver of the remote request responds with a Data Frame on the source bus.
5. The Data Frame is stored in the source object.
6. The Data Frame is copied to the destination object (gateway action).
7. TXRQ is set in the destination object (assuming $GDFS_{source}$ = 1).
8. The new data stored in the destination object is transmitted on the destination bus, in response to the initial remote request on the destination bus.

22.4.12.10CAN FD - 64 byte Messages

In order to support higher than 8 data bytes payload (e.g 64bytes data payload) using current message object structure the data byte buffer (MODATALn and MODATAHn) has to be extended.

Thus an additional CAN FD 64 bytes message mode, MOFCR.MMC=5 is added. When CAN FD 64 bytes message mode is selected, additional message objects are used to store the extra data bytes.

The additional message objects used are specified by the pointer on MOFGPR.BOT and MOFGPR.TOP register bits. (i.e those message object registers (MOFCR, MOFGPR, MOIPR, MOAMR, MODATAL, MODATAH and MOAR) are used to store the extra data bytes with their alternate register view on EMOzDATAn at the same address location. MOCTR is the only register that is not used for data storage it retains its original function.

As an example for a 64 byte message, data bytes 0-7 are stored in the message object, similar to a standard message object, data bytes 8-35 are stored in the message object to which MOFGPR.BOT refers to and data bytes 36-63 are stored in the message object to which MOFGPR.TOP refers to. Data byte 0 refers to the first byte transferred within a CAN frame. For shorter than 64 bytes messages, unused data bytes are padded upon reception and ignored upon transmission.

The additional message objects chosen to store the extra data bytes must not take part in CAN communication i.e either they are allocated to a list that does not belong to an active CAN node or have that particular message object MOCTR register bits MOCTRn.RXEN, MOCTRn.TXEN0 (and/or TXEN1, TXRQ) cleared, i.e (RXEN=0, TXEN0=0, TXEN1=0 and TXRQ=0). MOCTR.MSGVAL remains the same, data is stored in the extra message objects when MSGVAL is set. When MSGVAL of the base object is cleared, an ongoing data transfer to TOP and BOT objects are aborted, thereby freeing objects BOT and TOP. Clearing MSGVAL bits of BOT, TOP objects and the extra message objects do not stop an ongoing data transfer and are not considered at all.

For optimum performance it is recommended to place the extra message objects outside active CAN node lists, so they do not take part in CAN acceptance filtering.

22.4.13 Measurement for Oscillator Calibration

The chip can be driven by an oscillator which is less accurate than required by the CAN specification, if it is possible to detect the deviation and to change the oscillator frequency during runtime. The MultiCAN module can measure the time interval between the start of a CAN frame and a certain edge on the bus. The timer hardware is accessed via Measurement Control Register MECR (see **Page 22-92**) and Measurement Status Register MESTAT (see **Page 22-94**).

A 16-bit timer is cleared and started by the first falling (dominant) edge of a CAN frame on the input line of the CAN node (selected by MECR.NODE). The timer is incremented by the module control clock f_{CLC}. The timer content is captured when an edge specified by MECR.ANYED is detected on the input line of the CAN node. However, the timer must have reached threshold MECR.TH before; so edges occurring earlier cannot cause a capture. Only the first edge after threshold is considered, and the node itself may not be sending. Bit field CAPT in the status register contains the captured timer value, and bit CAPRED indicates the type of edge that caused the capture. On a capture event, bit

CAPE in the same register will be set. If bit MECR.CAPEIE = 1, a node interrupt will be generated. With the starting edge of the following CAN frame, a new measurement cycle begins. To avoid an overflow on the measurement and to get a measurement result MESTAT.CAPE bit has to be cleared before the measurement end condition occurs.

To avoid wrong capture results due to timer overflow, the timer will be stopped when $FFFF_H$ is reached. If MECR.TH = 0000_H, the timer is always stopped and the capture function is disabled.

Some important issues should be mentioned:

- The timing of the measured CAN frame should be as exact as possible.
- No unadjusted CAN stations - including the selected MultiCAN node - should participate actively in the communication. The selected node can be set to Analyzer Mode.
- When setting the timer threshold and evaluating the capture result, the tolerances including the oscillator deviation must be considered.
- It may not be possible to use a well-defined CAN message for measurement. Then worst-case-scenarios according to the CAN protocol must be observed. E.g. in a data or remote frame, the first rising (recessive) edge might occur after five bit times, and the next falling one after additional five bit times.
- Also error and overload frames which may lead to unexpected capture results should be taken into account.
- Edges occurring a considerable time after the start of a CAN frame will yield good resolution but may produce ambiguous results if the oscillator is not yet sufficiently adjusted. Therefore, only one step for measurement and calibration may not be sufficient.
- As there is only one oscillator on the chip, its calibration influences the timing of the whole system and particularly the timing of other CAN nodes.

22.5 Use Case Example MultiCAN+

This section explains the core functionality of the MultiCAN+ module with a code example. The example realizes sending a CAN message via internal CAN-bus from node 0 to node 1.

The MultiCAN+ module for the TC27x consists of 1 module (i.e MultiCAN with 4 CAN nodes), representing 4 serial communication interfaces. Each CAN node can either be connected to a port or to the internal CAN bus (see **Figure 22-28**). So a maximum of 4 CAN channels can be realized with the MultiCAN+ module (For more information and further functions see **Section 22.2**).

All CAN nodes share a common set of 256 message objects. A message object function like a container for a specific CAN message; both transmitting and receiving of CAN messages can be realized. The message objects are organized in double-chained lists, each list is dedicated to a certain CAN node (list 1 is node 0, list 2 is node 1, etc.). After a reset, all message objects are unallocated and therefore assigned to list 0, this list does not belong to a CAN node. During initialization it is possible to allocate the message objects individually to certain CAN node lists. Each allocated message object can be set up with all necessary information like the message ID etc. (see chapter 26.2 and following for further explanations of the CAN module).

In the use case example CAN node 0 will send a CAN message via internal CAN bus to CAN node 1. The transmitting message object (MO) will be MO 0 and the receiving message object will be MO 1. As soon as the CAN frame successfully receives at MO 1 a receive interrupt will occur. The initialization process follows the following order:

1. Load global MuliCAN+ module registers
2. Initialize the CAN nodes
3. Allocate the message objects to the CAN nodes
4. Initialize the message objects
5. Start the CAN nodes
6. Start transmit request for CAN message from node 0 to node 1.
7. Receive message at node 1, Rx interrupt occurs.

Step description to initialize the MultiCAN+ module:

(Line 1) reset ENDINIT to get access to ENDINIT protected registers. (see also ENDINIT protection chapter 8.9.3(LINK)).

(Line 2) enable control of the module, in clock control register CLC (**CLC**).

(Line 3) read back (dummy variable has to be defined). The reading process ensures that the write process from line 2 is done.

(Line 4) load fractional divider to $f_{CAN} = f_{ASYN\_CAN}$ (see also 26.3.2 Clock Control (**Fractional Divider**), f_{ASYN_CAN} see **MCR**).

(Line 5) set ENDINIT to lock the protected register again.

(Line 6) set clk source to f_{ASYN_CAN} in module control register MCR(**MCR**).

Note: The reconfiguration of the clk source must be done by two writes and a certain delay between these. See MCR for more details.

(Line 7) The setting of protection CCE[6] and INIT[0] activates the initialization and configuration mode for CAN node 0. This is necessary for the upcoming changes in CAN node 0. (see also node configuration register NCRn (**CAN_NCRx (x = 0-3)**))

(Line 8) This example uses the internal loop-back mode, so this line connects CAN node 0 to the internal CAN Bus. (see also Figure 26-13(**Figure 22-17**) and node port control register NPCR(**CAN_NPCRx (x = 0-3)**))

(Line 9) The CAN bit time is subdivided into different segments. (see also 26.3.6.1 Bit Timing Unit(**Bit Timing Unit**)). Assuming f_{CAN} = 100MHz this line then sets the baudrate to 500kBaud and the sample point to 80% in the node bit timing register NBTR (**CAN_NBTRx (x = 0-3)**).

Note: The FM PLL should be off. Otherwise a stable CAN communication is not ensured

(Line 10 - 12) same as line 7 - 9 but with node 1.

(Line 13) The allocation of the message objects to certain CAN node lists function via a list command panel. The panel control register PANCTR(**PANCTR**) can only be written if both busy flags are reseted. Therefore this while loop waits until the register is ready.

(Line 14) This line allocates message object 0 to list 1 (belongs to CAN node 0).

(Line 15) see line 13.

(Line 16) This line allocates message object 1 to list 2 (belongs to CAN node 0).

(Line 17) Initialize MO 0 in the message object register MOCTR(**CAN_MOCTRz (z = 0-254)**) as transmit MO by setting bits [27:25]. Set also MSGVAL[21], that's the main switch bit of the MO.

(Line 18) this line sets the message data length of MO 0 to 8 bytes.(see also message object function control register MOFCR (**CAN_MOFCRn (n = 0-255)**)).

(Line 19) the message ID of MO 0 gets set to standard message (11 bit length) with a message ID of 0xFF in the Message object arbitration register MOAR (**CAN_MOARn (n = 0-255)**).

(Line 20) Initialize MO 1 in the message object register MOCTR as receive MO by setting bit RXEN[23]. Set also MSGVAL[21], that's the main switch bit of the MO.

(Line 21) the receive interrupt gets enabled in the message object function control register MOFCR .

(Line 22) same as Line 19 but for MO 1. The same message ID is necessary to receive CAN messages from the bus with this specific ID.

(Line 23) the Rx interrupt gets connected to the CAN interrupt output line 1.(see also MOIPR(**CAN_MOIPRn (n = 0-255)**))

(Line 24) This line enables the Rx interrupt in the service request control register SRC_CANINT1 and sets the interrupt priority to CAN_SR1INT (1...255)

(Line 25) The interruptHandlerInstall function gets called (this function has to be written first, see interrupt handler example (Chapter 17.10.1) for more details). This function installs the interrupt service routine (ISR) entry address in the interrupt vector array with the priority CAN_SRN1INT.

(Line 26) The 4 lower data bytes are getting loaded in the MODATAL(**CAN_MODATALn (n = 0-255)**) register. the data itself is here just an example.

(Line 27) The 4 higher data bytes are getting loaded in the MODATAH(**CAN_MODATAHn (n = 0-255)**) register. (just an data example as well)

(Line 28) This line resets INIT[0] and CCE[6] bit in the node control register from node 0. The node is now synchronizing itself to the bus.

(Line 29) same as line 28, but with node 1.

(Line 30) The NEWDATA bit gets set in the MOCTR register, this should always be done after a write process in the data registers from line 26/27. The transmit request bit TXRQ gets set, this starts the transmission of the CAN message. The RTSEL gets reset to ensure the transmission.

(Line 31) If the message is received the MOCTR.NEWDAT[19] bit in the receive MO 1 is set. This line just waits for the reception. The occurrence of the Rx interrupt can also be used as a proof that the message arrived.

Note: The Rx ISR function prototype would be: void CAN1_Rx_irq (void); here could be your ISR code;

Initialization of the MultiCAN+ module:

```
// Load global MultiCAN+ registers:
(1)  SCU_vResetENDINIT (0);     // enable ENDINIT reg
(2)  CAN_CLC = 0x000;           // disable module control
(3)  dummy = CAN_CLC;           //read to check the made changes
(4)  CAN_FDR = (1 << 14)| 0x3FF;     //DM=1,STEP=1023
(5)  SCU_vSetENDINIT (0);       // lock ENDINIT reg
(6)  CAN_MCR = 0x1;             // CLKSEL=1
//Init CAN nodes 0 and 1:
(7)  CAN_NCR0 = (1 << 6)| 1;    // CCE=1,INIT=1
(8)  CAN_NPCR0 = (1 << 8);      // LBM=1
(9)  CAN_NBTR0 = 0x3EC9;        //set bit segments
(10) CAN_NCR1 = (1 << 6)| 1;    // CCE=1,INIT=1
(11) CAN_NPCR1 = (1 << 8);      // LBM=1
```

```
(12) CAN_NBTR1 = 0x3EC9;        //set bit segments
//Allocate message objects to CAN nodes:
(13) while(CAN_PANCTR.U & (0x00000100 | 0x00000200)); // busy?
(14) CAN_PANCTR = (1 << 24)|(0 << 16)| 2; // MO 0 to list 1
(15) while(CAN_PANCTR.U & (0x00000100 | 0x00000200)); // busy?
(16) CAN_PANCTR = (2 << 24)|(1 << 16)| 2; // MO 1 to list 2
//Init MO_0 (list 1, node 0)
(17) CAN_MOCTR0 = (1<<27)|(1<<26)|(1<<25)|(1<<21); // set to Tx
(18) CAN_MOFCR0 = (8 << 24);              // DLC=8
(19) CAN_MOAR0 =  (1 << 30)|(0xFF << 18); // PRI=01,ID=0xFF
//Init MO_1 (list 2, node 1)
(20) CAN_MOCTR1 = (1 << 23)|(1 << 21);    // set to Rx
(21) CAN_MOFCR1 = (1 << 16);              // RXIE=1
(22) CAN_MOAR1 =  (1 << 30)|(0xFF << 18);  // PRI=01, ID=0xFF
(23) CAN_MOIPR1 = 0x1;          // RXINP=1 -> select INT_O1
(24) SRC_CANINT1 = (1 << 10) | CAN_SRN1INT; // enable INT_01
(25) interruptHandlerInstall (CAN_SRN1INT, & CAN1_Rx_irq);
// Load Data, Start CAN nodes
(26) CAN_MODATAL0 = 0x0D0D0D0D; // load data, lower 4 Bytes
(27) CAN_MODATAH0 = 0x0E0E0E0E; // load data, higher 4 Bytes
(28) CAN_NCR0 &= ~((1<<6)| 1);  // reset CCE and INIT
(29) CAN_NCR1 &= ~((1<<6)| 1);  // reset CCE and INIT
// set transmit request to send message
(30) CAN_MOCTR0 = (1<<24)|(1<<19)|(1<<6);//TXRQ=1,NEWDAT=1
(31) while((CAN_MOSTAT1.B.NEWDAT) != 1);       //check if Rx
```

Note: Before an interrupt is able to occur, the interrupt system has to be globally enabled. The Interrupt Control Register (ICR) holds the global interrupt enable bit (ICR.IE) which enables the CPU service request system. Most compiler support the attribute (or similar):
__enable();
to set this bit. (See also Architecture Manual for more details)

22.6 MultiCAN+ Kernel Registers

This section describes the kernel registers of the MultiCAN+ module. All MultiCAN+ kernel register names described in this section are also referenced in other parts of the TC27x User's Manual by the module name prefix "CAN_".

MultiCAN+ Kernel Register Overview

The MultiCAN+ Kernel include three blocks of registers:

- Global Module Registers
- Node Registers, for each CAN node x
- Message Object Registers, for each message object n

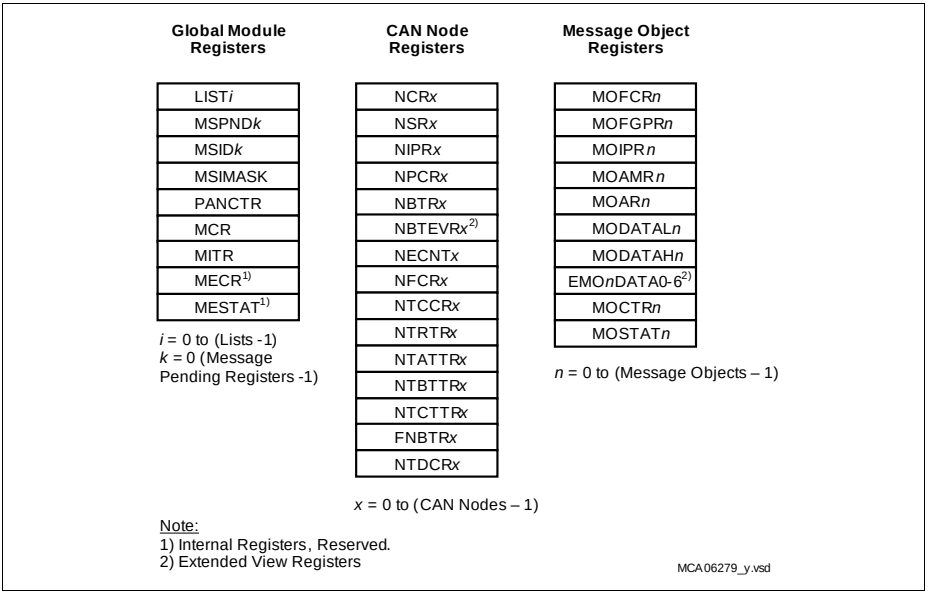

Figure 22-26 MultiCAN+ Kernel Registers

The registers of the MultiCAN+ module kernel are listed below.

Table 22-9 Registers Address Space - MultiCAN+ Kernel Registers

Module	Base Address	End Address	Note
CAN	$F001\ 8000_H$	$F001\ BFFF_H$	-

1) The absolute register address is calculated as follows:
Module Base Address (**Table 22-9**) + Offset Address (shown in this column)
Further, the following ranges for parameters i, k, x, and n are valid: i = 0-15, k = 0-7, x = 0-3, n = 0-255.

2) Accesses to empty addresses: nBE

List of Access Protection Abbreviations

U - User Mode

SV - Supervisor Mode

BE - Bus Error

nBE - no Bus Error

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

SE - Safety ENDINIT

Figure 22-27 shows the MultiCAN+ register address map.

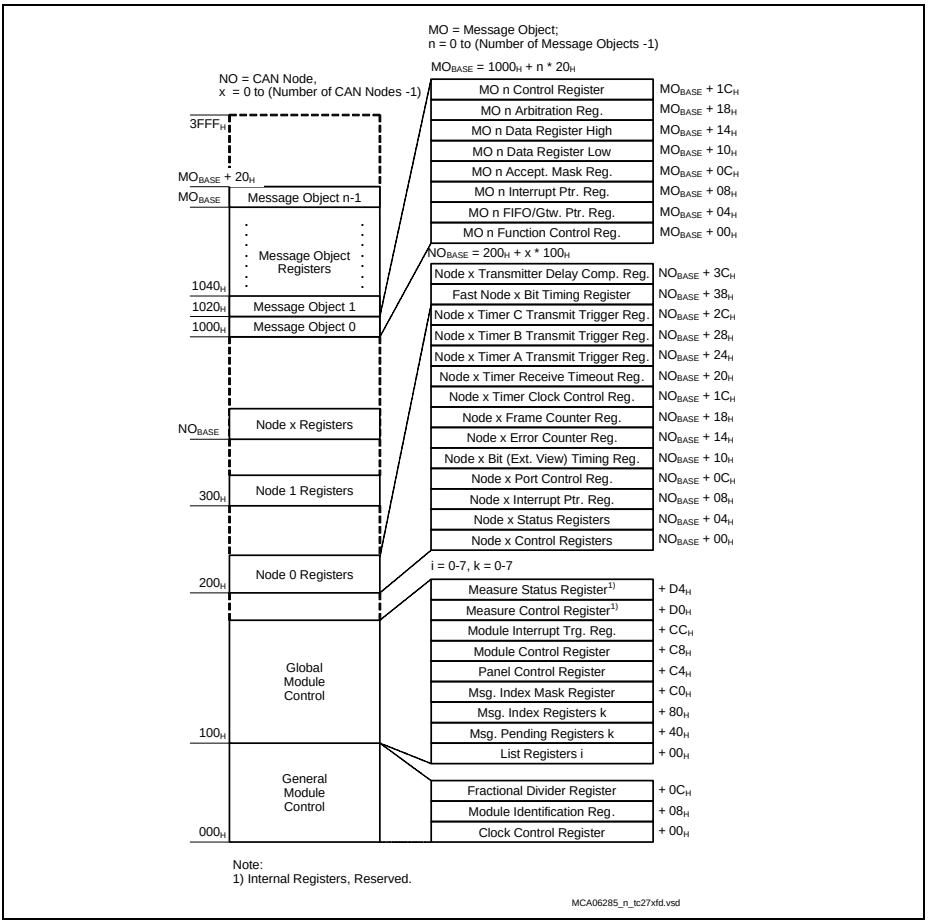

Figure 22-27 MultiCAN+ Register Address Map

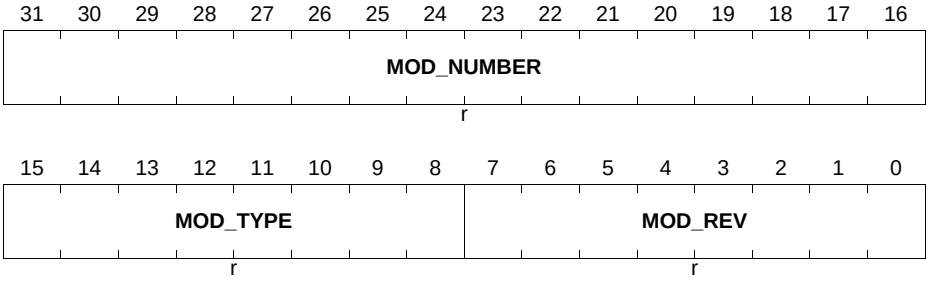
22.6.1 Global Module Registers

All list operations such as allocation, de-allocation and relocation of message objects within the list structure are performed via the Command Panel. It is not possible to modify the list structure directly by software by writing to the message objects and the LIST registers.

Module Identification Register.

ID

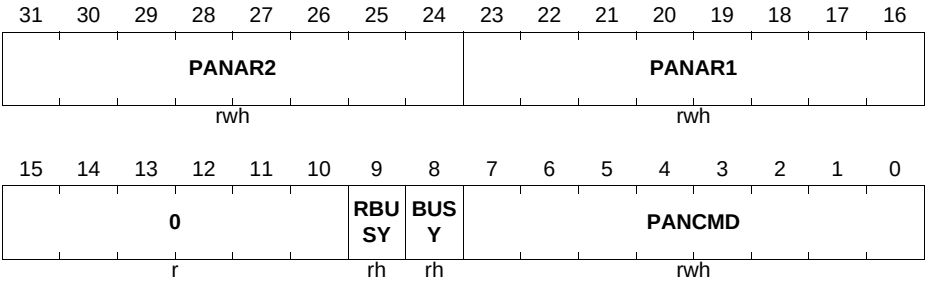
Module Identification Register (008$_H$) Reset Value: 00B5 C0XX$_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the revision number. The value of a module revision starts with 01$_H$ (first revision).
MOD_TYPE	[15:8]	r	**Module Type** C0$_H$ Define the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines the MultiCAN+ module identification number (=00B5H)

The Panel Control Register PANCTR is used to start a new command by writing the command arguments and the command code into its bit fields.

PANCTR
Panel Control Register **($1C4_H$)** **Reset Value: $0000\ 0301_H$**



Field	Bits	Type	Description
PANCMD	[7:0]	rwh	**Panel Command** This bit field is used to start a new command by writing a panel command code into it. At the end of a panel command, the NOP (no operation) command code is automatically written into PANCMD. The coding of PANCMD is defined in **Table 22-11**.
BUSY	8	rh	**Panel Busy Flag** 0_B Panel has finished command and is ready to accept a new command. 1_B Panel operation is in progress.
RBUSY	9	rh	**Result Busy Flag** 0_B No update of PANAR1 and PANAR2 is scheduled by the list controller. 1_B A list command is running (BUSY = 1) that will write results to PANAR1 and PANAR2, but the results are not yet available.
PANAR1	[23:16]	rwh	**Panel Argument 1** See **Table 22-11**.
PANAR2	[31:24]	rwh	**Panel Argument 2** See **Table 22-11**.
0	[15:10]	r	**Reserved** Read as 0; should be written with 0.

Panel Commands

A panel operation consists of a command code (PANCMD) and up to two panel arguments (PANAR1, PANAR2). Commands that have a return value deliver it to the PANAR1 bit field. Commands that return an error flag deliver it to bit 31 of the Panel Control Register, this means bit 7 of PANAR2.

Table 22-11 Panel Commands

PANCMD	PANAR2	PANAR1	Command Description
00_H	–	–	**No Operation** Writing 00_H to PANCMD has no effect. No new command is started.
01_H	**Result:** Bit 7: ERR Bit 6-0: undefined	–	**Initialize Lists** Run the initialization sequence to reset the CTRL and LIST fields of all message objects. List registers LIST[7:0] are set to their reset values. This results in the de-allocation of all message objects. The initialization command requires that bits NCRx.INIT and NCRx.CCE are set for all CAN nodes. Bit 7 of PANAR2 (ERR) reports the success of the operation: 0_B Initialization was successful 1_B Not all NCRx.INIT and NCRx.CCE bits are set. Therefore, no initialization is performed. The initialize lists command is automatically performed with each reset of the MultiCAN+ module, but with the exception that all message object registers are reset, too.
02_H	**Argument:** List Index	**Argument:** Message Object Number	**Static Allocate** Allocate message object to a list. The message object is removed from the list that it currently belongs to, and appended to the end of the list, given by PANAR2. This command is also used to deallocate a message object. In this case, the target list is the list of unallocated elements (PANAR2 = 0).

Table 22-11 Panel Commands (cont'd)

PANCMD	PANAR2	PANAR1	Command Description
03_H	**Argument:** List Index **Result:** Bit 7: ERR Bit 6-0: undefined	**Result:** Message Object Number	**Dynamic Allocate** Allocate the first message object of the list of unallocated objects to the selected list. The message object is appended to the end of the list. The message number of the message object is returned in PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0_B Success. 1_B The operation has not been performed because the list of unallocated elements was empty.
04_H	**Argument:** Destination Object Number	**Argument:** Source Object Number	**Static Insert Before** Remove a message object (source object) from the list that it currently belongs to, and insert it before a given destination object into the list structure of the destination object. The source object thus becomes the predecessor of the destination object.
05_H	**Argument:** Destination Object Number **Result:** Bit 7: ERR Bit 6-0: undefined	**Result:** Object Number of inserted object	**Dynamic Insert Before** Insert a new message object before a given destination object. The new object is taken from the list of unallocated elements (the first element is chosen). The number of the new object is delivered as a result to PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0_B Success. 1_B The operation has not been performed because the list of unallocated elements was empty.

Table 22-11 Panel Commands (cont'd)

PANCMD	PANAR2	PANAR1	Command Description
06_H	**Argument:** Destination Object Number	**Argument:** Source Object Number	**Static Insert Behind** Remove a message object (source object) from the list that it currently belongs to, and insert it behind a given destination object into the list structure of the destination object. The source object thus becomes the successor of the destination object.
07_H	**Argument:** Destination Object Number **Result:** Bit 7: ERR Bit 6-0: undefined	**Result:** Object Number of inserted object	**Dynamic Insert Behind** Insert a new message object behind a given destination object. The new object is taken from the list of unallocated elements (the first element is chosen). The number of the new object is delivered as result to PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0_B Success. 1_B The operation has not been performed because the list of unallocated elements was empty.
08_H - FF_H	–	–	**Reserved**

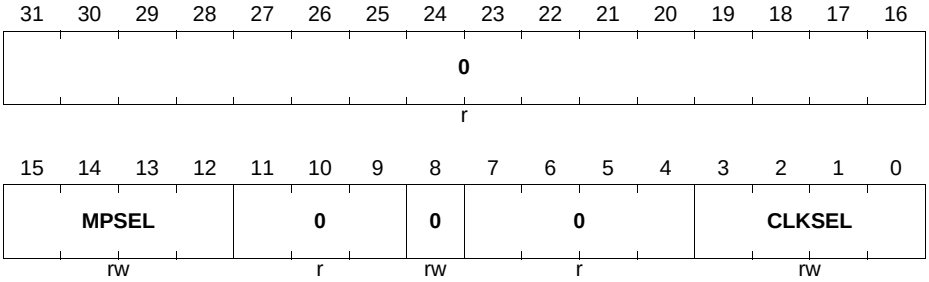
The Module Control Register MCR contains basic settings that determine the operation of the MultiCAN+ module.

The write access to the lowest byte of the MCR register is possible only if the CCE bits of all CAN nodes are set (NCRx.CCE bits). The NCRx.INIT bits will be automatically set when the lowest byte of the MCR register is written, independent of the setting of the CCE bits. The INIT bits have to be reset by software in order to activate the CAN nodes.

The reconfiguration of the clock source has to be done by using two writes: first a write of zero to the CLKSEL bit field, and then a second write defining the new clock source. Between the first and the second write a delay of 4 / f_A + 2 / f_{CAN} number of cycles must be inserted by software, where f_A is the frequency being switched off with the first write. Exception: in case that f_{ASYN_CAN} is selected as the baud rate logic clock (MCR.CLKSEL = 1), no delay cycles between the writes are necessary. In both cases, simply using one write defining the new clock source is not allowed.

Note: If the baud rate logic is supplied from an unstable clock source, or no clock at all, the CAN functionality is not guaranteed.

MCR
Module Control Register (1C8$_H$) Reset Value: 0000 0000$_H$

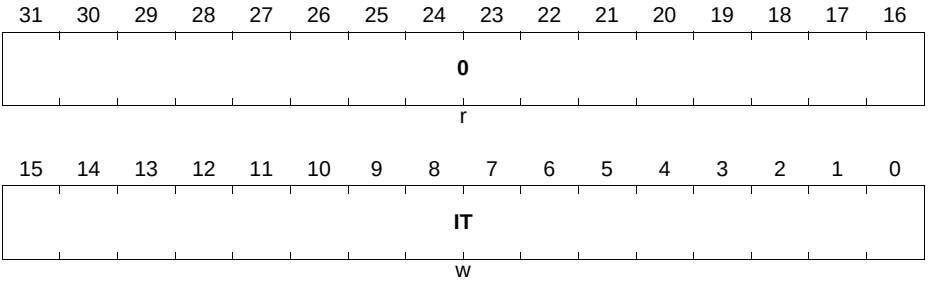


Field	Bits	Type	Description
CLKSEL	[3:0]	rw	**Baud Rate Logic Clock Select** 0000_B No clock supplied 0001_B f_{ASYN_CAN} 0010_B Oscillator Clock 0100_B E-Ray clock (f_{ERAY}) 1000_B hard wired to 0 $...{}_B$ not allowed
0	8	rw	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
MPSEL	[15:12]	rw	**Message Pending Selector** Bit field MPSEL makes it possible to select the bit position of the message pending bit after a message reception/transmission by a mixture of the MOIPRn register bit fields RXINP, TXINP, and MPN. Selection details are given in **Figure 22-21** on **Page 22-49**.
0	[31:16], [11:9],[7:4]	r	**Reserved** Read as 0; should be written with 0.

The Interrupt Trigger Register ITR is used to trigger interrupt requests on each interrupt output line by software.

MITR
Module Interrupt Trigger Register (1CC$_H$) **Reset Value: 0000 0000$_H$**



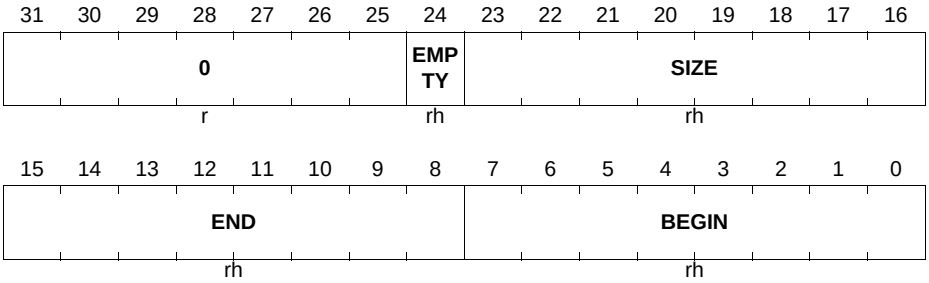
Field	Bits	Type	Description
IT	[15:0]	w	**Interrupt Trigger** Writing a 1 to IT[m] (m = 0-15) generates an interrupt request on interrupt output line INT_O[m]. Writing a 0 to IT[m] has no effect. Bit field IT is always read as 0. Multiple interrupt requests can be generated with a single write operation to MITR by writing a 1 to several bit positions of IT.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

List Pointer and List Register

Each CAN node has a list that determines the allocated message objects. Additionally, a list of all unallocated objects is available. Furthermore, general purpose lists are available which are not associated to a CAN node. The List Registers are assigned in the following way:

- LIST0 provides the list of all unallocated objects
- LIST1 provides the list for CAN node 0
- LIST2 provides the list for CAN node 1
- ...
- LIST4 provides the list for CAN node 3

LIST0
List Register 0 **(100_H)** **Reset Value: 00FF FF00$_H$**
LISTn (n = 1-15)
List Register n **(100_H+n*4_H)** **Reset Value: 0100 0000$_H$**



Field	Bits	Type	Description
BEGIN	[7:0]	rh	**List Begin** BEGIN indicates the number of the first message object in list i.
END	[15:8]	rh	**List End** END indicates the number of the last message object in list i.
SIZE	[23:16]	rh	**List Size** SIZE indicates the number of elements in the list i. SIZE = number of list elements - 1 SIZE = 0 indicates that list i is empty.

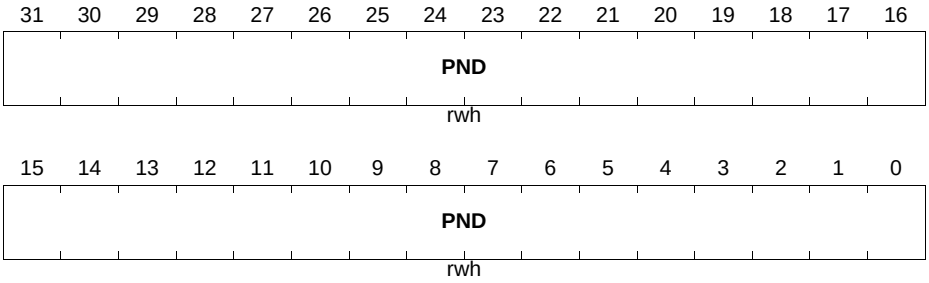
Field	Bits	Type	Description
EMPTY	24	rh	**List Empty Indication** 0_B At least one message object is allocated to list i. 1_B No message object is allocated to the list i. List i is empty.
0	[31:25]	r	**Reserved** Read as 0.

Message Notifications

When a message object n generates an interrupt request upon the transmission or reception of a message, then the request is routed to the interrupt output line selected by the bit field MOIPRn.TXINP or MOIPRn.RXINP of the message object n. As there are more message objects than interrupt output lines, an interrupt routine typically processes requests from more than one message object. Therefore, a priority selection mechanism is implemented in the MultiCAN+ module to select the highest priority object within a collection of message objects.

The Message Pending Register MSPNDk contains the pending interrupt notification of list i.

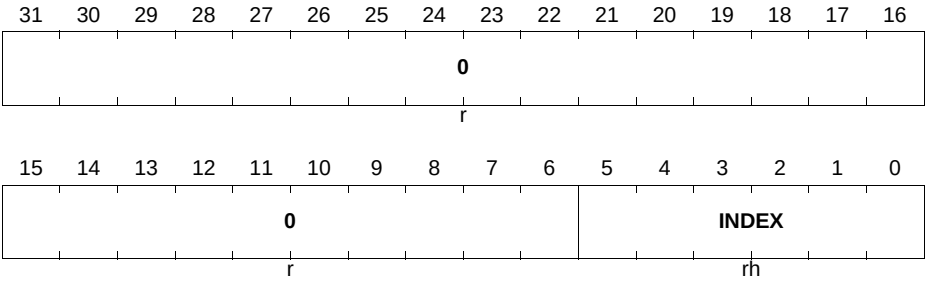
MSPNDk (k = 0-7)
Message Pending Register k **(140_H+k*4_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
PND	[31:0]	rwh	**Message Pending** When a message interrupt occurs, the message object sets a bit in one of the MSPND register, where the bit position is given by the MPN[4:0] field of the IPR register of the message object. The register selection n is given by the higher bits of MPN. The register bits can be cleared by software (write 0). Writing a 1 has no effect.

Each Message Pending Register has a Message Index Register MSIDk associated with it. The Message Index Register shows the active (set) pending bit with lowest bit position within groups of pending bits.

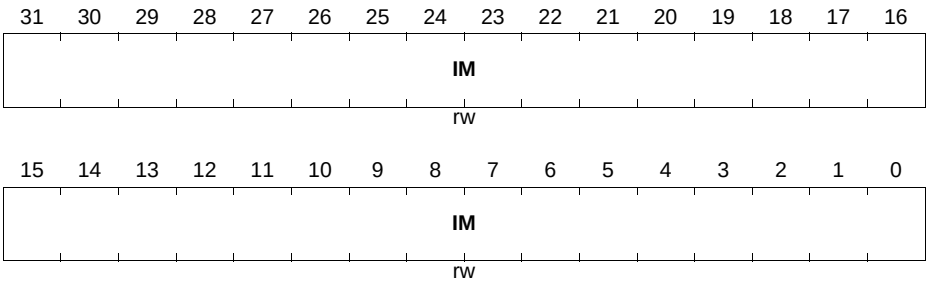
MSIDk (k = 0-7)
Message Index Register k **(180_H+k*4_H)** **Reset Value: 0000 0020_H**



Field	Bits	Type	Description
INDEX	[5:0]	rh	**Message Pending Index** The value of INDEX is given by the bit position i of the pending bit of MSPNDk with the following properties: 1. MSPNDk[i] & IM[i] = 1 2. i = 0 or MSPNDk[i-1:0] & IM[i-1:0] = 0 If no bit of MSPNDk satisfies these conditions then INDEX reads 100000_B. Thus INDEX shows the position of the first pending bit of MSPNDk, in which only those bits of MSPNDk that are selected in the Message Index Mask Register are taken into account.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

The Message Index Mask Register MSIMASK selects individual bits for the calculation of the Message Pending Index. The Message Index Mask Register is used commonly for all Message Pending registers and their associated Message Index registers.

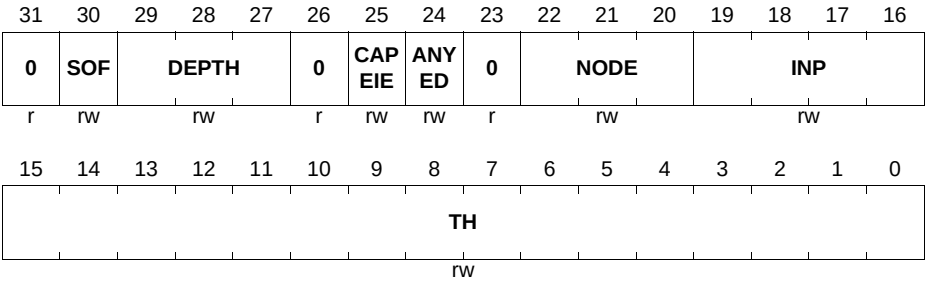
MSIMASK
Message Index Mask Register ($1C0_H$) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
IM	[31:0]	rw	**Message Index Mask** Only those bits in MSPNDk for which the corresponding Index Mask bits are set contribute to the calculation of the Message Index.

The Measurement Control Register MECR controls the CAN edge timing measurement function for calibration purposes.

MECR
Measurement Control Register ($1D0_H$) Reset Value: $0000\ 0000_H$

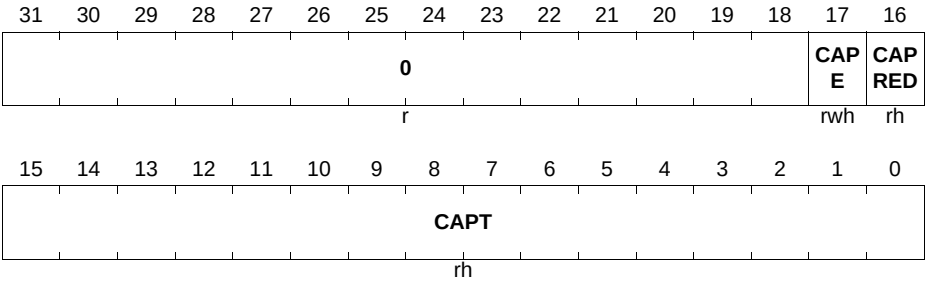


Field	Bits	Type	Description
TH	[15:0]	rw	**Threshold** This bit field contains the threshold value for the measurement timer. If TH = 0000_H, the timer is stopped and the capture function is disabled.
INP	[19:16]	rw	**Interrupt Node Pointer** INP selects the interrupt output line INT_Om (m = 0-15) for a capture event interrupt. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
NODE	[22:20]	rw	**Node** This bit field determines the CAN node x whose input line RXDCANx is used for start and capture of the measurement timer. 000_B Node 0 001_B Node 1 $\ldots_B$ … 011_B Node 3

Field	Bits	Type	Description
ANYED	24	rw	**Any Edge** This bit enables capture on any edge of CAN input line specified by NODE. 0_B Capture on falling (dominant) edge only 1_B Capture on rising (recessive) or falling (dominant) edge
CAPEIE	25	rw	**Capture Event Interrupt Enable** This bit enables the capture event interrupt. 0_B Capture event interrupt is disabled 1_B Capture event interrupt is enabled Bit field INP selects the interrupt output line which becomes activated at this type of interrupt.
DEPTH	[29:27]	rw	**Digital Glitch Filter Depth** DEPTH determines the number of input samples clocked with f_{CLC} that are taken into account for the calculation of the floating average. The higher DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 000_B off, default 001_B Filter depth of 8 cycles 010_B Filter depth of 16 cycles 011_B Filter depth of 32 cycles 100_B Filter depth of 64 cycles 101_B Filter depth of 128 cycles 110_B Filter depth of 255 cycles 111_B not allowed, reserved
SOF	30	rw	**Start Of Frame** This bit selects falling edge or any edge as measurement for start of frame detection. 0_B Measurement starts with any falling edge 1_B Measurement starts with falling Start of Frame edge. i.e any falling edge that occurs while the CAN node is in idle state
0	23, 26, 31	r	**Reserved** Read as 0; should be written with 0.

The Measurement Status Register MESTAT contains the status information of the CAN edge timing measurement.

MESTAT
Measurement Status Register (1D4$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
CAPT	[15:0]	rh	**Captured Timer** This bit field contains the captured measurement timer content. The timer itself is cleared and started by the first falling (dominant) edge of a CAN frame on the input line of the CAN node specified by MECR.NODE. The timer is incremented by the module control clock f_{CLC} and will be stopped when FFFF$_H$ is reached. If MECR.TH = 0000$_H$, the timer is always stopped. A capture will take place if all the following conditions are met: 1. MECR.TH > 0000$_H$ 2. Timer is cleared and started by new frame 3. Timer reaches MECR.TH 4. This node is not sending and first edge (as specified by MECR.ANYED) after 3. occurs on input line Capture will be repeated for the following CAN frames until MECR.TH is cleared.
CAPRED	16	rh	**Captured Rising Edge** This bit indicates the type of edge that caused the last capture event. 0_B Capture occurred on falling (dominant) edge 1_B Capture occurred on rising (recessive) edge

Field	Bits	Type	Description
CAPE	17	rwh	**Capture Event** This flag is set on a capture event. It must be reset by software. 0_B No capture event has occurred since last flag reset 1_B Capture event has occurred since last flag reset An interrupt request is generated if MECR.CAPEIE = 1. If CAPE=1 then no further measurement results are posted to MESTAT.CAPT and MESTAT.CAPRED. CAPE bit has to be cleared to re-enable update of MESTAT.CAPT and MESTAT.CAPRED.
0	[31:18]	r	**Reserved** Read as 0; should be written with 0.

22.6.2 CAN Node Registers

The CAN node registers are built in for each CAN node of the MultiCAN+ module. They contain information that is directly related to the operation of the CAN nodes and are shared among the nodes.

The Node Control Register contains basic settings that determine the operation of the CAN node.

CAN_NCRx (x = 0-3)
Node x Control Register **(200_H+x*100_H)** **Reset Value: 0000 0041_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						FDEN	SUSEN	CALM	CCE	TXDIS	CANDIS	ALIE	LECIE	TRIE	INIT
r						rw	rw	rw	rw	rw	rw	rw	rw	rw	rwh

Field	Bits	Type	Description
INIT	0	rwh	**Node Initialization** 0_B Resetting bit INIT enables the participation of the node in the CAN traffic. If the CAN node is in the bus-off state, the ongoing bus-off recovery (which does not depend on the INIT bit) is continued. With the end of the bus-off recovery sequence the CAN node is allowed to take part in the CAN traffic. If the CAN node is not in the bus-off state, a sequence of 11 consecutive recessive bits must be detected before the node is allowed to take part in the CAN traffic. 1_B Setting this bit terminates the participation of this node in the CAN traffic. Any ongoing frame transfer is cancelled and the transmit line goes recessive. If the CAN node is in the bus-off state, then the running bus-off recovery sequence is continued. If the INIT bit is still set after the successful completion of the bus-off recovery sequence, i.e. after detecting 128 sequences of 11 consecutive recessive bits (11×1), then the CAN node leaves the bus-off state but remains inactive as long as INIT remains set. Bit INIT is automatically set when the CAN node enters the bus-off state (see **Page 22-31**).
TRIE	1	rw	**Transfer Interrupt Enable** TRIE enables the transfer interrupt of CAN node x. This interrupt is generated after the successful reception or transmission of a CAN frame in node x. 0_B Transfer interrupt is disabled. 1_B Transfer interrupt is enabled. Bit field NIPRx.TRINP selects the interrupt output line which becomes activated at this type of interrupt.

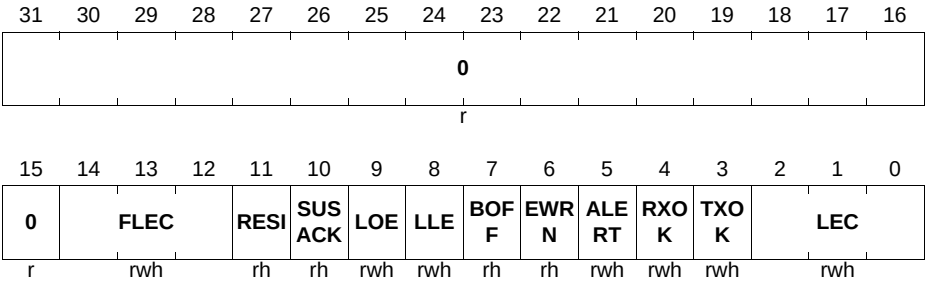
Field	Bits	Type	Description
LECIE	2	rw	**LEC Indicated Error Interrupt Enable** LECIE enables the last error code interrupt of CAN node x. This interrupt is generated with each hardware update of bit field NSRx.LEC with LEC > 0 (CAN protocol error). 0_B Last error code interrupt is disabled. 1_B Last error code interrupt is enabled. Bit field NIPRx.LECINP selects the interrupt output line which becomes activated at this type of interrupt.
ALIE	3	rw	**Alert Interrupt Enable** ALIE enables the alert interrupt of CAN node x. This interrupt is generated by any one of the following events: • A change of bit NSRx.BOFF • A change of bit NSRx.EWRN • A List Length Error, which also sets bit NSRx.LLE • A List Object Error, which also sets bit NSRx.LOE 0_B Alert interrupt is disabled. 1_B Alert interrupt is enabled. Bit field NIPRx.ALINP selects the interrupt output line which becomes activated at this type of interrupt.
CANDIS	4	rw	**CAN Disable** Setting this bit disables the CAN node. The CAN node first waits until it is bus-idle or bus-off. Then bit NSRx.SUSACK and NCRx.INIT is automatically set, and an alert interrupt is generated if bit ALIE is set.
TXDIS	5	rw	**Transmit Disable** Setting this bit disables the transmission on CAN node x as soon as bus-idle is reached. Reception and bits in MOSTATn, e.g. TXRQ, will not be influenced.
CCE	6	rw	**Configuration Change Enable** 0_B The Bit Timing Register, the Port Control Register, Error Counter Register and NCRx.FDEN bit may only be read. All attempts to modify them are ignored. 1_B The Bit Timing Register, the Port Control Register, Error Counter Register and NCRx.FDEN bit may be read and written.

Field	Bits	Type	Description
CALM	7	rw	**CAN Analyzer Mode** If this bit is set, then the CAN node operates in Analyzer Mode. This means that messages may be received, but not transmitted. No acknowledge is sent on the CAN bus upon frame reception. Active-error flags are sent recessive instead of dominant. The transmit line is continuously held at recessive (1) level. Bit CALM can be written only while bit INIT is set.
SUSEN	8	rw	**Suspend Enable** This bit makes it possible to set the CAN node into Suspend Mode via OCDS (on chip debug support): 0_B An OCDS suspend trigger is ignored by the CAN node. 1_B An OCDS suspend trigger disables the CAN node: As soon as the CAN node becomes bus-idle or bus-off, bit INIT is internally forced to 1 to disable the CAN node. The actual value of bit INIT remains unchanged. Bit SUSEN is reset via OCDS Reset.
FDEN	9	rw	**CAN Flexible Data-Rate Enable** This bit enables the CAN FD feature: 0_B CAN FD disabled. Message transfer for CAN frames using classical CAN Format. 1_B CAN FD enabled. Message transfer for CAN frames using CAN FD Format[1]. Bit FDEN is protected by CCE and INIT bit. Please see **Section 22.4.12.4** and **Table 22-18**
0	[31:10]	r	**Reserved** Read as 0; should be written with 0.

1) Message transmission in Classical CAN, Long Frame or Long + Fast CAN FD Frames. Message Reception according to CAN FD Protocol Specification, (i.e Able to Receive Classical CAN Format Frames ISO11898-1 Long Frame and Long + Fast CAN FD Frames)

The Node Status Register NSRx reports errors as well as successfully transferred CAN frames.

CAN_NSRx (x = 0-3)
Node x Status Register **(204_H+x*100_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
LEC	[2:0]	rwh	**Last Error Code** This bit field indicates the type of the last (most recent) CAN error. The encoding of this bit field is described in **Table 22-12**.
TXOK	3	rwh	**Message Transmitted Successfully** 0_B No successful transmission since last (most recent) flag reset. 1_B A message has been transmitted successfully (error-free and acknowledged by at least another node). TXOK must be reset by software (write 0). Writing 1 has no effect.
RXOK	4	rwh	**Message Received Successfully** 0_B No successful reception since last (most recent) flag reset. 1_B A message has been received successfully. RXOK must be reset by software (write 0). Writing 1 has no effect.

Field	Bits	Type	Description
ALERT	5	rwh	**Alert Warning** The ALERT bit is set upon the occurrence of one of the following events (the same events which also trigger an alert interrupt if ALIE is set): • A change of bit NSRx.BOFF • A change of bit NSRx.EWRN • A List Length Error, which also sets bit NSRx.LLE • A List Object Error, which also sets bit NSRx.LOE ALERT must be reset by software (write 0). Writing 1 has no effect.
EWRN	6	rh	**Error Warning Status** 0_B No warning limit exceeded. 1_B One of the error counters REC or TEC reached the warning limit EWRNLVL.
BOFF	7	rh	**Bus-off Status** 0_B CAN controller is not in the bus-off state. 1_B CAN controller is in the bus-off state.
LLE	8	rwh	**List Length Error** 0_B No List Length Error since last (most recent) flag reset. 1_B A List Length Error has been detected during message acceptance filtering. The number of elements in the list that belongs to this CAN node differs from the list SIZE given in the list termination pointer. LLE must be reset by software (write 0). Writing 1 has no effect.
LOE	9	rwh	**List Object Error** 0_B No List Object Error since last (most recent) flag reset. 1_B A List Object Error has been detected during message acceptance filtering. A message object with wrong LIST index entry in the Message Object Status Register has been detected. LOE must be reset by software (write 0). Writing 1 has no effect.

Field	Bits	Type	Description
SUSACK	10	rh	**Suspend Acknowledge** 0_B The CAN node is not in Suspend Mode or a suspend request is pending, but the CAN node has not yet reached bus-idle or bus-off. 1_B The CAN node is in Suspend Mode: The CAN node is inactive (bit NCR.INIT internally forced to 1) due to an OCDS suspend request.
RESI	11	rh	**Received Error State Indicator Flag** This bit is an error flag that is set when the ESI flag in a received CAN FD frame is set. 0_B Last received CAN FD message did not have its ESI flag set. 1_B Last received CAN FD message had its ESI flag set.
FLEC	[14:12]	rwh	**Fast Last Error Code** This bit field indicates the type of the last (most recent) CAN error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. The encoding of this bit field is described in **Table 22-12**. This field will be cleared to zero when a CAN FD frame with its BRS flag set has been transferred (reception or transmission) without error.
0	[31:15]	r	**Reserved** Read as 0; should be written with 0.

Encoding of the LEC Bit field

Table 22-12 Encoding of the LEC Bit field

LEC Value	Signification
000_B	**No Error:** No error was detected for the last (most recent) message on the CAN bus.
001_B	**Stuff Error:** More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.
010_B	**Form Error:** A fixed format part of a received frame has the wrong format.

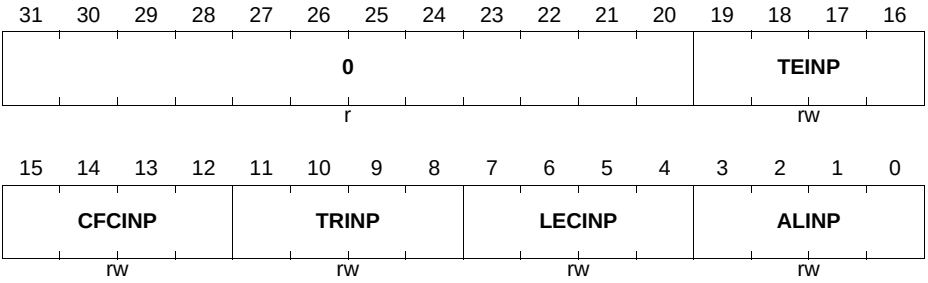
Table 22-12 Encoding of the LEC Bit field (cont'd)

LEC Value	Signification
011_B	**Ack Error:** The transmitted message was not acknowledged by another node.
100_B	**Bit1 Error:** During a message transmission, the CAN node tried to send a recessive level (1) outside the arbitration field and the acknowledge slot, but the monitored bus value was dominant.
101_B	**Bit0 Error:** Two different conditions are signaled by this code: 1. During transmission of a message (or acknowledge bit, active-error flag, overload flag), the CAN node tried to send a dominant level (0), but the monitored bus value was recessive. 2. During bus-off recovery, this code is set each time a sequence of 11 recessive bits has been monitored. The CPU may use this code as indication that the bus is not continuously disturbed.
110_B	**CRC Error:** The CRC checksum of the received message was incorrect.
111_B	**CPU write to LEC:** Whenever the CPU writes the value 111 to LEC, it takes the value 111. Whenever the CPU writes another value to LEC, the written LEC value is ignored.

Note: When a frame in CAN FD format reached data phase with BRS flag set, the next CAN event (error/valid frame) will be shown in FLEC instead of LEC. An error in a fixed stuff bit of CAN FD CRC will be shown as Form and not Stuff Error. Correspondingly CAN event (error/valid frame) will be shown back at LEC after the first bit of the CRC delimiter when CAN FD switches from Data bit rate to Nominal bit rate.

The five interrupt pointers in the Node Interrupt Pointer Register NIPRx select one out of the sixteen interrupt outputs individually for each type of CAN node interrupt. See also **Page 22-35** for more CAN node interrupt details.

CAN_NIPRx (x = 0-3)
Node x Interrupt Pointer Register (208_H+x*100_H) **Reset Value: 0000 0000_H**

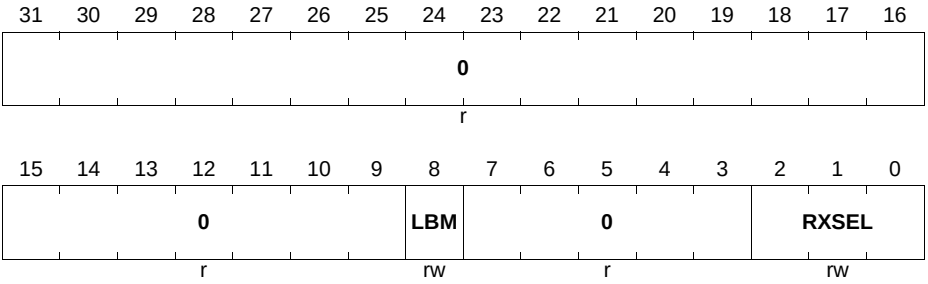


Field	Bits	Type	Description
ALINP	[3:0]	rw	**Alert Interrupt Node Pointer** ALINP selects the interrupt output line INT_Om (m = 0-15) for an alert interrupt of CAN Node x. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
LECINP	[7:4]	rw	**Last Error Code Interrupt Node Pointer** LECINP selects the interrupt output line INT_Om (m = 0-15) for an LEC interrupt of CAN Node x. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.

Field	Bits	Type	Description
TRINP	[11:8]	rw	**Transfer OK Interrupt Node Pointer** TRINP selects the interrupt output line INT_Om (m = 0-15) for a transfer OK interrupt of CAN Node x. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
CFCINP	[15:12]	rw	**Frame Counter Interrupt Node Pointer** CFCINP selects the interrupt output line INT_Om (m = 0-15) for a frame counter overflow interrupt of CAN Node x. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
TEINP	[19:16]	rw	**Timer Event Interrupt Node Pointer** TEINP selects the interrupt output line INT_Om (m = 0-15) for a timer event interrupt of CAN Node x. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
0	[31:20]	r	**Reserved** Read as 0; should be written with 0.

The Node Port Control Register NPCRx configures the CAN bus transmit/receive ports. NPCRx can be written only if bit NCRx.CCE is set.

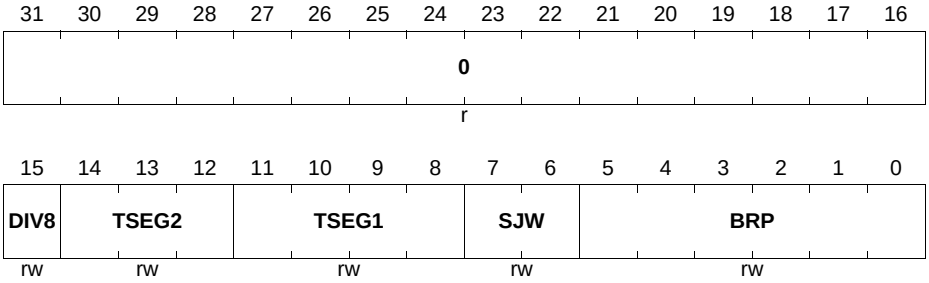
CAN_NPCRx (x = 0-3)
Node x Port Control Register **($20C_H$+x*100_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RXSEL	[2:0]	rw	**Receive Select** RXSEL selects one out of 8 possible receive inputs. The CAN receive signal is performed only through the selected input. *Note: In TC27x, only specific combinations of RXSEL are available (see also **"Node Receive Input Selection" on Page 22-168** for description and the page before for RXSEL selections).*
LBM	8	rw	**Loop-Back Mode** 0_B Loop-Back Mode is disabled. 1_B Loop-Back Mode is enabled. This node is connected to an internal (virtual) loop-back CAN bus. All CAN nodes which are in Loop-Back Mode are connected to this virtual CAN bus so that they can communicate with each other internally. The external transmit line is forced recessive in Loop-Back Mode.
0	[7:3], [31:9]	r	**Reserved** Read as 0; should be written with 0.

The Node Bit Timing Register NBTRx contains all parameters to set up the bit timing for the CAN transfer. NBTRx can be written only if bit NCRx.CCE is set. Please note that NBTRx is a register with two views, depending on NCRx.FDEN settings different view applies. (i.e When NCRx.FDEN=0, CAN_NBTRx view applies and when NCRx.FDEN=1, CAN_NBTEVRx applies)

CAN_NBTRx (x = 0-3)
Node x Bit Timing Register **(210_H+x*100_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
BRP	[5:0]	rw	**Baud Rate Prescaler** The duration of one time quantum is given by (BRP + 1) clock cycles if DIV8 = 0. The duration of one time quantum is given by 8 × (BRP + 1) clock cycles if DIV8 = 1.
SJW	[7:6]	rw	**(Re) Synchronization Jump Width** (SJW + 1) time quanta are allowed for re-synchronization.
TSEG1	[11:8]	rw	**Time Segment Before Sample Point** (TSEG1 + 1) time quanta is the user-defined nominal time between the end of the synchronization segment and the sample point. It includes the propagation segment, which takes into account signal propagation delays. The time segment may be lengthened due to re-synchronization. Valid values for TSEG1 are 2 to 15.

Field	Bits	Type	Description
TSEG2	[14:12]	rw	**Time Segment After Sample Point** (TSEG2 + 1) time quanta is the user-defined nominal time between the sample point and the start of the next synchronization segment. It may be shortened due to re-synchronization. Valid values for TSEG2 are 1 to 7.
DIV8	15	rw	**Divide Prescaler Clock by 8** 0_B A time quantum lasts (BRP+1) clock cycles. 1_B A time quantum lasts 8 × (BRP+1) clock cycles.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

The Node Bit Timing Extended View Register NBTEVRx is applicable only when NCRx.FDEN=1 (CAN FD enabled). NBTEVRx contains all parameters to set up CAN bit timing for Nominal Bit Rate. NBTRx register can be written only if bit NCRx.CCE is set.

CAN_NBTEVRx (x = 0-3)

Node x Bit Timing Extended View Register(210_H+x*100_H) Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DIV8	0			SJW				0		BRP					
rw	r			rw				r		rw					

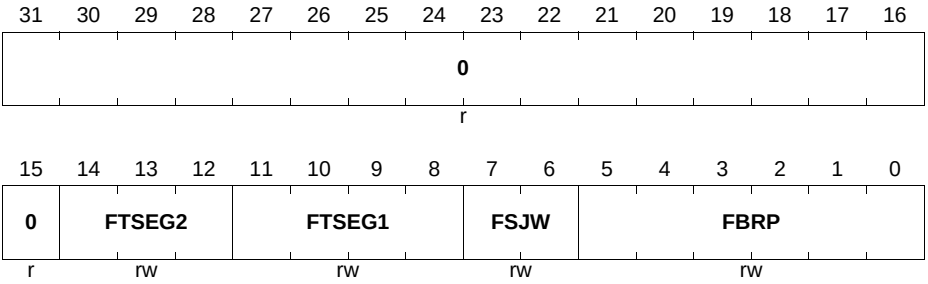
Field	Bits	Type	Description
BRP	[5:0]	rw	**Baud Rate Prescaler** The duration of one time quantum is given by (BRP + 1) clock cycles if DIV8 = 0. The duration of one time quantum is given by 8 × (BRP + 1) clock cycles if DIV8 = 1.
SJW	[11:8]	rw	**(Re) Synchronization Jump Width** (SJW + 1) time quanta are allowed for re-synchronization.
DIV8	15	rw	**Divide Prescaler Clock by 8** 0_B A time quantum lasts (BRP+1) clock cycles. 1_B A time quantum lasts 8 × (BRP+1) clock cycles.
TSEG2	[20:16]	rw	**Time Segment After Sample Point** (TSEG2 + 1) time quanta is the user-defined nominal time between the sample point and the start of the next synchronization segment. It may be shortened due to re-synchronization. Valid values for TSEG2 are 1 to 31.

Field	Bits	Type	Description
TSEG1	[27:22]	rw	**Time Segment Before Sample Point** (TSEG1 + 1) time quanta is the user-defined nominal time between the end of the synchronization segment and the sample point. It includes the propagation segment, which takes into account signal propagation delays. The time segment may be lengthened due to re-synchronization. Valid values for TSEG1 are 2 to 63.
0	[7:6], [14:12], 21, [31:28]	r	**Reserved** Read as 0; should be written with 0.

The Fast Node Bit Timing Register, FNBTRx contains all parameters to set up CAN bit timing for Data Bit Rate. FNBTRx can be written only if bit NCRx.CCE is set.

CAN_FNBTRx (x = 0-3)

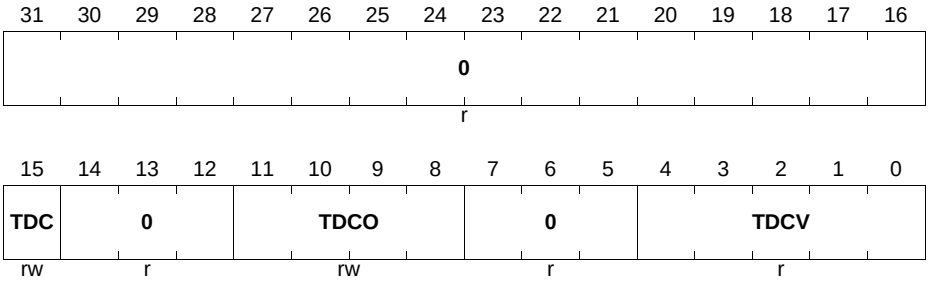
Fast Node x Bit Timing Register (238_H+x*100_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
FBRP	[5:0]	rw	**Fast Baud Rate Prescaler** The duration of one time quantum is given by (BRP + 1) clock cycles.
FSJW	[7:6]	rw	**Fast (Re) Synchronization Jump Width** (SJW + 1) time quanta are allowed for re-synchronization.
FTSEG1	[11:8]	rw	**Fast Time Segment Before Sample Point** (TSEG1 + 1) time quanta is the user-defined nominal time between the end of the synchronization segment and the sample point. It includes the propagation segment, which takes into account signal propagation delays. The time segment may be lengthened due to re-synchronization.
FTSEG2	[14:12]	rw	**Fast Time Segment After Sample Point** (TSEG2 + 1) time quanta is the user-defined nominal time between the sample point and the start of the next synchronization segment. It may be shortened due to re-synchronization.
0	[31:15]	r	**Reserved** Read as 0; should be written with 0.

The Transmitter Delay Compensation Register, TDCRx contains all parameters to setup the Transmitter Delay Compensation Feature and the corresponding status bits. NTDCRx register can be written only if bit NCRx.CCE is set.

CAN_NTDCRx (x = 0-3)
Node x Transmitter Delay Compensation Register
($23C_H$+x*100_H) **Reset Value: 0000 0000_H**

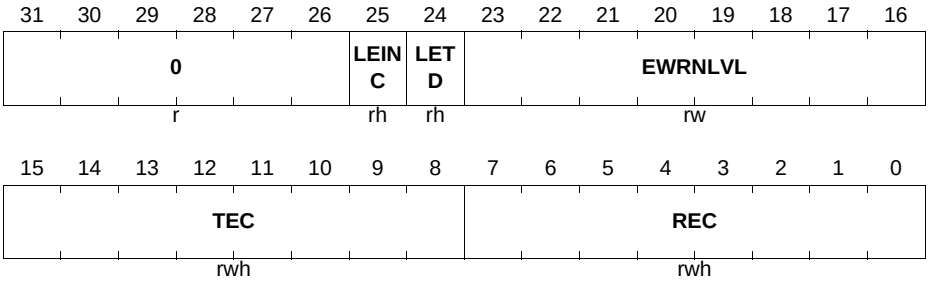


Field	Bits	Type	Description
TDCV	[4:0]	r	**Transmitter Delay Compensation Value** This bit field shows the secondary sample point which is the sum of the measured Transmitter Delay (from CAN Transmit to Receive) and Transmitter Delay compensation offset, NTDCRz.TDCO. Valid values for TDCV are 0 to 31 times of time quanta t_Q.
TDCO	[11:8]	rw	**Transmitter Delay Compensation Offset** This bit field defines the Transmitter Delay compensation offset that is added to the measured Transmitter Delay (from CAN Transmit to Receive) which forms the secondary sample point. Valid values for TDCO are 0 to 15 times of time quanta t_Q.
TDC	15	rw	**Transmitter Delay Compensation Enable** This bit enables the Transmitter Delay Compensation feature: 0_B Transmitter Delay Compensation disabled. 1_B Transmitter Delay Compensation enabled.

Field	Bits	Type	Description
0	[7:5], [14:12], [31:16]	r	**Reserved** Read as 0; should be written with 0.

The Node Error Counter Register NECNTx contains the CAN receive and transmit error counter as well as some additional bits to ease error analysis. NECNTx can be written only if bit NCRx.CCE is set.

CAN_NECNTx (x = 0-3)
Node x Error Counter Register (214_H+x*100_H) Reset Value: 0060 0000_H

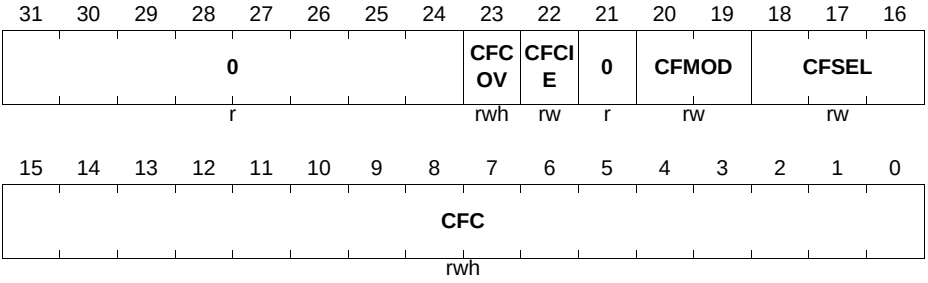


Field	Bits	Type	Description
REC	[7:0]	rwh	**Receive Error Counter** Bit field REC contains the value of the receive error counter of CAN node x.
TEC	[15:8]	rwh	**Transmit Error Counter** Bit field TEC contains the value of the transmit error counter of CAN node x.
EWRNLVL	[23:16]	rw	**Error Warning Level** Bit field EWRNLVL determines the threshold value (warning level, default 96) to be reached in order to set the corresponding error warning bit EWRN.
LETD	24	rh	**Last Error Transfer Direction** 0_B The last error occurred while the CAN node x was receiver (REC has been incremented). 1_B The last error occurred while the CAN node x was transmitter (TEC has been incremented).
LEINC	25	rh	**Last Error Increment** 0_B The last error led to an error counter increment of 1. 1_B The last error led to an error counter increment of 8.

Field	Bits	Type	Description
0	[31:26]	r	**Reserved** Read as 0; should be written with 0.

The Node Frame Counter Register NFCRx contains the actual value of the frame counter as well as control and status bits of the frame counter.

CAN_NFCRx (x = 0-3)
Node x Frame Counter Register (218_H+x*100_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CFC	[15:0]	rwh	**CAN Frame Counter** In Frame Count Mode (CFMOD = 00_B), this bit field contains the frame count value. In Time Stamp Mode (CFMOD = 01_B), this bit field contains the captured bit time count value, captured with the start of a new frame. In all Bit Timing Analysis Modes[1] (CFMOD = 10_B), CFC always displays the number of f_{CAN} clock cycles (measurement result) minus 1. Example: a CFC value of 34 in measurement mode CFSEL = 000_B means that 35 f_{CAN} clock cycles have been elapsed between the most recent two dominant edges on the receive input. In Error Count Mode (CFMOD = 11_B), this bit field contains the total amount of error frames received or error detected by the node.

Field	Bits	Type	Description
CFSEL	[18:16]	rw	**CAN Frame Count Selection** This bit field selects the function of the frame counter for the chosen frame count mode. **Frame Count Mode** Bit 0 If Bit 0 of CFSEL is set, then CFC is incremented each time a foreign frame (i.e. a frame not matching to a message object) has been received on the CAN bus. Bit 1 If Bit 1 of CFSEL is set, then CFC is incremented each time a frame matching to a message object has been received on the CAN bus. Bit 2 If Bit 2 of CFSEL is set, then CFC is incremented each time a frame has been transmitted successfully by the node. **Time Stamp Mode** The frame counter is incremented (internally) at the beginning of a new bit time. The value is sampled during the SOF bit of a new frame. The sampled value is visible in the CFC field. **Bit Timing Mode** The available bit timing measurement modes are shown in **Table 22-13**. If CFCIE is set, then an interrupt on request node x (where x is the CAN node number) is generated with a CFC update. **Error Count Mode** The frame counter is incremented when an error frame is received or an error is detected by the node. (001_B to 110_B) (see **Table 22-12** for **Encoding of the LEC Bit field**).
CFMOD	[20:19]	rw	**CAN Frame Counter Mode** This bit field determines the operation mode of the frame counter. 00_B Frame Count Mode: The frame counter is incremented upon the reception and transmission of frames. 01_B Time Stamp Mode: The frame counter is used to count bit times. 10_B Bit Timing Mode: The frame counter is used for analysis of the bit timing. 11_B Error Count Mode: The frame counter is used for counting when an error frame is received or an error is detected by the node.

Field	Bits	Type	Description
CFCIE	22	rw	**CAN Frame Count Interrupt Enable** CFCIE enables the CAN frame counter overflow interrupt of CAN node x. 0_B CAN frame counter overflow interrupt is disabled. 1_B CAN frame counter overflow interrupt is enabled. Bit field NIPRx.CFCINP selects the interrupt output line that is activated at this type of interrupt.
CFCOV	23	rwh	**CAN Frame Counter Overflow Flag** Flag CFCOV is set upon a frame counter overflow (transition from $FFFF_H$ to 0000_H). In bit timing analysis mode, CFCOV is set upon an update of CFC. An interrupt request is generated if CFCIE = 1. 0_B No overflow has occurred since last flag reset. 1_B An overflow has occurred since last flag reset. CFCOV must be reset by software.
0	21, [31:24]	r	**Reserved** Read as 0; should be written with 0.

1) The value of NFCRx.CFC is valid one module cycle later when NFCRx.CFCOV is set.

Bit Timing Analysis Modes

Table 22-13 Bit Timing Analysis Modes (CFMOD = 10)

CFSEL	Measurement
000_B	Whenever a dominant edge (transition from 1 to 0) is monitored on the receive input, the time (measured in clock cycles) between this edge and the most recent dominant edge is stored in CFC.
001_B	Whenever a recessive edge (transition from 0 to 1) is monitored on the receive input the time (measured in clock cycles) between this edge and the most recent dominant edge is stored in CFC.
010_B	Whenever a dominant edge is received as a result of a transmitted dominant edge, the time (clock cycles) between both edges is stored in CFC.
011_B	Whenever a recessive edge is received as a result of a transmitted recessive edge, the time (clock cycles) between both edges is stored in CFC.
100_B	Whenever a dominant edge that qualifies for synchronization is monitored on the receive input, the time (measured in clock cycles) between this edge and the most recent sample point is stored in CFC.

Table 22-13 Bit Timing Analysis Modes (CFMOD = 10) (cont'd)

CFSEL	Measurement
101_B	With each sample point, the time (measured in clock cycles) between the start of the new bit time and the start of the previous bit time is stored in CFC[11:0]. Additional information is written to CFC[15:12] at each sample point: CFC[15]: Transmit value of actual bit time CFC[14]: Receive sample value of actual bit time CFC[13:12]: CAN bus information (see **Table 22-14**)
110_B	Reserved, do not use this combination.
111_B	Reserved, do not use this combination.

Table 22-14 CAN Bus State Information

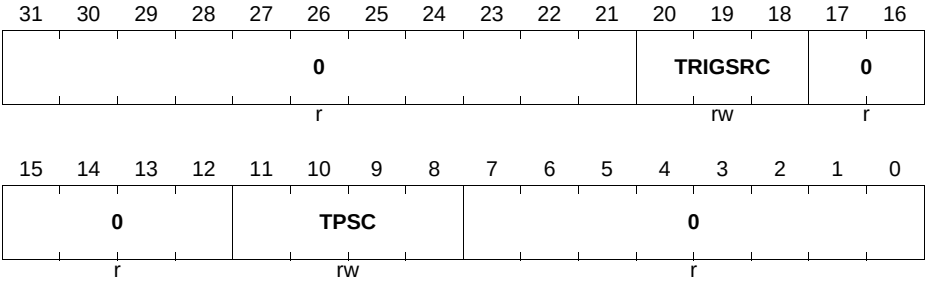
CFC[13:12]	CAN Bus State
00_B	**NoBit** The CAN bus is idle, performs bit (de-) stuffing or is in one of the following frame segments: SOF, SRR, CRC, delimiters, first 6 EOF bits, IFS.
01_B	**NewBit** This code represents the first bit of a new frame segment. The current bit is the first bit in one of the following frame segments: Bit 10 (MSB) of standard ID (transmit only), RTR, reserved bits, IDE, DLC(MSB), bit 7 (MSB) in each data byte and the first bit of the ID extension.
10_B	**Bit** This code represents a bit inside a frame segment with a length of more than one bit (not the first bit of those frame segments that is indicated by NewBit). The current bit is processed within one of the following frame segments: ID bits (except first bit of standard ID for transmission and first bit of ID extension), DLC (3 LSB) and bits 6-0 in each data byte.
11_B	**Done** The current bit is in one of the following frame segments: Acknowledge slot, last bit of EOF, active/passive-error frame, overload frame. Two or more directly consecutive Done codes signal an Error Frame.

The Node x Timer Clock Control, Node x Timer Receive Timeout and Node x Timer A/B/C Transmit Trigger Registers offer additional timing functions for the node.

The Node x Timer Clock Control Register NTCCRx controls the functions of the node timer.

CAN_NTCCRx (x = 0-3)

Node x Timer Clock Control Register ($21C_H$+x*100_H) **Reset Value: 0000 0000_H**



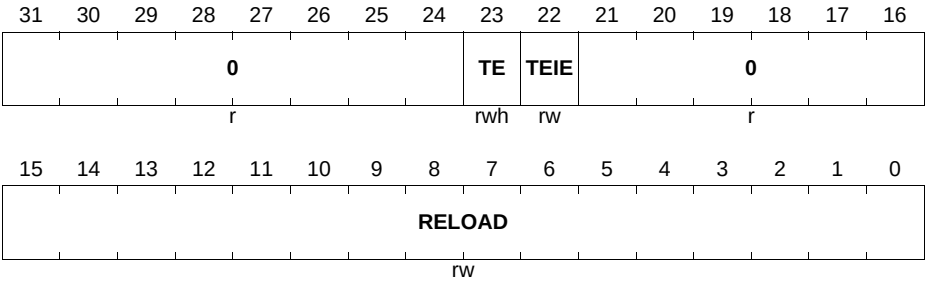
Field	Bits	Type	Description
0	[7:0]	r	**Reserved** Read as 0; should be written with 0.
TPSC	[11:8]	rw	**Timer Prescaler** The duration of one timer clock is given by (TPSC + 1) CAN bit times for all NTCCRx.TRIGSRC settings.
0	[17:12]	r	**Reserved** Read as 0; should be written with 0.
TRIGSRC	[20:18]	rw	**Trigger Source** This bit selects the trigger source for the different modes in the node timer. 000_B Node x Timer is decremented per f_{CLC} timing to 0. 001_B System Timer (STM) trigger event enabled. Node x Timer is decremented per STM trigger event prescaled by (TPSC + 1). 010_B General Timer (GTM) trigger event enabled. Node x Timer is decremented per GTM trigger event prescaled by (TPSC + 1). 011_B Reserved, do not use. $\ldots_B$ ... 111_B Reserved, do not use.

Field	Bits	Type	Description
0	[31:21]	r	**Reserved** Read as 0; should be written with 0.

The Node x Timer Receive Timeout Register NTRTx controls the node timing functions for Receive Timeout Mode.

CAN_NTRTRx (x = 0-3)

Node x Timer Receive Timeout Register (220_H+x*100_H) Reset Value: 0000 0000_H

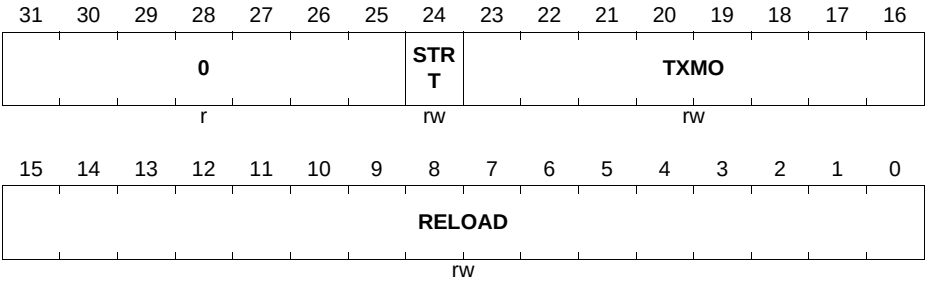


Field	Bits	Type	Description
RELOAD	[15:0]	rw	**Reload Value** This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
0	[21:16]	r	**Reserved** Read as 0; should be written with 0.
TEIE	22	rw	**Timer Event Interrupt Enable** This bit enables the node timer event interrupt of CAN node x. 0_B Timer event interrupt is disabled 1_B Timer event interrupt is enabled Bit field NIPRx.TEINP selects the interrupt output line which becomes activated at this type of interrupt.
TE	23	rwh	**Timer Event** This flag is set on a node timer transition from 1 to 0 in Receive Timeout Mode. This bit must be reset (i.e Write to '0') by software, writing a '1' has no effect. 0_B No timer event has occurred since last flag reset 1_B Timer event has occurred since last flag reset An interrupt request is generated if TEIE = 1.
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

The Node x Timer A Transmit Trigger Register NTATTx controls the node timing functions for Transmit Trigger Mode.

CAN_NTATTRx (x = 0-3)

Node x Timer A Transmit Trigger Register (224_H+x*100_H) Reset Value: 0000 0000_H

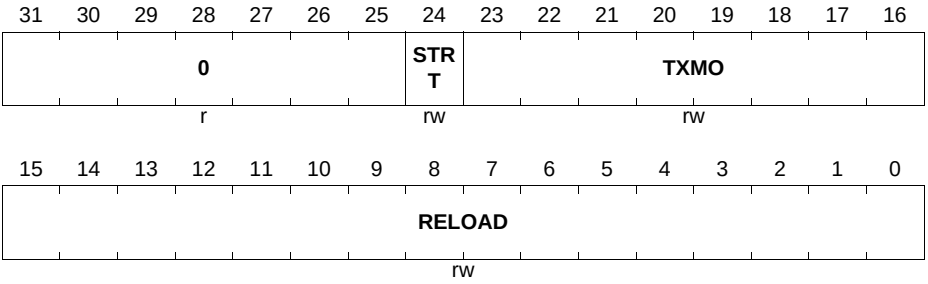


Field	Bits	Type	Description
RELOAD	[15:0]	rw	**Reload Value** This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	[23:16]	rw	**Transmit Message Object** On a transmit trigger event selected by bit TRIGSRC, the transmit request bit MOSTATn.TXRQ of message object number n will be set. Note: The NTATTRx.STRT timer has to be stopped before a new value can be programmed into TXMO, i.e 1) Program NTATTR.STRT=0 2) Program NTATTR.TXMO with new value
STRT	24	rw	**Timer Start** This bit field controls the operation of the timer. 0_B Timer is stopped. 1_B Timer is started.
0	[31:25]	r	**Reserved** Read as 0; should be written with 0.

The Node x Timer B Transmit Trigger Register NTBTTx controls the node timing functions for Transmit Trigger Mode.

CAN_NTBTTRx (x = 0-3)

Node x Timer B Transmit Trigger Register (228_H+x*100_H) Reset Value: 0000 0000_H

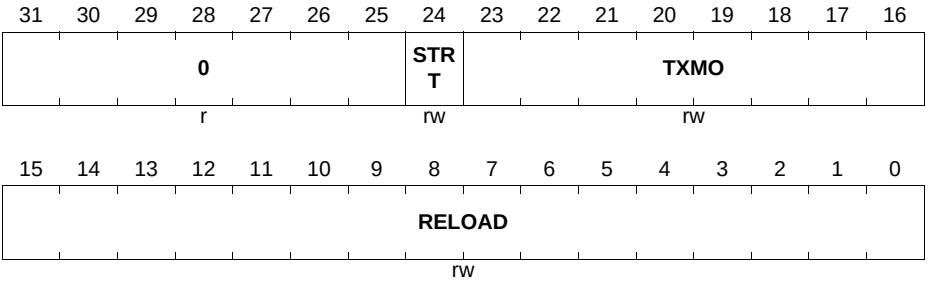


Field	Bits	Type	Description
RELOAD	[15:0]	rw	**Reload Value** This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	[23:16]	rw	**Transmit Message Object** On a transmit trigger event selected by bit TRIGSRC, the transmit request bit MOSTATn.TXRQ of message object number n will be set. Note: The NTBTTRx.STRT timer has to be stopped before a new value can be programmed into TXMO, i.e 1) Program NTBTTR.STRT=0 2) Program NTBTTR.TXMO with new value
STRT	24	rw	**Timer Start** This bit field controls the operation of the timer. 0_B Timer is stopped. 1_B Timer is started.
0	[31:25]	r	**Reserved** Read as 0; should be written with 0.

The Node x Timer C Transmit Trigger Register NTCTTx controls the node timing functions for Transmit Trigger Mode.

CAN_NTCTTRx (x = 0-3)

Node x Timer C Transmit Trigger Register ($22C_H$+x*100_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
RELOAD	[15:0]	rw	**Reload Value** This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	[23:16]	rw	**Transmit Message Object** On a transmit trigger event selected by bit TRIGSRC, the transmit request bit MOSTATn.TXRQ of message object number n will be set. Note: The NTCTTRx.STRT timer has to be stopped before a new value can be programmed into TXMO, i.e 1) Program NTCTTR.STRT=0 2) Program NTCTTR.TXMO with new value
STRT	24	rw	**Timer Start** This bit field controls the operation of the timer. 0_B Timer is stopped. 1_B Timer is started.
0	[31:25]	r	**Reserved** Read as 0; should be written with 0.

22.6.3 Message Object Registers

The Message Object Control Register MOCTRn and the Message Object Status Register MOSTATn are located at the same address offset within a message object address block (offset address $1C_H$). The MOCTRn is a write-only register that makes it possible to set/reset CAN transfer related control bits through software. Therefore the reset value is written as 0x0, even though the read part of the register has a different reset value.

CAN_MOCTRz (z = 0-254)
Message Object z Control Register($101C_H$+z*20_H) **Reset Value: 00000000_H**
CAN_MOCTR255
Message Object 255 Control Register($2FFC_H$) **Reset Value: 00000000_H**

w				w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
RESRXPND, SETRXPND	0, 16	w	**Reset/Set Receive Pending** These bits control the set/reset condition for RXPND (see **Table 22-15**).
RESTXPND, SETTXPND	1, 17	w	**Reset/Set Transmit Pending** These bits control the set/reset condition for TXPND (see **Table 22-15**).
RESRXUPD, SETRXUPD	2, 18	w	**Reset/Set Receive Updating** These bits control the set/reset condition for RXUPD (see **Table 22-15**).
RESNEWDAT, SETNEWDAT	3, 19	w	**Reset/Set New Data** These bits control the set/reset condition for NEWDAT (see **Table 22-15**).

Field	Bits	Type	Description
RESMSGLST, SETMSGLST	4, 20	w	**Reset/Set Message Lost** These bits control the set/reset condition for MSGLST (see **Table 22-15**).
RESMSGVAL, SETMSGVAL	5, 21	w	**Reset/Set Message Valid** These bits control the set/reset condition for MSGVAL (see **Table 22-15**).
RESRTSEL, SETRTSEL	6, 22	w	**Reset/Set Receive/Transmit Selected** These bits control the set/reset condition for RTSEL (see **Table 22-15**).
RESRXEN, SETRXEN	7, 23	w	**Reset/Set Receive Enable** These bits control the set/reset condition for RXEN (see **Table 22-15**).
RESTXRQ, SETTXRQ	8, 24	w	**Reset/Set Transmit Request** These bits control the set/reset condition for TXRQ (see **Table 22-15**).
RESTXEN0, SETTXEN0	9, 25	w	**Reset/Set Transmit Enable 0** These bits control the set/reset condition for TXEN0 (see **Table 22-15**).
RESTXEN1, SETTXEN1	10, 26	w	**Reset/Set Transmit Enable 1** These bits control the set/reset condition for TXEN1 (see **Table 22-15**).
RESDIR, SETDIR	11, 27	w	**Reset/Set Message Direction** These bits control the set/reset condition for DIR (see **Table 22-15**).
0	[15:12], [31:28]	w	**Reserved** Should be written with 0.

Table 22-15 Reset/Set Conditions for Bits in Register MOCTRn

RESy Bit[1)]	SETy Bit	Action on Write
Write 0	Write 0	Leave element unchanged
	No write	
No write	Write 0	
Write 1	Write 1	

Table 22-15 Reset/Set Conditions for Bits in Register MOCTRn (cont'd)

RESy Bit[1)]	SETy Bit	Action on Write
Write 1	Write 0	Reset element
	No write	
Write 0	Write 1	Set element
No write		

1) The parameter "y" stands for the second part of the bit name ("RXPND", "TXPND", … up to "DIR").

The MOSTATn is a read-only register that indicates message object list status information such as the number of the current message object predecessor and successor message object, as well as the list number to which the message object is assigned.

CAN_MOSTAT0
Message Object 0 Status Register (101C$_H$) **Reset Value: 0100 0000$_H$**
CAN_MOSTATn (n = 1-254)
Message Object n Status Register(101C$_H$+n*20$_H$)
Reset Value: ((n+1)*01000000$_H$)+((n-1)*00010000$_H$)
CAN_MOSTAT255
Message Object 255 Status Register (2FFC$_H$) **Reset Value: FFFE0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PNEXT								PPREV							
rh								rh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LIST				DIR	TX EN1	TX EN0	TX RQ	RX EN	RTS EL	MSG VAL	MSG LST	NEW DAT	RX UPD	TX PND	RX PND
rh				rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RXPND	0	rh	**Receive Pending** 0_B No CAN message has been received. 1_B A CAN message has been received by the message object n, either directly or via gateway copy action. RXPND is set by hardware and must be reset by software.
TXPND	1	rh	**Transmit Pending** 0_B No CAN message has been transmitted. 1_B A CAN message from message object n has been transmitted successfully over the CAN bus. TXPND is set by hardware and must be reset by software.

Field	Bits	Type	Description
RXUPD	2	rh	**Receive Updating** 0_B No receive update ongoing. 1_B Message identifier, DLC, and data of the message object are currently updated.
NEWDAT	3	rh	**New Data** 0_B No update of the message object n since last flag reset. 1_B Message object n has been updated. NEWDAT is set by hardware after a received CAN frame has been stored in message object n. NEWDAT is cleared by hardware when a CAN transmission of message object n has been started. NEWDAT should be set by software after the new transmit data has been stored in message object n to prevent the automatic reset of TXRQ at the end of an ongoing transmission.
MSGLST	4	rh	**Message Lost** 0_B No CAN message is lost. 1_B A CAN message is lost because NEWDAT has become set again when it has already been set.
MSGVAL	5	rh	**Message Valid** 0_B Message object n is not valid. 1_B Message object n is valid. Only a valid message object takes part in CAN transfers.

Field	Bits	Type	Description
RTSEL	6	rh	**Receive/Transmit Selected** 0_B Message object n is not selected for receive or transmit operation. 1_B Message object n is selected for receive or transmit operation. **Frame Reception:** RTSEL is set by hardware when message object n has been identified for storage of a CAN frame that is currently received. Before a received frame becomes finally stored in message object n, a check is performed to determine if RTSEL is set. Thus the CPU can suppress a scheduled frame delivery to this message object n by clearing RTSEL by software. **Frame Transmission:** RTSEL is set by hardware when message object n has been identified to be transmitted next. A check is performed to determine if RTSEL is still set before message object n is actually set up for transmission and bit NEWDAT is cleared. It is also checked that RTSEL is still set before its message object n is verified due to the successful transmission of a frame. RTSEL needs to be checked only when the context of message object n changes, and a conflict with an ongoing frame transfer shall be avoided. In all other cases, RTSEL can be ignored. RTSEL has no impact on message acceptance filtering. RTSEL is not cleared by hardware.
RXEN	7	rh	**Receive Enable** 0_B Message object n is not enabled for frame reception. 1_B Message object n is enabled for frame reception. RXEN is evaluated for receive acceptance filtering only.

Field	Bits	Type	Description
TXRQ	8	rh	**Transmit Request** 0_B No transmission of message object n is requested. 1_B Transmission of message object n on the CAN bus is requested. The transmit request becomes valid only if TXRQ, TXEN0, TXEN1 and MSGVAL are set. TXRQ is set by hardware if a matching Remote Frame has been received correctly. TXRQ is reset by hardware if message object n has been transmitted successfully and NEWDAT is not set again by software.
TXEN0	9	rh	**Transmit Enable 0** 0_B Message object n is not enabled for frame transmission. 1_B Message object n is enabled for frame transmission. Message object n can be transmitted only if both bits, TXEN0 and TXEN1, are set. The user may clear TXEN0 in order to inhibit the transmission of a message that is currently updated, or to disable automatic response of Remote Frames.
TXEN1	10	rh	**Transmit Enable 1** 0_B Message object n is not enabled for frame transmission. 1_B Message object n is enabled for frame transmission. Message object n can be transmitted only if both bits, TXEN0 and TXEN1, are set. TXEN1 is used by the MultiCAN+ module for selecting the active message object in the Transmit FIFOs.

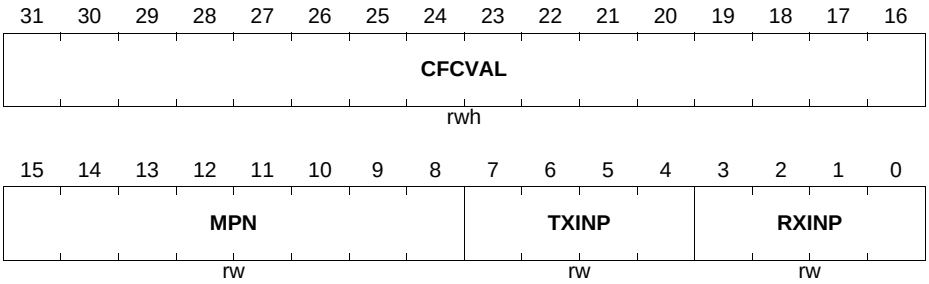
Field	Bits	Type	Description
DIR	11	rh	**Message Direction** 0_B Receive Object selected: With TXRQ = 1, a Remote Frame with the identifier of message object n is scheduled for transmission. On reception of a Data Frame with matching identifier, the message is stored in message object n. 1_B Transmit Object selected: If TXRQ = 1, message object n is scheduled for transmission of a Data Frame. On reception of a Remote Frame with matching identifier, bit TXRQ is set.
LIST	[15:12]	rh	**List Allocation** LIST indicates the number of the message list to which message object n is allocated. LIST is updated by hardware when the list allocation of the object is modified by a panel command.
PPREV	[23:16]	rh	**Pointer to Previous Message Object** PPREV holds the message object number of the previous message object in a message list structure.
PNEXT	[31:24]	rh	**Pointer to Next Message Object** PNEXT holds the message object number of the next message object in a message list structure.

Table 22-16 MOSTATn Reset Values

Message Object	PNEXT	PPREV	Reset Value
0	1	0	$0100\ 0000_H$
1	2	0	$0200\ 0000_H$
2	3	1	$0301\ 0000_H$
3	4	2	$0402\ 0000_H$
…	…	…	…
255	255	254	$FFFE\ 0000_H$

The Message Object Interrupt Pointer Register MOIPRn holds the message interrupt pointers, the message pending number, and the frame counter value of message object n.

CAN_MOIPRn (n = 0-255)
Message Object n Interrupt Pointer Register
(1008_H+n*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RXINP	[3:0]	rw	**Receive Interrupt Node Pointer** RXINP selects the interrupt output line INT_Om (m = 0-15) for a receive interrupt event of message object n. RXINP can also be taken for message pending bit selection (see **Page 22-49**). 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $…_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
TXINP	[7:4]	rw	**Transmit Interrupt Node Pointer** TXINP selects the interrupt output line INT_Om (m = 0-15) for a transmit interrupt event of message object n. TXINP can also be taken for message pending bit selection (see **Page 22-49**). 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $…_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
MPN	[15:8]	rw	**Message Pending Number** This bit field selects the bit position of the bit in the Message Pending Register that is set upon a message object n receive/transmit interrupt.

Field	Bits	Type	Description
CFCVAL	[31:16]	rwh	**CAN Frame Counter Value** When a message is stored in message object n or message object n has been successfully transmitted, the CAN frame counter value NFCRx.CFC is then copied to CFCVAL.

The Message Object Function Control Register MOFCRn contains bits that select and configure the function of the message object. It also holds the CAN data length code.

CAN_MOFCRn (n = 0-255)
Message Object n Function Control Register
(1000_H+n*20_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
MMC	[3:0]	rw	**Message Mode Control** MMC controls the message mode of message object n. 0000_B Standard Message Object 0001_B Receive FIFO Base Object 0010_B Transmit FIFO Base Object 0011_B Transmit FIFO Slave Object 0100_B Gateway Source Object 0101_B CANFD 64 bytes Message Mode $\ldots_B$ ... 1111_B Do not use
RXTOE	4	rw	**Receive Time-Out Enable** RXTOE enables participation of message in receive time-out check which is performed via a Timer controlled by the register NTRTR of the corresponding node. 0_B Message does not take part in receive time-out check 1_B Message takes part in receive time-out check Applicable to receive messages and to transmit messages waiting for remote frames.

Field	Bits	Type	Description
BRS	5	rwh	**Bit Rate Switch** 0_B Message Object transmission/reception without bit rate switching. 1_B Message Object transmission/reception with bit rate switching. Please see **Section 22.4.12.4** and **Table 22-18**
FDF	6	rwh	**CAN FD Frame Format** 0_B Message Object transmission/reception in Classical CAN Frame Format. 1_B Message Object transmission/reception in CAN FD Format (new DLC coding and CRC) Please see **Section 22.4.12.4** and **Table 22-18**
GDFS	8	rw	**Gateway Data Frame Send** 0_B TXRQ is unchanged in the destination object. 1_B TXRQ is set in the gateway destination object after the internal transfer from the gateway source to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes.
IDC	9	rw	**Identifier Copy** 0_B The identifier of the gateway source object is not copied. 1_B The identifier of the gateway source object (after storing the received frame in the source) is copied to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes.
DLCC	10	rw	**Data Length Code Copy** 0_B Data length code is not copied. 1_B Data length code of the gateway source object (after storing the received frame in the source) is copied to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes.

Field	Bits	Type	Description
DATC	11	rw	**Data Copy** 0_B Data fields are not copied. 1_B Data fields in registers MODATALn and MODATAHn of the gateway source object (after storing the received frame in the source) are copied to the gateway destination. Applicable only to a gateway source object; ignored in other nodes.
RXIE	16	rw	**Receive Interrupt Enable** RXIE enables the message receive interrupt of message object n. This interrupt is generated after reception of a CAN message (independent of whether the CAN message is received directly or indirectly via a gateway action). 0_B Message receive interrupt is disabled. 1_B Message receive interrupt is enabled. Bit field MOIPRn.RXINP selects the interrupt output line which becomes activated at this type of interrupt.
TXIE	17	rw	**Transmit Interrupt Enable** TXIE enables the message transmit interrupt of message object n. This interrupt is generated after the transmission of a CAN message. 0_B Message transmit interrupt is disabled. 1_B Message transmit interrupt is enabled. Bit field MOIPRn.TXINP selects the interrupt output line which becomes activated at this type of interrupt.

Field	Bits	Type	Description
OVIE	18	rw	**Overflow Interrupt Enable** OVIE enables the FIFO full interrupt of message object n. This interrupt is generated when the pointer to the current message object (CUR) reaches the value of SEL in the FIFO/Gateway Pointer Register. 0_B FIFO full interrupt is disabled. 1_B FIFO full interrupt is enabled. If message object n is a Receive FIFO base object, bit field MOIPRn.TXINP selects the interrupt output line which becomes activated at this type of interrupt. If message object n is a Transmit FIFO base object, bit field MOIPRn.RXINP selects the interrupt output line which becomes activated at this type of interrupt. For all other message object modes, bit OVIE has no effect.
FRREN	20	rw	**Foreign Remote Request Enable** Specifies whether the TXRQ bit is set in message object n or in a foreign message object referenced by the pointer CUR. 0_B TXRQ of message object n is set on reception of a matching Remote Frame. 1_B TXRQ of the message object referenced by the pointer CUR is set on reception of a matching Remote Frame.
RMM	21	rw	**Transmit Object Remote Monitoring** 0_B Remote monitoring is disabled: Identifier, IDE bit, and DLC of message object n remain unchanged upon the reception of a matching Remote Frame. 1_B Remote monitoring is enabled: Identifier, IDE bit, and DLC of a matching Remote Frame are copied to transmit object n in order to monitor incoming Remote Frames. Bit RMM applies only to transmit objects and has no effect on receive objects.

Field	Bits	Type	Description
SDT	22	rw	**Single Data Transfer** If SDT = 1 and message object n is not a FIFO base object, then MSGVAL is reset when this object has taken part in a successful data transfer (receive or transmit). If SDT = 1 and message object n is a FIFO base object, then MSGVAL is reset when the pointer to the current object CUR reaches the value of SEL in the FIFO/Gateway Pointer Register. With SDT = 0, bit MSGVAL is not affected.
STT	23	rw	**Single Transmit Trial** If this bit is set, then TXRQ is cleared on transmission start of message object n. Thus, no transmission retry is performed in case of transmission failure.
DLC	[27:24]	rwh	**Data Length Code** Bit field determines the number of data bytes for message object n. In Classical CAN Format: A value of DLC > 8 results in a data length of 8 data bytes. If a frame with DLC > 8 is received, the received value is stored in the message object. In CAN FD format, valid values for DLC are 0 to 15. See **Table 22-17**
0	7, [15:12], 19, [31:28]	rw	**Reserved** Read as 0 after reset; value last written is read back; should be written with 0.

Coding of DLC in CAN FD

Table 22-17 Coding of DLC in CAN FD

DLC Value	Description
0000_B	0 Data Byte for Message Object n.
$\cdots_B$	...
1000_B	8 Data Byte for Message Object n.
1001_B	12 Data Byte for Message Object n.
1010_B	16 Data Byte for Message Object n.

Table 22-17 Coding of DLC in CAN FD (cont'd)

DLC Value	Description
1011_B	20 Data Byte for Message Object n.
1100_B	24 Data Byte for Message Object n.
1101_B	32 Data Byte for Message Object n.
1110_B	48 Data Byte for Message Object n.
1111_B	64 Data Byte for Message Object n.

CAN FD Transmit And Receive Behavior

Message transmission and reception behavior of CAN data frames is summarized at **Table 22-18** below.

Table 22-18 CAN FD Transmit And Receive Behavior

FDEN	FDF[1)]	BRS[1)]	Transmit Behavior
0_B	0_B	0_B	Classical CAN Frames (ISO 11898-1)
0_B	0_B	1_B	Classical CAN Frames (ISO 11898-1)
0_B	1_B	0_B	Transmission Cancelled[2)] (i.e TXRQ bit cleared)
0_B	1_B	1_B	Transmission Cancelled[2)] (i.e TXRQ bit cleared)
1_B	0_B	0_B	Classical CAN Frames (ISO 11898-1)
1_B	0_B	1_B	Classical CAN Frames (ISO 11898-1)
1_B	1_B	0_B	Long Frame (i.e CAN FD frame with BRS = 0, whole frame transmitted with slow baudrate)
1_B	1_B	1_B	Long + Fast Frame (i.e CAN FD frame with BRS = 1, switching fast baudrate for dataphase)
FDEN	**FDF[3)]**	**BRS[3)]**	**Receive Behavior[4)]**
0_B	$0/1_B$	$0/1_B$	- Classical CAN Frames
1_B	$0/1_B$	$0/1_B$	- Classical CAN Frames - Long Frames - Long + Fast Frames

1) User writes

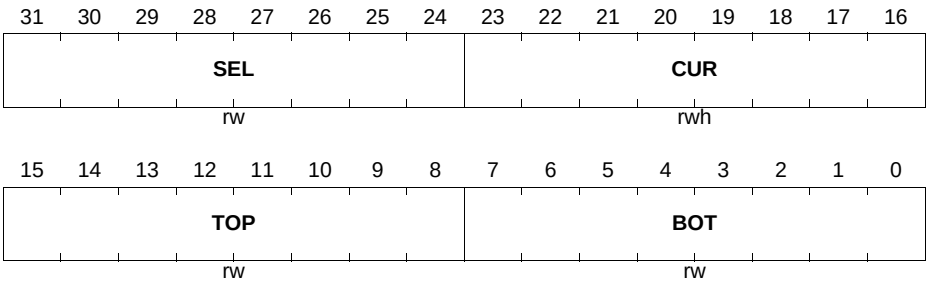
2) TXRQ in message object is cleared upon transmit setup and transmit setup cancelled. CAN node is not blocked and able to transmit other message objects.

3) Hardware writes

4) Please note that Remote Frames Request do not change BRS and FDF bits.

The Message Object FIFO/Gateway Pointer register MOFGPRn contains a set of message object link pointers that are used for FIFO and gateway operations.

CAN_MOFGPRn (n = 0-255)
Message Object n FIFO/Gateway Pointer Register
(1004_H+n*20_H) **Reset Value: 0000 0000_H**

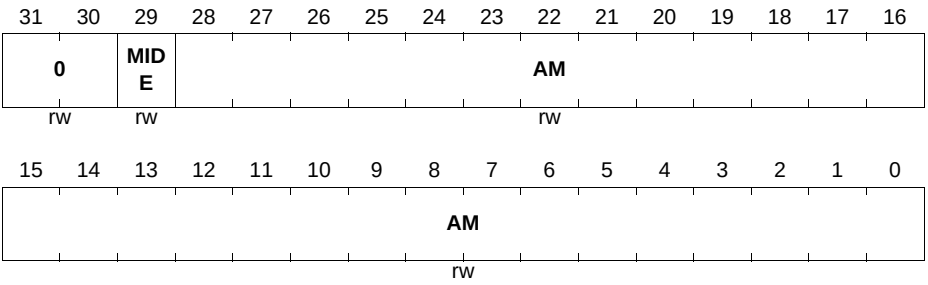


Field	Bits	Type	Description
BOT	[7:0]	rw	**Bottom Pointer** Bit field BOT points to the first element in a FIFO structure. Or in the case when MOFCR.MMC=5, CAN FD 64 bytes message mode, BOT points to where Data bytes 8-35 are stored in the message object.
TOP	[15:8]	rw	**Top Pointer** Bit field TOP points to the last element in a FIFO structure. Or in the case when MOFCR.MMC=5, CAN FD 64 bytes message mode, BOT points to where Data bytes 36-63 are stored in the message object.
CUR	[23:16]	rwh	**Current Object Pointer** Bit field CUR points to the actual target object within a FIFO/Gateway structure. After a FIFO/gateway operation CUR is updated with the message number of the next message object in the list structure (given by PNEXT of the Message Object Status Register) until it reaches the FIFO top element (given by TOP) when it is reset to the bottom element (given by BOT).

Field	Bits	Type	Description
SEL	[31:24]	rw	**Object Select Pointer** Bit field SEL is the second (software) pointer to complement the hardware pointer CUR in the FIFO structure. SEL is used for monitoring purposes (FIFO interrupt generation).

Message Object n Acceptance Mask Register MOAMRn contains the mask bits for the acceptance filtering of the message object n.

CAN_MOAMRn (n = 0-255)
Message Object n Acceptance Mask Register
($100C_H$+n*20_H) **Reset Value: 3FFF FFFF$_H$**

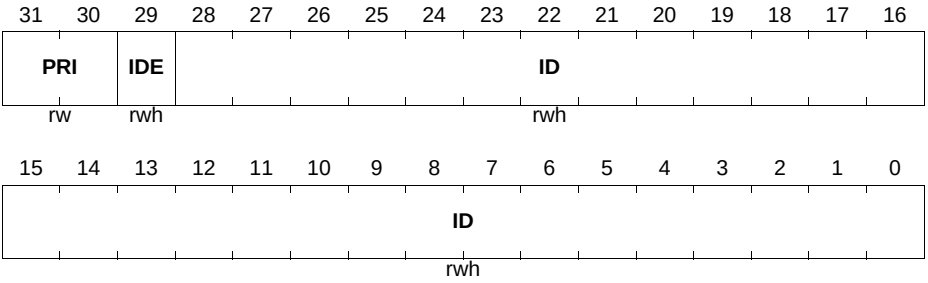


Field	Bits	Type	Description
AM	[28:0]	rw	**Acceptance Mask for Message Identifier** Bit field AM is the 29-bit mask for filtering incoming messages with standard identifiers (AM[28:18]) or extended identifiers (AM[28:0]). For standard identifiers, bits AM[17:0] are “don’t care”.
MIDE	29	rw	**Acceptance Mask Bit for Message IDE Bit** 0_B Message object n accepts the reception of both, standard and extended frames. 1_B Message object n receives frames only with matching IDE bit.
0	[31:30]	rw	**Reserved** Read as 0 after reset; value last written is read back; should be written with 0.

Message Object n Arbitration Register MOARn contains the CAN identifier of the message object.

CAN_MOARn (n = 0-255)
Message Object n Arbitration Register

(1018_H+n*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
ID	[28:0]	rwh	**CAN Identifier of Message Object n** Identifier of a standard message (ID[28:18]) or an extended message (ID[28:0]). For standard identifiers, bits ID[17:0] are “don’t care”.
IDE	29	rwh	**Identifier Extension Bit of Message Object n** 0_B Message object n handles standard frames with 11-bit identifier. 1_B Message object n handles extended frames with 29-bit identifier.

Field	Bits	Type	Description
PRI	[31:30]	rw	**Priority Class** PRI assigns one of the four priority classes 0, 1, 2, 3 to message object n. A lower PRI number defines a higher priority. Message objects with lower PRI value always win acceptance filtering for frame reception and transmission over message objects with higher PRI value. Acceptance filtering based on identifier/mask and list position is performed only between message objects of the same priority class. PRI also determines the acceptance filtering method for transmission: 00_B Reserved. 01_B Transmit acceptance filtering is based on the list order. This means that message object n is considered for transmission only if there is no other message object with valid transmit request (MSGVAL & TXEN0 & TXEN1 = 1) somewhere before this object in the list. 10_B Transmit acceptance filtering is based on the CAN identifier. This means, message object n is considered for transmission only if there is no other message object with higher priority identifier + IDE + DIR (with respect to CAN arbitration rules) somewhere in the list (see **Table 22-19**). 11_B Transmit acceptance filtering is based on the list order (as PRI = 01_B).

Transmit Priority of Msg. Objects based on CAN Arbitration Rules

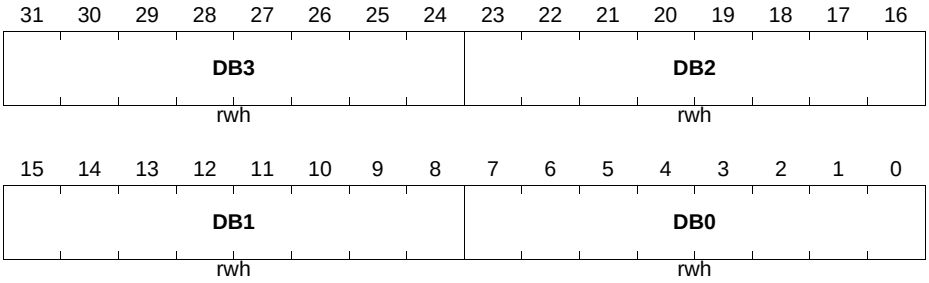
Table 22-19 Transmit Priority of Msg. Objects Based on CAN Arbitration Rules

Settings of Arbitrarily Chosen Message Objects A and B, (A has higher transmit priority than B)	Comment
A.MOAR[28:18] < B.MOAR[28:18] (11-bit standard identifier of A less than 11-bit standard identifier of B)	Messages with lower standard identifier have higher priority than messages with higher standard identifier. MOAR[28] is the most significant bit (MSB) of the standard identifier. MOAR[18] is the least significant bit of the standard identifier.
A.MOAR[28:18] = B.MOAR[28:18] A.MOAR.IDE = 0 (send Standard Frame) B.MOAR.IDE = 1 (send Extended Frame)	Standard Frames have higher transmit priority than Extended Frames with equal standard identifier.
A.MOAR[28:18] = B.MOAR[28:18] A.MOAR.IDE = B.MOAR.IDE = 0 A.MOSTAT.DIR = 1 (send Data Frame) B.MOSTAT.DIR = 0 (send Remote Fame)	Standard Data Frames have higher transmit priority than standard Remote Frames with equal identifier.
A.MOAR[28:0] = B.MOAR[28:0] A.MOAR.IDE = B.MOAR.IDE = 1 A.MOSTAT.DIR = 1 (send Data Frame) B.MOSTAT.DIR = 0 (send Remote Frame)	Extended Data Frames have higher transmit priority than Extended Remote Frames with equal identifier.
A.MOAR[28:0] < B.MOAR[28:0] A.MOAR.IDE = B.MOAR.IDE = 1 (29-bit identifier)	Extended Frames with lower identifier have higher transmit priority than Extended Frames with higher identifier. MOAR[28] is the most significant bit (MSB) of the overall identifier (standard identifier MOAR[28:18] and identifier extension MOAR[17:0]). MOAR[0] is the least significant bit (LSB) of the overall identifier.

Message Object n Data Register Low MODATALn contains the lowest four data bytes of message object n. Unused data bytes are set to zero upon reception and ignored for transmission.

CAN_MODATALn (n = 0-255)
Message Object n Data Register Low

(1010_H+n*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DB0	[7:0]	rwh	**Data Byte 0 of Message Object n**
DB1	[15:8]	rwh	**Data Byte 1 of Message Object n**
DB2	[23:16]	rwh	**Data Byte 2 of Message Object n**
DB3	[31:24]	rwh	**Data Byte 3 of Message Object n**

Message Object n Data Register High MODATAH contains the highest four data bytes of message object n. Unused data bytes are set to zero upon reception and ignored for transmission.

CAN_MODATAHn (n = 0-255)
Message Object n Data Register High

(1014_H+n*20_H) **Reset Value: 0000 0000$_H$**

DB3	[31:24]	rwh	**Data Byte 3 of Message Object n**

22.7 MultiCAN+ Module Implementation

This section describes CAN module interfaces with the clock control, port connections, interrupt control, and address decoding.

22.7.1 Interfaces of the MultiCAN+ Module

Figure 22-28 shows the TC27x specific implementation details and interconnections of the MultiCAN+ module. The I/O lines of the MultiCAN+ module (two I/O lines of each CAN node) are connected to the Ports listed in**Table 22-22**. The MultiCAN+ module is also supplied by clock control, interrupt control, and address decoding logic. MultiCAN+ interrupts can be directed to the DMA, CPU, GTM modules which are able to trigger DMA transfers and GTM, CPU operations.

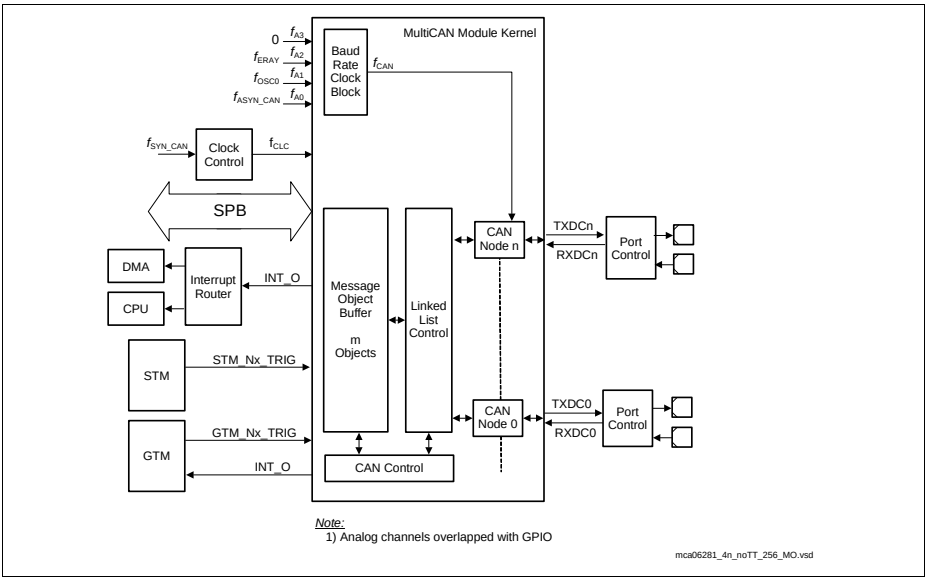

Figure 22-28 MultiCAN+ Module Implementation and Interconnections with n := 4 and m := 256 for AURIX

22.7.2 MultiCAN+ Module External Registers

The registers listed in **Figure 22-29** are not included in the MultiCAN+ module kernel, some registers must be programmed for proper operation of the MultiCAN+ module.

22.7.2.1 System Registers

OCDS Trigger Bus (OTGB)

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status **($0E8_H$)** **Reset Value: $0000\ 0000_H$**

0	[23:4], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register 0

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B,.. ,EN31 -> TAG ID 011111_B.

ACCEN0

Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

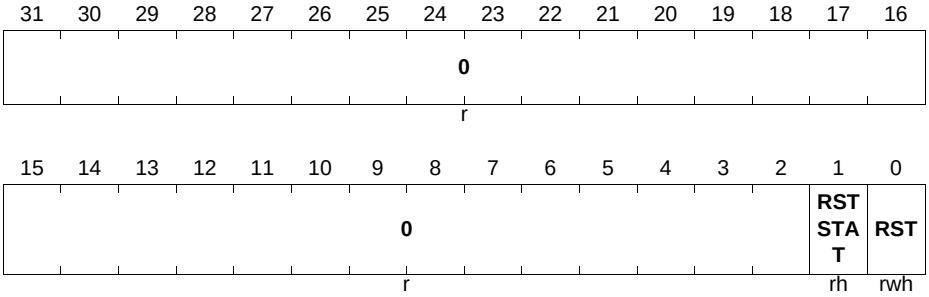
Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers related to the module kernel that should be reset (kernel 0 or kernel 1).The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing to it with ´1´.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 ($0F4_H$) Reset Value: $0000\ 0000_H$



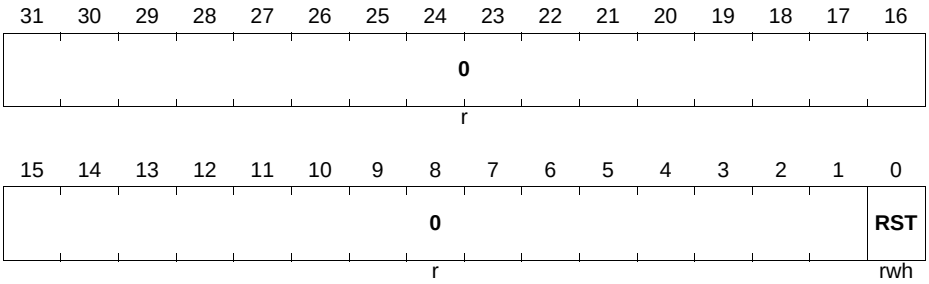
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.

Field	Bits	Type	Description
RSTSTAT	1	rw	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers (CAN_KRSTx1.RST and CAN_KRSTx0.RST) related to the module kernel that should be reset (kernel 0 or kernel 1). The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($0F0_H$)** **Reset Value: $0000\ 0000_H$**

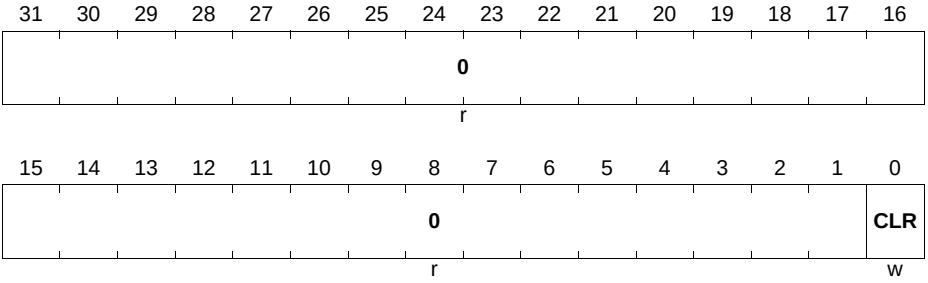


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Clear Register

The Kernel Reset Clear Register is used to clear the Kernel Reset Status bit (CAN_KRST0.RSTSTAT).

KRSTCLR
Kernel Reset Status Clear Register (0EC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

22.7.3 MultiCAN+ Clock Interconnects With SCU

The MultiCAN+ module clock inputs are connected to System Control Unit (SCU) clock control unit (CCU) as shown in **Figure 22-30** and **Table 22-21** below.

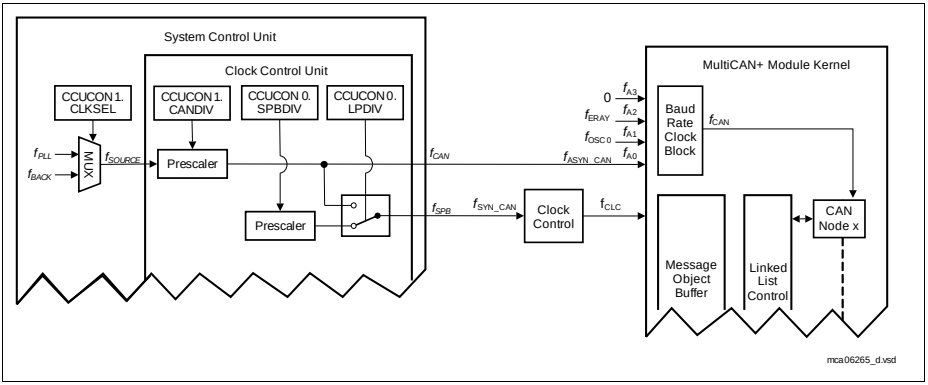


Figure 22-30 MultiCAN+ Clock Interconnects with SCU

Table 22-21 MultiCAN+ Clock Interconnects

CAN Clock Inputs	Connected to	Description
f_{ASYN_CAN}	SCU	f_{ASYN_CAN} of the MultiCAN+ module is one of the clock inputs of the Baud Rate Clock Block, providing the MultiCAN+ module timer clock f_{CAN}. f_{ASYN_CAN} connects to SCU CCU f_{CAN} and is controlled by CCUCON1.CANDIV. The CCUCON1.CANDIV is able to select different values of prescalers based on a selectable f_{PLL} or f_{BACK} source.
f_{SYN_CAN}	SCU	f_{SYN_CAN} of the MultiCAN+ module is the clock input of the Clock Control Register Block, providing the main kernel clock f_{CLC}. f_{SYN_CAN} connects to SCU CCU and is multiplexed between f_{SPB} and f_{CAN}. In normal mode, f_{SYN_CAN} is connected to f_{SPB} where else in pretended networking mode (CCUCON0.LPDIV >0), f_{SYN_CAN} connects to f_{CAN} of SCU CCU.

Note: The f_{CAN} mentioned on the SCU chapter does not refer to the same f_{CAN} that is mentioned on the MultiCAN+ chapter.

11. *The f_{CAN} mentioned on the SCU chapter refers in general to connection for MultiCAN+ clocking inputs f_{ASYN_CAN} and f_{SYN_CAN}. Depending on the settings of CCUCON1.CANDIV and CCUCON0.LPDIV different clock sources are connected (See **Table 22-21**).*
12. *The f_{CAN} mentioned on the MultiCAN+ chapter refers to the module timer clock (See **Section 22.7.4.2**).*

22.7.4 Module Clock Generation

This chapter describes the way the module get's its clock.

22.7.4.1 Clock Selection

The bit timing machine and the rest of the MultiCAN+ module are separate frequency domains and can be driven by separate independent frequencies. The bit timing unit can be driven by the SPB bus clock or with the direct oscillator clock, and the rest of the chip is driven only by the SPB bus clock.

The purpose of supplying the bit timing unit with a direct oscillator clock is to avoid the clock jitter added by the PLL, necessary when the chip is driven by a low cost ceramic resonator instead of by high precision quartz crystal.

Selecting the clock source for the bit timing unit is done by programming the bit-field MCR.CLKSEL.

Enabling and disabling the clock of the module by using CLC.DISR affects always both frequency domains, so that when f_{CLC} is switched off, f_A is also switched off.

22.7.4.2 Fractional Divider

As shown in **Figure 22-31**, the clock signals for the MultiCAN+ module are generated and controlled by a clock control unit. This clock generation unit is responsible for the enable/disable control, the clock frequency adjustment, and the debug clock control. This unit includes two registers:

- CAN_CLC: generation of the module control clock f_{CLC}
- CAN_FDR: frequency control of the module timer clock f_{CAN}

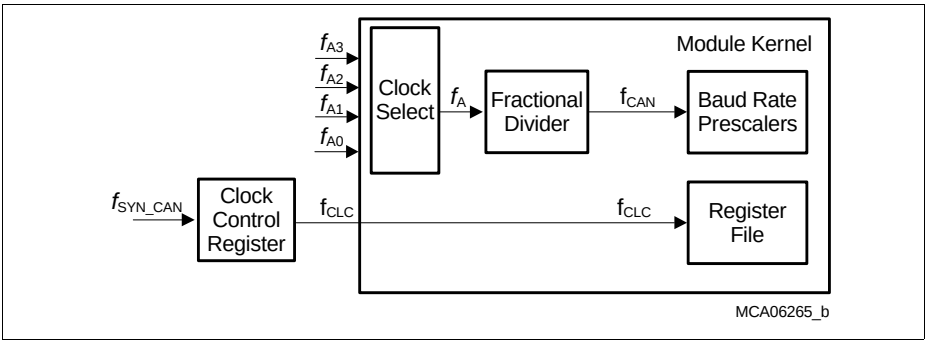

Figure 22-31 MultiCAN+ Module Clock Generation

The f_{SYN_CAN} is identical to f_{SPB}.

The module control clock f_{CLC} is used inside the MultiCAN+ module for control purposes such as clocking of control logic and register operations. The frequency of f_{CLC} is identical to the system clock frequency f_{SPB}. The clock control register CAN_CLC makes it possible to enable/disable f_{CLC} under certain conditions.

The module timer clock f_{CAN} is used inside the MultiCAN+ module as input clock for all timing relevant operations (e.g. bit timing). The settings in the CAN_FDR register determine the frequency of the module timer clock f_{CAN} according the following two formulas:

$$f_{CAN} = f_A \times \frac{1}{n} \quad \text{with n = 1024 - CAN\_FDR.STEP} \tag{22.2}$$

$$f_{CAN} = f_A \times \frac{n}{1024} \quad \text{with n = 0-1023} \tag{22.3}$$

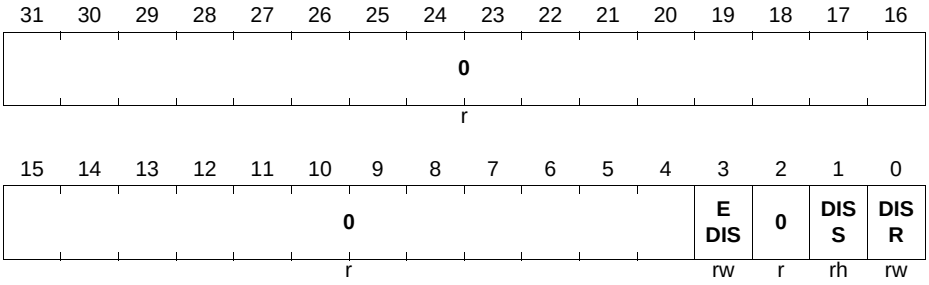
Equation (22.2) applies to normal divider mode (CAN_FDR.DM = 01_B) of the fractional divider. **Equation (22.3)** applies to fractional divider mode (CAN_FDR.DM = 10_B).

Note: The CAN module is disabled after reset. In general, after reset, the module control clock f_{CLC} must be switched on (writing to register CAN_CLC) before the frequency of the module timer clock f_{CAN} is defined (writing to register CAN_FDR).

CAN Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{CAN} module clock signal, sleep mode and fast shut-off mode for the module.

CLC
CAN Clock Control Register (000_H) Reset Value: 0000 0003$_H$



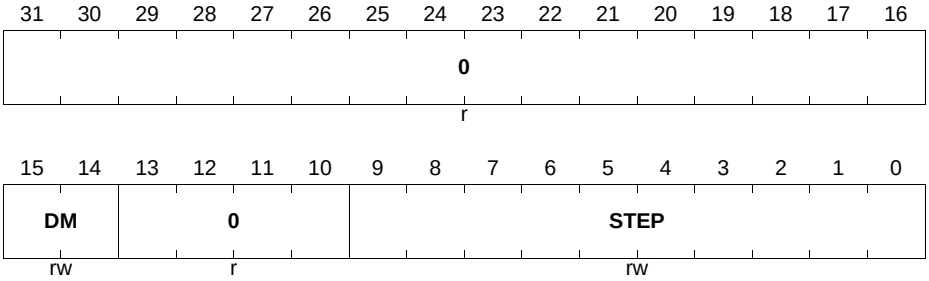
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. Note that no register access is possible to any register while module is disabled.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
0	[31:4], 2	r	**Reserved** Read as 0; should be written with 0.

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency.

The fractional divider register allows the programmer to control the clock rate of the module timer clock f_{CAN}.

FDR

CAN Fractional Divider Register ($00C_H$) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for the result.
DM	[15:14]	rw	**Divider Mode** This bit field selects normal divider mode, fractional divider mode, and off-state.
0	[13:10], [31:16]	r	**Reserved** Read as 0; should be written with 0.

22.7.5 Port and I/O Line Control

The interconnections between the MultiCAN+ module and the port I/O lines are controlled in the port logic. Additionally to the port input selection, the following port control operations must be executed:

- Input/output function selection (IOCR registers)
- Pad driver characteristics selection for the outputs (PDR registers)

22.7.5.1 Input/Output Function Selection in Ports

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as pull-up/down devices, port direction (input/output), open-drain, and alternate output selections. The I/O lines for the MultiCAN+ module are controlled by the port input/output control registers, which are described in the port chapter. In case of discrepancies between port chapter and CAN chapter, the description in the port chapter is correct.

Table 22-22 shows the corresponding pins, sorted by node. Even though the table is pair wise, it is possible to select a different pairing for RXD and TXD. In addition the RXSEL value to be programmed for the Receive Pins is part of this table. For more information on RXSEL please see **Chapter 22.7.5.2**.

Table 22-22 MultiCAN+ I/O Control Selection and Setup for TC27x

Node	RXD	NPCRx.RXSEL	TXD
CAN0	P02.1 / RXDCAN0A	000_B	P02.0 / TXDCAN0
	P20.7 / RXDCAN0B	001_B	P20.8 / TXDCAN0

	P32.2 / RXDCAN3B	001_B	P32.3 / TXDCAN3
	P20.0 / RXDCAN3C	010_B	P20.3 / TXDCAN3
	P11.10 / RXDCAN3D	011_B	P11.12 / TXDCAN3
	P20.9 / RXDCAN3E	100_B	P20.10 / TXDCAN3

22.7.5.2 Node Receive Input Selection

Additionally to the I/O control selection, as defined in the port chapter, the selection of a CAN node's receive input line requires that bit field RXSEL in its node port control register NPCRx must be set according to **Table 22-22**. Values for NPCRx.RXSEL other than those of the table mentioned above will result in a recessive receive input for node x. As a hint A results in 0x0, B in 0x1 until H resulting in the value of 0x7.

This feature allows, for example, a CAN node which operates in analyzer mode to monitor the receive operations of its neighbor CAN node.

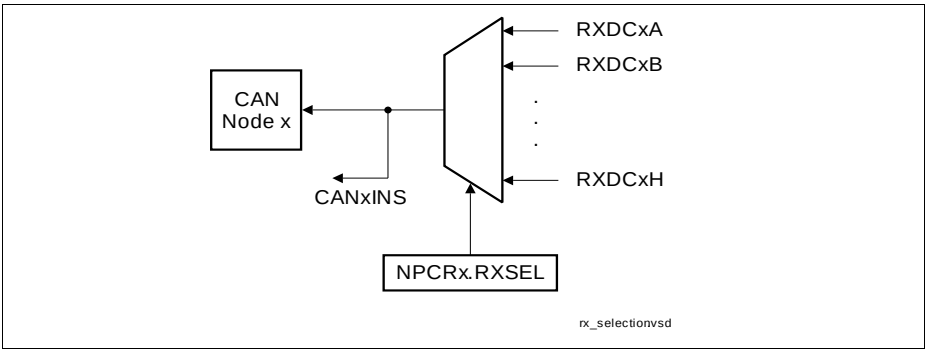

Figure 22-32 CAN Module Receive Input Selection

22.7.5.3 CAN Transmit Trigger Inputs

The CAN transmit trigger inputs of MultiCAN are used to trigger for transmission of a message. In the TC27x, these input lines are connected as shown in **Table 22-23**.

Table 22-23 CAN Transmit Trigger Inputs

Receive Input	Connected to	From / to Module
CAN Node 0		
STM_N0_TRIG	stm0.systim_irq_o(0)	System Timer Module (STM)
GTM_N0_TRIG	gtm.can_trig_0_o	General Timer Module (GTM)
...		
...	...	...
CAN Node 3		
STM_N3_TRIG	stm0.systim_irq_o(0)	System Timer Module (STM)
GTM_N3_TRIG	gtm.can_trig_3_o	General Timer Module (GTM)

22.7.5.4 Connections to Interrupt Router Inputs

The interrupt output line INT_O0-15 is connected to the Interrupt Router module, see **Table 22-24**.

Table 22-24 Interrupt Router Inputs

Interrupt Router Input	Connected to CAN Interrupt Output
SRC_CANINT0	INT_O0
SRC_CANINT1	INT_O1
SRC_CANINT2	INT_O2
SRC_CANINT3	INT_O3
SRC_CANINT4	INT_O4
SRC_CANINT5	INT_O5
SRC_CANINT6	INT_O6
SRC_CANINT7	INT_O7
SRC_CANINT8	INT_O8
SRC_CANINT9	INT_O9
SRC_CANINT10	INT_O10
SRC_CANINT11	INT_O11
SRC_CANINT12	INT_O12
SRC_CANINT13	INT_O13
SRC_CANINT14	INT_O14
SRC_CANINT15	INT_O15

22.7.5.5 Connections to General Timer Module (GTM) Inputs

The interrupt output line INT_O12-15 of MultiCAN+ is connected to the General Timer Module, see **Table 22-25**.

Table 22-25 General Timer Module Inputs

GTM Input	Connected to CAN Interrupt Output
Timer input (gtm.tim_0_muxin_1_i(13))	INT_O12 (mcan0.int_req_o(12))
Timer input (gtm.tim_0_muxin_2_i(13))	INT_O13 (mcan0.int_req_o(13))
Timer input (gtm.tim_0_muxin_3_i(13))	INT_O14 (mcan0.int_req_o(14))
Timer input (gtm.tim_0_muxin_4_i(13))	INT_O15 (mcan0.int_req_o(15))

22.7.6 Interrupt Control

The interrupt control logic in the MultiCAN+ module uses an interrupt compressing scheme that allows high flexibility in interrupt processing. There are hardware and software interrupt sources available:

- CAN node interrupts:
  - Five different interrupt sources for each of the 4 CAN nodes = 5 * 4 interrupt sources
- Message object interrupts:
  - Two interrupt source for each message object = 2 * 256 interrupt sources
- One register (MITR) to initiate 16 interrupts via software

Each of the hardware initiated interrupt sources is controlled by a 4-bit interrupt pointer that directs the interrupt source to one of the 16 interrupt outputs INT_Om (m = 0-15). This makes it possible to connect more than one interrupt source (between one and all) to one interrupt output line. The interrupt wiring matrix shown in **Figure 22-33** is built up according to the following rules:

- Each output of the 4-bit interrupt pointer demultiplexer is connected to exactly one OR-gate input of the INT_Om line. The number “m” of the corresponding selected INT_Om interrupt output line is defined by the interrupt pointer value.
- Each INT_Om output line has an input OR gate which is connected to all interrupt pointer demultiplexer outputs which are selected by an identical 4-bit pointer value.

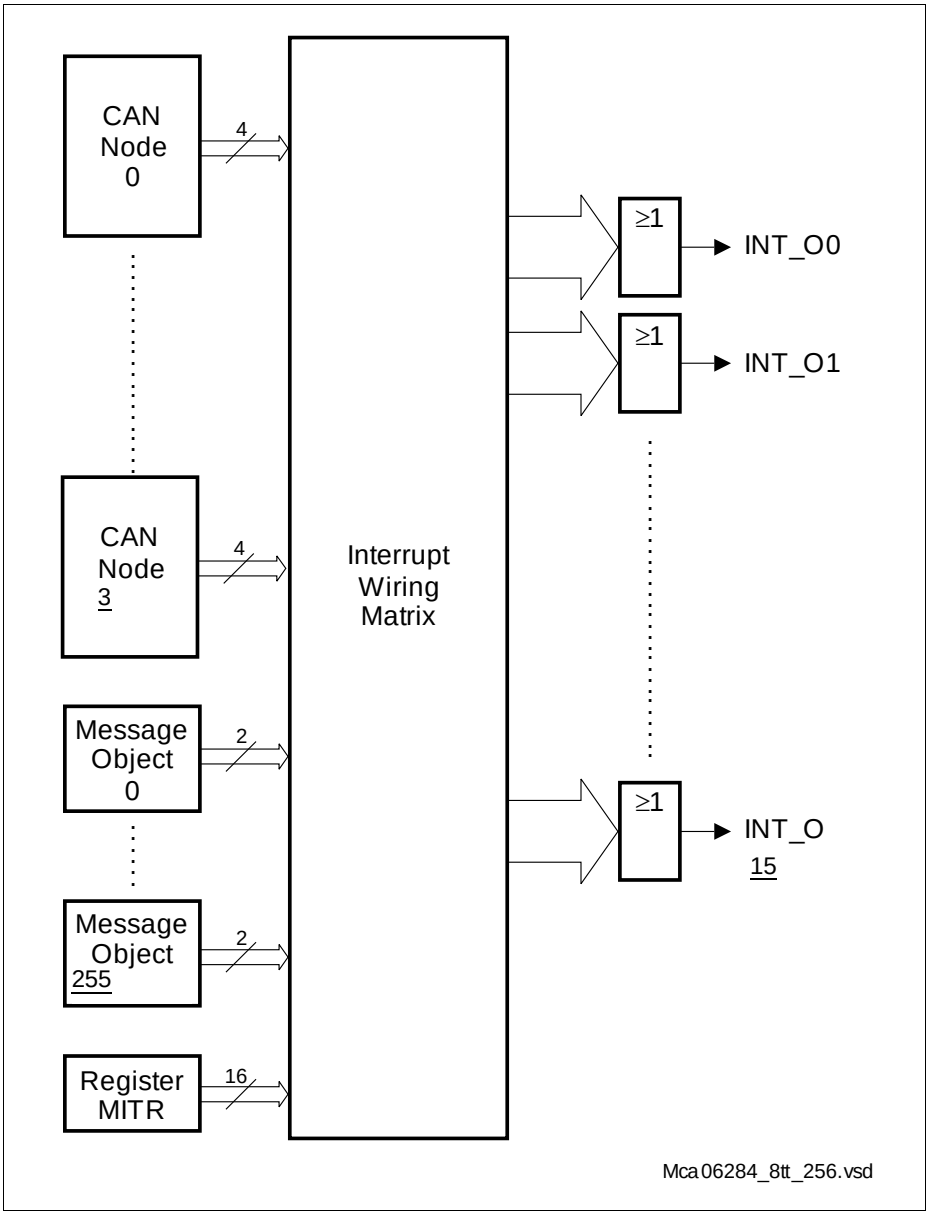

Figure 22-33 Interrupt Compressor

22.7.7 MultiCAN+ Module Register Address Map

The complete MultiCAN+ module register address map of **Figure 22-34** also shows the general implementation-specific registers for clock control, module identification, interrupt service request control and the absolute address information.

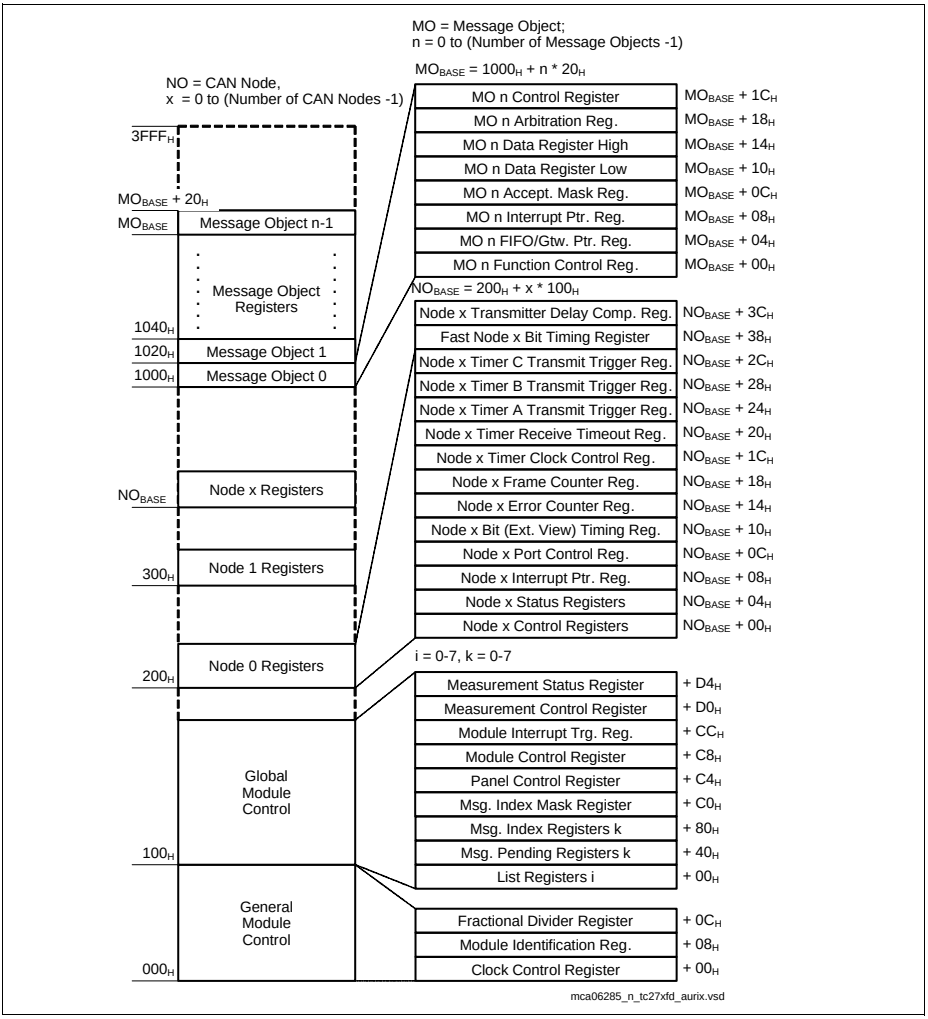

Figure 22-34 MultiCAN+ Register Address Map including CAN FD

22.8 MultiCAN+ Soft Configuration

There is one property of the MultiCAN+ module that can be configured via external signals. The MultiCAN+ module reads the configuration of these properties from PERCFG register.

- CAN FD on/off for the device is configured in PERCFG.CANFDEN (which is bit 8 of the corresponding register).

MultiCAN+ Soft Configuration can only restrict the module. That means that only the numbers equal or smaller than the number of physically available resources in the module may be used. Otherwise, an unpredictable behavior occurs.

22.9 Revision history

External revision history only shows major changes of MultiCAN+ module versions.

External Revision History (from MultiCAN+ v3.0 to MultiCAN+ v3.1)

- As per review meeting on 4Sep12 with designer, Removed for below: This bulleted point is not applicable to TC27x.
  - Section 1.1.3.5 on Intermission removed as same as CAN V2.0B Bosch specs, under Section 9.1 Protocol Modifications, point 2.
  - Section 1.1.3.5 on Suspend transmission removed as same as CAN V2.0B Bosch specs, under Section 3.1.5 Interframe Spacing, Suspend Transmission.
  - Section 1.1.4.1 on Resynchronization removed as same as CAN V2.0B Bosch specs, under Section 8 Bit timing requirements, Resynchronization.
  - Section 1.1.4.1 on Synchronization rules, removed point 1,2 and 4. Point 3 and 5 are kept as new requirements in CAN FD.
  - Section 1.5.2 on Integrating mode, removed as same as CAN V2.0B Bosch specs, under Section 2 Sleep Mode / Wake-up.
- As per review meeting on 4Sep12 with designer, Added for below: This bulleted point is not applicable to TC27x.
  - Additional text under MOFCRn.DLC, “Also if DLC>8 is programmed for message transmission, message transmit will be disabled.”
- This bulleted point is not applicable to TC27x.
- Added at Section 1.6.4 OCDS suspend, Note on “During suspend mode, kernel registers may be accessed only when the kernel clock is running”

External Revision History (from MultiCAN+ v3.1 to MultiCAN+ v3.2)

- As per AURIX JF on 1oct12, after bosch meeting on discussion of baudrates, request for below: This bulleted point is not applicable to TC27x.
  - Modified on Section 1.1.3.1 on Fig1-2 CAN FD data frames changed to 64 data bytes and removed footnote on “Current design supports up to 8 data bytes payload only”
  - Removed on Section 1.3.1 footnote on “supports message transfer of data length code 0 to 8 data bytes with no Transmitter Delay compensation”
  - Removed on Section 1.5 “8 data bytes, no Transmitter Delay compensation “
  - Modified on Section 1.5.1, table 1-3, point 4 on Transmitter Delay compensation from “not implemented” to “implemented”
  - Removed on Section 1.6.8.1 on CAN Restricted operation mode.
  - Modified on MOFCR.DLC bit to support for more than 8 data bytes, have included 12, 16, 20, 24, 32, 48, 64 data bytes option.
  - Added Section 1.5.2 Transmitter Delay Compensation and FNBTRx.TDC, FNBTRx.TDCO, FNBSTATx.TDCV.
- This bulleted point is not applicable to TC27x.

External Revision History (from MultiCAN+ v3.2 to MultiCAN+ v3.3)

- Modified MultiCAN+ clocking from SCU for below
  - Various diagrams and text that refers "$f_{MULTICAN}$" to "f_{ASYN_CAN}" and "f_{SYN_CAN}". Also added Section 1.13.3 MultiCAN+ Clock Interconnects with SCU
  - Section 1.6.2 Table 1-5 footnote changed from "To guarantee the minimum operating frequencies when low power mode is enabled, fCLC is switched in fMULTICAN to a operating clock source, when SCU register CCUCON." to "To guarantee the minimum operating frequencies when low power mode (pretended networking mode) is enabled (i.e when frequency of fSPB is reduced), fSYN_CAN and fCLC are switched from fSPB to fCAN when SCU register CCUCON0.LPDIV>0."
- Renamed Fast Node x Bit Timing Status Register to Node x Transmitter Delay Compensation Register and moved FNBTRx.TDC, FNBTRx.TDCO to NTDCRx.TDC, NTDCRx.TDCO.

External Revision History (from MultiCAN+ v3.3 to MultiCAN+ v3.4)

- As per mail on "Widening of NBTR register field while maintaining compatibility and more" modified for below:
- This bulleted point is not applicable to TC27x.
  - Rearranged FNBTRx register bits to use same layout as NBTRx for lowest 16bits and empty for upper 32bits
  - Changed address of FNBTRx to 0x0238 and NTDCRx to 0x23C
  - Swapped on NTDCRx register bits on TDC =Bit 15 and TDCO= Bits 11-8
  - Added NBTEVRx, Node Bit Timing Extended View Register. NBTEVRx view applies when NCRx.FDEN=1 and NBTRx view applies when NCRx.FDEN=0.
  - NBTEVRx. TSEG1 is 6 bits, valid values from 2 to 63
  - NBTEVRx. TSEG2 is 4 bits, valid values are 1 to 15
  - NBTEVRx.SJW is 4 bits, valid values are 1 to 15

External Revision History (from MultiCAN+ v3.4 to MultiCAN+ v3.5)

- As per review feedback on V3.3 CANFD specs review modified for below: This bulleted point is not applicable to TC27x.
  - Removed on Section1.1.3.1 text on point 2e "In current CAN FD implementation, up to 8 data bytes payload are supported only"
  - Added on Table1-4 Minimum Operating Frequencies, footnote "To guarantee the minimum operating frequencies when low power mode."
  - Removed on Section 1.4.12.4 "vice versa"
  - Update of Table 1-24 MultiCAN+ Clock Interconnects
- Additional modifications for below: This bulleted point is not applicable to TC27x.
  - Added on NCRx.FDEN footnote on "Message transmission in Long & Fast CAN FD Frames. Message Reception according to CAN FD Protocol Specification, (i.e

Able to Receive Classical CAN Format Frames ISO11898-1 and Long + Fast CAN FD Frames)"
  - Added on Table 1-8 Coding of DLC in CAN FD and MOFCRx.DLC
  - Added MOFCR.FDF, MOFCR.BRS bit to indicate message format reception when MOFCRx.MOFM =1 (CAN FD enabled) (i.e received frame in classical CAN or CAN FD format)
  - Added on NSRx.FLEC, fast last error code to indicate the error code during the fast bit rate.
  - Added note on Table 1-13 Encoding of LEC bit field, "When a frame in CAN FD format reached data phase with BRS flag set, the next CAN event (error/valid frame) will be shown in FLEC instead of LEC. An error in a fixed stuff bit of CAN FD CRC will be shown as Form and not Stuff Error."
- This bulleted point is not applicable to TC27x.

External Revision History (from MultiCAN+ v3.5 to MultiCAN+ v3.6)

- This bulleted point is not applicable to TC27x.
- This bulleted point is not applicable to TC27x.

External Revision History (from MultiCAN+ v3.6 to MultiCAN+ v3.7)

- As per mail on "Message Mode proposal for CAN FD 64 data bytes" modified for below. This bulleted point is not applicable to TC27x.
  - Added **Section 22.4.12.10** on CAN FD 64 byte Message Mode
  - Added **CAN_EMOzDATA0 (z = 0-255)** Extended Message Object Data Register and on Table 1-11
  - Modified on MOFCR.MMC bit 101 to CAN FD 64 bytes message mode.
- As per TC24x_tag_coverage.xls added tags AURIX_GEN1:5246, 5396, 5373, 5374:
- As per CAN FD weekly meeting on 21Nov12, modified for MOFCR.BRS and MOFCR.FDF bit from rh to rwh.

External Revision History (from MultiCAN+ v3.7 to MultiCAN+ v3.8)

- Added note on **Section 22.4.6.5** "The transmit request bits (i.e NTATTx.TXMO / NTBTTx.TXMO / NTCTTx.TXMO) in the timer control register of a node is able to trigger transmit request (MOSTATn.TXRQ) of message object in a list belonging to any other CAN nodes".
- As per MultiCAN+ V3.7 feedback review
  - Modified on CAN_NBTEVRx text to "NBTEVRx contains all parameters to setup CAN bit timing for Nominal Bit Rate".
  - Modified on CAN_FNBTRx text to "FNBTRx contains all parameters to setup CAN bit timing for Data Bit Rate".
  - Modified on CAN_FNBTRx register bits name to FTSEG1, FTSEG2, FSJW and FBRP.

– Modified on CAN_NBTEVRx.TSEG2 to 5bits, bit20 to bit16.

External Revision History (from MultiCAN+ v3.8 to MultiCAN+ v3.9)

- As per MultiCAN+ V3.7 feedback review.
  – As per mail “CCE protection of register tdcr” added on CAN_NTDCR register “NTDCRx register can be written only if bit NCRx.CCE is set.”. Removed on NTDCR.TDC text on “this bit is CCE and INIT protected”.
  – Added on soft configuration section a footnote on CAN FD “When CAN FD is disabled by PRDCFG, access to CAN FD registers do not generate a bus error. To verify CAN FD is disabled, try to set NCRx.FDEN bit and read back the NCRx register values, the NCRx.FDEN bits remain cleared.”
  – Modified on NTDCR.TDCV text from fcan/fclc to time quanta “Valid values for TDCV are 0 to 31 times of time quanta t_Q”
  – Modified on NTDCR.TDCO text from facn/fclc to time quanta “Valid values for TDCO are 0 to 15 times of time quanta t_Q.”
  – Added text under Section CAN FD 64 bytes Message Mode “When MSGVAL of the base object is cleared, an ongoing data transfer to TOP and BOT objects are aborted, thereby freeing objects BOT and TOP. Clearing MSGVAL bits of BOT, TOP objects and the extra message objects do not stop an ongoing data transfer and are not considered at all.”
  – Added text on NCRx.FDEN, MOFCR.MOFM, MOFCR.BRS and MOFCR.FDF bits “Please see Table 1-19 CAN FD Transmit and Receive Behavior.

External Revision History (from MultiCAN+ v3.9 to MultiCAN+ v3.10)

- As per MultiCAN+ V3.7 feedback review
  – Updated Table 1-19 CAN FD Transmit and Receive Behavior, corrected for transmit behavior “Classical CAN Frames” FDEN from 0_B to X_B.

External Revision History (from MultiCAN+ v3.10 to MultiCAN+ v3.11)

- As per MultiCAN+ V3.7 feedback review
  – Updated Table 1-30 MultiCAN+ I/O control Selection and Setup and Table 1-36 Receive Input Selection
  – Added Table 1-9 “Minimum Operating Frequencies for CAN FD [MHz]”
- This bulleted point is not applicable to TC27x.
- Updated on Section 1.6.2 Clock Control on example of equation 1.1 to “As an example, when f_{CLC} = 10MHz, f_{CAN} = 20MHz, No of active CAN nodes =2, Baudratemax=[(8x50ns) + (8x100ns) + (4x2x100ns)] = 2000ns = 500 KBaud
- This bulleted point is not applicable to TC27x.

External Revision History (from MultiCAN+ v3.11 to MultiCAN+ v3.12)

- This bulleted point is not applicable to TC27x.

- Modified on Section 1.1.3.2 Remote Frames, paragraph from “Remote frames is only defined in CAN format, Remote frames and RTR bit do not exist for CAN FD format. ~~In a CAN FD node, Remote frames request are always replied back in CAN format and will never receive replies in CAN FD format.~~” to “Remote frames is only defined in CAN format, Remote frames and RTR bit do not exist for CAN FD format. Remote frame requests do not change the format of the preconfigured reply data frames (i.e FDF and BRS bits of preconfigured data frames are not changed on remote frame requests, reply data frames may be in CAN base/extended or CAN FD base/extended).”
- Modified on Table 1-20 CAN FD Transmit and Receive Behavior on receive behavior to FDEN=0, MOFM=X, BRS=0/1, FDF=0/1- Classical CAN Frames, FDEN=1, MOFM=X, BRS=0/1, FDF=0/1- Classical CAN Frames, Long Frames, Long + Fast Frames.
- Added on Table 1-20 CAN FD Transmit and Receive Behavior, footnote on receive behavior “Please note that Remote Request Frames do not change BRS and FDF bits.”

External Revision History (from MultiCAN+ v3.12 to MultiCAN+ v3.13)

- Modified for below
  - Added on MCR.CLKSEL bit option 0100_B E-Ray clock “(Feray)”.
  - Added Fig1-52 MultiCAN+ Interconnects with SCU on section 1.13.3 MultiCAN+ Clock Interconnects With SCU.
- This bulleted point is not applicable to TC27x.

External Revision History (from MultiCAN+ v3.13 to MultiCAN+ v3.14)

- Removed NSRx.RESI bit would generate interrupt on NSRx.ALERT and NCRx.ALIE. Also modified NSRx.RESI bit to ‘rh’ changed description to “This bit is an error flag that is set when the ESI flag in a received CAN FD frame is set.” and “0_b-Last received CAN FD message did not have its ESI flag set. 1_b-Last received CAN FD message had its ESI flag set.”
- Addition to note on Table 1-13 Encoding of LEC bit field, “Correspondingly CAN event (error/valid frame) will be shown back at LEC after the first bit of the CRC delimiter when CAN FD switches from Data bit rate to Nominal bit rate”.

External Revision History (from MultiCAN+ v3.14 to MultiCAN+ v3.15)

- Removal of MOFCR.MOFM bit. Update of Table 1-20 CAN FD Transmit and Receive Behaviour.
- Update of Table 1-5 Minimum Operating Frequencies for CAN FD [MHz].
  - Addition of Acceleration Factor rows for values from 1 to 8
  - Modified on Footnote 3) with addition of Base Nominal Bit Rate is 1Mbit/s and addition “when several nodes operate at different acceleration factor A.F, only the

node operating the highest acceleration factor need to be considered for the required minimum operating frequency requirement."

External Revision History (from MultiCAN+ v3.15 to MultiCAN+ v3.16)

- Section 1.6.12.4 Message Object Format updated with removal of MOFCR.MOFM and replaced with description of NCRx.FDEN and MOFCRn.FDF, MOFCRn.BRS bits.
- CAN FD feature added for TC27x C-step, TC26x B-step, TC29x B-step.
- Updated on features list, with bullet item "Supports an acceleration factor of 8 when operating in CAN FD mode per Bosch CAN FD V1.0 April17th 2012"

External Revision History (from MultiCAN+ v3.16 to MultiCAN+ v3.17)

- This bulleted point is not applicable to TC27x.
- Updated Table 1-5 Minimum Operating Frequencies for CAN FD [MHz], with corrected values from multican_performance_canfd_16apr13.xls
  – Modified Acceleration Factor rows for values from 1 to 5 and at various places that mentions AF to 1 to 5.

External Revision History (from MultiCAN+ v3.17 to MultiCAN+ v3.18)

- Added additional text on Section 1.5.2 Transmitter Delay Compensation to describe more details on secondary sample point implementation.
- Added on footnote of Table 1-5 Minimum Operating Frequencies for CAN FD "When message objects are configured as transmit or receive FIFO structures i.e MOFCRn.MMC = 0001/0010, only the base object of 1 is counted towards the minimum frequency requirement, all other slave objects on the FIFO do not count towards the minimum frequency requirement. See Section 1.6.12.5.
- Relabel tags CAN_NUMBER_NODES to CAN1_NUMBER_NODES on Table1-2.

External Revision History (from MultiCAN+ v3.18 to MultiCAN+ v3.19)

- Text enhancements below:
  – Under Section 1.1.3.1, abbreviation added for FDF, BRS, ESI bit
  – Under Section 1.1.3.3, amended from "shall switch back" to "will switch back"
  – Under Section 1.3, amended from "on every nodes" to "on all nodes"
  – Under Section 1.3.1, amended from "measured Transmitter Delay" to measured loop delay"
  – Under CAN_MOFCR on CAN FD Transmit and Receive Behavior, added text "Message transmission and reception behavior of CAN data frames is summarized at Table 1-20 below."
  – Under CAN_MOFGPR.TOP/BOT added text MOFGPR.BOT points to data byte 8-35 and MOFGPR.TOP points to 36-63.

External Revision History (from MultiCAN+ v3.19 to MultiCAN+ v3.20)

- All reference to EDL is renamed to FDF, register bit MOFCR.EDL is renamed to MOFCR.FDF, functionality remains the same.

External Revision History (from MultiCAN+ v3.20 to MultiCAN+ v3.21)

- This bulleted point is not applicable to TC27x.
- Corrected typo error at Table 1-27 MultiCAN+ I/O control selection & setup for P01.4 to P01_IOCR4.PC4 and P01.3 to P01_IOCR0.PC3.

External Revision History (from MultiCAN+ v3.21 to MultiCAN+ v3.22)

- Changed CAN FD descriptions to customer relevant information.

External Revision History (from MultiCAN+ v3.22 to MultiCAN+ v3.23)

- Corrected spelling bugs

External Revision History (from MultiCAN+ v3.23 to MultiCAN+ v3.24)

- Changes for XMC device frequencies, not applying for AURIX devices

External Revision History (from MultiCAN+ v3.24 to MultiCAN+ v3.25)

- Changes for XMC port naming. Correcting XMC specification by removing AURIX relevant issues.

External Revision History (from MultiCAN+ v3.25 to MultiCAN+ v3.26)

- Corrected memory space for XCM1000.
- Fixed pad naming for all devices.
- CLC and FDR are existing on all modules, which are existent in one microcontroller.

External Revision History (from MultiCAN+ v3.26 to MultiCAN+ v3.27)

- Corrected interrupt mapping for XCM1000.

External Revision History (from MultiCAN+ v3.27 to MultiCAN+ v3.28)

- CRC issue of CAN FD documented.

External Revision History (from MultiCAN+ v3.28 to MultiCAN+ v3.29)

- MCR register, formula for clock switching mathematically not correct. As no clock cycles were calculated. Exchanged to clock cycles..

23 Single Edge Nibble Transmission (SENT)

This chapter describes the SENT Interface of the TC27x. It contains the following sections:

- Functional description of the SENT kernel (see **"Overview" on Page 23-2**)
- SENT kernel register descriptions (see **"SENT Kernel Registers" on Page 23-22**)
- TC27x implementation-specific details and registers of the SENT module (port connections and control, interrupt control, address decoding, and clock control, see **"SENT Module Implementation" on Page 23-70**

23.1 SENT Kernel Description

Figure 23-1 shows a global view of the SENT interface.

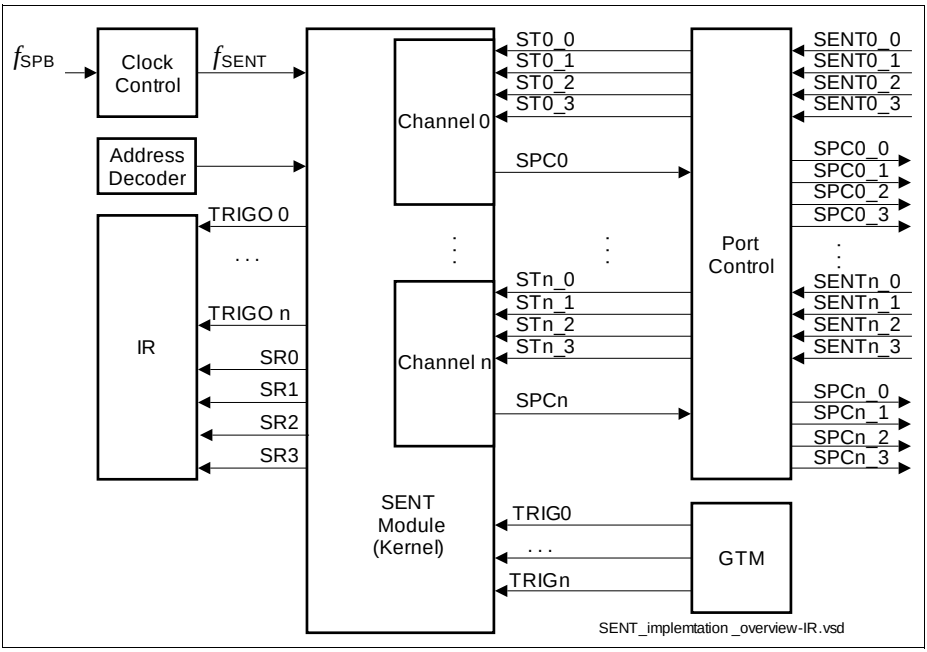

Figure 23-1 General Block Diagram of the SENT Interface

The SENT module communicates with the external world via one I/O line for each channel. The STx lines are the receive data input signals. They can overlay ADC inputs. If the optional SPC mode is used, they can be used on a port configured with an open drain transistor. This way the optional SPC data can be transmitted and the line is used bidirectionally. In case of an external transceiver, receive and transmit path can be routed to two different ports.

23.1.1 Overview

The SENT interface provides a serial communication link typically used to connect sensors or other peripheral devices.

Clock control, address decoding, and service request control are managed by the SENT module kernel.

The SENT IP-module performs communication according to the SENT specification J2716 JAN2010.
While staying compliant to this standard, it is able to cover as well the Short PWM Code (SPC) protocol extensions. This enhances the standardized SENT protocol defined by J2716 JAN2010. SPC enables the use of enhanced protocol functionality like “synchronous”, “range selection” and “ID selection” protocol mode.

Receive data on a SENT channel can be set up according to the underlying application. In particular the number of nibbles forming one value is configurable.

The message storage consists of two 32-bit registers for each channel, representing a flexible double buffer system.

In SPC mode, maintaining the sample and transmission schedule as well as providing message status information is support.

The register set of the SENT module can be accessed directly by the CPU for configuration, data read out and status query.

The SENT IP-module supports the following features:

Features

- Conformance with SENT protocol specification J2716 JAN2010
- Data rates of up to 65,8 kbit/s at 3 µs tick length and 6 data nibbles on each channel
- Support of standard tick times (3 µs through 90 µs) and
- Message tick time programmable between 0.2 µs and 90 µs
- 10 SENT channels working independently in parallel
- Status nibble optionally included in the checksum (default not included)
- Sticky interrupt flags, error interrupt optional (default disabled)
- Configurable frame length (default is 24 bit), max data size is 32 bits
- Serial data processing optional (default: disabled)
- Option for bigger frame lengths (must still be fix for each application)
- transparent mode (nibble CRCs are written to the receive control register for SW processing)
- Support of SPC
- Support of trailing Pause Nibble of any length (even longer than 70 ticks)
- Indication of system status: STOP, INITIALIZED, RUNNING, SYNCHRONIZED
- The receiver module will monitor the message for the following error conditions:
  - Calibration pulse length deviates more than +/-25% from the nominal 56 ticks
  - Too many or too few nibbles between calibration pulses.
  - Checksum error.
  - Successive calibration pulse differ by more than 1.5625%
  - Any nibble data values measured as < 0 or >15.
- When any of those errors is detected, the receiver module shall declare that a message error has occurred and ignore the entire message.
- Any of those errors shall cause the receiver to begin searching for a valid calibration pulse to re synchronize.
- Option to enable/disable the check of the next calibration pulse before validation of received data
- Digital Glitch filter suppressing noise
- Buffer overrun detection
- Optional output inversion for use of external open drain transistor
- Optional input inversion for use of external open transistor for level shifting
- Interrupt on status nibble violation
- Programmable Nibble sorting to support LSN or HSN first and relief CPU
- Time stamp generation
- Watch Dog on incoming frames

23.1.2 General Operation

The Single Edge Nibble Transmission encoding scheme (SENT) is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/D converters and PWM and as a simpler low cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

Figure 23-3 shows a typical TC27x application in which a SENT interface reads a sensor device.

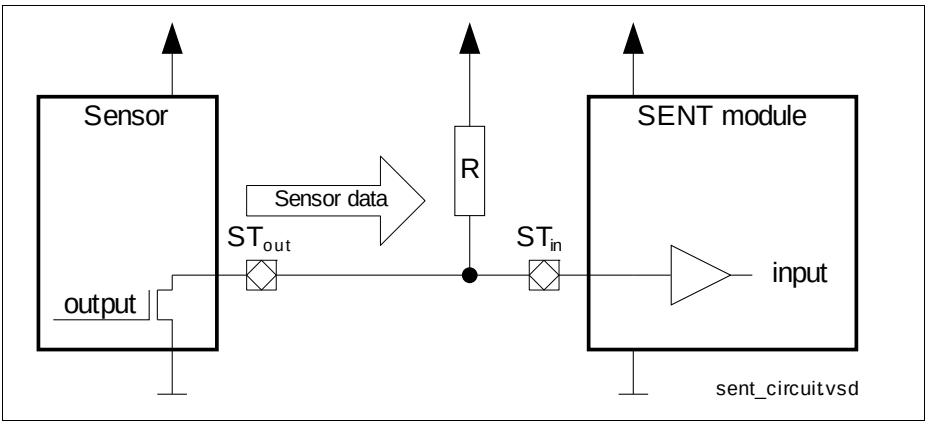

Figure 23-2 SENT to External Device Connection

SENT communication is unidirectional from sensor to controller without any synchronization. The sensor signal is transmitted as a series of PWM blocks measured as falling to falling edge times.

The Short PWM Code (SPC) extension overcomes the drawback of unidirectionality as said above while keeping conformance to the standard.

Figure 23-3 shows a typical TC27x application in which an SPC enabled SENT ECU reads an SPC enabled SENT sensor device.

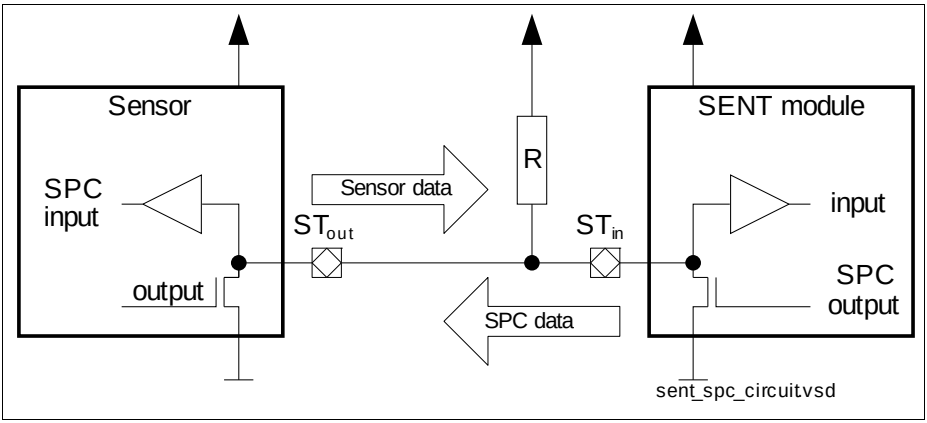

Figure 23-3 SENT SPC to External Device Connection

Some applications are:

- Read out of the external throttle position sensor (e.g. SENT enabled linear hall sensor)
- Receiving pedal position
- Synchronize sampling and read out of up to four sensors on one single line (SPC)
- Selection of 1 out of 4 sensors connected to a single SENT channel.
- Serial connections of the TC27x to other peripheral devices

23.1.2.1 Definitions

SENT: Single Edge Nibble Transmission

Nibble: Four Bit value between 0 and 15 = half a Byte = one character in hex (0 to F)

SPC: Short PWM Code

PWM: Pulse Width Modulation

ASIC: Application Specific Integrated Circuit

CAN: Controller Area Network

LIN: Local Interconnect Network

ISO: International Organization for Standardization

ECU: Electronic Control Unit

FSM: Finite State Machine

23.1.3 Standard SENT Operation

Standard SENT Mode supports communication fully compliant to J2716 JAN2010, in which only the external device is sending and the ECU is receiving. In this unidirectional communication, both transmitter and receiver use the same data frame format and have the same baud rate. These settings are defined at system integration time and do not change for a given application. Data is received on pin ST. **Figure 23-4** shows the block diagram of the SENT Module when operating in Standard SENT Mode.

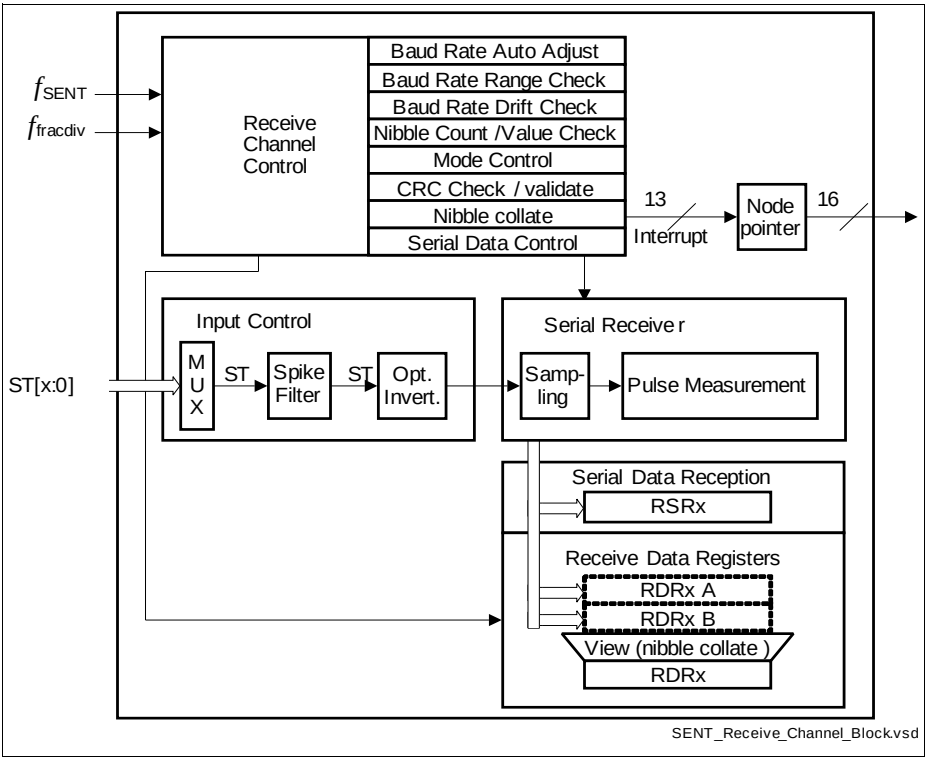

Figure 23-4 Standard SENT Mode Operation

23.1.3.1 Frame Formats and Definitions

This section describes the frame formats and definitions of the SENT protocol.

Basic Definitions

Figure 23-5 shows the layout and definitions of a standard SENT frame. Note that the SENT standard does not specify whether the most significant nibble or the least significant nibble is sent out first.

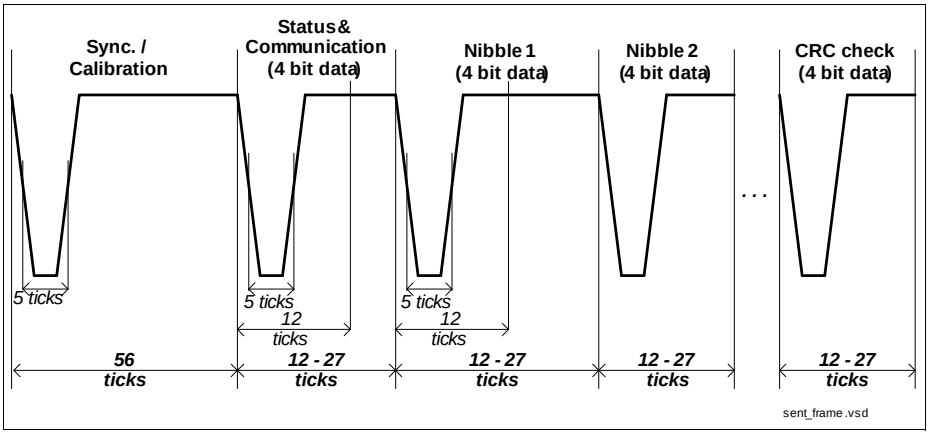

Figure 23-5 Standard Encoding Frame

Serial Data Encoding in Status and Communication Nibble

The Status and Communication nibble is used by sensors that transmit extra serial data such as part numbers or diagnostic information. Data bits from this nibble are constructed across multiple SENT messages to form a Short Serial Message or an Enhanced Serial Message. These messages are alternately referred to as “Slow Channel” data in the J2716 specification.

Table 23-1 Short Serial Data Encoding

Bit Number	Bit Function
0	Reserved for specific application
1	Reserved for specific application
2	Serial Data message bits
3	Message start = 1, otherwise = 0

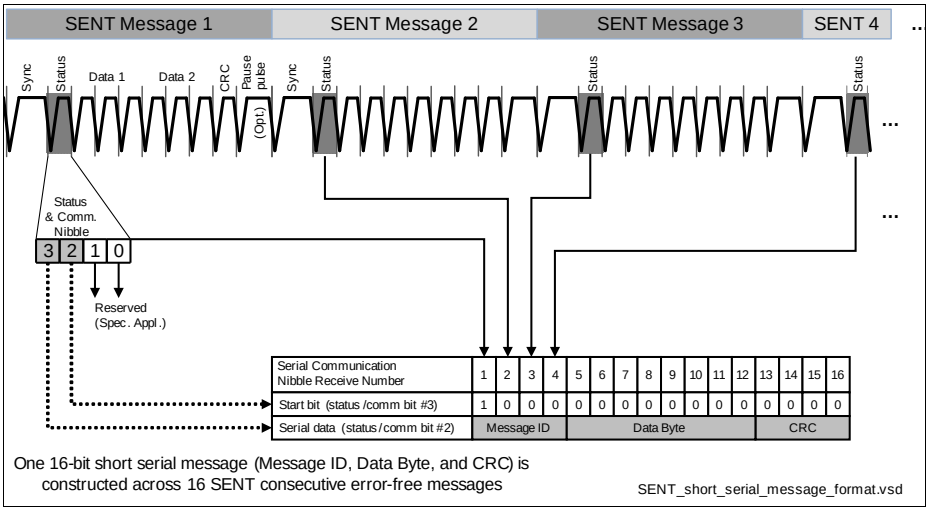

Figure 23-6 Short Serial Message, Serial Data Encoding over 16 messages

Short Serial Message Format

The SENT kernel supports the Short Serial Message Format defined in the J2716 specification. The Short Serial Message Format provides 16 bits of data, constructed across 16 SENT messages. Each of the 16 messages contains one bit of Short Serial Message data in Status and Communication nibble bit 2.

Serial data is communicated in a 16-bit sequence as shown in **Table 23-2**. The start of a Short Serial Message is indicated by a 1 in bit 3 of the Status and Communication nibble. That SENT message and the next 15 must be successfully received (no errors) for the Short Serial Message data to be received. The CRC generation is identical to the CRC generation on the data nibbles. Short Serial Message data is provided in the SDSx register.

Table 23-2 Short Serial Message Format

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Startbit (bit # 3)	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Serial Data (bit # 2)	Message ID				Data Byte								CRC			

CRC Calculation

SENT signal data and Short Serial Message data is secured with a 4 bit CRC. The standard CRC calculation method is defined in the J2716 JAN2010 specification.

RCR.CRZ defines, if a zero nibble is added for calculation or not.

The alternative checksum nibble is a 4-bit CRC of the data nibbles (including the status nibble if RCR.SNI is set, as used in sensor TLE4998). The CRC is calculated using a polynomial x^4 +x^3 + x^2 + 1 with a seed value of 0101.

In order to facilitate CRC implementations and to avoid ambiguities, an example implementation of the alternative 4-bit CRC is given below. This is used e.g. in the sensor TLE4998 for the signal data. See **Figure 23-7** for details.

```
// Fast way for any µC with low memory and compute capabilities
// contains input data (status nibble, 6 data nibble, CRC)
char Data[8] = {…};
// required variables and LUT
char CheckSum, i;
char CrcLookup[16] = {0, 13, 7, 10, 14, 3, 9, 4, 1, 12, 6, 11, 15,
2, 8, 5};
CheckSum= 5; // initialize checksum with seed “0101”
for (i=0; i<7; i++) {
     CheckSum = CheckSum ^ Data[i];
     CheckSum = CrcLookup[CheckSum];
};
// finally check if Data[7] is equal to CheckSum
```

Note: For the “Enhanced Serial Message Frame Format”, an own 6-bit CRC calculation method is defined by the standard.

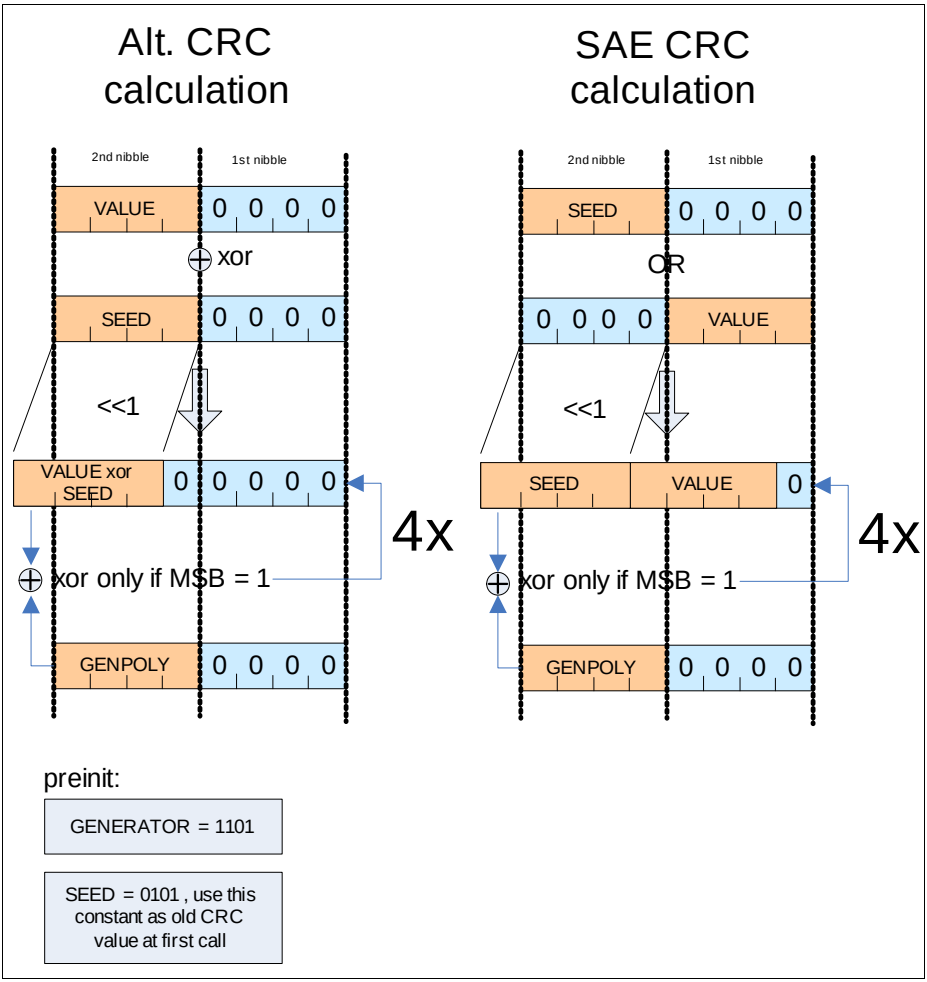

Figure 23-7 Alternate vs. SAE CRC Calculation

Enhanced Serial Message Format

The SENT kernel supports the Enhanced Serial Message Format defined in the J2716 specification. The Enhanced Serial Message Format provides 21 bits of message data and a 6-bit CRC, constructed across 18 SENT messages.The serial data is transmitted bit wise per frame in bits [3:2] of the Status and Communication nibbles of 18 consecutive messages from the transmitter.

Table 23-3 Enhanced Serial Data Encoding

Bit Number	Bit Function
0	Reserved for specific application
1	Reserved for specific application
2	Serial Data message bits
3	Message start = **1** 1 1 1 1 1 0

Enhanced Serial Message Frame

Serial data is communicated in an 18 frame sequence as shown in **Table 23-4**. The start of an Enhanced Serial Message is indicated by the unique pattern “1111110” in bit #3 of the status and communication nibble, constructed across 7 SENT messages. In message 1 - 6 they are set to “1”. In message 7, 13 and 18 they are set to “0”. 18 consecutive SENT messages must be successfully received (no errors) for the Enhanced Serial Message data to be received. The 6-bit Enhanced Serial Message CRC is different from the 4-bit CRC on SENT (fast channel) messages. (See SENT Standard)

An Enhanced Serial Message contains 21 bits of message data and a 6-bit frame-check sequence. A configuration bit (serial data bit #3 of the 8th SENT message's Serial Communication Nibble) determines how the SENT module interprets the serial data.

- Configuration bit = 0: 12-bit data and 8-bit message ID, see **Table 23-5**
- Configuration bit = 1: 16-bit data and 4-bit message ID, see **Table 23-6**

Enhanced Serial Message data is provided in the SDSx register.

Table 23-4 Enhanced Serial Data Frame

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial Data (bit # 3)	1	1	1	1	1	1	0	C	8-bit ID (7-4)				0	8-bit ID (3-0) or 4-bit data				0
Serial Data (bit # 2)	6-bit CRC						12-bit data field											

Note:

13. *Message 8 Status Nibble bit # 3 is Configuration Bit C that defines the Enhanced Serial Data format:*
    *0: 12-bit data, 8-bit ID, see **Table 23-5***
    *1: 16-bit data, 4-bit ID, see **Table 23-6***
14. *Messages 17-14 Status Nibble bit # 3 contain either the lower 4 bits (Bit 3-0) of 8bit ID or 4 additional data bits.*

Table 23-5 shows in detail the frame structure for Enhanced Serial Data Frames with Configuration Bit = 0.

Table 23-5 Configuration Bit = 0

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial Data (bit # 3)	1	1	1	1	1	1	0	0	8-bit ID (7-4)				0	8-bit ID (3-0)				0
Serial Data (bit # 2)	6-bit CRC						12-bit data field											

Table 23-6 shows in detail the frame structure for Enhanced Serial Data Frames with Configuration Bit = 1.

Table 23-6 Configuration Bit = 1

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial Data (bit # 3)	1	1	1	1	1	1	0	1	4-bit ID (3-0)				0	4-bit data (15-12)				0
Serial Data (bit # 2)	6-bit CRC						12-bit data field											

23.1.4 SPC Operation

The module supports a SPC (Short PWM Code) protocol, which enhances the standardized SENT protocol (Single Edge Nibble Transmission) defined by J2716 JAN2010. SPC enables the use of enhanced protocol functionality due to the ability to select between “synchronous”, “range selection” and “ID selection” protocol mode or even “bidirectional transmit mode”.

23.1.4.1 Synchronous Transmission

In the “synchronous” mode, the sensor (slave) starts to transfer a complete data frame only after a low pulse is forced by the master on the OUT pin. This means that the data line is bidirectional - an open drain output of the micro controller (master) sends the trigger pulse. The sensor then initiates a sync pulse and starts to calculate the new output data value. After the synchronization period, the data follows in form of a standard SENT frame, starting with the status, data and CRC nibbles. At the end, an end pulse allows the CRC nibble decoding and indicates that the data line is idle again. The timing diagram in **Figure 23-8** visualizes a synchronous transmission

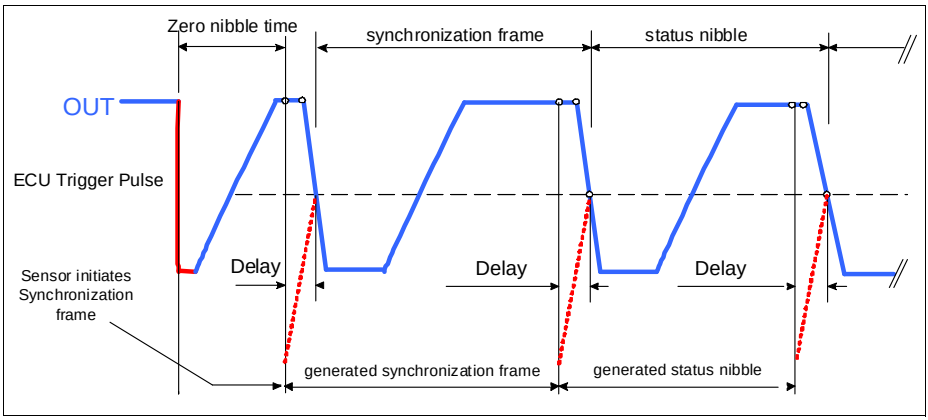

Figure 23-8 Synchronous Transmission (SPC)

23.1.4.2 Range Selection

The low time duration of the master can be used to select the range of the sensor in SPC dynamic range selection mode.

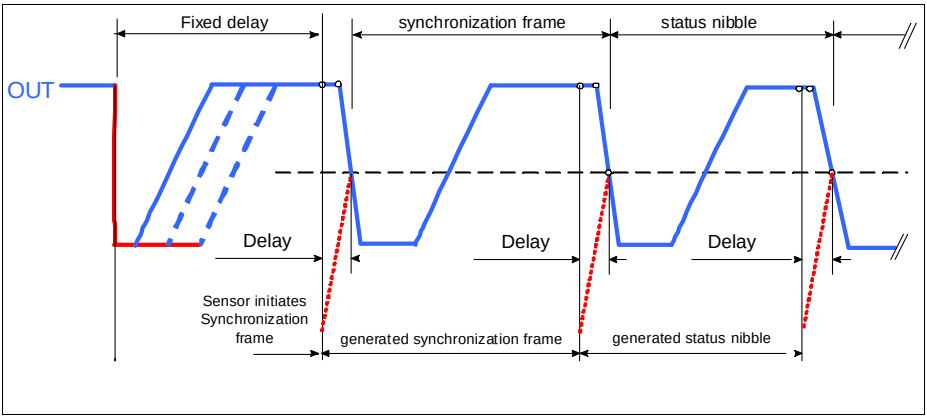

Figure 23-9 Range (SPC)

23.1.4.3 ID Selection

This functionality is similar to the previous mode, but instead of switching the range of one sensor, one of up to four sensors are selectable on a bus (bus mode, 1 master with up to 4 slaves). This allows parallel connection of up to 4 sensors using only three lines (VDD, GND, OUT), as illustrated in **Figure 23-10**.

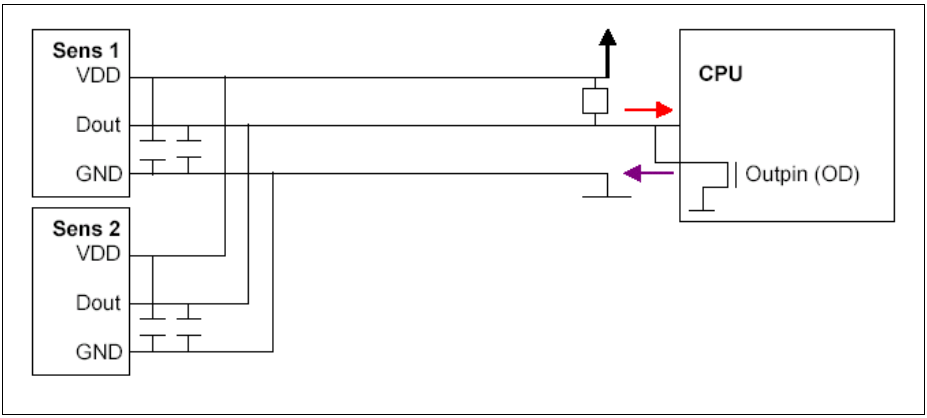

Figure 23-10 ID Selection (SPC)

23.1.4.4 Bidirectional Transmit Mode

After addressing the sensor the ECU interrupts the sensor sync pulse by pulling down the line. The ECU starts to transmit own nibbles on the time base of the selected sensor. The ECU has to adapt the sensors timing from an earlier received cycle.

The sensor detects the falling edge that infringes the protocol and switches to receive mode as illustrated in **Figure 23-11**.

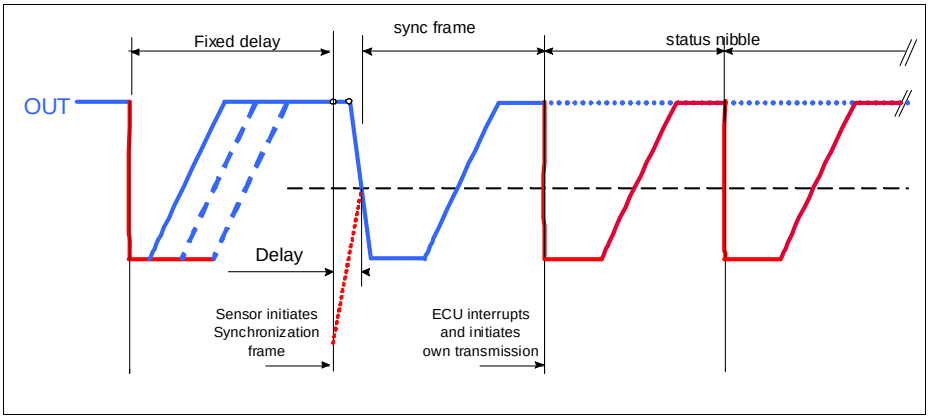

Figure 23-11 Bidirectional Transmit Mode (SPC)

23.1.4.5 SPC Timing

An SPC transmission is initiated by a Master pulse on the OUT pin. To detect a low level on the OUT pin, the voltage must be below a threshold Vthf. The sensor detects that the OUT line has been released as soon as Vthr is crossed. **Figure 23-12** shows the timing definitions for the master pulse. The master low time tmlow as well as the total trigger time tmtr are individual for the different SPC modes and are given in the sensors specifications.It is recommended to chose the typical master low time exactly between the minimum and the maximum possible time given by the connected sensor: tmlow,typ = (tmlow,min + tmlow,max) / 2.

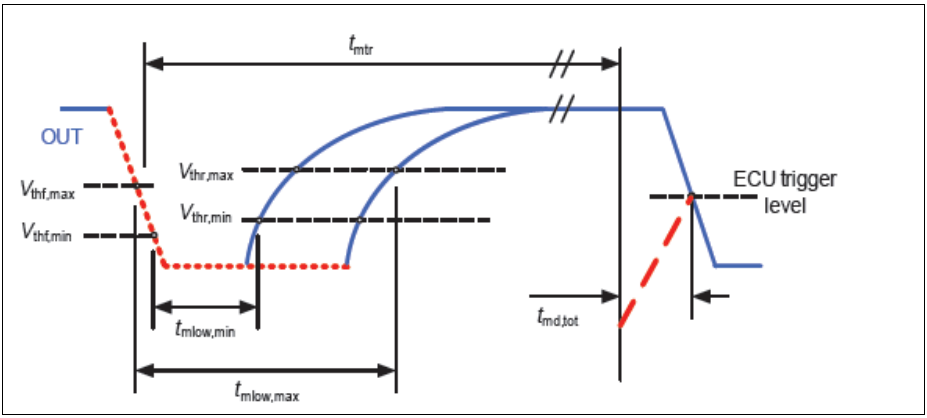

Figure 23-12 Timing (SPC)

23.1.4.6 Abort of Frames

Only a reset condition of the device, a hard suspend or choosing Mode 0 by clearing bit field SCRx.TRIG can abort a current SPC transmission immediately. During hard suspend, the port output drives its current value until suspend is terminated. If the receive channel becomes disabled, the soft suspend mode is requested, or the sleep mode is entered, the SENT module still does start a new frame transmission. If one of these three conditions becomes active during a running frame transmission, the frame transmission is completely finished before the requested abort state is entered. Note that in this case no frame finished interrupt is generated any more.

Note: Received frames are aborted immediately on a disable, suspend or sleep request.

23.1.5 Baud Rate Generation

The nominal baud rate of each channel is individually adjustable. This is required as it is depending from the connected sensor and its current deviation from nominal frequency.

The actual baud rate of the channel follows automatically the baud rate of the connected device and its current deviation from nominal frequency. The adaptation range is +- 25% as specified in J2716 JAN2010.

Chapter 23.1.5 shows in detail how the baud rate for each channel is adjusted. 1 / f_{tick_x} defines the resulting tick length.

In the first stage, a global fractional divider serves as pre divider. Its intermediate frequency $f_{fracdiv}$ can be set up so that it is handy as input frequency for the different SENT channels. The clock signal f_{pdiv} of a channel must always be at least 20 times the nominal tick frequency of the channel. This is to allow for the highly flexible and big tolerance of +-25% versus the sending device. In addition the module must be able to detect a deviation in the length of 2 consecutive Synchronization / Calibration pulses of 1.5625% (1/64) and adapt the own baud rate. The tick time is typically 3 µs but can vary by standard and take values up to 10 µs. Future application might require even shorter tick times for higher repetition rates. This is why this implementation allows for an even extended range of 0.2 … 90 µs. To achieve this each channel has its own fractional divider. This allows to downscale the frequency of f_{tick} precisely to the required tick frequency. For details on the principles of a fractional divider, please refer to the SCU chapter of TC27x section “Clock Control”.

The SENT module provides two clock signals to the channels (**Figure 23-13**):

- f_{SENT}
  This is the module clock that is used inside the SENT kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{SENT} is always identical to the system clock frequency f_{SYS}. The clock control register SENT_CLC makes it possible to enable/disable f_{SENT} under certain conditions.
- $f_{fracdiv}$
  This clock is the module clock that is used inside the SENT kernel for baud rate generation of the serial channels. The fractional divider register SENT_FDR controls the frequency of $f_{fracdiv}$. Usually not required and set to 1.

The channels generate two local clock signals:

- f_{pdiv_x}
  This clock is the channel clock that is used inside the SENT channel x for baud rate generation of the serial channel. The divider register SENT_CPDRx controls the frequency of f_{pdiv_x}.
- f_{tick_x}
  This clock is the channel clock that is used inside the SENT channel as the baud rate frequency. The fractional divider register SENT_CFDRx controls the frequency of

f_{tick_x}.The higher the value of DIV the higher the precision with which the Synchronization / Calibration pulse and the deviation in the length of 2 consecutive Synchronization / Calibration pulses (drift) can be measured.
DIV must be set in an interval of [560, 3276].

Each time a Synchronization / Calibration pulse starts DIVM is measured. DIVM is the result of measuring the calibration pulse duration with f_{pdiv_x}. At the end of the Synchronization / Calibration pulse this value is taken as new divider of the CFDR.

Each time a pulse starts, the internal accumulator of the CFDR is preset with DIVM / 2. This is required to center the data eye and to make the margin symmetrical.

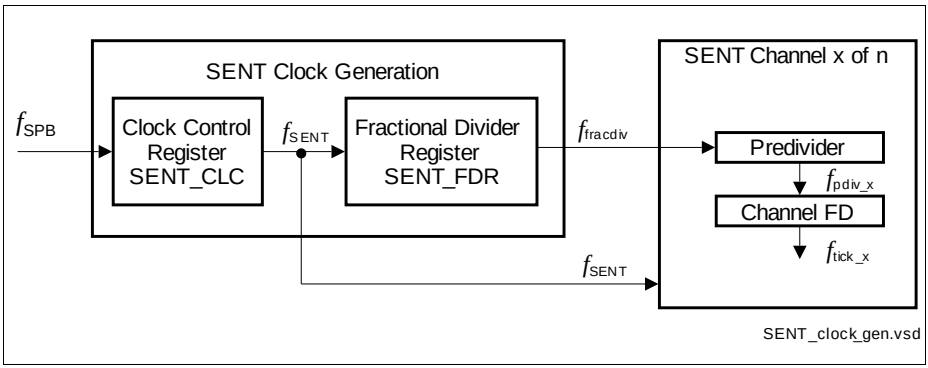

Figure 23-13 SENT Module Clock Generation

The following two formulas define the frequency of $f_{fracdiv}$:

$f_{fracdiv} = f_{SENT}$ / (1024 - SENT_FDR.STEP); FDR.DM = 01_B (23.1)

$f_{fracdiv} = f_{SENT}$ x SENT_FDR.STEP / 1024 with STEP = 0 … 1023; FDR.DM = 10_B (23.2)

The following formula defines the frequency of f_{pdiv_x}:

$f_{pdiv\_x} = f_{fracdiv}$ / (SENT_CPDRx.PDIV + 1) (23.3)

The following formula defines the nominal frequency of f_{tick_x}. For the actual frequency of f_{tick_x} DIV is replaced by DIVM after the current sensor frequency was validly measured.

$f_{tick\_x} = f_{pdiv\_x}$ x 56 / SENT_CFDRx.DIV with DIV = 560 … 3276 (23.4)

23.1.6 Error Detection Capabilities

Each SENT channel can detect and signal the following error conditions:

Protocol Level:

- Calibration pulse length deviates more than +/-25% from the nominal 56 ticks
- Too many or too few nibbles between calibration pulses
- Checksum error
- Successive calibration pulse differ by more than 1.5625%
- Any nibble data values measured as < 0 or >15
- Wrong Status and Communication nibbles
- Serial Communication CRC error

Transfer Management Level:

- Receive Data Buffer Overrun
- SPC Data Buffer Underrun

23.1.7 Digital Glitch Filter

Very slow slopes and signal noise can lead to fast transitions of the input signal. These unwanted transitions are suppressed by a digital glitch filter similar to a Filter and Prescaler Cell (FPC) in Delayed Debounce Filter Mode with up and down (no reset).

It is built for filtering very fast transitions only. The filter calculates the integral of the signal. If the integral reaches a programmable saturation point, the signal change is notified to the pulse measurement unit. Thus it helps to find the exact pulse length for said slow slopes in noisy environment.

The glitch filter is clocked with f_{pdiv}. If the state of the input sample differs from the current output signal value, the internal counter is incremented by one. When the state of the input sample matches the current output signal value and the timer is not in idle, the timer is decremented by one. When the timer matches the compare value stored in IOCRx.DEPTH, the level of the output signal line is inverted. The timer will be reset and set to idle state again.

The depth of the filter can be programmed to a value between 1 and 15. Typically a depth of 3 to 5 T_{pdiv} is sufficient. By default it is cleared. If IOCRx.DEPTH is cleared the filter is inactive. Nevertheless, the input signal is sampled with f_{pdiv}.

The internal signal after the filter will change value not before the new value was sampled DEPTH times. If during this period a spike occurs, it takes 2 x T_{pdiv} times longer for the internal signal to change value. The filters principal implies a delay of the signal by (DEPTH x T_{pdiv}).

Upon detection of glitch during rising or falling edge, IOCRx.REG or IOCRx.FEG is set. The rising / falling edge glitch flags must be reset by software.

Figure 23-14 shows the digital glitch filter:

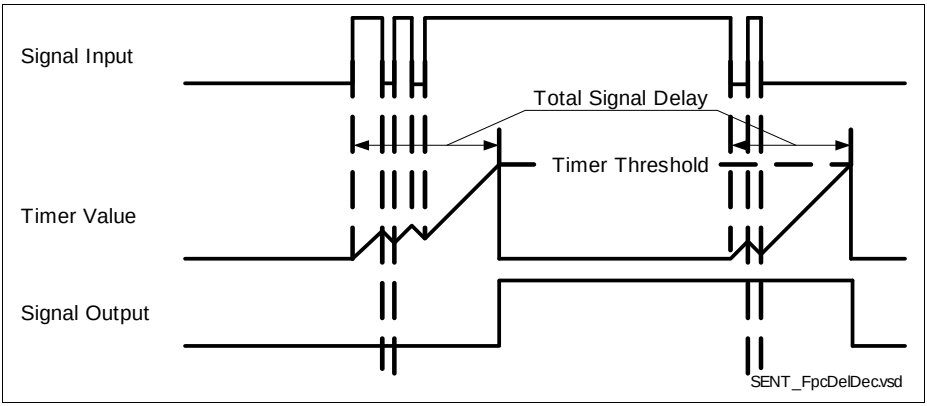

Figure 23-14 Digital Glitch Filter

23.1.8 Interrupts

4 Interrupt request lines are available for the SENT module.

RDI indicates a receive data interrupt. It is activated when a received frame is moved to a Receive Data Register RDR. RSI indicates a receive frame success interrupt, i.e. the CRC was successful. Both RDI and RSI will be issued together in normal use cases where the frame size is not bigger than 8 nibbles and CRC is correct. RBI indicates a receive buffer overrun interrupt. It is activated when a new frame is transferred to a Receive Data Register RDR while the old value was still not read by the host (“overwrite”), i.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set. TDI indicates a transmit interrupt. It is activated when data is moved from a SCR to a transmit shift register. TBI indicates a transfer buffer under run interrupt. It is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. In addition the protocol error interrupts are available: FRI, FDI, NNI, NVI, CRCI. If one of the protocol interrupts is activated, data is to be treated as invalid according to J2716 JAN2010. WSI, SDI SCRI treat the interrupts referring to the Status and Communication nibble. WDI is the Watch Dog Error Interrupt. It is issued if the time between two frames is too long.

For acceleration of the interrupt service routine, a Register INTOV is implemented that holds a flag for each channel. This flag is automatically set if there is an interrupt pending for the channel which is enabled. It is automatically reset, if no more enabled interrupt is pending for this channel.

The interrupt request or the corresponding interrupt set bit (in register INTSET) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in register INTSTATx. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLR.
If more than one interrupt source is connected to the same interrupt node pointer (in register INPx), the requests are combined to one common line.

23.1.9 Trigger Outputs

Any interrupt source can be used as trigger output TRIGO outside the module. Each TRIGO is connected to a IR input. See **Table 23-9 “Service Request Lines of SENT” on Page 23-71**.

23.2 SENT Kernel Registers

This section describes the kernel registers of the SENT module. All SENT kernel register names described in this section will be referenced in other parts of the TC27x User's Manual by the module name prefix "SENT_" for the SENT interface.

All registers in the SENT address spaces are reset with the application reset (definition see SCU section "Reset Operation").

SENT Kernel Register Overview

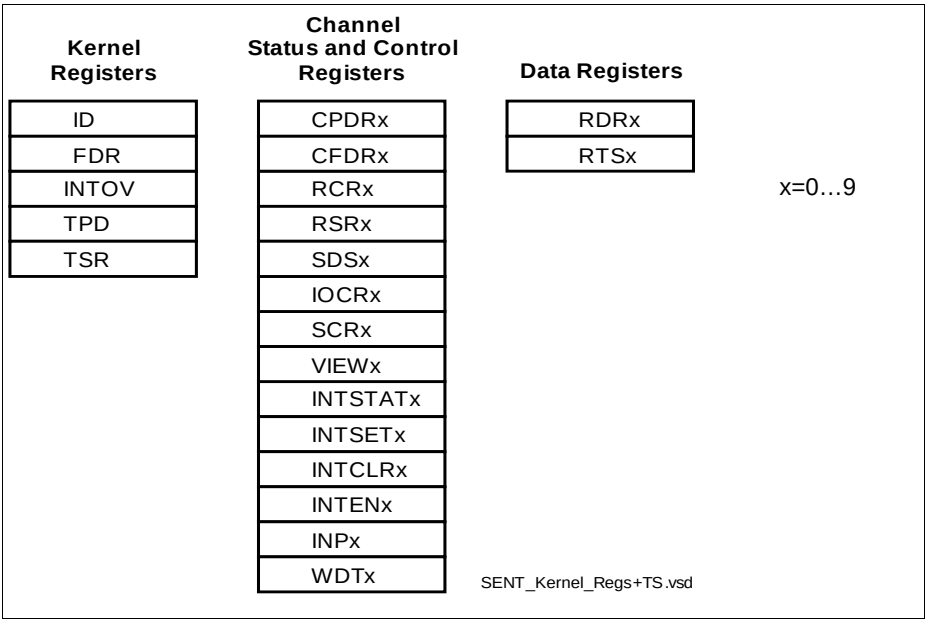

Figure 23-15 SENT Kernel Registers

The complete and detailed address map of the SENT module is described in **Table 23-7** on **Page 23-22**.

Note: x can take the values 0 … 9

Table 23-7 Registers Address Space - SENT Kernel Registers

U - User Mode

SV - Supervisor Mode

BE - Bus Error

nBE - no Bus Error

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

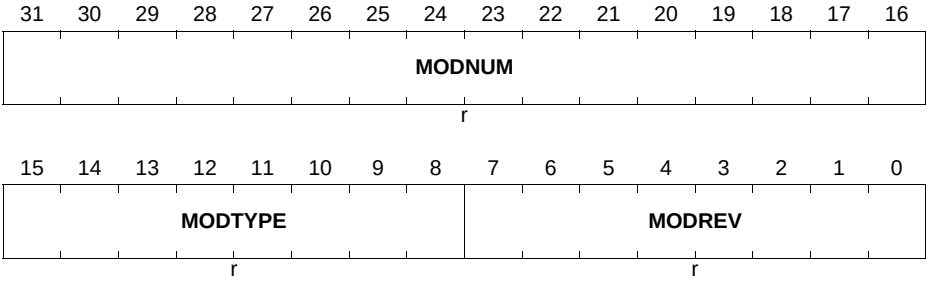
SE - Safety ENDINIT

23.2.1 Module Control

Module Identification Register

The SENT Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register (08$_H$) Reset Value: 0080 C0XX$_H$

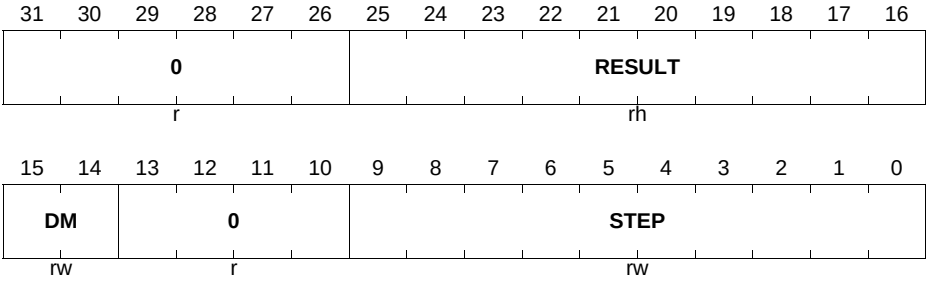


Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field defines the module as a 32-bit module: C0$_H$
MODNUM	[31:16]	r	**Module Number Value** This bit field defines the module identification number for the SENT: 0080$_H$

Fractional Divider Register

The Fractional Divider Register controls the input clock $f_{fracdiv}$ of all SENT channels.

SENT_FDR
SENT Fractional Divider Register ($0C_H$) Reset Value: $0000\ 0000_H$

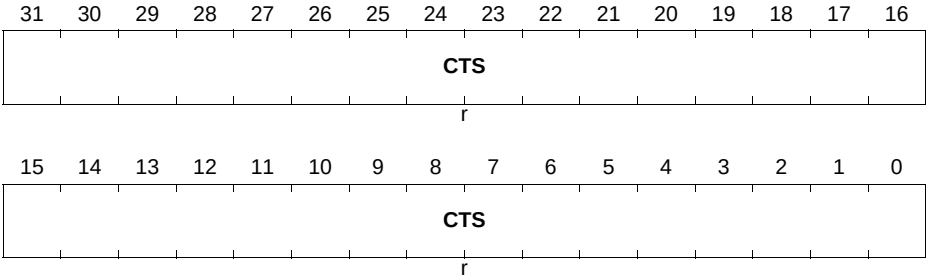


Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
DM	[15:14]	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.
0	[13:10], [31:26]	r	**Reserved** Read as 0; should be written with 0.

Module Time Stamp Register

The SENT Module Time Stamp Register contains read-only information about the current time given in clock cycles generated from TPD since last reset while module was clocked. Writing to TPD clears this register.

TSR
Time Stamp Register **(18_H)** **Reset Value: 0000 0000$_H$**

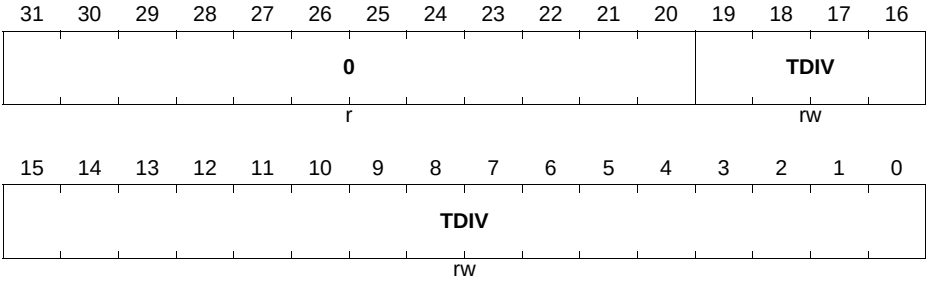


Field	Bits	Type	Description
CTS	[31:0]	r	**Current Time Stamp for the Module** This bit field shows the current time stamp.

Module Time Stamp Pre Divider Register

The SENT Module Time Stamp Predivider Register contains the pre divider that defines the time resolution of TSR. Writing to TPD clears register TSR.

TPD
Time Stamp Predivider Register ($1C_H$) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
TDIV	[19:0]	rw	**Divider Factor of Pre Divider for TSR** Divides $f_{fracdiv}$ by (TDIV + 1) and drives TSR.
0	[31:20]	r	**Reserved** Read as 0; should be written with 0.

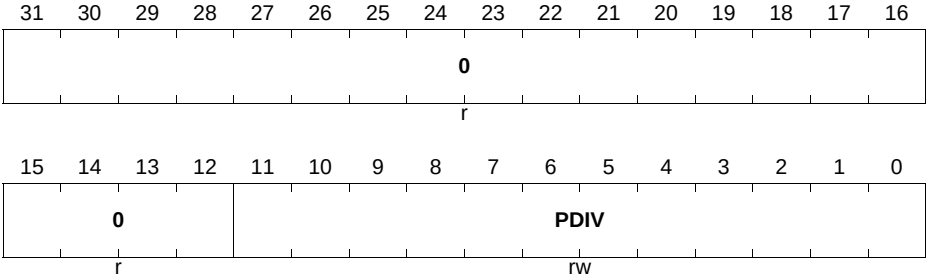
23.2.2 Channel Baud Rate Registers

Channel Pre Divider Register

The Channel Pre Divider Register CPDRx contains the pre divider that is related to the SENT channel baud rate.

See **Equation (23.3)**

CPDRx (x = 0-9)
Channel Pre Divider Register x **(100_H+40_H*x)** **Reset Value: 0000 0000_H**



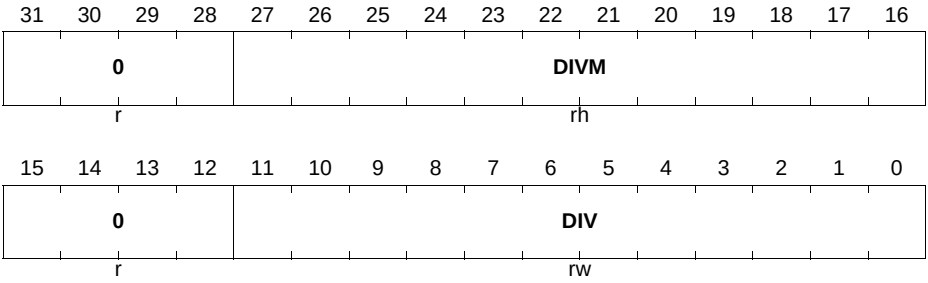
Field	Bits	Type	Description
PDIV	[11:0]	rw	**Divider Factor of Pre Divider for Channel x** Divides $f_{fracdiv}$ by (PDIV + 1) and delivers f_{pdiv_x} to the Channel Fractional Divider. RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV.
0	[31:12]	r	**Reserved** Read as 0; should be written with 0.

Channel Fractional Divider Register

The Channel Fractional Divider Register CFDRx contains control bits/bit fields that are related to the SENT channel baud rate.

See **Equation (23.4)** in **Chapter 23.1.5** for a detailed description.

CFDRx (x = 0-9)
Channel Fractional Divider Register x(104_H+40_H*x) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DIV	[11:0]	rw	**Divider Value** Initial and reference divider value for the CFDR. DIV must be programmed > 0. If cleared, DIV becomes 1. If written, DIVM is updated automatically with the same value.RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV.
DIVM	[27:16]	rh	**Measured Divider Value** DIVM is automatically updated by HW to adjust the receiver frequency to the current sender frequency. This value is kept automatically in the range of 75% DIV < DIVM < 125% DIV Write data is ignored.
0	[15:12], [31:28]	r	**Reserved** Read as 0; should be written with 0.

23.2.3 Receiver Control and Status Registers

Receiver Control Register

The Receiver Control Register RCRx contains control bits/bit fields that are related to the SENT receiver operation.

RCRx (x = 0-9)
Receiver Control Register x **(108_H+40_H*x)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0												SUSEN	IDE	ESF	CRZ
r												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FRL								CFC	CDIS	SCDIS	SDP	SNI	ACE	IEP	CEN
rw								rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
CEN	0	rw	**Channel Enable** When CEN is set, the receiver of channel x is enabled. The internal receiver state machine can be initialized by switching the channel off and on. This does not change the current register content. 0_B channel x disabled (default) 1_B channel x enabled
IEP	1	rw	**Ignore End Pulse** When IEP is set, an end pulse is ignored. An end pulse can be generated in SPC mode or as pause pulse. 0_B End Pulse not ignored (default) 1_B End Pulse ignored For systems with an end pulse, during synchronize or re-synchronize of reception, if calibration pulses are detected one immediately following the other, the first calibration pulse shall be ignored as it may be a pause pulse with duration matching the calibration pulse range.

Field	Bits	Type	Description
ACE	2	rw	**Alternative CRC Mode Enable** When ACE is set, the CRC is calculated in an alternative way for both: fast (signal) and slow (serial message) data path. *Note: If ESF is set, the standard 6 bit CRC is always used for the serial message and ACE is ignored.* 0_B Serial CRC calculation as specified in J2716 JAN2010 (default) 1_B Alternative: 4 bit in parallel CRC calculation as used e.g. in hall sensor TLE4998C.
SNI	3	rw	**Status Nibble Included in CRC** When SNI is set, the status Nibble is included in (signal data) CRC. 0_B Status Nibble not included in CRC (default) 1_B Status Nibble included in CRC (as used e.g. in hall sensor TLE4998C).
SDP	4	rw	**Serial Data Processing Mode** This bit switches automatic serial data processing on. 0_B Automatic Serial Data Processing is disabled. Status and Communication nibble can be read from RSRx for SW processing. (default) 1_B Automatic Serial Data Processing is enabled. Status and Communication nibble can be read from RSRx; Message ID, Serial Data and SCRC can be read from SDSx after serial data interrupt SDI is activated.
SCDIS	5	rw	**CRC for Serial Data Disabled Mode** This bit selects the CRC disabled mode. 00_B CRC is enabled (default) 01_B CRC is disabled CRC nibble can be read from SDSx. The CPU must perform the CRC on the current data by SW.

Field	Bits	Type	Description
CDIS	6	rw	**CRC Disabled Mode** This bit selects the CRC disabled mode. 00_B CRC is enabled (default) 01_B CRC is disabled CRC nibble can be read from RSRx. The CPU must perform the CRC on the current data by SW.

Field	Bits	Type	Description
CFC	7	rw	**Consecutive Frame Check** This bit determines the way the most recently received frame buffer is indicated as valid. 0_B **Check against Past Sync Pulse** The current Synchronization / Calibration Pulse is compared to the Synchronization / Calibration Pulse received immediately before. The whole frame is invalid if the Synchronization / Calibration Pulse length differs from the length of the Synchronization / Calibration Pulse before by more than 1.5625%. In this case of error, its length is not used as new reference. In case the check passes and no other error occurs the Frame Buffer is indicated valid immediately after CRC calculation result is correct. Resynchronization: On the third successive calibration pulse error, the current calibration pulse value is considered as valid and the message accepted unless the message frame contains other errors. In both cases a receive data interrupt (RDI), or a referring error interrupt is issued. 1_B **Check against Future Sync Pulse** The current Synchronization / Calibration Pulse is compared with the Synchronization / Calibration Pulse received immediately after the current frame. The whole frame is invalid if the Synchronization / Calibration Pulse length differs from the length of the following Synchronization / Calibration Pulse by more than 1.5625%. Resynchronization: In this case of error, the current length is used as new reference. Note: The whole frame can be indicated valid only after additionally measuring the Synchronization / Calibration Pulse of the successive frame.

Field	Bits	Type	Description
FRL	[15:8]	rw	**Frame Length** FRL determines the number of data nibbles per frame that the SENT channel x is setup for. Note that FRL does not include the Synchronization / Calibration Pulse, the Status and Communication nibble, the CRC nibble nor the additional zero length nibble that might be introduced by use of SPC. 00000000_B No data nibble 00000001_B 1 data nibble 00000010_B 2 data nibbles 00000011_B 3 nibbles ... ... 00001000_B 8 nibbles Maximum in normal length mode ... ... 11111111_B 255 nibbles If more than 8 nibbles are configured, please note: In addition to the receive success interrupt RSI at the successfully received end of a frame, a receive data interrupt RDI is issued each time 8 nibbles have been transferred to the Receive Data Register RDRx. At the end of a frame, RDI is issued if RSI is issued. If an error occurred, RDI is not set at the end of a frame. If no CRC has been received at the point in time where RDI is issued, the receive data interrupt is no indication whether or not the transfer was successful so far. A CRC Error Interrupt is issued at the end of the frame if Automatic CRC check is enabled and the CRC is wrong.

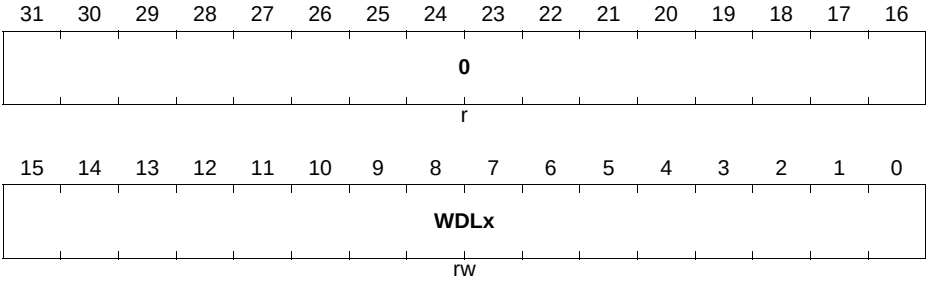
Field	Bits	Type	Description
CRZ	16	rw	**CRC with Zero Nibble for Serial Data** This bit selects the CRC method. If CRZ is cleared, augmentation is selected, (i.e a ZERO NIBBLE is added at the end of CRC calculation (only in calculation)). E.g. as 7th nibble (in case of 6 data nibbles) 00_B Augmentation is selected for both 4-bit message CRC and the 4-bit CRC of the serial messages (legacy, 16 frames) (default) 01_B Augmentation is switched off for both 4-bit message CRC and the 4-bit CRC of the serial messages (legacy, 16 frames). The enhanced serial message (18 Frames, 6-bit CRC) is not controlled by CRZ but the 6-bit CRC is always augmented according to standard.
ESF	17	rw	**Enhanced Serial Frame Mode** This bit selects the serial frame structure. 0_B short (16 frames, 4 bit ID, 8 bit data, 4 bit CRC) 1_B enhanced (18 frames, 4 or 8 bit ID, 12 or 16 bit data, 6 bit CRC)
IDE	18	rw	**Ignore Drift Error Mode** This bit selects if drift errors lead to frame rejection and if an interrupt (INTSTAT.FDI) is generated. Used, if sensors are triggered by SPC. During a long pause period the accumulated drift could be more than 1.5625%. In this special case setting IDE is useful. 0_B Drift Errors enabled (default) 1_B Drift Errors disabled
SUSEN	19	rw	**Suspend Enable** This bit makes it possible to set the SENT channel into Suspend Mode via OCDS (on chip debug support): 0_B An OCDS suspend trigger is ignored by this SENT channel. 1_B An OCDS suspend trigger disables the SENT channel: As soon as the SPC sender logic of the SENT channel becomes idle, the module is stopped while all registers of the channel stay readable. The receiver is stopped unconditionally. A partly received frame is discarded. Bit SUSEN is reset via OCDS Reset.

Field	Bits	Type	Description
0	[31:20]	r	**Reserved** Read as 0; should be written with 0.

Watch Dog Timer Register

The Watch Dog Timer Register WDTx contains the time out value for channel x.
The internal Watch Dog timer is cleared and started automatically each time an RDI (Receive Data Interrupt Request Flag) is set in the INTSTAT of the referring channel and also on any write to WDL that sets WDL>0. The value entered here defines the time in multiples of T_{tick_x} (defined in CFDR) from the last RDI on channel x.
The internal Watch Dog Timer is compared to WDLx.
A match triggers interrupt WDI and stops the internal Watch Dog Counter x.
After such a match, the Watch Dog Timer will be cleared and started automatically with clearing bit WDI (by setting INTCLR.WDI). I.e. the Watch Dog Counter is running only if interrupt flag WDI is cleared.
If WDL is cleared, the WDTx is stopped/disabled.

WDTx (x = 0-9)
Watch Dog Timer Register x **(134_H + x * 40_H)** **Reset Value: 0000 0000_H**

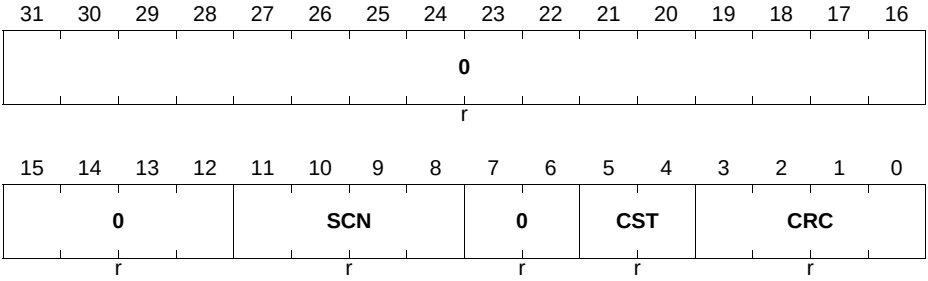


Field	Bits	Type	Description
WDLx	[15:0]	rw	**Watch Dog Timer Limit** for channel x .
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

Receiver Status Register

The Receive Status Register provides the status information of channel x.

RSRx (x = 0-9)
Receive Status Register x **($10C_H$+40_H*x)** **Reset Value: 0000 0000_H**



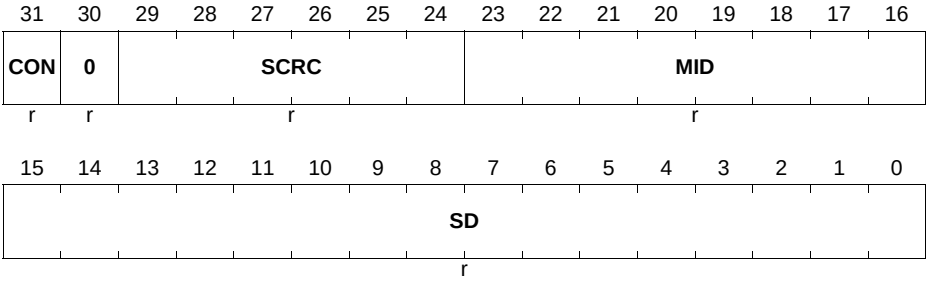
Field	Bits	Type	Description
CRC	[3:0]	r	**CRC** of last frame. CRC_0 is on bit position 0.
CST	[5:4]	r	**Channel Status** CST shows the current status of channel x. 00_B STOP Channel is disabled and can be configured 01_B INITIALIZED Channel is configured and enabled and no Synchronization / Calibration Pulse was received since last enable. 10_B RUNNING one or more Synchronization / Calibration Pulses were received and Frequency Range or Frequency Drift not or no longer in range. Fallback status from SYNCHRONIZED. 11_B SYNCHRONIZED Frequency Range and Frequency Drift in range
SCN	[11:8]	r	**Status and Communication Nibble** of last frame. SCN_0 is on bit position 8.
0	[7:6], [31:12]	r	**Reserved** Read as 0; should be written with 0.

Serial Data and Status Register

The Serial (Receive) Data and Status Register provides the data and status information of channel x.

SDSx (x = 0-9)

Serial Data and Status Register x (110_H+40_H*x) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SD	[15:0]	r	**Serial Data** of last serial data frame. SD_0 is on bit position 0. If RCR.ESF is cleared 8 bits of data are available and bits [15:8] are zero. If RCR.ESF is set and if SDS.CON is cleared 12 bits of data are available and bits [15:12] are zero.
MID	[23:16]	r	**Message ID** of last serial data frame. ID_0 is on bit position 16. If RCR.ESF is cleared, or if SDS.CON is set, bits [23:20] are zero.
SCRC	[29:24]	r	**SCRC** CRC of last serial data frame. CRC_0 is on position 24. If RCR.ESF is cleared, bits [29:28] are always zero.
CON	31	r	**Configuration bit** of last serial frame. 0_B 12-bit data and 8-bit message ID 1_B 16-bit data and 4-bit message ID
0	30	r	**Reserved** Read as 0; should be written with 0.

23.2.4 Input and Output Control

Input and Output Control Register Functions

The Input and Output Control Register IOCRx determines for the SENT channel x:

for the receiver:

- the alternate input
- the filter depth
- the input signal polarity

for the SPC Unit

- the trigger source
- the output signal polarity

IOCRx (x = 0-9)

Input and Output Control Register x(114_H+40_H*x) **Reset Value: X000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
ALTI	[1:0]	rw	**Alternate Input Select** Selects the alternate input for channel y: 0000_B Alternate Input 0 selected 0001_B Alternate Input 1 selected $…_B$ … 0011_B Alternate Input 3 selected

Field	Bits	Type	Description
DEPTH	[7:4]	rw	**Digital Glitch Filter Depth** DEPTH determines the number of port input samples clocked with f_{pdiv} that are taken into account for the calculation of the floating average. The higher DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 0000_B off, default 0001_B 1 T_{pdiv} 0010_B 2 0011_B 3 $\cdots_B$ … 1111_B 15
OIE	8	rw	**Output Inverter Enable Channel x** Selects the Pulse Polarity of the output of channel x 0_B Pulse polarity is active low 1_B Pulse polarity is active high
IIE	9	rw	**Input Inverter Enable Channel x** Selects the Pulse Polarity of the input of channel x 0_B Pulse polarity is active low 1_B Pulse polarity is active high
CEC	10	w	**Clear Edge Counter** If this bit is set, IOCR.EC is cleared. Always reads back as ‘0’.
REG	12	rh	**Rising Edge Glitch Flag for Channel x** Shows the status of the glitch detection of channel x 0_B No Glitch detected on rising edge 1_B Glitch detected on rising edge REG is cleared by setting CREG.
FEG	13	rh	**Falling Edge Glitch Flag for Channel x** Shows the status of the glitch detection of channel x 0_B No Glitch detected on falling edge 1_B Glitch detected on falling edge FEG is cleared by setting CFEG.
CREG	14	rw	**Clear Rising Edge Glitch Flag for Channel x** Clears the status flag REG 0_B REG is not cleared 1_B REG is cleared CREG always read zero.

Field	Bits	Type	Description
CFEG	15	rw	**Clear Falling Edge Glitch Flag for Channel x** Clears the status flag FEG 0_B FEG is not cleared 1_B FEG is cleared CFEG always read zero.
ETS	[19:16]	rw	**External Trigger Select** Selects the external trigger line if SCRx.TRIG is programmed to 11_B. 0000_BTRIG0 0001_BTRIG1 ... ... 9_D TRIG9 ... ... 1111_Breserved
EC	[27:20]	rh	**Edge Counter** This bit field contains a counter with saturation (stops at 0xFF). It is incremented with any falling edge that appears on the input pin selected by IOCR.ALTI. Note that this holds true in all states (STOP, INITIALIZED, RUNNING, SYNCHRONIZED). It is intended for debugging, in particular to find a bubbling idiot that sends before enabling the module.
CTR	28	rw	**Clear Trigger Monitor Flag for Channel x** Clears the status flag TRM 0_B TRM is not cleared 1_B TRM is cleared CTR always read zero. Reset value of CTR is 0.
TRM	29	rh	**Trigger Monitor Flag for Channel x** Shows the status of the trigger detection of channel x 0_B No Trigger detected 1_B Trigger detected (one or several) TRM is cleared by setting CTR. Reset value of TRM is 0.
RXM	30	rh	**Receive Monitor for Channel x** Shows the status of the receive signal of channel x after glitch filtering and inverted as specified by IIE. 0_B Current signal is low. 1_B Current signal is high. Reset value of RXM is X.

Field	Bits	Type	Description
TXM	31	rh	**Transmit Monitor for Channel x** Shows the status of the transmit signal of channel x inverted as specified by OIE. 0_B Current signal is low. 1_B Current signal is high. Reset value of TXM is X.
0	[3:2], 11	r	**Reserved** Read as 0; should be written with 0.

23.2.5 Receive Data Registers

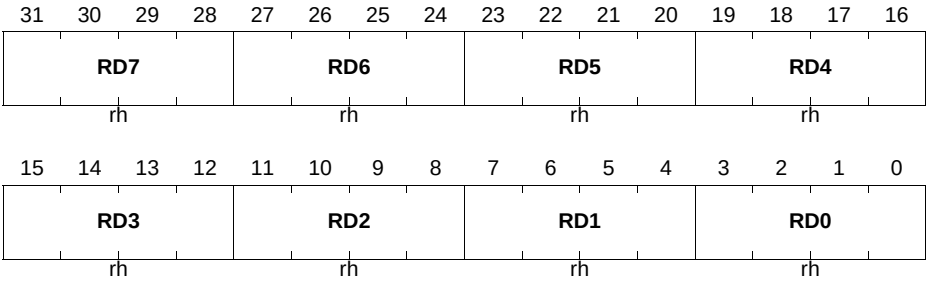
Receive Data Registers RDRx

The Receive Data Registers RDRx for channel x shows the data content of a received data frame. Register VIEWx is used to sort the nibbles.

Note: Register VIEW must be set up correctly to see all data nibbles of the frame! By default the application software set VIEW to 7654 3210$_H$.

Note: The internal receive buffer is always cleared (0x0000 0000$_H$) at each frame start. Thus unused nibbles are always read as zero.

RDRx (x = 0-9)
Receive Data Register x **(80_H+x*4_H)** **Reset Value: 0000 0000_H**

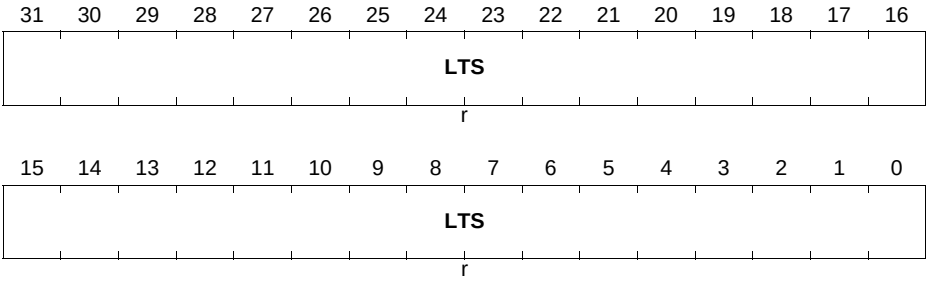


Field	Bits	Type	Description
RDy (y = 0-7)	[4*y+3 :4*y]	rh	**Receive Data Nibble y** RDy shows the nibble from the received frame that is sorted to this position. It can be selected by any of VIEWx.RDNPy (y = 0-7). By default all nibbles are sorted to RD0 as the reset value of VIEW is 0x0000 0000_H. I.e. at the end of frame reception RD0 contains the last data nibble of the frame.

Channel Receive Time Stamp Register

The SENT Channel x Receive Time Stamp Register contains read-only information about the time the last frame for channel x was received. Time is captured with the second falling edge, i.e. at the Status/Communication data pulse.

RTSx (x=0-9)
Receive Time Stamp Register x ($A80_H+x*4_H$) Reset Value: 0000 0000_H



Field	Bits	Type	Description
LTS	[31:0]	r	**Last Receive Time Stamp for Channel x** This bit field shows the time stamp of the last frame on channel x.

Receive Data View Register VIEWx

The Receive Data View Registers VIEWx stores the nibble pointers. They determine the sequence in which the received data nibbles are presented to the host. This reduces the SW effort to sort the nibbles.
The data nibble that is received first in the received frame is moved to the location given in register VIEW.RDNP0, the second to VIEW.RDNP1 and so on until VIEW.RDNP7.
If more than one VIEW.RDNPx point to a certain location in RDR, the last one will overwrite the previous ones.
Example: two 12 bit values are transmitted. One with highest significant nibble first and one with lowest significant nibble first. The frame looks like this: 456321_H. Note that the 1 is received as first data nibble and the 4 comes in as last data nibble.
The actual signal values are $0x123_H$ and $0x456_H$. By using VIEWx this can be sorted out into two 16bit values by HW. In the example VIEWx would be set to: 73 654 012_H. 73 is a dummy value and is not regarded if not more than 6 nibbles are received in a frame. The Register RDRx looks like this: 0x0456 0123_H to the host.

In the example RDR nibbles 3 and 7 contain $0x0000_B$ as the Receive Buffer is always cleared (0x0000 0000_H) before new data is received.

If a frame contains more than eight nibbles and the sorting can not be specified statically, VIEW can be set to e.g. 7654 3210_H.

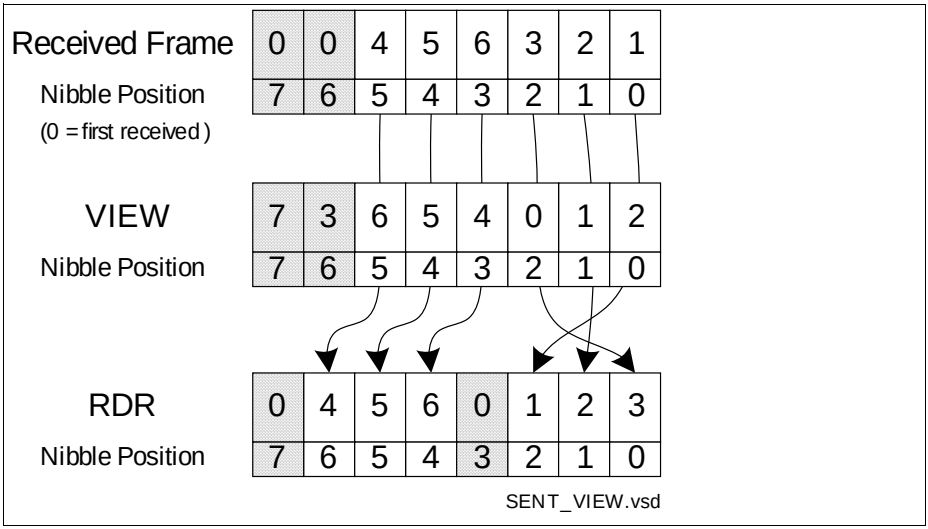


Figure 23-16 Functionality of VIEW Register

VIEWx (x = 0-9)

Receive Data View Register x ($11C_H$+40_H*x) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RDNPy (y = 0-7)	[4*y+2 :4*y]	rw	**Receive Data Target Nibble Pointer y** RDNPy points to the Nibble in Receive Data Register RDRx where the nibble y from the received frame is sorted to. Nibble 0 is the first data nibble in the frame. It gets moved to the position defined in RDNP0. And on. 000_B Nibble 0 selected 001_B Nibble 1 selected $\ldots_B$ … 111_B Nibble 7 selected *Note: RDNPy must be written before first frame reception. All RDNPy must have different values. (Higher RDNPy overwrite lower RDNPy.)*
0	3, 7, 11, 15, 19, 23, 27, 31	r	**Reserved** Read as 0; should be written with 0.

23.2.6 SPC Control

SPC Control Registers SCRx

The SPC Control Register SCR contains data to be transmitted during the sync pulse of the data frames. It contains as well the trigger control bits required for sending nibbles from the SENT module to the sensor / external SENT device.

The SPC Control Register is used to control the trigger mode and time base of the SPC channel transmission.

Data and the control bits are collected in this single register to ease transfer of multiple pulses in cases where dynamic switching of the trigger condition is required.

The SPC Control Register is build to control single pulse transfers only.

Thus it is possible to change the control settings of an individual channel from pulse to pulse as it is required in SPC mode “Bidirectional transmit”. Here it might be considered useful to change trigger mode between Mode 1 (immediately) and Mode 2 (falling edge of next Synchronization / Calibration Pulse with programmable delay).

In addition repeating transfers with the same control settings are supported. For a pulse transfer to be initiated a synchronization signal can be sufficient and no further SW intervention is required. Here the data can be changed (“ID-Selection” Mode) or simply left constant (“Sync” Mode). Only a HW trigger needs to be set up.

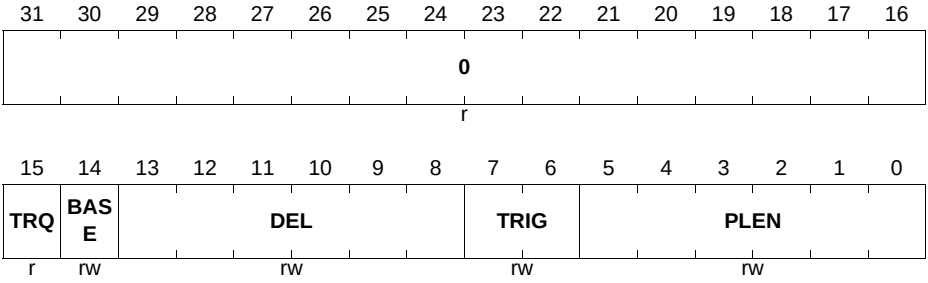
In Mode 0, SPC is deactivated for this channel. A write access to SCRx does not initiate an SPC pulse transmission. All state transmitter machines are initialized.

In Mode 1, an SPC pulse is sent, each time SPC Control Register SCRx is written to. If a transfer is ongoing, the channel waits automatically until the internal transmission register is ready. Transmit Buffer Underflow bit TBIx is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. After the data was transferred to the internal transmission register, interrupt TDIx signals that a new value can be written. INTSTATx.TDIx must be cleared by SW. Independently from this interrupt pending bit, a new interrupt pulse is generated on each transfer of an SPC pulse.
This mode is important for back to back transfers of several nibbles as in bidirectional SPC mode.

In Mode 2, an SPC pulse is sent, each time the first falling edge of any Synchronization / Calibration Pulse is received. In this mode, the programmable delay DEL is most useful. In SPC mode “Bidirectional Transmit” this mode is useful to synchronize the transmission. TDIx and TBIx work as in Mode 1.

In Mode 3, an SPC pulse is sent (with current DEL and PLEN) after each external trigger event (defined by IOCRx.ETS). This is most useful in SPC “sync” mode. TDIx and TBIx work as in Mode 1.

SCRx (x = 0-9)
SPC Control Register x **(118_H+40_H*x)** **Reset Value: 0000 0000_H**

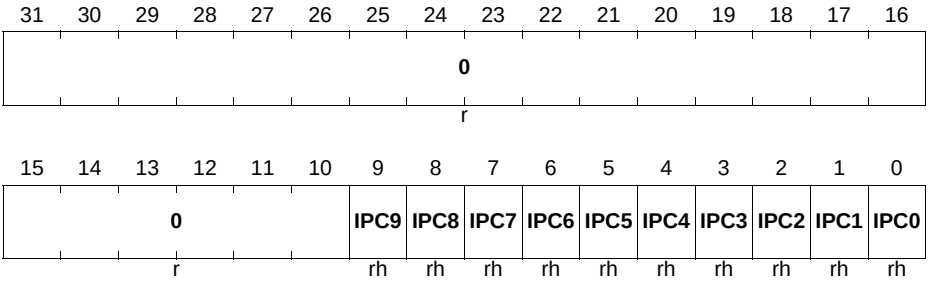


Field	Bits	Type	Description
PLEN	[5:0]	rw	**Pulse Length** Defines the length of the pulse in tick times. The time base is the measured tick time of the latest received frame if selected so by BASE. In case this measured tick time was invalid or not already available after enable of the channel, the nominal time base of the module is used. 000000_B Pulse length is 0 ticks 000001_B Pulse length is 1 tick ... ... 111111_B Pulse length is 63 ticks

Field	Bits	Type	Description
TRIG	[7:6]	rw	**Trigger Source and Mode Selection** Selects the Trigger Source and Mode. The internal sender state machine can be initialized by switching the channel off (TRIG is cleared) and on. This does not change the current register content. 00_B No Pulse is generated, OFF When cleared, an ongoing transfer is stopped immediately and the transmit output is driven recessive. 01_B Pulse starts immediately (no auto repetition) 10_B Pulse starts each time the first falling edge of any Synchronization / Calibration Pulse is received (auto repetition on next Sync. / Cal. Pulses) 11_B Pulse starts after each external trigger event. (auto repetition on next trigger) IOCRx.ETS selects the source of this event.
DEL	[13:8]	rw	**Delay Length** Selects how long the SPC pulse is delayed after the trigger condition. The time base is the measured tick time of the latest received frame if selected so by BASE. In case this measured tick time was invalid or not already available after enable of the channel, the nominal time base of the module is used. 000000_B Pulse is not delayed 000001_B Pulse is delayed by 1 tick ... ... 111111_B Pulse is delayed by 63 ticks
BASE	14	rw	**Time Base** Selects the Pulse Time Base 0_B Pulse is based on measured frequency of last Synchronization/Calibration Pulse 1_B Pulse is based on nominal frequency
TRQ	15	r	**Transfer Request in Progress** While an SPC Pulse is being sent this bit is set. Write access is ignored.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

23.2.7 Interrupt Control Registers

INTOV
Interrupt Overview Register **(14_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
IPCy (y = 0-9)	y	rh	**Interrupt Pending on Channel y** If any interrupt requested flag is set for channel y in register INTSTATy AND the referring interrupt is enabled in INTENx then IPCy is set. It is automatically reset if all flags in INTSTATy are cleared for which the referring interrupt is enabled in INTENx. *Note: Not all IPC0-9 are available, the number of Interrupt Pending on Channel is equivalent to the SENT channels available, e.g 4 SENT channels has 4 Interrupt Pending IPC0-3 and vice versa.*
0	[31:10]	r	**Reserved** Read as 0.

Interrupt Status Register

The Interrupt Status Register INTSTATx contains status bits that show the status of any interrupt of SENT channel x.

Note: The bits are set independently from the referring Interrupt Enable in Register INTENx. Thus they can be used as status bits as well e.g. by a SW based on polling.

INTSTATx (x = 0-9)
Interrupt Status Register x **(120_H+40_H*x)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r		rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RSI	0	rh	**Receive Success Interrupt Request Flag** This bit is set at the successfully received end of a frame. Depending on bit RCRx.CDIS this indicates a successful check of the CRC. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.RSI. This bit can be set by bit INTSETx.RSI. This bit is set independently from INTENx.

Field	Bits	Type	Description
RDI	1	rh	**Receive Data Interrupt Request Flag** RDI is activated when a received frame is moved to a Receive Data Register RDR. Both RDI and RSI will be issued together in normal use cases where the frame size is not bigger than 8 nibbles and CRC is correct or not checked (if RCRx.CDIS is cleared). 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.RDI. This bit can be set by bit INTSETx.RDI. This bit is set independently from INTENx.
RBI	2	rh	**Receive Buffer Overflow Interrupt Request Flag** This bit is set after a frame has been received while the old one was not read from RDRx. I.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set.The old data is overwritten by the new data. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is NOT cleared by reading RDRx. This bit can be cleared by bit INTCLRx.RBI. This bit can be set by bit INTSETx.RBI. This bit is set independently from INTENx.
TDI	3	rh	**Transfer Data Interrupt Request Flag** This bit is set after the trigger condition was detected. Data to be transferred has been moved internally. Thus a new value can be written to SCRx. This can be used for back to back transfers. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is automatically cleared by writing SCRx. This bit can be cleared by bit INTCLRx.TDI. This bit can be set by bit INTSETx.TDI. This bit is set independently from INTENx.

Field	Bits	Type	Description
TBI	4	rh	**Transmit Buffer Underflow Interrupt Request Flag** This bit is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is NOT cleared by writing SCRx. This bit can be cleared by bit INTCLRx.TBI. This bit can be set by bit INTSETx.TBI. This bit is set independently from INTENx.
FRI	5	rh	**Frequency Range Interrupt Request Flag** This bit is set after a Synchronization / Calibration pulse was received that deviates more than +- 25% from the nominal value. The referring data is ignored. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.FRI. This bit can be set by bit INTSETx.FRI. This bit is set independently from INTENx.
FDI	6	rh	**Frequency Drift Interrupt Request Flag** This bit is set after a subsequent Synchronization / Calibration pulse was received that deviates more than 1.5625% (1/64) from its predecessor. (See RCR.CFC) 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.FDI. This bit can be set by bit INTSETx.FDI. This bit is set independently from INTENx.

Field	Bits	Type	Description
NNI	7	rh	**Number of Nibbles Wrong Request Flag** This bit is set after a more nibbles have been received than expected or a Synchronization / Calibration Pulse is received too early thus too few nibbles have been received. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.NNI. This bit can be set by bit INTSETx.NNI. This bit is set independently from INTENx.
NVI	8	rh	**Nibbles Value out of Range Request Flag** This bit is set after a too long or too short nibble pulse has been received. I.e. value < 0 or value > 15. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.NVI. This bit can be set by bit INTSETx.NVI. This bit is set independently from INTENx.
CRCI	9	rh	**CRC Error Request Flag** This bit is set if the CRC fails. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.CRCI. This bit can be set by bit INTSETx.CRCI. This bit is set independently from INTENx.

Field	Bits	Type	Description
WSI	10	rh	**Wrong Status and Communication Nibble Error Request Flag** In Short Serial Frame Mode (RCR.ESF is cleared), this bit is set if the Status and Communication nibble shows a start bit in a frame other than frame number n x 16. In Enhanced Serial Frame Mode this bit is without function. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.WSI. This bit can be set by bit INTSETx.WSI. This bit is set independently from INTENx.
SDI	11	rh	**Serial Data Receive Interrupt Request Flag** This bit is set after all serial data bits have been received via the Status and Communication nibble. Depending on bit RCRx.SCDIS this indicates a successful check of the CRC. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.SDI. This bit can be set by bit INTSETx.SDI. This bit is set independently from INTENx.
SCRI	12	rh	**Serial Data CRC Error Request Flag** This bit is set if the CRC of the serial message fails. In Enhanced Serial Message Format, this includes a check of the Serial Communication Nibble for correct 0 values of bit 3 in frames 7, 13 and 18. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.SCRI. This bit can be set by bit INTSETx.SCRI. This bit is set independently from INTENx.

Field	Bits	Type	Description
WDI	13	rh	**Watch Dog Error Request Flag** This bit is set if the Watch Dog Timer of the channel x expires. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.WDI. This bit can be set by bit INTSETx.WDI. This bit is set independently from INTENx.
0	[31:14]	r	**Reserved** Read as 0.

Interrupt Set Register

The Interrupt Set Register INTSETx contains control bits that trigger an interrupt pulse for any interrupt of SENT channel x.

INTSETx (x = 0-9)
Interrupt Set Register x **(124_H+40_H*x)** **Reset Value: 0000 0000_H**

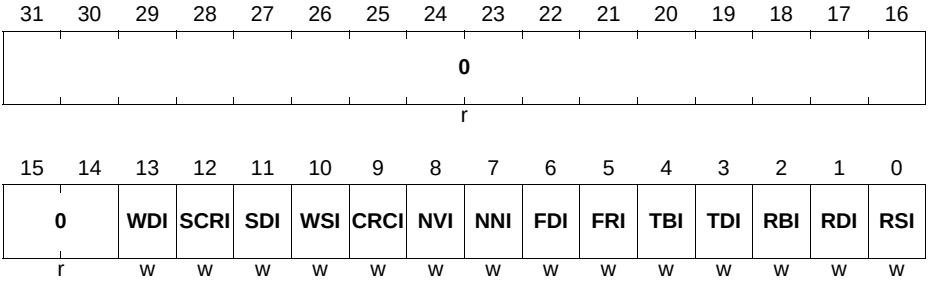
Interrupt Clear Register

The Interrupt Clear Register INTCLRx contains control bits that clear the status of any interrupt of SENT channel x.

INTCLRx (x = 0-9)
Interrupt Clear Register x **(128_H+40_H*x)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RSI	0	w	**Clear Interrupt Request Flag RSI** Setting this bit clears bit INTSTATx.RSI. Clearing this bit has no effect. Reading this bit returns always zero.
RDI	1	w	**Clear Interrupt Request Flag RDI** Setting this bit clears bit INTSTATx.RDI. Clearing this bit has no effect. Reading this bit returns always zero.
RBI	2	w	**Clear Interrupt Request Flag RBI** Setting this bit clears bit INTSTATx.RBI. Clearing this bit has no effect. Reading this bit returns always zero.
TDI	3	w	**Clear Interrupt Request Flag TDI** Setting this bit clears bit INTSTATx.TDI. Clearing this bit has no effect. Reading this bit returns always zero.
TBI	4	w	**Clear Interrupt Request Flag TBI** Setting this bit clears bit INTSTATx.TBI. Clearing this bit has no effect. Reading this bit returns always zero.

Field	Bits	Type	Description
FRI	5	w	**Clear Interrupt Request Flag FRI** Setting this bit clears bit INTSTATx.FRI. Clearing this bit has no effect. Reading this bit returns always zero.
FDI	6	w	**Clear Interrupt Request Flag FDI** Setting this bit clears bit INTSTATx.FDI. Clearing this bit has no effect. Reading this bit returns always zero.
NNI	7	w	**Clear Interrupt Request Flag NNI** Setting this bit clears bit INTSTATx.NNI. Clearing this bit has no effect. Reading this bit returns always zero.
NVI	8	w	**Clear Interrupt Request Flag NVI** Setting this bit clears bit INTSTATx.NVI. Clearing this bit has no effect. Reading this bit returns always zero.
CRCI	9	w	**Clear Interrupt Request Flag CRCI** Setting this bit clears bit INTSTATx.CRCI. Clearing this bit has no effect. Reading this bit returns always zero.
WSI	10	w	**Clear Interrupt Request Flag WSI** Setting this bit clears bit INTSTATx.WSI. Clearing this bit has no effect. Reading this bit returns always zero.
SDI	11	w	**Clear Interrupt Request Flag SDI** Setting this bit clears bit INTSTATx.SDI. Clearing this bit has no effect. Reading this bit returns always zero.
SCRI	12	w	**Clear Interrupt Request Flag SCRI** Setting this bit clears bit INTSTATx.SCRI. Clearing this bit has no effect. Reading this bit returns always zero.
WDI	13	w	**Clear Interrupt Request Flag WDI** Setting this bit clears bit INTSTATx.WDI. Clearing this bit has no effect. Reading this bit returns always zero.
0	[31:14]	r	**Reserved** Read as 0; should be written with 0.

Interrupt Enable Register

The Interrupt Enable Register INTENx contains control bits that enable the interrupt source of any interrupt of SENT channel x.

Note: The Interrupt Status bits in register INTSTATx are set independently from the Interrupt Enable in Register INTENx.

INTENx (x = 0-9)
Interrupt Enable Register x **($12C_H$+40_H*x)** **Reset Value: 0000 0000_H**

Interrupt Node Pointer Register

The Interrupt Node Pointer Register INPx contains the node pointers of SENT channel x.

Note: Node Pointer ERRI is one single node pointer for the following error interrupts:

- FRI
- FDI
- NNI
- NVI
- CRCI
- WSI
- SCRI

INPx (x = 0-9)

Interrupt Node Pointer Register x (130_H+40_H*x) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RSI	[3:0]	rw	**Interrupt Node Pointer for Interrupt RSI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RSI (if enabled by bit INTENx.RSI). 0000_B Interrupt node 0 is selected 0001_B Interrupt node 1 is selected 0010_B Interrupt node 2 is selected 0011_B Interrupt node 3 is selected 0100_B Trigger Output TRIGO 0 is selected 0101_B Trigger Output TRIGO 1 is selected ... ... 1001_B Trigger Output TRIGO 5 is selected 1010_B Reserved, do not use ... ... 1111_B Reserved, do not use
RDI	[7:4]	rw	**Interrupt Node Pointer for Interrupt RDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RDI (if enabled by bit INTENx.RDI). For bit field definition, see RSI.
RBI	[11:8]	rw	**Interrupt Node Pointer for Interrupt RBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RBI (if enabled by bit INTENx.RBI). For bit field definition, see RSI.
TDI	[15:12]	rw	**Interrupt Node Pointer for Interrupt TDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.TDI (if enabled by bit INTENx.TDI). For bit field definition, see RSI.
TBI	[19:16]	rw	**Interrupt Node Pointer for Interrupt TBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.TBI (if enabled by bit INTENx.TBI). For bit field definition, see RSI.

Field	Bits	Type	Description
ERRI	[23:20]	rw	**Interrupt Node Pointer for Interrupt FRI, FDI, NNI, NVI, CRCI, WSI, SCRI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.FRI (if enabled by bit INTENx.FRI) or INTSTATx.FDI (if enabled by bit INTENx.FDI) or INTSTATx.NNI (if enabled by bit INTENx.NNI) or INTSTATx.NVI (if enabled by bit INTENx.NVI) or INTSTATx.CRCI (if enabled by bit INTENx.CRCI) or INTSTATx.WSI (if enabled by bit INTENx.WSI) or INTSTATx.SCRI (if enabled by bit INTENx.SCRI) For bit field definition, see RSI.
SDI	[27:24]	rw	**Interrupt Node Pointer for Interrupt SDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.SDI (if enabled by bit INTENx.SDI). For bit field definition, see RSI.
WDI	[31:28]	rw	**Interrupt Node Pointer for Interrupt WDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.WDI (if enabled by bit INTENx.WDI). For bit field definition, see RSI.

23.3 SENT Module Implementation

This section describes the SENT module interface as it is implemented in the TC27x. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

23.3.1 Interface Connections of the SENT Module

Figure 23-17 shows the TC27x-specific implementation details and interconnections of the SENT module.

The SENT module is supplied with a separate clock control, address decoding, and interrupt control logic. Outputs of the GTM module are connected to the 10 timer inputs.

The serial data inputs of the receive channels of the SENT module as well as the SPC outputs (SPCn) are connected to GPIO lines. If SPC outputs are used, they are usually mapped to the same port pin like the referring SENT data input line as this minimizes the pin count requirement.

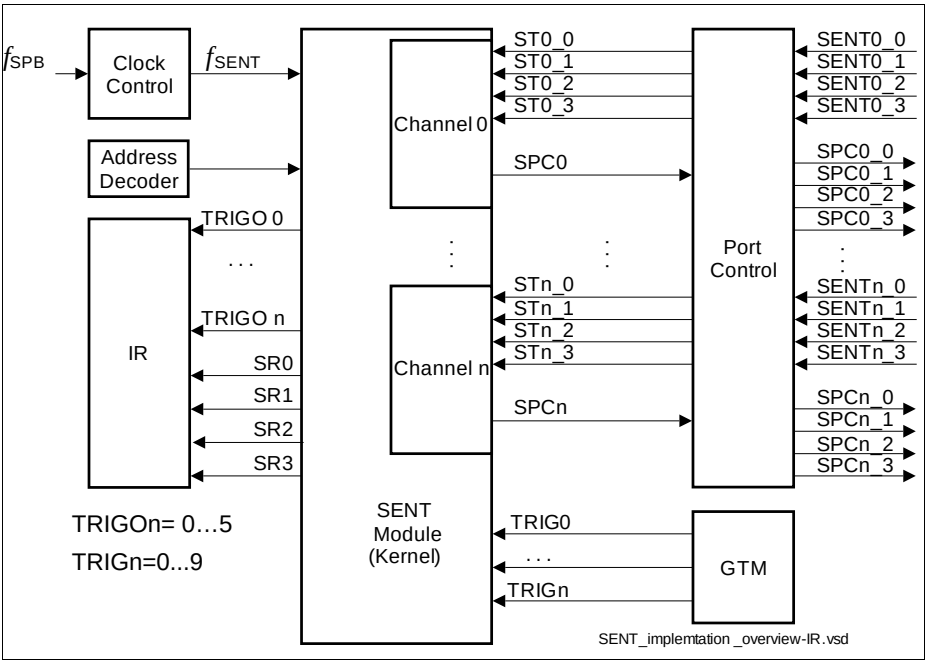

Figure 23-17 SENT Module Implementation and Interconnections

23.3.1.1 On-Chip Connections

This section describes the on-chip connections of the SENT module.

23.3.1.2 Interrupt and DMA Controller Service Requests

The trigger outputs of the SENT module are connected via the Interrupt router. The request lines are connected as shown in **Table 23-9**.

Table 23-9 Service Request Lines of SENT

INP value	Request Line	Connected to	Description
0000_b	SR0	SRC_SENT0	Interrupt Router SENT Request 0
0001_b	SR1	SRC_SENT1	Interrupt Router SENT Request 1
0010_b	SR2	SRC_SENT2	Interrupt Router SENT Request 2
0011_b	SR3	SRC_SENT3	Interrupt Router SENT Request 3
0100_b	TRIGO0	SRC_SENT4	Interrupt Router SENT Request 4
0101_b	TRIGO1	SRC_SENT5	Interrupt Router SENT Request 4
0110_b	TRIGO2	SRC_SENT6	Interrupt Router SENT Request 6
0111_b	TRIGO3	SRC_SENT7	Interrupt Router SENT Request 7
1000_b	TRIGO4	SRC_SENT8	Interrupt Router SENT Request 8
1001_b	TRIGO5	SRC_SENT9	Interrupt Router SENT Request 9
1010_b	TRIGO6	SRC_SENT10	Not Connected
...	...	...	...
1111_b	TRIGO11	SRC_SENT15	Not Connected

Trigger Inputs

The module has 10 Sent Channels and the same number of trigger inputs which can be randomly chosen by programming IOCRx.ETS. The trigger inputs (TRIG[9:0]) of the SENT module are connected to the GTM as shown in **Table 23-10**. n = [0 .. 9]

Table 23-10 Trigger Input Lines of SENT

Request Line	Connected to	Description
TRIG0	TRIG0	GTM.ADC_0_TRIG_0
TRIG1	TRIG1	GTM.ADC_1_TRIG_0
...	...	...

Table 23-10 Trigger Input Lines of SENT

Request Line	Connected to	Description
TRIG8	TRIG8	GTM.ADC_8_TRIG_0
TRIG9	TRIG9	GTM.DSADC_0_TRIG_0

23.3.2 SENT Module-Related External Registers

The registers listed in **Figure 23-18** are external of the SENT module kernel but must be programmed for proper operation of the SENT module.

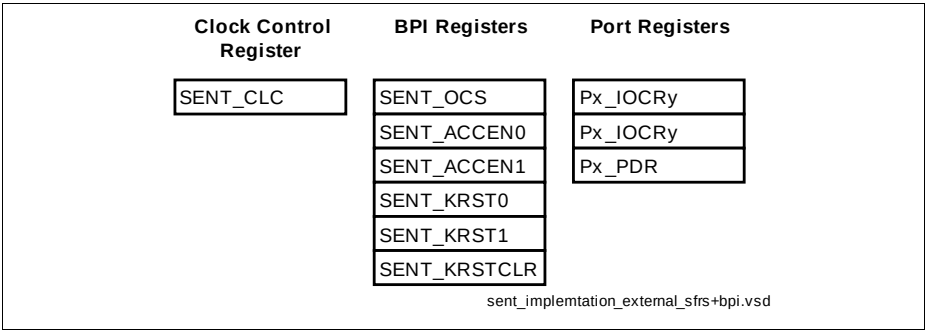

Figure 23-18 SENT Implementation-specific Special Function Registers

23.3.2.1 Port Control

The SENT input channels are overlaid with standard ADC channels as they are replacing former analog signals. Each channel is connected to two ADC channels that can be chosen alternatively. In addition each channel is connected to general purpose I//O lines as well. Each channel is connected to two different general purpose I/O lines that can be chosen alternatively. The selection from on of these 4 alternatives is done by application SW by programming SENT_IOCRx.ALTI respectively.

The SPC output lines are connected to the same I/O ports as the referring input channel. The ADC channels do not provide output functionality. The SPC I/O ports are controlled in the port logic (see also **Figure 23-17**). The following port control operations and selections must be executed for these I/O lines:

- Input/output function selection (Port IOCR registers)
- Pad driver characteristics selection for the outputs (Port PDR registers)

Input/Output Function Selection

SENT can be used in three different ways:

- ADC input (dedicated for ADC) overlaid with SENT digital input and no output option on this pin.
- SENT configured digital I/O lines (open drain, no push/pull, uses SDIR, single pin hardware direction control HW_DIR, SDIR is controlled by the data value: 0 = active out, 1 = passive/open drain, input)

- Standard general purpose input/output function on two lines for each channel (input on ADC alternative 1 or 2, or on I/O port alternative 1 while the output is chosen to be on I/O ports alternative 2.

The SENT module overlays dedicated analog to digital converter (ADC) pins as digital input port.

SENT physical layer uses 5V signal voltage levels. All SENT inputs are mapped to 5V compatible ADC pads. Vddm must be supplied with 5V for SENT operation.

SENT physical layer uses 5V signal voltage levels. All SENT inputs are mapped to 5V compatible ADC pads. Vddm must be supplied with 5V for SENT operation.

The SENT module can be configured to use input/output ports configured for use with SENT. These control settings for the port pins differ from the standard general purpose I/O lines in so far as

- they are controlled by the SENT module output data via their HW_DIR line
- they are configured to use no push/pull devices and to work in open drain mode if the output function is selected by the HW_DIR line of the port

The SENT module can be configured to use standard (push pull) general purpose I/O lines as well. Different port pins can be selected for input and for output. This allows the use of external transceiver devices.

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as port direction (input/output) with alternate output selection, pull-up/down devices, and open-drain selections. The I/O lines for the SENT module are controlled by the Port input/output control registers shown below.

Table 23-11 shows an overview how bits and bit fields must be programmed for the required I/O functionality of the SENT I/O lines.

Table 23-11 SENT I/O Control Selection and Setup

SENT Channel	Port Lines	Input Select Register	Input/Output Control Register Bits	I/O

23.3.3 BPI_FPI Module Registers

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock, sleep mode and disable mode for the module.

SENT_CLC
Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RMC								0				EDIS	0	DISS	DISR
rw								r				rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
RMC	[15:8]	rw	**8-bit Clock Divider Value in RUN Mode**
0	[31:16], [7:4], 2	r	**Reserved** Read as 0; should be written with 0.

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency, which is selected via bit field RMC in the CLC register. Therefore, increasing CLC.RMC may result in a longer FPI Bus read cycle access time for kernel registers and can also slow down the write throughput to the kernel registers.

15. *After a hardware reset operation, the f_{SENT} and $f_{fracdiv}$ clocks are switched off and the SENT module is disabled (DISS set).*

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status (E8$_H$) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Clock is switched off immediately. (SPC low pulse breaks immediately, Port Pin keeps the last value if suspend state is entered) 2_H Soft suspend (SPC low pulse will be finished before suspend state is entered) **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

ACCEN0
Access Enable Register 0 (FC_H) Reset Value: FFFF FFFF$_H$

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

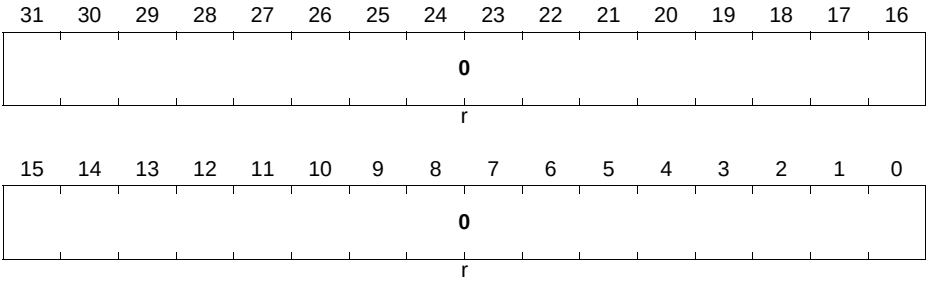
Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ACCEN1
Access Enable Register 1 **($F8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

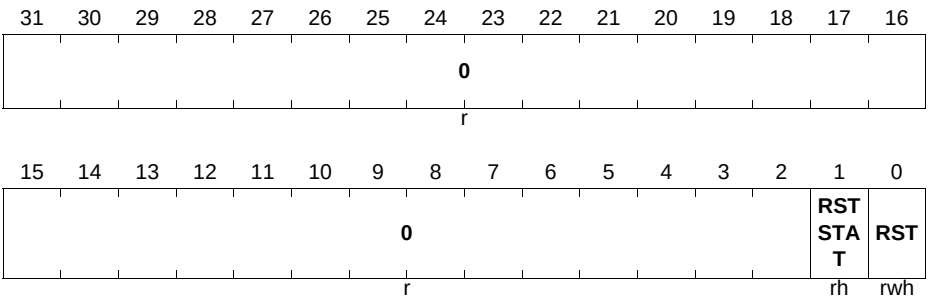
Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **($F4_H$)** **Reset Value: 0000 0000$_H$**

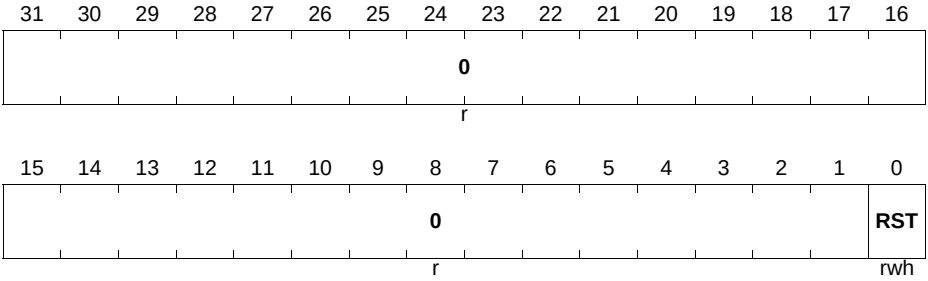


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($F0_H$)** **Reset Value: 0000 0000$_H$**



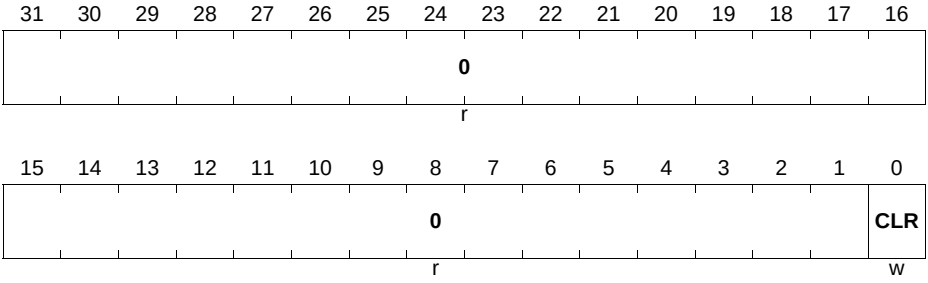
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (EC_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

23.4 Revision History

This User's Manual is based on: SAE Standard "SENT **Revision J2716 JAN2010**".

Table 23-12 Revision History

Version Number	Changes to Previous Version
Rev_0.1D	First Draft (Bullet Points ++)
Rev_0.2D	Second Draft (Bullet Points ++)
Rev_0.3D	First Review Version
Rev_0.4D	• RCRx.NINT removed as unnecessary FIFO support • Spelling Checked • Renamed INTNP to INP (request DE) • One common error node pointer in INP for FRI, FDI, NNI, NVI, CRCI, WSI, SCRI (reduce DE effort) • Interrupt Node Pointer in INPx increased from 2 bit to 4 bit • Renamed PVAL to PDIV in register CPDRx • RCRx.ASP "Additional Sync/Cal Pulse expected" deleted, not required • RCRx.ACE "Alternate CRC Mode" added, request customer • cleanup Register SCR • ISR0 (Input select register) deleted • AltIn and Filter DEPTH moved to IOCRx • SCRx.DEL moved to SDRx • SCRx deleted, BASE and TRQ moved to SDR • Restructured Chapters (interrupts after functional registers, implementation chapter cleaned up) • Simplified Baud rate generation (Fdtick removed)
Rev_0.5D	• Clean up Glitch filter Chapter • Detailed Baud Rate Generation • Added Address overview table

Table 23-12 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_0.6D	• Channel **Fractional Divider with variable divider** instead of variable dividend • Glitch filter based on F_pdiv and no longer on F_sent • Glitch detection added • Pre divider = PDIV and no longer PDIV + 1 • Compressed address overview table • Interrupt generation updated with figure • Trigger outputs renamed (RSI and SDI, no more TRIGO) and completed • RDI simplified - now independent from RSI • ETS wording corrected • INTOV now only updated for enabled interrupts (before: any change) • Renamed "SPC Data Register SDR" to "SPC Control Register SCR", it contains both data and control information • TDI wording optimized • External Registers Overview corrected • KSCFG removed
Rev_1.0D	First complete revision (To be done)
Rev_1.1D	• Moved Base Address to F032_1000 - F032_19FF (10x256 bytes) • Serial message ID added. SDSx.SCN moved to [19:16], SDSx.SCRC moved to [15:12], SDSx.MID placed at [11:8]. • RSI and TDI as trigger outputs replaced by 8 Trigger Outputs programmable in the INPs. • implemented first port mapping proposal from product
Rev_1.2	• Added hint to RCR.CEN that FSMs are initialized during enable • Port mapping updated to latest changes of CW08/47

Table 23-12 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.3	• Fixed INTENx Bit descriptions: all bits are rw and high active (typo) • added to feature list: "Programmable Nibble sorting to support LSN or HSN first and relief CPU" (was missing) • SENT_FDR.DM[1:0] added description of all 4 states of this bit field. (same as system level) • IOCR.DEPTH corrected f_{SENT} sent to f_{pdiv} (longer glitch tolerance) • Add Freeze-Disable Bit [10] to SENT_FDR (system requirement) • Pre divider factor is (PDIV + 1) and no longer PDIV (ease design) • Resulting Channel Fractional Divider is (DIV + 1) and no longer DIV • Add IOCR.TXM, RXM and TRM monitor bits (ease of validation) • RDRx added explanation: unused nibbles are shown as '0' (for clarity) • RDI and RSI: Read clears these bits NOT (request from AE) • Renamed Transmit Buffer Overflow to UNDER-Flow with change to respective functionality (data completely transmitted without new write) • RCRx.CFC: Wording improved and details added
Rev_1.4	• Added column Access Modes to Register Table • Updated **Figure 23-2**, **Figure 23-3**, **Figure 23-4** (beautification) • The clock signal f_{pdiv} of a channel must always be at least 20 (old value 10) times the nominal tick frequency, to cater for worst case. • INPx: Added reserved values • Corrected interrupt structure figure, no more separate DMA TRIGO lines. • RCRx, VIEWx and CFDRx Reset value corrected to 0x0000 0000 hex • Added explanations to RDRx and VIEWx • AI00050230 - SENT_FDR register located at "unusual" address: Moved CLC to offset 0x0Ch for consistency with other modules • Reduced ETS to 3 bit and ALTI to 2 bit width • "Zero Nibble Insertion in CRC" covered. See RCR.CRZ. • UTP AI00050205 - "Extended Serial Frame" covered. Added description of extended serial frame. SDS.SCN moved to RSR.SCN (Allows for an aligned representation of ID and Data as well as a fixed position for SCN) SDS.SD, SDS.MID, SDS.SCRC enlarged (to 16, 8 and 6 bit width) SDS.CON and RCR.ESF added • Resulting Channel Fractional Divider is DIV and no longer (DIV + 1)

Table 23-12 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.5	• Corrected TBIx description on Page 50. • SCR.TRQ corrected (deleted "Reads back zero") • Added hint to definition of Alternate CRC Mode (ACE) • Detailed RBI behavior. It is set if kernel wants to set RSI or RDI and finds RSI or RDI already set. • Detailed that RCR.CEN resets the receiver state machines only while SCR.TRIG resets the sender state machines. • RCR.WSI updated wrt. the special case "extended serial frame" (2009-06-24) • INSTAT.SCRI detailed wrt.: CRC check must include check for correct 0 values in Extended Serial Frame Format (2009-06-24) • Message tick time prolonged to 90 µs according to new standard (2009-06-24) • RCR.CFC (successive calibration pulse detection) adopted to new standard. (2009-06-24) • Updated INTSTAT.FDI wrt.: new additional error diagnostics (total frame length variation and ration calibration pulse/total frame length) in new standard. (2009-06-24)
Rev_1.6	• Added bit RCR.IDE (Ignore Drift Error) to cater for rare triggers by SPC. • Removed SV protection from SENT_FDR. • VIEW.RDNP must be set before reception. • SCR.TRQ spec' ed not active from request to pulse start. • Added "alternative CRC" spec from TLE4998 . • Changed wording for RBI. • New additional error diagnostics (total frame length variation and ration calibration pulse/total frame length) removed.
Rev_1.7	• Added note: RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV. • SCRI typo: frame 8, not 7 contains a zero value. • **Chapter 23.1.5** typo corrected: replaced f_{SENT} with $f_{fracdiv}$ • **Chapter 23.1.3.1** note added on *RCR.CRZ.* • Added hint to Chapter "Module Clock Generation" for details on CLC. • Updated Port connections and Trigger Output connections
Rev_1.8	• Changed functionality of VIEW. • Changed functionality of WSI.
Rev_1.9	• Added Time Stamping (RTSx, TSR, TPD). • SRCs removed for TC27x family

Table 23-12 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.10	• Added Tagging
Rev_1.11	• Added new BPI Registers
Rev_1.12	• Configured for 10 Channels, document automatization improved
Rev_1.13	• Writing to TPD clears TSR. • 10 interrupt sources available for TC27x • Added port mapping
Rev_1.14	• added Watch Dog Timer (Registers WDTx) • added new interrupt source for WDT: WDI • added new interrupt node pointer in INPx for WDI • added Edge Counter and Edge Counter Clear bit in IOCR • changed Time Stamp Trigger Qualifier (see register RTS)
Rev_1.15	• Modified **RCRx (x = 0-9)**.CRZ bit definitions: **CRC with Zero Nibble for Serial Data** This bit selects the CRC method. If CRZ is cleared, augmentation is selected, (i.e a ZERO NIBBLE is added at the end of CRC calculation (only in calculation)). E.g. as 7th nibble (in case of 6 data nibbles) 00-Augmentation is selected for both 4-bit message CRC and the 4-bit CRC of the serial messages (legacy, 16 frames) 01-Augmentation is switched off for both 4-bit message CRC and the 4-bit CRC of the serial messages (legacy, 16 frames) The extended serial message (18 Frames, 6-bit CRC) is not controlled by CRZ but the 6-bit CRC is always augmented according to standard.
Rev_1.16	• Modified **IOCRx (x = 0-9)**.CEC bit moved from bit position 2 to bit position 10.
Rev_1.17	• Modified **IOCRx (x = 0-9)**.EC bit from rw to rh. • Corrected on Watch dog Timer Register, statement from "The internal Watch Dog timer is cleared and started automatically each time an RDI (Receive Data Interrupt) is issued on the referring channel" to The internal Watch Dog timer is cleared and started automatically each time an RDI (Receive Data Interrupt Request Flag) is set in the INTSTAT of the referring channel.
Rev_1.18	• Modified **IOCRx (x = 0-9)** reset value to X000 0000 with additional text on IOCRx.CTR, IOCRx.TRM reset value is 0 and IOCRx.TXM, IOCRx.RXM reset value is X. •

Table 23-12 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.19	• Removed on Figure 1-1, Figure 1-26 obsolete signal HW_DIR. • Added List of Access Protection Abbreviations on **Table 23-8** • Modified on **Table 23-8**, SENT_INTSTAT, SENT_RTS, SENT_INTOV, SENT_RSR, write access to BE (Bus Error). • Modified on **Table 23-8**, for reserved locations, read/write accesses cause BE (bus error), SENT_ID write access causes BE (bus error).
Rev_1.20	• Modified on **Table 23-8**, for SENT_SDS write access causes BE (bus error). • Modified on **Table 23-8**, for SENT_RDR write access causes BE (bus error)
Rev_1.21	• Corrected on **Table 23-8** for SENT_RDRx register offset address to 80_H - 80_H+x*4_H.
Rev_1.22	• Modified text on OCS (OCDS Control and Status Register) to "The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32bit wide only and requires Supervisor Mode." • Modified for OCS.SUS for bit F_H removed and added others reserved (will not suspend)
Rev_1.23	• Updated **Table 23-11SENT I/O Control Selection and Setup**.
Rev_1.24	• Corrected on Table1-3 Service Request Lines for SENT, for last option 1111_B to TRIGO11, SRC_SENT15 • This bulleted point is not applicable for TC27x.
Rev_1.25	• This bulleted point is not applicable to TC27x, TC29x, TC24x.
Rev_1.26	• Added under CH_SENT_005 "Time stamp trigger qualifier changed."

Table 23-12 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.27	• Modified under Table1-6 SENT I/O Control Selection and Setup, for SENT channel1 in SPC mode (SPC1/P02.7) Input/Output control register bits from P00_IOCR0.PC1 = $1X110_B$ to P02.IOCR4.PC7 = $1X110_B$. • Added under Table 1-2 Registers Overview - SENT Kernel Registers, Write Access Mode with 'P' for SENT_CLC, SENT_FDR, SENT_TPD, SENT_OCS, SENT_ACCEN0, SENT_ACCEN1, SENT_KRST0, SENT_KRST1, SENT_KRSTCLR, SENT_CPDRx, SENT_CFDRx, SENT_RCRx, SENT_IOCRx, SENT_SCRx, SENT_VIEWx, SENT_INTSETx, SENT_INTCLRx, SENT_INTENx, SENT_INPx, SENT_WDTx, SENT_SRC3, SENT_SRC2, SENT_SRC1, SENT_SRC0 registers.
Rev_1.28	• Updated Table1-7 SENT I/O Control Selection and setup.
Rev_1.29	• Updated on Watch Dog Timer Register with addition of statement - and also on any write to WDL that sets WDL>0 to "The internal Watch Dog timer is cleared and started automatically each time an RDI (Receive Data Interrupt Request Flag) is set in the INTSTAT of the referring channel and also on any write to WDL that sets WDL>0."
Rev_1.30	• This bulleted point is not applicable for TC27x, TX29x, TC26x. • Changes done for this revision is not applicable for TC27x, TX29x, TC26x.
Rev_1.31	• Added note on Section under Port Control "*SENT physical layer uses 5V signal voltage levels. All SENT inputs are mapped to 5V compatible ADC pads. Vddm must be supplied with 5V for SENT operation."*
Rev_1.32	•

Table 23-12 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.33	• Modified for below: – Added Note on INTOV, Interrupt Overview Register "Not all IPC0-9 are available, the number of Interrupt Pending on Channel is equivalent to the SENT channels available, e.g 4 SENT channels has 4 Interrupt Pending IPC0-3 and vice versa." – Replaced "Fig 1-7 Standard Serial Data Encoding" in .emf with same "Table 1-1 Standard Serial Data Encoding" as framemaker table. – Replaced "Fig 1-8 Serial Data Frame" in .emf with same "Table 1-2 "Serial Data Frame" as framemaker table. – Replaced "Fig 1-9 Extended Serial Data Encoding" in .emf with same "Table 1-3 Extended Serial Data Encoding" as framemaker table. – Replaced "Fig1-11 Extended Serial Data Frame" in .emf with same "Table 1-4 Extended Serial Data Frame" – Replaced "Fig 1-12 Configuration Bit = 0" in .emf with same "Table 1-5 Configuration Bit = 0" – Replaced "Fig 1-13 Configuration Bit = 1" in .emf with same "Table 1-6 Configuration Bit = 1"
Rev_1.34	Changed minimum tick timer to 0.2 µs For TC29x only: • Removed SENT2D from P40.6 • Moved SENT5A from P40.9 to P40.5 and SENT4A from P40.8 to P40.4 where available in product
Rev_1.34a	Updated Serial Message Frame Chapter

24 FlexRay™ Protocol Controller (E-Ray)

The E-Ray IP-module performs communication according to the FlexRay™ [1] protocol specification v2.1, developed for automotive applications. With maximum specified clock the bitrate can be programmed to values up to 10 Mbit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

24.1 E-Ray Kernel Description

Figure 24-1 shows a global view of the E-Ray interface.

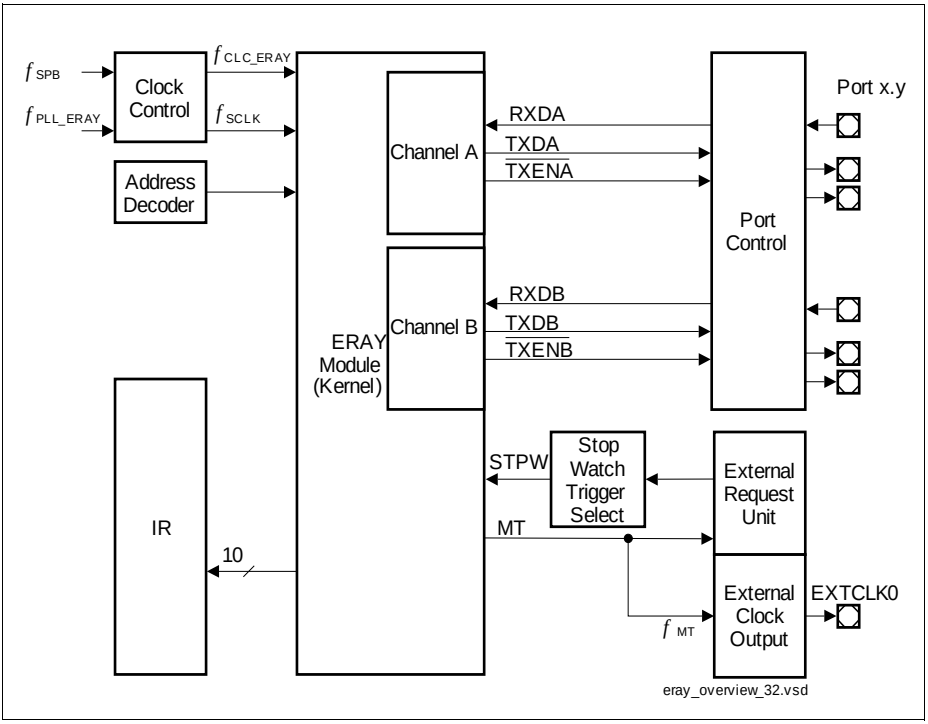


Figure 24-1 General Block Diagram of the E-Ray Interface

The E-Ray module communicates with the external world via three I/O lines each channel. The RXDAx and RXDBx lines are the receive data input signals, TXDA and

1) *Infineon®, Infineon Technologies®, are trademarks of Infineon Technologies AG. FlexRay™* is a trademark of FlexRay Consortium.

TXDB lines are the transmit output signals, $\overline{\text{TXENA}}$ and $\overline{\text{TXENB}}$ the transmit enable signals.

Clock control, address decoding, and service request control are managed outside the E-Ray module kernel.

24.2 Overview

For communication on a FlexRay™ network, individual Message Buffers with up to 254 data byte are configurable. The message storage consists of a single-ported Message RAM that holds up to 128 Message Buffers. All functions concerning the handling of messages are implemented in the Message Handler. Those functions are the acceptance filtering, the transfer of messages between the two FlexRay™ Channel Protocol Controllers and the Message RAM, maintaining the transmission schedule as well as providing message status information.

The register set of the E-Ray IP-module can be accessed directly by an external Host via the module's Host interface. These registers are used to control/configure/monitor the FlexRay™ Channel Protocol Controllers, Message Handler, Global Time Unit, System Universal Control, Frame and Symbol Processing, Network Management, Service Request Control, and to access the Message RAM via Input / Output Buffer.

The E-Ray IP-module supports the following features:

- Conformance with FlexRay™ protocol specification v2.1
- Data rates of up to 10 Mbit/s on each channel
- Up to 128 Message Buffers configurable
- 8 Kbyte of Message RAM for storage of e.g. 128 Message Buffers with max. 48 byte data field or up to 30 Message Buffers with 254 byte Data Sections
- Configuration of Message Buffers with different payload lengths possible
- One configurable receive FIFO
- Each Message Buffer can be configured as receive buffer, as transmit buffer or as part of the receive FIFO
- Host access to Message Buffers via Input and Output Buffer.
  Input Buffer: Holds message to be transferred to the Message RAM
  Output Buffer: Holds message read from the Message RAM
- Filtering for slot counter, cycle counter, and channel
- Maskable module service requests
- Network Management supported
- Four service request lines
- Automatic delayed read access to Output Command Request Register (OBCR) if a data transfer from Message RAM to Output Shadow Buffer (initiated by a previous write access to the OBCR) is ongoing.
- Automatic delayed read access to Input Command Request Register (IBCR) if a data transfer from Input Shadow Buffer to Message RAM to (initiated by a previous write access to the IBCR) is ongoing.

- Four Input Buffer for building up transmission Frames in parallel.
- Flag indicating which Input Buffer is currently accessible by the host.

24.3 Definitions

FlexRay™ Frame: Header Segment + Payload Segment

Message Buffer: Header Section + Data Section

Message RAM: Header Partition + Data Partition

Data Frame: FlexRay™ Frame that is not a NULL Frame

24.4 Block Diagram

The E-Ray is built up by the following main submodules:

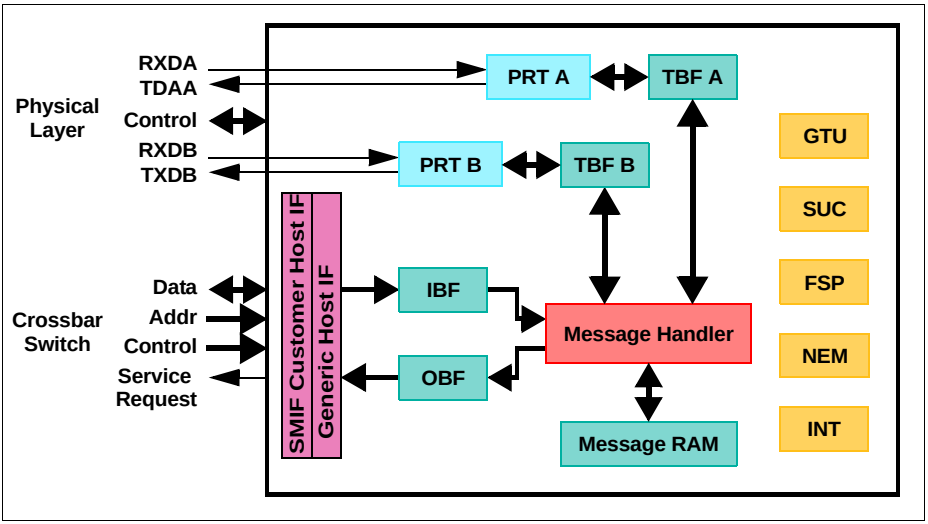

Figure 24-2 E-Ray Block Diagram

Customer Host Interface (CIF)

Connects the FPI Bus to the E-Ray IP-module via the Generic Host Interface.

Generic Host Interface (GIF)

The E-Ray IP-module is provided with an 8/16/32-bit Generic Host Interface prepared for the connection to a wide range of customer-specific Hosts. Configuration registers, status registers, and service request registers are attached to the respective blocks and can be accessed via the Generic Host Interface.

Input Buffer (IBF)

For write access to the Message Buffers configured in the Message RAM, the Host can write the Header and Data Section for a specific Message Buffer to the Input Buffer. The Message Handler then transfers the data from the Input Buffer to the selected Message Buffer in the Message RAM.

Because the Input Buffer (IBF) Scheme does only allow to write the entire Message Frame, not only parts of it, the number of IBF has been increased from originally 2 to 4. This enables to fill the buffer partly and at the end request transfer into Message RAM. Therefore 2 extra bits allow to switch between the two banks of IBF and one status bit signals the IBF currently active for Host writes.

Output Buffer (OBF)

For read access to a Message Buffer configured in the Message RAM the Message Handler transfers the selected Message Buffer to the Output Buffer. After the transfer has completed, the Host can read the Header and Data Section of the transferred Message Buffer from the Output Buffer.

Message Handler (MHD)

The E-Ray Message Handler controls data transfers between the following components:

- Input / Output Buffer and Message RAM
- Transient Buffer RAMs of the two FlexRay™ Protocol Controllers and Message RAM

Message RAM (MRAM)

The Message RAM consists of a single-ported RAM that stores up to 128 FlexRay™ Message Buffers together with the related configuration data (Header and Data Partition).

Transient Buffer RAM (TBF 1/2)

Stores the Data Section of two complete messages.

FlexRay™ Channel Protocol Controller (PRT A/B)

The FlexRay™ Channel Protocol Controllers consist of shift register and FlexRay™ protocol FSM. They are connected to the Transient Buffer RAMs for intermediate message storage and to the physical layer via bus driver BD.

They perform the following functionality:

- Control and check of bit timing
- Reception and transmission of FlexRay™ Frames and symbols
- Check of Header CRC
- Generation / check of Frame CRC

- Interfacing to bus driver

The FlexRay™ Channel Protocol Controllers have interfaces to:

- Physical Layer (bus driver)
- Transient Buffer RAM
- Message Handler
- Global Time Unit
- System Universal Control
- Frame and Symbol Processing
- Network Management
- Service Request Control

Global Time Unit (GTU)

The Global Time Unit performs the following functions:

- Generation of Microtick
- Generation of Macrotick
- Fault tolerant clock synchronization by FTM algorithm
  - Rate correction
  - Offset correction
- Cycle counter
- Timing control of static segment
- Timing control of dynamic segment (minislotting)
- Support of external clock correction

System Universal Control (SUC)

The System Universal Control controls the following functions:

- Configuration
- Wakeup
- Startup
- Normal Operation
- Passive Operation
- Monitor Mode

Frame and Symbol Processing (FSP)

The Frame and Symbol Processing controls the following functions:

- Checks the correct timing of Frames and symbols
- Tests the syntactical and semantical correctness of received Frames
- Sets the slot status flags

Network Management (NEM)

Handles of the Network Management vector

Service Request Control (INT)

The Service Request Controller performs the following functions:

- Provides error and status service request flags
- Enables and disables service request sources
- Assignment of service request sources to one of the two module service request lines
- Enables and disables module service request lines
- Manages the two service request timers
- Stop watch time capturing

24.5 Programmer's Model

The programmer's model of the E-Ray module follows the principle of memory mapped peripheral. Some portion of the memory follows the principle of segmented/paged memory organization.

24.5.1 Register Map

The E-Ray module allocates an address space of 4 Kbyte (000_H to $FFFF_H$). The registers are organized as 32-bit registers. 8/16-bit accesses are also supported. Host access to the Message RAM is done via the Input and Output Buffers. They buffer data to be transferred to and from the Message RAM under control of the Message Handler, avoiding conflicts between Host accesses and message reception / transmission. Addresses 0004_H - $000F_H$,$03C8_H$ - $03EC_H$ and 0800_H - $0FFF_H$ are reserved for customer specific purposes. All functions related to these addresses are located in the Customer Host Interface. The test registers located on address 0010_H and 0014_H are writable only under the conditions described in **"Special Registers" on Page 24-22**.

The assignment of the Message Buffers is done according to the scheme shown in **Table 24-1** below. The number N of available Message Buffers depends on the payload length of the configured Message Buffers. The maximum number of Message Buffers is 128. The maximum payload length supported is 254 byte.

The Message Buffers are separated into three consecutive groups:

- Static Buffers: Transmit / Receive Buffers assigned to static segment
- Static and Dynamic Buffers: Transmit / Receive Buffers assigned to static or dynamic segment
- FIFO- Receive FIFO

The Message Buffer separation configuration can be changed only in "DEFAULT_CONFIG" or "CONFIG" state only by programming the Message RAM Configuration register (MRC).

The first group starts with Message Buffer 0 and consists of static Message Buffers only. Message Buffer 0 is dedicated to hold the startup / SYNC Frame or the single slot Frame, if node transmit one, as configured by SUCC1.TXST, SUCC1.TXSY, and SUCC1.TSM

in the SUC Configuration Register 1 (SUCC1). In addition, Message Buffer 1 may be used for SYNC Frame transmission in case that SYNC Frames or single-slot Frames should have different payloads on the two channels. In this case bit MRC.SPLM has to be programmed to 1 and Message Buffers 0 and 1 have to be configured with the key slot ID and can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only.

The second group consists of Message Buffers assigned to the static or to the dynamic segment. Message Buffers belonging to this group may be reconfigured during run time from dynamic to static or vice versa depending on the state of MRC.SEC.

The Message Buffers belonging to the third group are concatenated to a single receive FIFO.

Table 24-1 Assignment of Message Buffers

Message Buffer 0	⇓ Static Buffers	
Message Buffer 1		
…		
	⇓ Static + Dynamic Buffers	⇐ **FDB**
	⇓ FIFO	⇐ **FFB**
Message Buffer N-1		
Message Buffer N		⇐ **LCB**

24.5.2 E-Ray Kernel Registers

This chapter describes all registers of the E-Ray kernel.

All registers in the E-Ray address spaces are reset with the application reset with one exception: OCS is reset with debug reset only. (Definition see SCU section “Reset Operation”)

Table 24-2 Registers Address Space E-Ray Kernel Register Address Space

1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

Note: Registers covered by the ACCENx write protection mechanism are marked with ´P´ in Access Mode, Write.

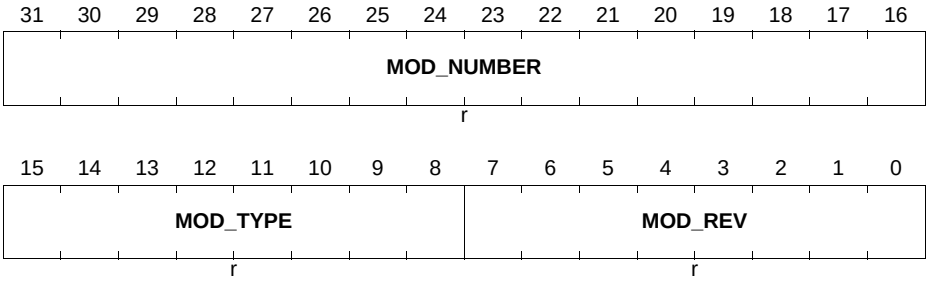
24.5.2.1 Customer Registers

The addresses 0004_H - $000F_H$,$03C8_H$ - $03EC_H$ and 0800_H - $0FFF_H$ are reserved for customer-specific registers.

Module Identification Register (ID)

This register contains bit fields identifying the E-Ray module in Infineons Module portfolio and is read only.

ID
Module Identification Register (0008_H) Reset Value: 0044 C0XX$_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Type** The value of this bit field is $C0_H$. It defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. For the E-Ray module the module identification number is 44_H.

Busy Control Register (CUST1)

The Busy Control Register enables the automatic delay scheme. Furthermore it signals a time-out service request for the automatic delay scheme. IBFS changes 2 clock cycles after any reset to ‘1’. Thus the application will read this bit as ‘1’ already at first access after any reset.

CUST1

Busy and Input Buffer Control Register

(0004_H) **Reset Value: $0000\ 0000_H$**

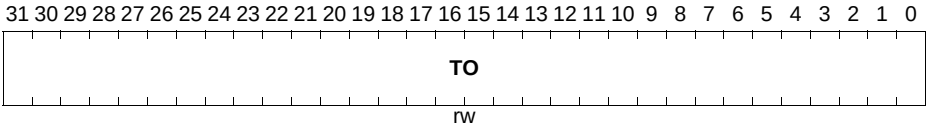
0	[6:5], [9:8], [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Customer Interface Time-out Counter Register (CUST3)

The Time-out Counter Register is realizing the time-out counter reload (startup) value for the automatic delay scheme (not the time-out down counter itself).

CUST3
Customer Interface Timeout Counter ($000C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TO	[31:0]	rw	**CIF Timeout Reload Value** The 32-bit down counter reload (start-up) value must be setup for the automatic delay scheme.

Automatic Delayed Write Access to OBCR and IBCR

Write and read accesses to the Output Buffer Control Register (OBCR) can be automatically stalled due to a ongoing transfer from the Message Buffer to the Output Buffer. Also write and read accesses to the Input Buffer Control Register (IBCR) may be automatically delayed due to a ongoing transfer from the Input Buffer to the Message Buffer.

This delay scheme can be controlled (enabled or disabled) by CUST1.IEN and CUST1.OEN. The maximum time to stall a write or read access is determined by a single time-out counter preluded with the 32-bit value specified in the bit field CUST3.TO. If the time-out counter counts down to zero before the transfer to/from the Message Buffer is completed, the access (read or write) will be canceled and a service request will be generated. A canceled read access provides a 0 value. A canceled write access does not modify any bits in the OBCR or IBCR. In addition the bit CUST1.INT0 of the service request status register will be set and must be reset by the host to disable the service request line.

The read and write access to the Output Buffer Control Register (OBCR) may be configured without automatic delay by clearing CUST1.OEN. Setting OBCR.REQ and immediately afterwards reading or writing OBCR, e.g. to set OBCR.VIEW will lead to a canceled read or write operation, e.g. OBCR.VIEW remains cleared, and an error is signalled by a set EIR.IOBA. Besides canceling the erroneous read or write operation, and setting the error bit, no further state change happens. So full operation is granted. OBCR remains read and write inaccessible until the transfer of data from the Message Buffer to the Output Buffer (MBF⇒OBF) is completed. During this time span all read and

write accesses to the Output Buffer Control Register (OBCR) are canceled. The transfer is completed when OBCR.OBSYS is cleared. Additionally signal TOBC may be used, e.g. for service request triggering, DMA triggering, or driving a pin, to communicate the access status.

The read and write access to the Output Buffer Control Register (OBCR) may be configured to be automatic delayed by setting CUST1.OEN and configuring CUST3.TO to the maximum stall time acceptable to the system. If setting OBCR.REQ and immediately afterwards reading or writing to OBCR, e.g. to set the OBCR.VIEW bit, this read or write will be stalled until either the maximum delay time elapsed (in this case the read or write operation is cancelled after the stall time, e.g. OBCR.VIEW remains cleared, and an error is signalled by setting EIR.IOBA) or the read or write completes normally, e.g. set OBCR.VIEW after the transfer of data from the Message Buffer to the Output Buffer (MBF⇒OBF) is finalized. During this time the bus is locked and no further access to the E-Ray module is possible due to the ongoing stalled read or write operation. Because no access is possible to the E-Ray module, read or write stall may only be detected through the signal TOBC or due to other not processed read or write accesses to the E-Ray module.

The read and write access to the Input Buffer Control Register (IBCR) may also be configured without automatic delay by clearing CUST1.IEN. By writing to IBCR.IBRH the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF), the content of the shadow IBF is copied into the MBF (IBF⇒MBF), and IBCR.IBSYS is set. Writing to IBCR.IBRH a second time while IBCR.IBSYS remained set (previously initiated copy process IBF⇒MBF ongoing) will correctly update IBCR.IBRH and set IBCR.IBSYH. This will set the signal IBUSY. A third access, read or write, to IBCR while IBCR.IBSYH remains set will cancel this third access and an error is signalled by setting EIR.IIBA. Besides canceling this last access to IBCR and setting the error bit, no further state change happens. So full operation is granted. IBCR remains read and write inaccessible until the transfer of data from the Input Shadow Buffer to the Message Buffer (IBF⇒MBF) is completed and once more the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF). During this time span all read and write accesses to the Input Buffer Control Register (IBCR) are canceled. The transfer is completed when IBCR.IBSYH is cleared. Additionally signal TIBC may be used, e.g. for service request triggering, DMA triggering, or driving a pin, to communicate the access status.

The read and write access to the Input Buffer Control Register (IBCR) may be configured for being automatically delayed by setting CUST1.IEN and configuring CUST3.TO to the maximum stall time acceptable to the system. By writing to IBCR.IBRH the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF), the content of the shadow IBF copied into the MBF, and IBCR.IBSYS is set. Writing to IBCR.IBRH a second time while IBCR.IBSYS remains set (previously initiated copy process ongoing) will correctly update IBCR.IBRH and set IBCR.IBSYH. A third access to IBCR while IBCR.IBSYH remains set will stall this read or write until either the maximum delay

time elapsed (in this case the read or write operation is cancelled after the stall time and an error is signalled by setting EIR.IOBA) or the read or write completes normally, after the transfer of data from the Input Shadow Buffer to the Message Buffer (IBF⇒MBF) is finalized and once more the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF). During this time the bus is locked and no further access to E-Ray module is possible due to the ongoing stalled read or write operation. Because no access is possible to the E-Ray module, read or write stall may only be detected through the signal TIBC or due to other not processed read or write accesses to the E-Ray module.

So setting CUST3.TO = $FFFFFFFF_H$, CUST1.IEN = 1, and CUST1.OEN = 1 will always grant a consistent data access of the host to the Output and Input Buffers without the need of reading and taking into account the status of OBCR.OBSYS or IBCR.IBSYH. But this simplified access may cause system latencies and system performance loss.

24.5.2.2 Special Registers

Test Register 1 (TEST1)

The Test Register 1 holds the control bits to configure the test modes of the E-Ray module. Write access to these bits is only possible if bit TEST1.WRTEN is set.

The Test Register 1 bits therefore can be used to test the interface to the physical layer (connectivity test) by driving / reading the respective pins.

When the E-Ray IP is operated in one of its test modes that requires TEST1.WRTEN to be set (RAM Test Mode, I/O Test Mode, Asynchronous Transmit Mode, and Loop Back Mode) only the selected test mode functionality is available.

The test functions are not available in addition to the normal operational mode functions, they change the functions of parts of the E-Ray module. Therefore normal operation as specified outside this chapter and as required by the FlexRay™ protocol specification and the FlexRay™ conformance test is not possible. Test mode functions may not be combined with each other or with FlexRay™ protocol functions.

The test mode features are intended for hardware testing or for FlexRay™ bus analyzer tools. They are not intended to be used in FlexRay™ applications

TEST1
Test Register 1 **(0010_H)** **Reset Value: $0000\ 0300_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0						AOB	AOA	0		TMC		0		ELBE	WRTEN
r						rh	rh	r		rw		r		rw	rw

Field	Bits	Type	Description
WRTEN	0	rw	**Write Test Register Enable** Enables write access to the test registers. To set the bit from 0 to 1 the test mode key has to be written as defined on **"Lock Register (LCK)" on Page 24-30**. The unlock sequence is not required when TEST1.WRTEN is kept at 1 while other bits of the register are changed. The bit can be reset to 0 at any time. 0_B Write access to test registers disabled. 1_B Write access to test registers enabled.

Field	Bits	Type	Description
ELBE	1	rw	**External Loop Back Enable** There are two possibilities to perform a loop back test. External loop back via physical layer or internal loop back for in-system self-test (default). In case of an internal loop back pins TXENA and TXENB are in their inactive state, pins TXDA and TXDB are set to HIGH, pins RXDA and RXDB are not evaluated. Bit ELBE is evaluated only when POC is in loop back mode and test multiplexer control is in non multiplexed mode TMC = 00. 0_B Internal loop back (default) 1_B External loop back
TMC	[5:4]	rw	**Test Multiplexer Control** 00_B Normal signal path (default). 01_B RAM Test Mode: Internal busses are multiplexed to make all RAM blocks of the E-Ray module directly accessible by the Host. This mode is intended to enable testing of the embedded RAM blocks during production testing. 10_B I/O Test Mode: Output pins are driven to the values defined by bits TXA, TXB, TXENA, TXENB. The values applied to the input pins can be read from register bits RXA and RXB. 11_B Reserved; should not be used.
AOA	8	rh	**Activity on A** The channel idle condition is specified in the FlexRay™ protocol spec v2.1, chapter 3, BITSTRB process (zChannelIdle). 0_B No activity detected, channel A idle 1_B Activity detected, channel A not idle
AOB	9	rh	**Activity on B** The channel idle condition is specified in the FlexRay™ protocol spec v2.1, chapter 3, BITSTRB process (zChannelIdle). 0_B No activity detected, channel B idle 1_B Activity detected, channel B not idle
RXA	16	rh	**Read Channel A Receive Pin** 0_B RXDA = 0 1_B RXDA = 1

Field	Bits	Type	Description
RXB	17	rh	**Read Channel B Receive Pin** 0_B RXDB = 0 1_B RXDB = 1
TXA	18	rwh	**Read or Write to Channel A Transmit Pin** 0_B TXDA = 0 1_B TXDA = 1
TXB	19	rwh	**Read or Write to Channel B Transmit Pin** 0_B TXDB = 0 1_B TXDB = 1
TXENA	20	rwh	**Read or Write to Channel A Transmit Enable Pin** 0_B $\overline{\text{TXENA}}$= 0 1_B $\overline{\text{TXENA}}$= 1
TXENB	21	rwh	**Read or Write to Channel B Transmit Enable Pin** 0_B $\overline{\text{TXENB}}$ = 0 1_B $\overline{\text{TXENB}}$= 1
CERA	[27:24]	rh	**Coding Error Report Channel A[1)]** Set when a coding error is detected on channel A. Reset to zero when register TEST1 is read or written. Once the CERA is set it will remain unchanged until the Host accesses the TEST1 register. 0000_B No coding error detected 0001_B Header CRC error detected 0010_B Frame CRC error detected 0011_B Frame Start Sequence FSS too long 0100_B First bit of Byte Start Sequence BSS seen LOW 0101_B Second bit of Byte Start Sequence BSS seen HIGH 0110_B First bit of Frame End Sequence FES seen HIGH 0111_B Second bit of Frame End Sequence FES seen LOW 1000_B CAS / MTS symbol seen too short 1001_B CAS / MTS symbol seen too long Other combinations are reserved.

Field	Bits	Type	Description
CERB	[31:28]	rh	**Coding Error Report Channel B[1)]** Set when a coding error is detected on channel B. Reset to zero when register TEST1 is read or written. Once the CERB is set it will remain unchanged until the Host accesses the TEST1 register. 0000_B No coding error detected 0001_B Header CRC error detected 0010_B Frame CRC error detected 0011_B Frame Start Sequence FSS too long 0100_B First bit of Byte Start Sequence BSS seen LOW 0101_B Second bit of Byte Start Sequence BSS seen HIGH 0110_B First bit of Frame End Sequence FES seen HIGH 0111_B Second bit of Frame End Sequence FES seen LOW 1000_B CAS / MTS symbol seen too short 1001_B CAS / MTS symbol seen too long Other combinations are reserved.
0	[3:2], [7:6], [15:10], [23:22]	r	**Reserved** Returns 0 if read; should be written with 0.

1) Coding errors are also signalled when the Communication Controller is in “MONITOR_MODE”. The error codes regarding CAS / MTS symbols concern only the monitored bit pattern, irrelevant whether those bit patterns are seen in the symbol window or elsewhere.

Asynchronous Transmit Mode (ATM)

The asynchronous transmit mode is entered by writing 1110_B to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1 (CHI command: ATM) while the Communication Controller is in “CONFIG” state and bit TEST1.WRTEN in the Test Register 1 is set. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit TEST1.WRTEN is not set, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. CCSV.POCS in the Communication Controller Status Vector will return 1110_B while the E-Ray module is in ATM mode. Asynchronous Transmit mode can be left by writing 0001_B (CHI command: “CONFIG”) to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1.

In ATM mode transmission of a FlexRay™ Frame is triggered by writing the number of the respective Message Buffer to the Input Buffer Command Request register (IBCR.IBRH) while bit IBCM.STXRS in the Input Buffer Command Mask register is set to 1. In this mode wake-up, startup, and clock synchronization are bypassed. The CHI command SEND_MTS results in the immediate transmission of an MTS symbol.

The cycle counter value of Frames send in ATM mode can be programmed via MTCCV.CCV (writable in ATM and loop back mode only).

Loop Back Mode

The loop back mode is entered by writing 1111_B to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1 (CHI command: LOOP_BACK) while the Communication Controller is in “CONFIG” state and bit TEST1.WRTEN in the Test Register 1 is set. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit TEST1.WRTEN is not set, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. CCSV.POCS in the Communication Controller Status Vector will show 0000 1101_H while the E-Ray module is in loop back mode.

Loop Back mode can be left by writing 0001_B (CHI command: “CONFIG”) to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1.

The loop back test mode is intended to check the module’s internal data paths. Normal, time triggered operation is not possible in loop back mode.

There are two possibilities to perform a loop back test. External loop back via physical layer (TEST1.ELBE = 1) or internal loop back for in-system self-test (TEST1.ELBE = 0). In case of an internal loop back pins $\overline{\text{TXENA}}$, $\overline{\text{TXENB}}$ are in their inactive state, pins TXDA and TXDB are set to HIGH, pins RXDAn and RXDBn are not evaluated.

When the Communication Controller is in loop back mode, a loop back test is started by the Host writing a message to the Input Buffer and requesting the transmission by writing to the Input Buffer Command Request register IBCR. The Message Handler will transfer the message into the Message RAM and then into the Transient Buffer of the selected channel. The Channel Protocol Controller (PRT) will read (in 32-bit words) the message from the transmit part of the Transient Buffer and load it into its Rx / Tx shift register. The serial transmission is looped back into the shift register; its content is written into the receive part of the channels’s Transient Buffer before the next word is loaded.

The PRT and the Message Handler will then treat this transmitted message like a received message, perform an acceptance filtering on Frame ID and receive channel, and store the message into the Message RAM if it passed acceptance filtering. The loop back test ends with the Host requesting this received message from the Message RAM and then checking the contents of the Output Buffer.

Each FlexRay™ channel is tested separately. The E-Ray cannot receive messages from the FlexRay™ bus while it is in the loop back mode.

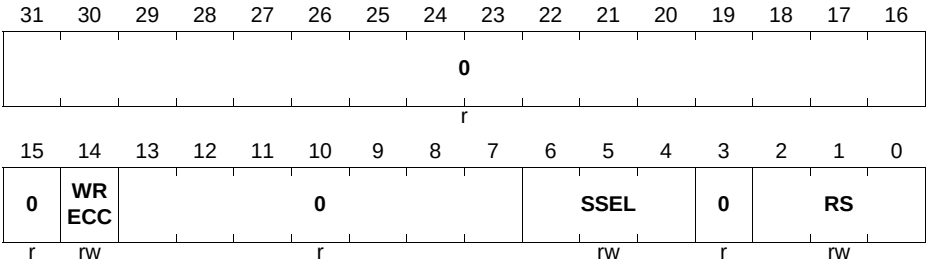
The cycle counter value of Frames used in loop back mode can be programmed via MTCCV.CCV (writable in ATM and loop back mode only).

Note that in case of an odd payload the last two bytes of the looped-back payload will be shifted by 16 bits to the right inside the last 32-bit data word.

Test Register 2 (TEST2)

The Test Register 2 holds all bits required for the RAM test of the seven embedded RAM blocks of the E-Ray module. Write access to this register is only possible when TEST1.WRTEN in the Test Register 1 is set to 1.

TEST2
Test Register 2 **(0014_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RS	[2:0]	rw	**RAM Select** In RAM Test mode the RAM blocks selected by RS are mapped to module address $0000\ 0400_H$ to $0000\ 07FF_H$ (1024 byte addresses). 000_B Input Buffer RAM 1 (IBF1) 001_B Input Buffer RAM 2 (IBF2) 010_B Output Buffer RAM 1 (OBF1) 011_B Output Buffer RAM 2 (OBF2) 100_B Transient Buffer RAM A (TBF1) 101_B Transient Buffer RAM B (TBF2) 110_B Message RAM (MBF) 111_B Reserved; should not be used.

Field	Bits	Type	Description
SSEL	[6:4]	rw	**Segment Select** To enable access to the complete Message RAM (8192 byte addresses) the Message RAM is segmented. 000_B access to RAM byte 0000_H to $03FF_H$ enabled 001_B access to RAM byte 0400_H to $07FF_H$ enabled 010_B access to RAM byte 0800_H to $0BFF_H$ enabled 011_B access to RAM byte $0C00_H$ to $0FFF_H$ enabled 100_B access to RAM byte 1000_H to $11FF_H$ enabled 101_B access to RAM byte 1400_H to $17FF_H$ enabled 110_B access to RAM byte 1800_H to $1BFF_H$ enabled 111_B access to RAM byte $1C00_H$ to $1FFF_H$ enabled
WR ECC	14	rw	**Write ECC Data Enable** Content of ECCW is transferred to the RAM: 0_B disabled 1_B enabled *Note: Test mode must be entered. See* ***"Test Register 1 (TEST1)" on Page 24-22***
0	3, [13:7], 15, [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

RAM Test Mode

In RAM test mode (TEST1.TMC = 1), one of the seven RAM blocks can be selected for direct RD/WR access by programming TEST2.RS.

For external access the selected RAM block is mapped to address space 400_H to $7FF_H$ (1024 byte addresses or 256 word addresses).

Because the length of the Message RAM exceeds the available address space, the Message RAM is segmented into segments of 1024 byte. The segments can be selected by programming TEST2.SSEL in the Test Register 2.

In RAM test mode the memory must be accessed with 32Bit accesses only.

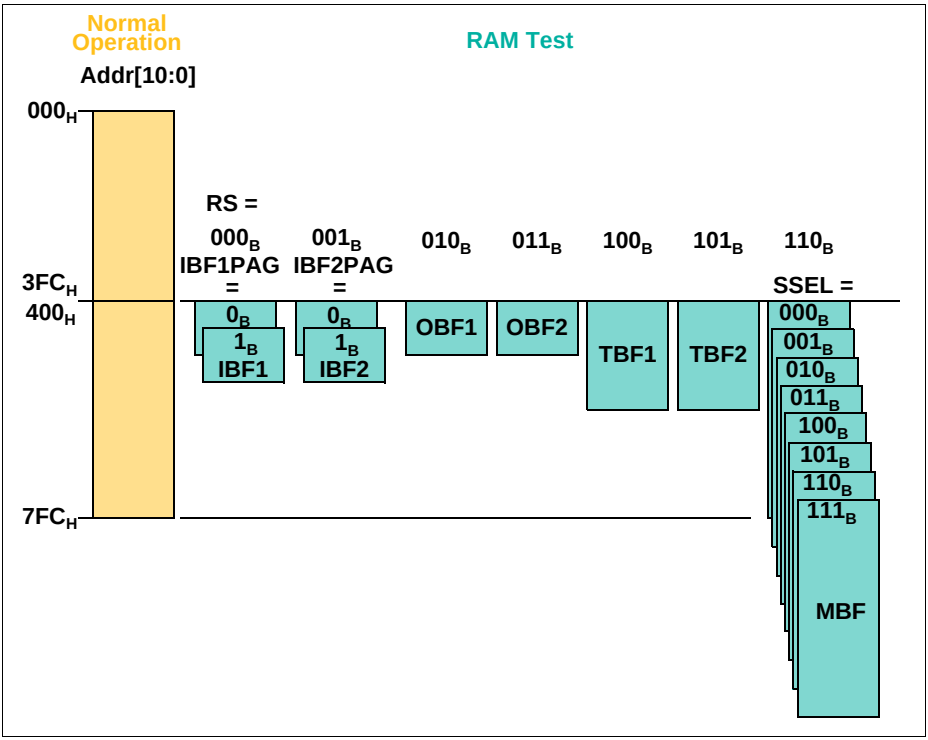


Figure 24-3 RAM test mode Access to E-Ray RAM Blocks

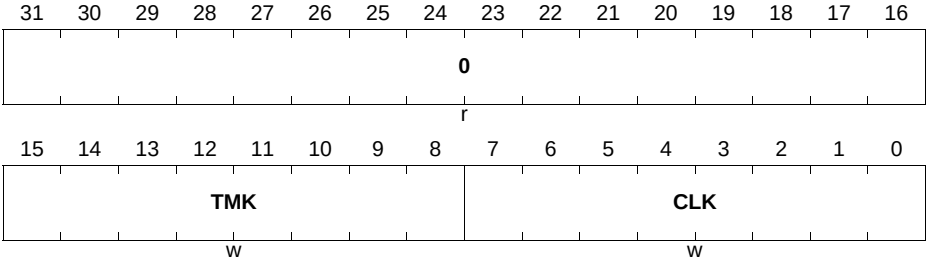
Lock Register (LCK)

The Lock Register is write-only. Reading the register will return 0000 0000_H.

LCK
Lock Register **($001C_H$)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CLK	[7:0]	w	**Configuration Lock Key** To leave “CONFIG” state by writing to SUCC1.CMD commands READY, MONITOR_MODE, ATM, LOOP_BACK) in the SUC Configuration Register 1, the write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). If the write sequence below is interrupted by other write accesses between the second write to the Configuration Lock Key and the write access to the SUCC1 register, the Communication Controller remains in “CONFIG” state and the sequence has to be repeated. First write: LCK.CLK = CE_H = $1100\ 1110_B$ Second write: LCK.CLK = 31_H = $0011\ 0001_B$ Third write: SUCC1.CMD Returns 0 if read

Field	Bits	Type	Description
TMK	[15:8]	w	**Test Mode Key** To set bit TEST1.WRTEN the write operation has to be directly preceded by two consecutive write accesses to the Test Mode Key. If the write sequence is interrupted by other write accesses between the second write to the Test Mode Key and the write access to the Test1 register, bit TEST1.WRTEN is not set to 1 and the sequence has to be repeated. First write: LCK.TMK = 75_H = 0111 0101_B Second write: LCK.TMK = $8A_H$ = 1000 1010_B Second write: TEST1.WRTEN = 1 Returns 0 if read
0	[31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: In case the Host uses 8/16-bit accesses to write the listed bit fields, the programmer has to ensure that no "dummy accesses" e.g. to the remaining register bytes / words are inserted by the compiler.

To exit "CONFIG" state by writing to SUCC1.CMD in the SUC Configuration Register 1, the write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key. If this write sequence is service requested by read accesses or write accesses to other locations, the Communication Controller remains in "CONFIG" state and the sequence has to be repeated.

First write: LCK.CLK = CE_H = 1100 1110_B

Second write: LCK.CLK = 31_H = 0011 0001_B

24.5.2.3 Service Request Registers

The address space from 0020_H to $007F_H$ is reserved for service request registers.

Error Service Request Select (EIR)

The flags are set when the Communication Controller detects one of the listed error conditions. They remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

EIR
Error Service Request Register (0020_H) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r				rwh	rwh	rwh	rwh	rh	rh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
PEMC	0	rwh	**POC Error Mode Changed** This flag is set whenever the error mode signalled by CCEV.ERRM in the Communication Controller Error Vector register has changed. 0_B Error mode has not changed 1_B Error mode has changed This flag is cleared by writing a 1.
CNA	1	rwh	**Command Not Accepted** The flag signals that the write access to the CHI command vector SUCC1.CMD in the SUC Configuration Register 1 was not successful because the requested command was not valid in the actual POC state, or because the CHI command was locked (CCL = 1). 0_B CHI command accepted 1_B CHI command not accepted This flag is cleared by writing a 1.

Field	Bits	Type	Description
SFBM	2	rwh	**SYNC Frames Below Minimum** This flag signals that the number of SYNC Frames received during the last communication cycle was below the limit required by the FlexRay™ protocol. May be set during startup and therefore should be cleared by the Host after the Communication Controller entered “NORMAL_ACTIVE” state. 0_B Sync node: 1 or more SYNC Frames received Non-sync node: 2 or more SYNC Frames received 1_B Less than the required minimum of SYNC Frames received This flag is cleared by writing a 1.
SFO	3	rwh	**SYNC Frame Overflow** Set when either the number of SYNC Frames received during the last communication cycle or the total number of SYNC Frames received during the last double cycle exceeds the maximum number of SYNC Frames as defined by GTUC02.SNM in the GTU Configuration Register 2. 0_B Number of received SYNC Frames ≤ GTUC02.SNM 1_B More SYNC Frames received than configured by GTUC02.SNM This flag is cleared by writing a 1.
CCF	4	rwh	**Clock Correction Failure** This flag is set at the end of the cycle whenever one of the following errors occurred: • Missing offset and / or rate correction • Clock Correction limit reached The clock correction status is monitored in registers CCEV and SFS. A failure may occur during startup, therefore bit CCF should be cleared by the Host after the Communication Controller entered “NORMAL_ACTIVE” state. 0_B Clock correction successful so far 1_B Clock correction failed This flag is cleared by writing a 1.

Field	Bits	Type	Description
CCL	5	rwh	**CHI Command Locked** The flag signals that the write access to the CHI command vector SUCC1.CMD was not successful because the execution of the previous CHI command has not yet completed. In this case bit EIR.CNA is also set to 1. 0_B CHI command accepted 1_B CHI command not accepted This flag is cleared by writing a 1.
EERR	6	rh	**ECC Error** The flag signals an ECC error to the Host. It is set whenever one of the flags MHDS.EIBF, MHDS.EOBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2 changes from 0 to 1. See also **"Message Handler Status (MHDS)" on Page 24-136**. This bit must be cleared at initialization of the module! 0_B No error detected 1_B Error detected
RFO	7	rh	**Receive FIFO Overrun** The flag is set by the Communication Controller when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. The actual state of the FIFO is monitored in register FSR. 0_B No receive FIFO overrun detected 1_B A receive FIFO overrun has been detected
EFA	8	rwh	**Empty FIFO Access** This flag is set by the Communication Controller when the Host requests the transfer of a message from the receive FIFO via Output Buffer while the receive FIFO is empty. 0_B No Host access to empty FIFO occurred 1_B Host access to empty FIFO occurred

Field	Bits	Type	Description
IIBA	9	rwh	**Illegal Input Buffer Access** This flag is set by the Communication Controller when the Host wants to modify a Message Buffer via Input Buffer while the Communication Controller is not in “CONFIG” or “DEFAULT_CONFIG” state and one of the following conditions applies: 1. The Host writes to the Input Buffer Command Request register to modify the: a) Header Section of Message Buffer 0, 1 if configured for transmission in key slot b) Header Section of static Message Buffers with buffer number < MRC.FDB while MRC.SEC = 01_B c) Header Section of any static or dynamic Message Buffer while MRC.SEC = $1x_B$ d) Header and / or Data Section of any message buffer belonging to the receive FIFO 2. The Host writes to any register of the Input Buffer while IBCR.IBSYS is set. 0_B No illegal Host access to Input Buffer occurred 1_B Illegal Host access to Input Buffer occurred
IOBA	10	rwh	**Illegal Output Buffer Access** This flag is set by the Communication Controller when the Host requests the transfer of a Message Buffer from the Message RAM to the Output Buffer while OBCR.OBSYS is set to 1. 0_B No illegal Host access to Output Buffer occurred 1_B Illegal Host access to Output Buffer occurred
MHF	11	rwh	**Message Handler Constraints Flag** The flag signals a Message Handler constraints violation condition. It is set whenever one of the flags MHDF.SNUA, MHDF.SNUB, MHDF.FNFA, MHDF.FNFB, MHDF.TBFA, MHDF.TBFB, MHDF.TNSA, MHDF.TNSB, MHDF.WAHP changes from 0 to 1. 0_B No Message Handler failure detected 1_B Message Handler failure detected

Field	Bits	Type	Description
EDA	16	rwh	**Error Detected on Channel A** This bit is set whenever one of the flags ACS.SEDA, ACS.CEDA, ACS.CIA, ACS.SBVA changes from 0 to 1. 0_B No error detected on channel A 1_B Error detected on channel A This flag is cleared by writing a 1.
LTVA	17	rwh	**Latest Transmit Violation Channel A** The flag signals a latest transmit violation on channel A to the Host. 0_B No latest transmit violation detected on channel A 1_B Latest transmit violation detected on channel A This flag is cleared by writing a 1.
TABA	18	rwh	**Transmission Across Boundary Channel A** The flag signals to the Host that a transmission across a slot boundary occurred for channel A. 0_B No transmission across slot boundary detected on channel A 1_B Transmission across slot boundary detected on channel A This flag is cleared by writing a 1.
EDB	24	rwh	**Error Detected on Channel B** This bit is set whenever one of the flags ACS.SEDB, ACS.CEDB, ACS.CIB, ACS.SBVB changes from 0 to 1. 0_B No error detected on channel B 1_B Error detected on channel B This flag is cleared by writing a 1.
LTVB	25	rwh	**Latest Transmit Violation Channel B** The flag signals a latest transmit violation on channel B to the Host. 0_B No latest transmit violation detected on channel B 1_B Latest transmit violation detected on channel B This flag is cleared by writing a 1.

Field	Bits	Type	Description
TABB	26	rwh	**Transmission Across Boundary Channel B** The flag signals to the Host that a transmission across a slot boundary occurred for channel B. 0_B No transmission across slot boundary detected on channel B 1_B Transmission across slot boundary detected on channel B This flag is cleared by writing a 1.
0	[15:12], [23:19], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

Status Service Request Register (SIR)

The flags are set whenever the Communication Controller detects one of the listed events. The flags remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

SIR
Status Service Request Register (0024$_H$) Reset Value: 0000 0000$_H$

Field	Bits	Type	Description
WST	0	rwh	**Wakeup Status** This flag is set when the wakeup status vector CCSV.WSV in the Communication Controller Status Vector register changes to a value other than UNDEFINED. 0_B Wake-up status unmodified 1_B Wake-up status modified (and not UNDEFINED) This flag is cleared by writing a 1.
CAS	1	rwh	**Collision Avoidance Symbol** This flag is set by the Communication Controller during STARTUP state when a CAS or potential CAS was received. 0_B No bit pattern matching the CAS symbol received 1_B Bit pattern matching the CAS symbol received This flag is cleared by writing a 1.
CYCS	2	rwh	**Cycle Start Service Request** This flag is set by the Communication Controller when a communication cycle starts 0_B No communication cycle started 1_B Communication cycle started This flag is cleared by writing a 1.

Field	Bits	Type	Description
TXI	3	rwh	**Transmit Service Request** This flag is set by the Communication Controller at the end of Frame transmission if bit WRHS1.MBI in the respective Message Buffer is set (see **Table 24-24**). 0_B No Frame transmitted from a transmit buffer with WRHS1.MBI = 1 1_B At least one Frame was transmitted from a transmit buffer with WRHS1.MBI = 1 This flag is cleared by writing a 1.
RXI	4	rwh	**Receive Service Request** This flag is set by the Communication Controller whenever the set condition of a Message Buffer ND flag is fulfilled and if bit WRHS1.MBI of that Message Buffer is set to 1(see **Table 24-24**). 0_B No ND flag of a receive buffer with WRHS1.MBI = 1 has been set to 1 1_B At least one ND flag of a receive buffer with WRHS1.MBI = 1 has been set to 1 This flag is cleared by writing a 1.
RFNE	5	rh	**Receive FIFO Not Empty** This flag is set by the Communication Controller when a received valid Frame was stored into the empty receive FIFO.m The actual state of the receive FIFO is monitored in register FSR 0_B Receive FIFO is empty 1_B Receive FIFO is not empty
RFCL	6	rh	**Receive FIFO Critical Level** This flag is set when a valid receive FIFO fill level FSR.RFFL is equal or greater than the critical level as configured by FCL.CL. 0_B Receive FIFO below critical level 1_B Receive FIFO critical level reached
NMVC	7	rwh	**Network Management Vector Changed** This service request flag signals a change in the Network Management Vector visible to the Host. 0_B No change in the Network Management vector 1_B Network Management vector changed This flag is cleared by writing a 1.

Field	Bits	Type	Description
TI0	8	rwh	**Timer Service Request 0** This flag is set whenever timer 0 matches the conditions configured in the Timer Service Request 0 Configuration Register T0C. A Timer Service Request 0 is also signalled by TINT0SRC . 0_B No Timer Service Request 0 1_B Timer Service Request 0 occurred This flag is cleared by writing a 1.
TI1	9	rwh	**Timer Service Request 1** This flag is set whenever the conditions programmed in the Timer Service Request 1 Configuration Register T1C are met. A Timer Service Request 1 is also signalled by TINT1SRC. 0_B No Timer Service Request 1 1_B Timer Service Request 1 occurred This flag is cleared by writing a 1.
TIBC	10	rwh	**Transfer Input Buffer Completed** This flag is set whenever a transfer from Input Buffer to the Message RAM has completed and bit IBCR.IBSYS in the Input Buffer Command Request register has been reset by the Message Handler. 0_B No transfer completed 1_B Transfer between Input Buffer and Message RAM completed This flag is cleared by writing a 1.
TOBC	11	rwh	**Transfer Output Buffer Completed** This flag is set whenever a transfer from Message RAM to the Output Buffer has completed and bit OBCR.OBSYS in the Output Buffer Command Request register has been reset by the Message Handler. 0_B No transfer completed 1_B Transfer between Message RAM and the Output Buffer completed This flag is cleared by writing a 1.
SWE	12	rwh	**Stop Watch Event** This flag is set after a stop watch activation when the current cycle counter and Macrotick value are stored in the Stop Watch Register 1 (STPW1). 0_B No Stop Watch Event 1_B Stop Watch Event occurred This flag is cleared by writing a 1.

Field	Bits	Type	Description
SUCS	13	rwh	**Startup Completed Successfully** This flag is set whenever a startup completed successfully and the Communication Controller entered “NORMAL_ACTIVE” state. 0_B No startup completed successfully 1_B Startup completed successfully This flag is cleared by writing a 1.
MBSI	14	rwh	**Message Buffer Status Service Request** This flag is set by the Communication Controller when the Message Buffer status MBS has changed and if bit RDHS1.MBI of that Message Buffer is set (see **Table 24-24**). 0_B No Message Buffer status change of Message Buffer with RDHS1.MBI= 1 has changed 1_B Message Buffer status of at least one Message Buffer with RDHS1.MBI= 1 has changed This flag is cleared by writing a 1.
SDS	15	rwh	**Start of Dynamic Segment** This flag is set by the Communication Controller when the dynamic segment starts. 0_B Dynamic segment not yet started 1_B Dynamic segment started
WUPA	16	rwh	**Wakeup Pattern Channel A** This flag is set by the Communication Controller when a wakeup pattern was received on channel A. Only set when the Communication Controller is in “WAKEUP”, “READY”, or “STARTUP” state, or when in Monitor mode. 0_B No wake-up pattern received on channel A 1_B Wake-up pattern received on channel A This flag is cleared by writing a 1.
MTSA	17	rwh	**MTS Received on Channel A** (vSS!ValidMTSA) Media Access Test symbol received on channel A during the proceeding symbol window. Updated by the Communication Controller for each channel at the end of the symbol window. 0_B No MTS symbol received on channel A 1_B MTS symbol received on channel A This flag is cleared by writing a 1.

Field	Bits	Type	Description
WUPB	24	rwh	**Wakeup Pattern Channel B** This flag is set by the Communication Controller when a wakeup pattern was received on channel B. Only set when the Communication Controller is in “WAKEUP”, “READY”, or “STARTUP” state, or when in Monitor mode. 0_B No wake-up pattern received on channel B 1_B Wake-up pattern received on channel B This flag is cleared by writing a 1.
MTSB	25	rwh	**MTS Received on Channel B** (vSS!ValidMTSB) Media Access Test symbol received on channel B during the proceeding symbol window. Updated by the Communication Controller for each channel at the end of the symbol window. 0_B No MTS symbol received on channel B 1_B MTS symbol received on channel B This flag is cleared by writing a 1.
0	[23:18], [31:26]	r	**Reserved** Returns 0 if read; should be written with 0.

Error Service Request Line Select (EILS)

The Error Service Request Line Select register assigns a service request generated by a specific error service request flag from register EIR to one of the two module service request lines INT0SRC or INT1SRC:

0 = Interrupt assigned to interrupt line (INT0SRC)

1 = Interrupt assigned to interrupt line (INT1SRC)

EILS

Status Service Request Line Select (SILS)

The Status Service Request Line Select register assign an service request generated by a specific status service request flag from register SIR to one of the two module service request lines INT0SRC or INT1SRC:

0 = Interrupt assigned to interrupt line INT0SRC

1 = Interrupt assigned to interrupt line INT1SRC

SILS

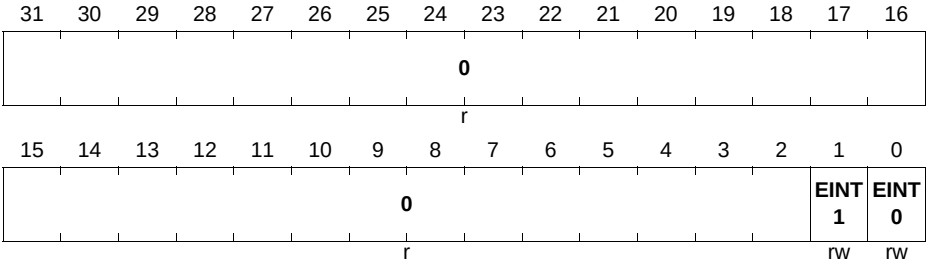
Service Request Line Enable (ILE)

Each of the two service request lines to the Host INT0SRC, INT1SRC can be enabled / disabled separately by programming bit EINT0 and EINT1.

ILE
Service Request Line Enable **(0040_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
EINT0	0	rw	**Enable Service Request Line 0** (INT0SRC) 0_B Service Request line disabled 1_B Service Request line enabled
EINT1	1	rw	**Enable Service Request Line 1** (INT1SRC) 0_B Service Request line disabled 1_B Service Request line enabled
0	[31:2]	r	**Reserved** Returns 0 if read; should be written with 0.

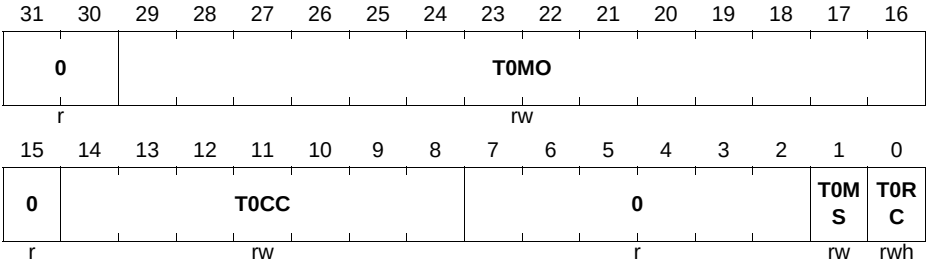
Timer 0 Configuration (T0C)

Absolute timer. Specifies in terms of cycle count and Macrotick the point in time when the timer 0 service request occurs. When the timer 0 service request is asserted, output signal TINT0SR is set to 1 for the duration of one Macrotick and SIR.TI0 is set to 1.

Timer 0 can be activated as long as the POC is either in “NORMAL_ACTIVE” state or in “NORMAL_PASSIVE” state. Timer 0 is deactivated when leaving “NORMAL_ACTIVE” state or “NORMAL_PASSIVE” state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by writing 0 to bit T0RC.

T0C
Timer 0 Configuration **(0044_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T0RC	0	rwh	**Timer 0 Run Control** 0_B Timer 0 halted 1_B Timer 0 running
T0MS	1	rw	**Timer 0 Mode Select** 0_B Single-shot mode 1_B Continuous mode
T0CC	[14:8]	rw	**Timer 0 Cycle Code** The 7-bit timer 0 cycle code determines the cycle set used for generation of the timer 0 service request. For details about the configuration of the cycle code see **“Cycle Counter Filtering” on Page 24-215**.
T0MO	[29:16]	rw	**Timer 0 Macrotick Offset** Configures the Macrotick offset from the beginning of the cycle where the service request is to occur. The Timer 0 Service Request occurs at this offset for each cycle of the cycle set.

Field	Bits	Type	Description
0	[7:2], 15, [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: The configuration of timer 0 is compared against the Macrotick counter value, there is no separate counter for timer 0. In case the Communication Controller leaves "NORMAL_ACTIVE" or "NORMAL_PASSIVE" state, or if timer 0 is halted by Host command, output signal TINT0SR *is reset to 0 immediately.*

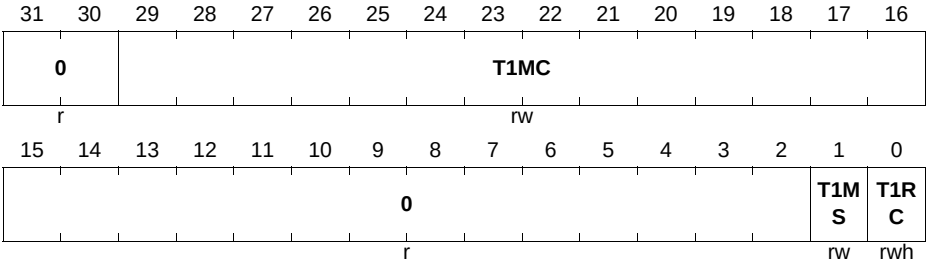
Timer 1 Configuration (T1C)

Relative timer. After the specified number of Macroticks has expired, the timer 1 service request is asserted, output signal TINT1SR is set to 1 for the duration of one Macrotick and SIR.TI1 is set to 1.

Timer 1 can be activated as long as the POC is either in “NORMAL_ACTIVE” state or in “NORMAL_PASSIVE” state. Timer 1 is deactivated when leaving “NORMAL_ACTIVE” state or “NORMAL_PASSIVE” state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by resetting bit T1RC to 0.

T1C
Timer 1 Configuration **(0048_H)** **Reset Value: 0002 0000$_H$**



Field	Bits	Type	Description
T1RC	0	rwh	**Timer 1 Run Control** 0_B Timer 1 halted 1_B Timer 1 running
T1MS	1	rw	**Timer 1 Mode Select** 0_B Single-shot mode 1_B Continuous mode
T1MC	[29:16]	rw	**Timer 1 Macrotick Count** When the configured Macrotick count is reached the timer 1 service request is generated. Valid values are: 2_H …$3FFF_H$ Macroticks in continuous mode 1_H …$3FFF_H$ Macroticks in single-shot mode
0	[15:2], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: In case the Communication Controller leaves "NORMAL_ACTIVE" or "NORMAL_PASSIVE" state, or if timer 1 is halted by Host command, output signal TINT1SR *is reset to 0 immediately.*

Stop Watch Register 1 (STPW1)

The stop watch is activated by a rising or falling edge on signal STPW, by a service request 0 or 1 event (rising edge on signal INT0SR or INT1SR) or by the Host by writing bit STPW1.SSWT to 1. With the Macrotick counter increment following next to the stop watch activation the actual cycle counter and Macrotick value are captured in the Stop Watch Register 1 STPW1 while the slot counter values for channel A and B are captured in the Stop Watch Register 2 STPW2.

STPW1
Stop Watch Register 1 **(004C$_H$)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								SMTV							
r								rh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		SCCV						0	EINT1	EINT0	EETP	SSWT	EDGE	SWMS	ESWT
r		rh						r	rw	rw	rw	rwh	rw	rw	rwh

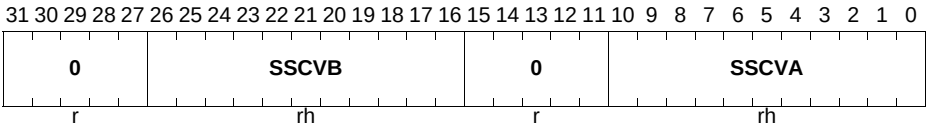
Field	Bits	Type	Description
ESWT	0	rwh	**Enable Stop Watch Trigger** If enabled an edge on input STPW or a service request 0 or 1 event (rising edge on signal INT0SR or INT1SR) activates the stop watch. In single-shot mode this bit is reset to 0 after the actual cycle counter and Macrotick value are stored in the Stop Watch register. 0_B Stop watch trigger disabled 1_B Stop watch trigger enabled
SWMS	1	rw	**Stop Watch Mode Select** It is not possible to change the Stop Watch Mode during enabled stop watch trigger (STPW1.ESWT) 0_B Single-shot mode 1_B Continuous mode
EDGE	2	rw	**Stop Watch Trigger Edge Select** 0_B Falling Edge 1_B Rising Edge

Field	Bits	Type	Description
SSWT	3	rwh	**Software Stop Watch Trigger** When the Host writes this bit to 1 the stop watch is activated. After the actual cycle counter and Macrotick value are stored in the Stop Watch register this bit is reset to 0. The bit is only writeable while ESWT = 0. 0_B Software trigger reset 1_B Stop watch activated by software trigger
EETP	4	rw	**Enable External Trigger Pin** Enables stop watch trigger event via signal STPW if ESWT = 1. 0_B Stop watch trigger via signal STPW disabled 1_B Edge on signal STPW triggers stop watch
EINT0	5	rw	**Enable Service Request 0 Trigger** Enables stop watch trigger by service request 0 event if ESWT = 1. 0_B Stop watch trigger by service request 0 disabled 1_B Service Request 0 event triggers stop watch
EINT1	6	rw	**Enable Service Request 1 Trigger** Enables stop watch trigger by service request 1 event if ESWT = 1. 0_B Stop watch trigger by service request 1 disabled 1_B Service Request 1 event triggers stop watch
SCCV	[13:8]	rh	**Stopped Cycle Counter Value** State of the cycle counter when the stop watch event occurred. Valid values are: $0…3F_H$ Valid Values
SMTV	[29:16]	rh	**Stopped Macrotick Value** State of the Macrotick counter when the stop watch event occurred. Valid values are: $0…3F_H$ Valid Values
0	7, [15:14], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: Bits ESWT and SSWT cannot be set to 1 simultaneously. In this case the write access is ignored, and both bits keep their previous values. Therefore either the external stop watch triggers or the software stop watch trigger may be used.

Stop Watch Register 2 (STPW2)

STPW2
Stop Watch Register 2 **(0050_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SSCVA	[10:0]	rh	**Stop Watch Captured Slot Counter Value Channel A** State of the slot counter for channel A when the stop watch event occurred. Valid values are 0 to 2047 (0_H to $7FF_H$).
SSCVB	[26:16]	rh	**Stop Watch Captured Slot Counter Value Channel B** State of the slot counter for channel B when the stop watch event occurred. Valid values are 0 to 2047 (0_H to $7FF_H$).
0	[15:11], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

24.5.2.4 Communication Controller Control Registers

This section describes the registers provided by the Communication Controller to allow the Host to control the operation of the Communication Controller. The FlexRay™ protocol specification requires the Host to write application configuration data in “CONFIG” state only. Please consider that the configuration registers are not locked for writing in “DEFAULT_CONFIG” state.

The configuration data is reset when “DEFAULT_CONFIG” state is entered from application reset. To change POC state from “DEFAULT_CONFIG” to “CONFIG” state the Host has to apply CHI command “CONFIG”. If the Host wants the Communication Controller to leave “CONFIG” state, the Host has to proceed as described on **“Lock Register (LCK)” on Page 24-30**.

SUC Configuration Register 1 (SUCC1)

SUCC1
SUC Configuration Register 1 (0080_H) Reset Value: $0C40\ 1000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				CCHB	CCHA	MTSB	MTSA	HCSE	TSM	WUCS	PTA				
r				rw	rw	rw	rw	rw	rw	rw	rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CSA					0	TXSY	TXST	PBSY	0			CMD			
rw					r	rw	rw	rh	r			rwh			

Field	Bits	Type	Description
CMD	[3:0]	rwh	**CHI Command Vector** The host may write any CHI command at any time, but certain commands are only enabled in specific POC states. A disabled command will not be executed, the CHI command vector CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”, and flag EIR.CNA in the Error Service Request register will be set to 1. In case the previous CHI command has not yet completed, EIR.CCL is set to 1 together with EIR.CNA; the CHI command needs to be repeated. Except for HALT state, POC state change command applied while the Communication Controller is already in the requested POC state will be ignored. 0000_B COMMAND_NOT_ACCEPTED” 0001_B CONFIG 0010_B READY 0011_B WAKEUP 0100_B RUN 0101_B ALL_SLOTS 0110_B HALT 0111_B FREEZE 1000_B SEND_MTS 1001_B ALLOW_COLDSTART 1010_B RESET_STATUS_INDICATORS 1011_B MONITOR_MODE 1100_B CLEAR_RAMS 1101_B Reserved 1110_B Reserved 1111_B Reserved Reading SUCC1.CMD shows whether the last CHI command was accepted. CCSV.POCS monitors the actual POC state. The reserved CHI commands code hardware test functions.
PBSY	7	rh	**POC Busy** Signals that the POC is busy and cannot accept a command from the Host. SUCC1.CMD is locked against write accesses. Set to 1 after hard reset during initialization of internal RAM blocks. 0_B POC not busy, SUCC1.CMD writable 1_B POC is busy, SUCC1.CMD locked

Field	Bits	Type	Description
TXST	8	rw	**Transmit Startup Frame in Key Slot**[1) 2)] (pKeySlotUsedForStartup) Defines whether the key slot is used to transmit startup Frames. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B No Startup Frame transmission in key slot, node is non-coldstarter 1_B Key slot used to transmit startup Frame, node is leading or following coldstarter
TXSY	9	rw	**Transmit SYNC Frame in Key Slot**[1) 2)] (pKeySlotUsedForSync) Defines whether the key slot is used to transmit SYNC Frames. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B No SYNC Frame transmission in key slot, node is neither sync nor coldstart node 1_B Key slot used to transmit SYNC Frames, node is sync node
CSA	[15:11]	rw	**Cold Start Attempts**[1)](gColdStartAttempts) Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node. It can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Must be identical in all nodes of a cluster. Valid values are 2 to 31.
PTA	[20:16]	rw	**Passive to Active**[1)] (pAllowPassiveToActive) Defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the Communication Controller is allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. If set to 00000_B the Communication Controller is not allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. It can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 31 even / odd cycle pairs.

Field	Bits	Type	Description
WUCS	21	rw	**Wakeup Channel Select[1)]** (pWakeupChannel) With this bit the Host selects the channel on which the Communication Controller sends the Wakeup pattern. The Communication Controller ignores any attempt to change the status of this bit when not in “DEFAULT_CONFIG” or “CONFIG” state. 0_B Send wakeup pattern on channel A 1_B Send wakeup pattern on channel B
TSM	22	rw	**Transmission Slot Mode[1)]** (pSingleSlotEnabled) Selects the initial transmission slot mode. In SINGLE slot mode the Communication Controller may only transmit in the preconfigured key slot. The key slot ID is configured in the Header Section of Message Buffer 0 respectively Message Buffers 0 and 1 depending on bit MRC.SPLM. In case SUCC1.TSM = 1, Message Buffer 0 respectively Message Buffers 0,1 can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only. In ALL slot mode the Communication Controller may transmit in all slots. The bit can be written in “DEFAULT_CONFIG” or “CONFIG” state only. The communication controller changes to ALL slot mode when the Host successfully applied the ALL_SLOTS command by writing SUCC1.CMD = 0101_B in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE”. The actual slot mode is monitored by CCSV.SLM. 0_B ALL Slot Mode 1_B SINGLE Slot Mode (default after application reset)
HCSE	23	rw	**Halt due to Clock Sync Error[1)]** (pAllowHaltDueToClock) Controls the transition to “HALT” state due to a clock synchronization error. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B Communication Controller will enter / remain in “NORMAL_PASSIVE” 1_B Communication Controller will enter “HALT” state
MTSA	24	rw	**Select Channel A for MTS Transmission[1) 3)]** The bit selects channel A for MTS symbol transmission. The flag is reset by default and may be modified only in “DEFAULT_CONFIG” or “CONFIG” state. 0_B Channel A disabled for MTS transmission 1_B Channel A selected for MTS transmission

Field	Bits	Type	Description
MTSB	25	rw	**Select Channel B for MTS Transmission[1) 3)]** The bit selects channel B for MTS symbol transmission. The flag is reset by default and may be modified only in "DEFAULT_CONFIG" or "CONFIG" state. 0_B Channel B disabled for MTS transmission 1_B Channel B selected for MTS transmission
CCHA	26	rw	**Connected to Channel A[1)]** (pChannels) Configures whether the node is connected to channel A. 0_B Not connected to channel A 1_B Node connected to channel A (default after application reset)
CCHB	27	rw	**Connected to Channel B[1)]** (pChannels) Configures whether the node is connected to channel B. 0_B Not connected to channel B 1_B Node connected to channel B (default after application reset)
0	[6:4], 10, [31:28]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in "DEFAULT_CONFIG" or "CONFIG" state only!

2) The protocol requires that both bits TXST and TXSY are set for coldstart nodes.

3) MTSA and MTSB may also be changed outside "DEFAULT_CONFIG" or "CONFIG" state when the write to SUCC1 register is directly preceded by the unlock sequence as described in Lock Register (LCK). This may be combined with CHI command "SEND_MTS". If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000_B.

COMMAND_NOT_ACCEPTED

SUCC1.CMD is reset to 0000_B due to one of the following conditions:

- Illegal command applied by the Host
- Host writes command_not_accepted
- Host applied new command while execution of the previous Host command has not completed

When SUCC1.CMD is reset to 0000_B, bit EIR.CNA in the Error Service Request register is set, and - if enabled - an service request is generated. Commands which are not accepted are not executed.

CONFIG

Go to POC state "CONFIG" when called in POC states "DEFAULT_CONFIG", "READY", or in "MONITOR_MODE". When called in "HALT" state transits to POC state

“DEFAULT_CONFIG“. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

READY

Go to POC state “READY” when called in POC states “CONFIG”, “NORMAL_ACTIVE”, “NORMAL_PASSIVE”, “STARTUP”, or “WAKEUP”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

WAKEUP

Go to POC state WAKEUP when called in POC state “READY”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

RUN

Go to POC state “STARTUP” when called in POC state “READY”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

ALL_SLOTS

Leave SINGLE slot mode after successful startup / integration at the next end of cycle when called in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE”. When called in any other state, SUCC1.CMD will be reset to
0000_B = “COMMAND_NOT_ACCEPTED”.

HALT

Set the halt request CCSV.HRQ bit in the Communication Controller Status Vector register and go to POC state “HALT” at the next end of cycle when called in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE“. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED“.

FREEZE

Set the freeze status indicator CCSV.FSI and go to POC state “HALT” immediately. Can be called from any state.

SEND_MTS

Send single MTS symbol during the next following symbol window on the channel configured by SUCC1.MTSA, SUCC1.MTSB, when called in POC state “NORMAL_ACTIVE”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

ALLOW_COLDSTART

The command resets bit CCSV.CSI to enable the node to become cold starter. When called in states “DEFAULT_CONFIG“, “CONFIG”, “HALT”, or “MONITOR_MODE“. SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. To become leading coldstarter it is also required that both TXST and TXSY are set.

RESET_STATUS_INDICATORS

Resets status flags CCSV.CSNI, CCSV.CSAI, CCSV.WSV to their default values. May be called in POC state READY. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

MONITOR_MODE

Enter MONITOR_MODE when called in POC state CONFIG. In this mode the Communication Controller is able to receive FlexRay™ Frames and wakeup pattern. It is also able to detect coding errors. The temporal integrity of received Frames is not checked. This mode can be used for debugging purposes, e.g. in case that the startup of a FlexRay™ network fails. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. For details see **“MONITOR_MODE” on Page 24-199**.

CLEAR_RAMS

Sets bit MHDS.CRAM in the Message Handler Status register when called in “DEFAULT_CONFIG” or “CONFIG” state. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. By setting MHDS.CRAM all internal RAM blocks are initialized to zero. Note that only the currently active IBF bank is cleared. To clear the 2nd bank as well, CUST1.IBF1PAG and CUST1.IBF2PAG need to be set and command CLEAR_RAMS need to be issued again. This is required in particular after an application reset. If the 2nd bank of IBF is left unused, this procedure is not required. During the initialization of the RAMs, SUCC1.PBSY will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMS.

The initialization of the E-Ray internal RAM blocks requires 2048 f_{CLC_ERAY} cycles. There should be no Host access to IBF or OBF during initialization of the internal RAM blocks after application reset or after assertion of CHI command CLEAR_RAMS. Before asserting CHI command CLEAR_RAMS the Host should make sure that no transfer between Message RAM and IBF / OBF or the Transient Buffer RAMs is ongoing. This command also resets the Message Buffer Status registers MHDS, LDTS, FSR, MHDF, TXRQ1, TXRQ2, TXRQ3, TXRQ4, NDAT1, NDAT2, NDAT3, NDAT4, MBSC1, MBSC2, MBSC3, and MBSC4.

Note: All accepted commands with exception of CLEAR_RAMS and SEND_MTS will cause a change of register CCSV after at most 8 cycles of the slower of the two clocks f_{CLC_ERAY} and f_{SCLK}, assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time Frame. Reading register CCSV will show data that is delayed by synchronization from f_{SCLK} to f_{CLC_ERAY} domain and by the Host-specific CPU interface.

Table 24-4 below references the CHI commands from the FlexRay™ Protocol Specification v2.1 (section 2.2.1.1, Table 2-2) to the E-Ray CHI command vector CMD.]

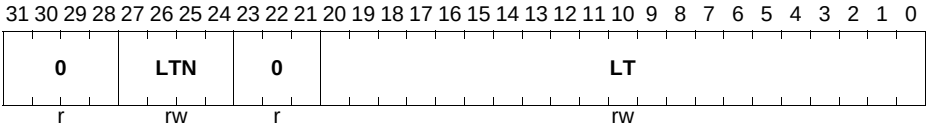
Table 24-4 Reference to CHI Host command summary from FlexRay™ protocol specification

CHI Command	Where processed (POC State)	CHI Command Vector CMD
ALL_SLOT	POC:NORMAL_ACTIVE, POC:NORMAL_PASSIVE	ALL_SLOTS
ALLOW_COLDSTART	All except POC:DEFAULT_CONFIG, POC:CONFIG, POC:HALT	ALLOW_COLDSTART
CONFIG	POC:DEFAULT_CONFIG, POC:READY	CONFIG
CONFIG_COMPLETE	POC:CONFIG	Unlock sequence & READY
DEFAULT_CONFIG	POC:HALT	CONFIG
FREEZE	All	FREEZE
HALT	POC:NORMAL_ACTIVE, POC:NORMAL_PASSIVE	HALT
READY	All except POC:DEFAULT_CONFIG, POC:CONFIG, POC:READY, POC:HALT	READY
RUN	POC:READY	RUN
WAKEUP	POC:READY	WAKEUP

SUC Configuration Register 2 (SUCC2)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

SUCC2
SUC Configuration Register 2 (0084_H) Reset Value: 0100 0504_H



Field	Bits	Type	Description
LT	[20:0]	rw	**Listen Timeout**[1] (pdListenTimeout) Configures wakeup / startup listen timeout in Microticks. The range for wakeup / startup listen timeout (pdListenTimeout) is 1284 to 1283846 (504_H to 139706_H) Microticks
LTN	[27:24]	rw	**Listen Time-out Noise**[1] (gListenNoise - 1) Configures the upper limit for startup and wakeup listen timeout in the presence of noise expressed as a multiple of the cluster constant pdListenTimeout. The range of pdListenTimeout 2 to 16. LTN must be configured identical in all nodes of a cluster. 1_H Listen Time-out Noise is equal 2 2_H Listen Time-out Noise is equal 3 $..._H$ ... F_H Listen Time-out Noise is equal 16
0	[23:21], [31:28]	r	**Reserved** Returns 0 if read; should be written with 0.

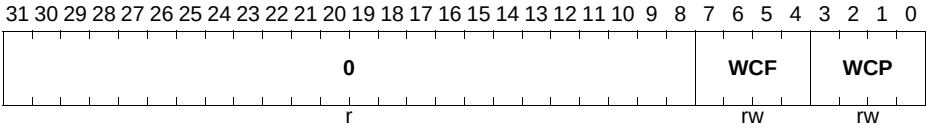
1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

Note: The wakeup / startup noise time-out is calculated as follows:
The wakeup / startup noise time-out = pdListenTimeout • gListenNoise
= LT • (LTN+ 1)

SUC Configuration Register 3 (SUCC3)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

SUCC3
SUC Configuration Register 3 (0088_H) Reset Value: 0000 0011_H



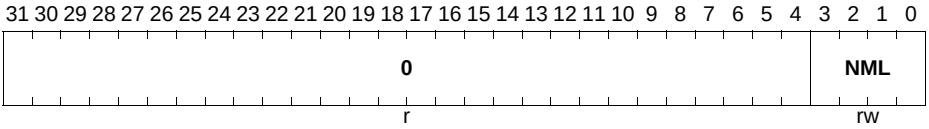
Field	Bits	Type	Description
WCP	[3:0]	rw	**Maximum Without Clock Correction Passive**[1)] (gMaxWithoutClockCorrectionPassive) Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from “NORMAL_ACTIVE” to “NORMAL_PASSIVE” state. Must be identical in all nodes of a cluster. Valid values are 1 to 15 (1_H to F_H) cycle pairs.
WCF	[7:4]	rw	**Maximum Without Clock Correction Fatal**[1)] (gMaxWithoutClockCorrecti on Fatal) Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from “NORMAL_ACTIVE” or “NORMAL_PASSIVE” to “HALT” state. Must be identical in all nodes of a cluster. Valid values are 1 to 15 (1_H to F_H)cycle pairs.
0	[31:8]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

NEM Configuration Register (NEMC)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

NEMC
NEM Configuration Register (008C$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
NML	[3:0]	rw	**Network Management Vector Length**[1)] (gNetworkManagementVectorLength) These bits configure the length of the NM Vector. The configured length must be identical in all nodes of a cluster. Valid values are 0 to 12 (0_H to C_H) bytes.
0	[31:4]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

PRT Configuration Register 1 (PRTC1)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

PRTC1
PRT Configuration Register 1 (0090_H) Reset Value: $084C\ 0633_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RWP						0	RXW									BRP		SPP		0	1	CASM						TSST			
rw						r	rw									rw		rw		r	r	rw						rw			

Field	Bits	Type	Description
TSST	[3:0]	rw	**Transmission Start Sequence Transmitter**[1)] (gdTSSTransmitter) Configures the duration of the Transmission Start Sequence (TSS) in terms of Bit Times (1 bit time = 4 Microticks = 100ns at 10Mbps). Must be identical in all nodes of a cluster. Valid values are 3 to 15 (3_H to F_H) Bit Times.
CASM	[10:4]	rw	**Collision Avoidance Symbol Maximum**[1)] (gdCASRxLowMax) Configures the upper limit of the acceptance window for a collision avoidance symbol (CAS). Valid values are 67 to 99 (43_H to 63_H). Most significant bit of CASM is hard wired to 1 and can not be modified.
SPP	[13:12]	rw	**Strobe Point Position**[1)] Defines the sample count value for strobing. The strobed bit value is set to the voted value when the sample count is incremented to the value configured by SPP. 00_B Sample 5 (default) 01_B Sample 4 10_B Sample 6 11_B Reserved; should not be used. *Note: The current revision 2.1 of the FlexRay™ protocol requires that SPP = 00_B. The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.*

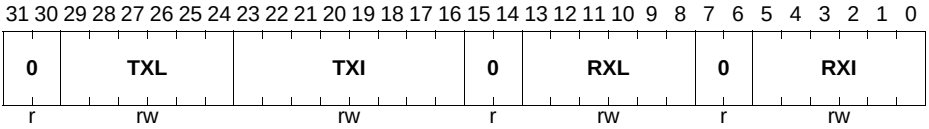
Field	Bits	Type	Description
BRP	[15:14]	rw	**Baud Rate Prescaler**[1] (gdSampleClockPeriod, pSamplePerMicrotick) The baud rate prescaler configures the baud rate on the FlexRay™ bus. The baud rates listed below are valid with a sample clock f_{SCLK}= 80 MHz. One bit time always consists of 8 samples independent of the configured baud rate. 00_B 10 Mbit/s (1 Microtick= 25 ns; twice sampled with f_{SCLK}) gdSampleClockPeriod = 12.5 ns = 1 / f_{SCLK} pSamplesPerMicrotick = 2 01_B 5 Mbit/s (1 Microtick= 25ns; single sampled with f_{SCLK} / 2) gdSampleClockPeriod = 25 ns = 2 / f_{SCLK} pSamplesPerMicrotick = 1 10_B 2.5 Mbit/s (1 Microtick = 50ns; single sampled with f_{SCLK} / 4) gdSampleClockPeriod = 50 ns = 4 / f_{SCLK} pSamplesPerMicrotick = 1 11_B Reserved; should not be used (2.5 Mbit/s (1 Microtick = 50 ns; single sampled with f_{SCLK} / 4) gdSampleClockPeriod = 50 ns = 4 / f_{SCLK} pSamplesPerMicrotick = 1
RXW	[24:16]	rw	**Wakeup Symbol Receive Window Length**[1] (gdWakeupSymbolRxWindow**)** Configures the number of Bit Times used by the node to test the duration of the received wakeup pattern. Must be identical in all nodes of a cluster. Valid values are 76 to 301 ($4C_H$ to $12D_H$) Bit Times.
RWP	[31:26]	rw	**Repetitions of Tx Wakeup Pattern**[1] (pWakeupPattern) Configures the number of repetitions (sequences) of the Tx wakeup symbol. Valid values are 2 to 63 (2_H to $3F_H$).
0	11, 25	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

PRT Configuration Register 2 (PRTC2)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

PRTC2
PRT Configuration Register 2 (0094_H) Reset Value: $0F2D\ 0A0E_H$



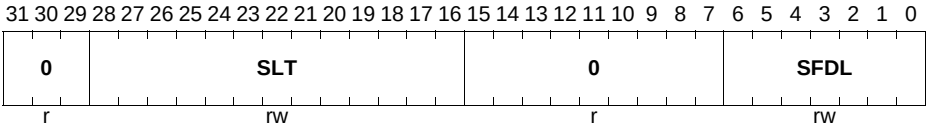
Field	Bits	Type	Description
RXI	[5:0]	rw	**Wakeup Symbol Receive Idle**[1)] (gdWakeupSymbolRxIdle) Configures the number of Bit Times used by the node to test the duration of the idle phase of the received wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 14 to 59 (E_H to $3B_H$) Bit Times.
RXL	[13:8]	rw	**Wakeup Symbol Receive Low**[1)] (gdWakeupSymbolRxLow) Configures the number of Bit Times used by the node to test the duration of the low phase of the received wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 10 to 55 (A_H to 37_H) Bit Times.
TXI	[23:16]	rw	**Wakeup Symbol Transmit Idle**[1)] (gdWakeupSymbolTxIdle) Configures the number of Bit Times used by the node to transmit the idle phase of the wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 45 to 180 ($2D_H$ to $B4_H$)Bit Times.
TXL	[29:24]	rw	**Wakeup Symbol Transmit Low**[1)] (gdWakeupSymbolTxLow) Configures the number of Bit Times used by the node to transmit the low phase of the wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 15 to 60 (F_H to $3C_H$) Bit Times.
0	[7:6], [15:14], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

MHD Configuration Register (MHDC)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

MHDC
MHD Configuration Register **(0098_H)** **Reset Value: $0000\ 0000_H$**



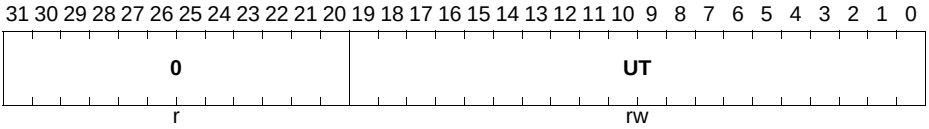
Field	Bits	Type	Description
SFDL	[6:0]	rw	**Static Frame Data Length** (gPayloadLengthStatic)[1)] Configures the cluster-wide payload length for all Frames sent in the static segment in double byte. The payload length must be identical in all nodes of a cluster. Valid values are 0 to 127 (0 to $7F_H$).
SLT	[28:16]	rw	**Start of Latest Transmit** (pLatestTx)[1)] Configures the maximum minislot value allowed before inhibiting Frame transmission in the dynamic segment of the cycle. There is no transmission dynamic segment if SLT is reset to zero. Valid values are 0 to 7981 (0 to $1F2D_H$) minislots.
0	[15:7], [31:29]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 1 (GTUC01)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC01
GTU Configuration Register 1 (00A0$_H$) **Reset Value: 0000 0280$_H$**



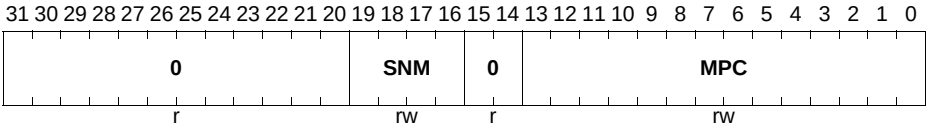
Field	Bits	Type	Description
UT	[19:0]	rw	**Microtick per Cycle** (pMicroPerCycle)[1)] Configures the duration of the communication cycle in Microticks. Valid values are 640 to 640000 (280$_H$ to 9C400$_H$) Microticks.
0	[31:20]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 2 (GTUC02)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC02
GTU Configuration Register 2 (00A4$_H$) Reset Value: 0002 000A$_H$



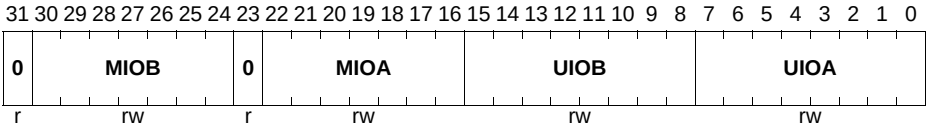
Field	Bits	Type	Description
MPC	[13:0]	rw	**Macrotick Per Cycle** (gMacroPerCycle)[1)] Configures the duration of one communication cycle in Macroticks. The cycle length must be identical in all nodes of a cluster. Valid values are 10 to 16000 (A_H to $3E80_H$) Macroticks.
SNM	[19:16]	rw	**Sync Node Max** (gSyncNodeMax)[1)] Maximum number of Frames within a cluster with SYNC Frame indicator bit SYN set to 1. Must be identical in all nodes of a cluster. Valid values are 2 to 15 (2_H to F_H).
0	[15:14], [31:20]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 3 (GTUC03)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC03
GTU Configuration Register 3 (00A8$_H$) Reset Value: 0202 0000$_H$



Field	Bits	Type	Description
UIOA	[7:0]	rw	**Microtick Initial Offset Channel A**[1)] (pMicroInitialOffset[A]) Configures the number of Microticks between the actual time reference point on channel A and the subsequent Macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[A] and therefore has to be set for each channel independently. Valid values are 0 to 240 (0_H to $F0_H$) Microticks.
UIOB	[15:8]	rw	**Microtick Initial Offset Channel B**[1)] (pMicroInitialOffset[B]) Configures the number of Microticks between the actual time reference point on channel B and the subsequent Macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[B] and therefore has to be set for each channel independently. Valid values are 0 to 240 (0_H to $F0_H$) Microticks.
MIOA	[22:16]	rw	**Macrotick Initial Offset Channel A** (gMacroInitialOffset[A])[1)] Configures the number of Macroticks between the static slot boundary and the subsequent Macrotick boundary of the secondary time reference point based on the nominal Macrotick duration. Must be identical in all nodes of a cluster. Valid values are 2 to 72 (2_H to 48_H) Macroticks.
MIOB	[30:24]	rw	**Macrotick Initial Offset Channel B** (gMacroInitialOffset[B])[1)] Configures the number of Macroticks between the static slot boundary and the subsequent Macrotick boundary of the secondary time reference point based on the nominal Macrotick duration. Must be identical in all nodes of a cluster. Valid values are 2 to 72 (2_H to 48_H) Macroticks.

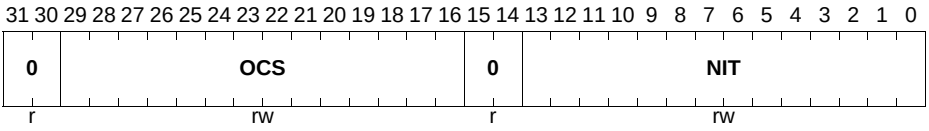
Field	Bits	Type	Description
0	23, 31	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 4 (GTUC04)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only. For details about configuration of NIT and OCS see **“Configuration of Network Idle Time (NIT) Start and Offset Correction Start” on Page 24-188**.

GTUC04
GTU Configuration Register 4 (00AC$_H$) Reset Value: 0008 0007$_H$



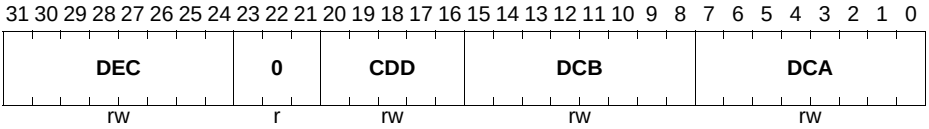
Field	Bits	Type	Description
NIT	[13:0]	rw	**Network Idle Time Start** [1] (gMacroPerCycle - gdNIT - 1) Configures the starting point of the Network Idle Time (NIT) at the end of the communication cycle expressed in terms of Macroticks from the beginning of the cycle. The start of network idle time (NIT) is recognized if Macrotick = gMacroPerCycle - gdNIT -1 and the increment pulse of Macrotick is set. Must be identical in all nodes of a cluster. Valid values are 7 to 15997 (7_H to $3E7D_H$) Macroticks.
OCS	[29:16]	rw	**Offset Correction Start**[1] (gOffsetCorrectionStart - 1) Determines the start of the offset correction within the network idle time (NIT) phase, calculated from start of cycle. Must be identical in all nodes of a cluster. For cluster consisting of E-Ray implementations only, it is sufficient to program OCS = NIT + 1. Valid values are 8 to 15998 (8_H to $3E7E_H$) Macroticks.
0	[15:14], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 5 (GTUC05)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC05
GTU Configuration Register 5 (00B0$_H$) Reset Value: 0E00 0000$_H$



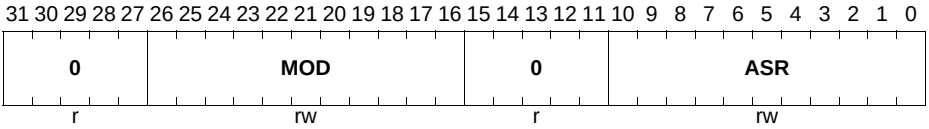
Field	Bits	Type	Description
DCA	[7:0]	rw	**Delay Compensation Channel A**[1)] (pDelayCompensation[A]) Used to compensate for reception delays on channel A. This covers assumed propagation delay up to cPropagationDelayMax for Microticks in the range of 0.0125µs to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied. Valid values are 0 to 200 (0_H to $C8_H$) Microticks.
DCB	[15:8]	rw	**Delay Compensation Channel B**[1)] (pDelayCompensation[B]) Used to compensate for reception delays on channel B. This covers assumed propagation delay up to cPropagationDelayMax for Microticks in the range of 0.0125 to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied. Valid values are 0 to 200 (0_H to $C8_H$) Microticks.
CDD	[20:16]	rw	**Cluster Drift Damping** (pClusterDriftDamping)[1)] Configures the cluster drift damping value used in clock synchronization to minimize accumulation of rounding errors. Valid values are 0 to 20 (0_H to 14_H) Microticks.
DEC	[31:24]	rw	**Decoding Correction** (pDecodingCorrection)[1)] Configures the decoding correction value used to determine the primary time reference point. Valid values are 14 to 143 (E_H to $8F_H$) Microticks.
0	[23:21]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 6 (GTUC06)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC06
GTU Configuration Register 6 (00B4$_H$) Reset Value: 0002 0000$_H$



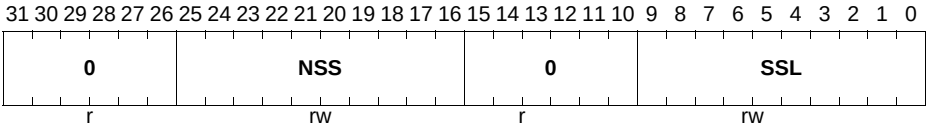
Field	Bits	Type	Description
ASR	[10:0]	rw	**Accepted Startup Range**[1] (pdAcceptedStartupRange) Number of Microticks constituting the expanded range of measured deviation for startup Frames during integration. Valid values are 0 to 1875 (0_H to 753_H) Microticks.
MOD	[26:16]	rw	**Maximum Oscillator Drift** (pdMaxDrift)[1] Maximum drift offset between two nodes that operate with unsynchronized clocks over one communication cycle in Microticks. Valid values are 2 to 1923 (2_H to 783_H) Microticks.
0	[15:11], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 7 (GTUC07)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC07
GTU Configuration Register 7 (00B8$_H$) Reset Value: 0002 0004$_H$



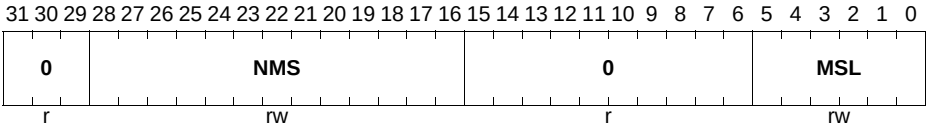
Field	Bits	Type	Description
SSL	[9:0]	rw	**Static Slot Length** (gdStaticSlot)[1)] Configures the duration of a static slot in Macroticks. The static slot length must be identical in all nodes of a cluster. Valid values are 4 to 659 (4_H to 293_H) Macroticks.
NSS	[25:16]	rw	**Number of Static Slots** (gNumberOfStaticSlots)[1)] Configures the number of static slots in a cycle. At least 2 coldstart nodes must be configured to startup a FlexRay™ network. The number of static slots must be identical in all nodes of a cluster. Valid values are 2 to 1023 (2_H to $3FF_H$).
0	[15:10], [31:26]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 8 (GTUC08)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC08
GTU Configuration Register 8 (00BC$_H$) Reset Value: 0000 0002$_H$



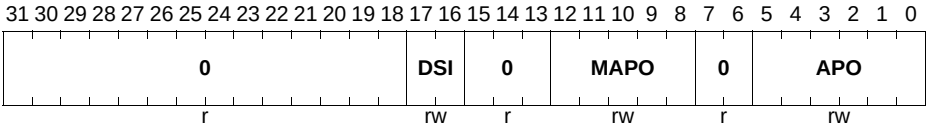
Field	Bits	Type	Description
MSL	[5:0]	rw	**Minislot Length** (gdMinislot)[1)] Configures the duration of a minislot in Macroticks. The minislot length must be identical in all nodes of a cluster. Valid values are 2 to 63 (2_H to $3F_H$) Macroticks.
NMS	[28:16]	rw	**Number of Minislots** (gNumberOfMinislots)[1)] Configures the number of minislots within the dynamic segment of a cycle. The number of minislots must be identical in all nodes of a cluster. Valid values are 0 to 7986 (0_H to $1F32_H$).
0	[15:6], [31:29]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 9 (GTUC09)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC09
GTU Configuration Register 9 ($00C0_H$) Reset Value: $0000\ 0101_H$



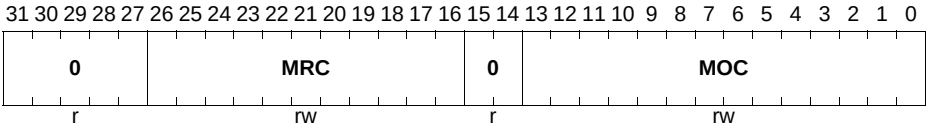
Field	Bits	Type	Description
APO	[5:0]	rw	**Action Point Offset** (gdActionPointOffset)[1)] Configures the action point offset in Macroticks within static slots and symbol window. Must be identical in all nodes of a cluster. Valid values are 1 to 63 (1_H to $3F_H$) Macroticks.
MAPO	[12:8]	rw	**Minislot Action Point Offset**[1)] (gd Minislot Action Point Offset) Configures the action point offset in Macroticks within the minislots of the dynamic segment. Must be identical in all nodes of a cluster. Valid values are 1 to 31 (1_H to $1F_H$) Macroticks.
DSI	[17:16]	rw	**Dynamic Slot Idle Phase**[1)] (gdDynamicSlotIdlePhase) The duration of the dynamic slot idle phase has to be greater or equal than the idle detection time. Must be identical in all nodes of a cluster. Valid values are 0 to 2 Minislot.
0	[7:6], [15:13], [31:18]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 10 (GTUC10)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC10
GTU Configuration Register 10 ($00C4_H$) Reset Value: $0002\ 0005_H$

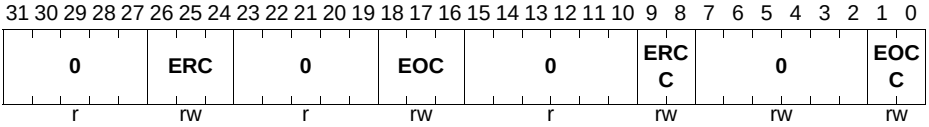


Field	Bits	Type	Description
MOC	[13:0]	rw	**Maximum Offset Correction**[1] (pOffsetCorrectionOut) Holds the maximum permitted offset correction value to be applied by the internal clock synchronization algorithm (absolute value). The Communication Controller checks only the internal offset correction value against the maximum offset correction value. Valid values are 5 to 15266 (5_H to $3BA2_H$) Microticks.
MRC	[26:16]	rw	**Maximum Rate Correction**[1] (pRateCorrectionOut) Holds the maximum permitted rate correction value to be applied by the internal clock synchronization algorithm. The communication controller checks only the internal rate correction value against the maximum rate correction value (absolute value). Valid values are 2 to 1923 (2_H to 783_H) Microticks.
0	[15:14], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 11 (GTUC11)

GTUC11
GTU Configuration Register 11 (00C8$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
EOCC	[1:0]	rw	**External Offset Correction Control** (pExternOffsetControl) By writing to EOCC the external offset correction is enabled as specified below. Should be modified only outside network idle time (NIT). 00_B No external clock correction 01_B No external clock correction 10_B External offset correction value subtracted from calculated offset correction value 11_B External offset correction value added to calculated offset correction value
ERCC	[9:8]	rw	**External Rate Correction Control** (pExternRateControl) By writing to ERCC the external rate correction is enabled as specified below. Should be modified only outside network idle time (NIT). 00_B No external rate correction 01_B No external rate correction 10_B External rate correction value subtracted from calculated rate correction value 11_B External rate correction value added to calculated rate correction value
EOC	[18:16]	rw	**External Offset Correction**[1)] (pExternOffsetCorrection) Holds the external clock offset correction value in Microticks to be applied by the internal synchronization algorithm. The value is subtracted / added from / to the calculated offset correction value. The value is applied during network idle time (NIT). May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 7 Microticks.

Field	Bits	Type	Description
ERC	[26:24]	rw	**External Rate Correction**[1] (pExternRateCorrection) Holds the external rate correction value in Microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated rate correction value. The value is applied during network idle time (NIT). May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 7 Microticks.
0	[7:2], [15:10], [23:19], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

24.5.2.5 Communication Controller Status Registers

During 8/16-bit accesses to status variables coded with more than 8/16-bit, the variable might be updated by the Communication Controller between two accesses (non-atomic read accesses). The status vector may change faster than the Host can poll the status vector, depending on f_{CLC_ERAY} frequency.

Communication Controller Status Vector (CCSV)

CCSV

Communication Controller Status Vector(0100_H) **Reset Value: $0010\ 4000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	**CSI**	**CSAI**	**CSNI**	**0**		**SLM**		**HRQ**	**FSI**	**POCS**					
r	rh	rh	rh	r		rh		rh	rh	rh					

Field	Bits	Type	Description
POCS	[5:0]	rh	**Protocol Operation Control Status** Indicates the actual state of operation of the Communication Controller Protocol Operation Control 000000_B “DEFAULT_CONFIG” state 000001_B “READY” state 000010_B “NORMAL_ACTIVE” state 000011_B “NORMAL_PASSIVE” state 000100_B “HALT” state 000101_B “MONITOR_MODE” state 000110_B … 001110_B are reserved. 001111_B “CONFIG” state Indicates the actual state of operation of the POC in the wakeup path 010000_B WAKEUP_STANDBY state 010001_B “WAKEUP_LISTEN” state 010010_B “WAKEUP_SEND” state 010011_B “WAKEUP_DETECT” state 010100_B … 011111_B are reserved. Indicates the actual state of operation of the POC in the startup path 100000_B “STARTUP_PREPARE” state 100001_B “COLDSTART_LISTEN” state 100010_B “COLDSTART_COLLISION_RESOLUTION state 100011_B “COLDSTART_CONSISTENCY_CHECK” state 100100_B “COLDSTART_GAP state 100101_B “COLDSTART_JOIN” State 100110_B “INTEGRATION_COLDSTART_CHECK” state 100111_B “INTEGRATION_LISTEN” state 101000_B “INTEGRATION_CONSISTENCY_CHECK” state 101001_B “INITIALIZE_SCHEDULE” state 101010_B “ABORT_STARTUP” state 101011_B “STARTUP_SUCCESS” state 101100_B … 111111_B are reserved.

Field	Bits	Type	Description
FSI	6	rh	**Freeze Status Indicator** (vPOC!Freeze**)** Indicates that the POC has entered the “HALT” state due to CHI command “FREEZE” or due to an error condition requiring an immediate POC halt. Reset by transition from “HALT” to “DEFAULT_CONFIG” state.
HRQ	7	rh	**Halt Request** (vPOC!CHIHaltRequest) Indicates that a request from the Host has been received to halt the POC at the end of the communication cycle. Reset by transition from “HALT” to “DEFAULT_CONFIG” state or when entering “READY” state.
SLM	[9:8]	rh	**Slot Mode** (vPOC!SlotMode) Indicates the actual slot mode of the POC in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE. Default is “SINGLE”. Changes to “ALL”, depending on configuration bit SUCC1.TSM. In “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state the CHI command “ALL_SLOTS” will change the slot mode from “SINGLE” over “ALL_PENDING” to “ALL”. Set to SINGLE in all other states. 00_B SINGLE 01_B Reserved 10_B ALL_PENDING 11_B ALL
CSNI	12	rh	**Coldstart Noise Indicator** (vPOC!ColdstartNoise) Indicates that the cold start procedure occurred under noisy conditions. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state or from “READY” to “STARTUP” state.
CSAI	13	rh	**Coldstart Abort Indicator** Coldstart aborted. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state or from “READY” to “STARTUP” state.

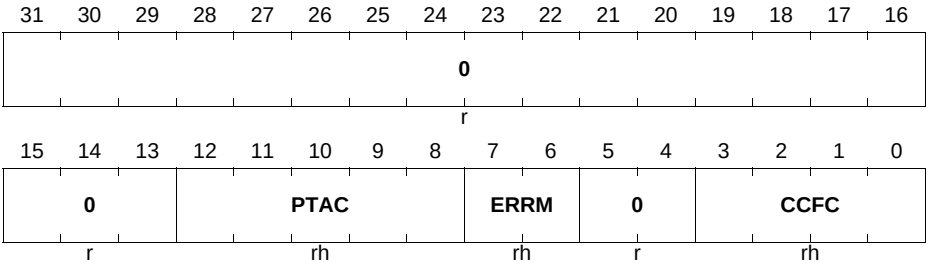
Field	Bits	Type	Description
CSI	14	rh	**Cold Start Inhibit** (vColdStartInhibit) Indicates that the node is disabled from cold starting. The flag is set whenever the POC enters “READY” state due to CHI command “READY”. The flag has to be reset under control of the Host by CHI command “ALLOW_COLDSTART” (SUCC1.CMD = 1001_B). 0_B Cold starting of node enabled 1_B Cold starting of node disabled
WSV	[18:16]	rh	**Wakeup Status** (vPOC!WakeupStatus) Indicates the status of the current wakeup attempt. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state. 000_B UNDEFINED. Wakeup not yet executed by the Communication Controller. 001_B RECEIVED_HEADER. Set when the Communication Controller finishes wakeup due to the reception of a Frame Header without coding violation on either channel in “WAKEUP_LISTEN” state. 010_B RECEIVED_WUP. Set when the Communication Controller finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in “WAKEUP_LISTEN” state. 011_B COLLISION_HEADER. Set when the Communication Controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid Header on either channel. 100_B COLLISION_WUP. Set when the Communication Controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel. 101_B COLLISION_UNKNOWN. Set when the Communication Controller stops wakeup by leaving “WAKEUP_DETECT” state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid Frame Header. 110_B TRANSMITTED. Set when the Communication Controller has successfully completed the transmission of the wakeup pattern. 111_B Reserved

Field	Bits	Type	Description
RCA	[23:19]	rh	**Remaining Coldstart Attempts** (vRemainingColdstartAttempts) Indicates the number of remaining coldstart attempts. The RUN command resets this counter to the maximum number of coldstart attempts as configured by SUCC1.CSA.
PSL	[29:24]	rh	**POC Status Log** Status of CCSV.POCS immediately before entering “HALT” state. Set when entering “HALT” state. Set to “HALT” when FREEZE command is applied during “HALT” state. Reset to 000000_B when leaving “HALT” state.
0	[11:10], 15, [31:30]	rh	**Reserved** Returns 0 if read; should be written with 0.

Communication Controller Error Vector (CCEV)

Reset by transition from “HALT” to “DEFAULT_CONFIG” state or when entering “READY” state.

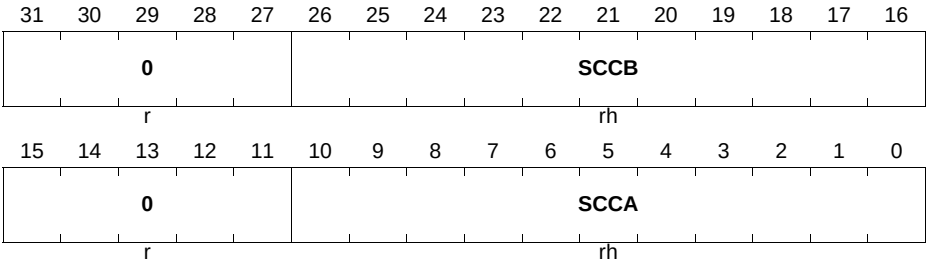
CCEV
Communication Controller Error Vector (0104_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CCFC	[3:0]	rh	**Clock Correction Failed Counter** (vClockCorrectionFailed) The Clock Correction Failed Counter is incremented by one at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active. The Clock Correction Failed Counter is reset to 0 at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active. The Clock Correction Failed Counter stops at 15.
ERRM	[7:6]	rh	**Error Mode** (vPOC!ErrorMode) Indicates the actual error mode of the POC. 00_B “ACTIVE” (green) 01_B “PASSIVE” (yellow) 10_B “COMM_HALT” (red) 11_B Reserved
PTAC	[12:8]	rh	**Passive to Active Count** (vAllowPassiveToActive) Indicates the number of consecutive even / odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from “NORMAL_PASSIVE” state to “NORMAL_ACTIVE” state. The transition takes place when PTAC equals SUCC1.PTA.
0	[5:4], [31:13]	r	**Reserved** Returns 0 if read; should be written with 0.

Slot Counter Value (SCV)

SCV
Slot Counter Value **(0110_H)** **Reset Value: $0000\ 0000_H$**

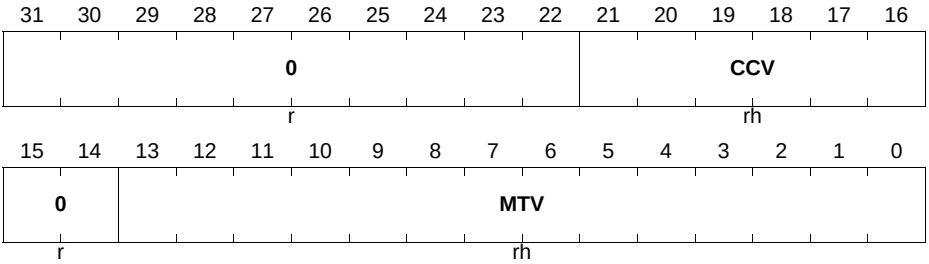


Field	Bits	Type	Description
SCCA	[10:0]	rh	**Slot Counter Channel A** (vSlotCounter[A]**)** Current slot counter value on channel A. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 2047 (0_H to $7FD_H$).
SCCB	[26:16]	rh	**Slot Counter Channel B** (vSlotCounter[B]**)** Current slot counter value on channel B. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 2047 (0_H to $7FD_H$).
0	[15:11], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

Macrotick and Cycle Counter Value (MTCCV)

MTCCV

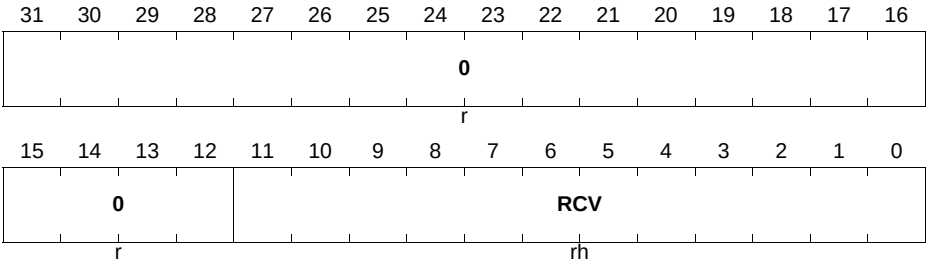
Macrotick and Cycle Counter Value (0114$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
MTV	[13:0]	rh	**Macrotick Value** (vMacrotick) Current Macrotick value. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 16000 (0_H to $3E80_H$).
CCV	[21:16]	rh	**Cycle Counter Value** (vCycleCounter) Current cycle counter value. The value is incremented by the Communication Controller at the start of a communication cycle. Valid values are 0 to 63 (0_H to $3F_H$).
0	[15:14], [31:22]	r	**Reserved** Returns 0 if read; should be written with 0.

Rate Correction Value (RCV)

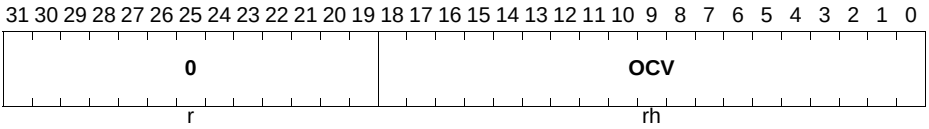
RCV
Rate Correction Value **(0118_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RCV	[11:0]	rh	**Rate Correction Value** (vRateCorrection) Rate correction value (two's complement). Calculated internal rate correction value before limitation. If the RCV value exceeds the limits defined by GTUC10.MRC, flag SFS.RCLR is set to 1.
0	[31:12]	r	**Reserved** Returns 0 if read; should be written with 0.

Offset Correction Value (OCV)

OCV
Offset Correction Value **($011C_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
OCV	[18:0]	rh	**Offset Correction Value** (vOffsetCorrection) Offset correction value (two's complement). Calculated internal offset correction value before limitation. If the OCV value exceeds the limits defined by GTUC10.MOC flag SFS.OCLR is set to 1.
0	[31:19]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: The external rate / offset correction value is added to the limited rate / offset correction value.

SYNC Frame Status (SFS)

The maximum number of valid SYNC Frames in a communication cycle is 15.

SFS

SYNC Frame Status **(0120_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

VSBO				VSBE				VSAO				VSAE			
rh				rh				rh				rh			

Field	Bits	Type	Description
VSAE	[3:0]	rh	**Valid SYNC Frames Channel A, even communication cycle** Holds the number of valid SYNC Frames received on channel A in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each even communication cycle. This bit field is only valid if the channel A is assigned to the Communication Controller by SUCC1.CCHA.
VSAO	[7:4]	rh	**Valid SYNC Frames Channel A, odd communication cycle** Holds the number of valid SYNC Frames received on channel A in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each odd communication cycle. This bit field is only valid if the channel A is assigned to the Communication Controller by SUCC1.CCHA.
VSBE	[11:8]	rh	**Valid SYNC Frames Channel B, even communication cycle** Holds the number of valid SYNC Frames received on channel B in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each even communication cycle. This bit field is only valid if the channel B is assigned to the Communication Controller by SUCC1.CCHB.

Field	Bits	Type	Description
VSBO	[15:12]	rh	**Valid SYNC Frames Channel B, odd communication cycle** Holds the number of valid SYNC Frames received on channel B in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each odd communication cycle. This bit field is only valid if the channel B is assigned to the Communication Controller by SUCC1.CCHB.
MOCS	16	rh	**Missing Offset Correction Signal** The Missing Offset Correction flag signals to the Host, that no offset correction calculation can be performed because no SYNC Frames were received. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Offset correction signal valid 1_B Missing offset correction signal
OCLR	17	rh	**Offset Correction Limit Reached** The Offset Correction Limit Reached flag signals to the Host, that the offset correction value has exceeded its limit as defined by GTUC10.MOC. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Offset correction below limit 1_B Offset correction limit reached
MRCS	18	rh	**Missing Rate Correction Signal** The Missing Rate Correction Flag signals to the Host, that no rate correction calculation can be performed because no pairs of even / odd SYNC Frames were received. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Rate correction signal valid 1_B Missing rate correction signal
RCLR	19	rh	**Rate Correction Limit Reached** The Rate Correction Limit Reached flag signals to the Host, that the rate correction value has exceeded its limit.as defined by GTUC10.MRC. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Rate correction below limit 1_B Rate correction limit reached
0	[31:20]	r	**Reserved** Returns 0 if read; should be written with 0.

Symbol Window and network idle time (NIT) Status (SWNIT)

Symbol window related status information. Updated by the Communication Controller at the end of the symbol window for each channel. During startup the status data is not updated.

Note: MTSA and MTSB may be changed outside "DEFAULT_CONFIG" or "CONFIG" state when the write to SUC Configuration Register 1 (SUCC1) register is directly preceded by the unlock sequence as described in ***"Lock Register (LCK)" on Page 24-30****. This may be combined with CHI command SEND_MTS. If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000$_B$*

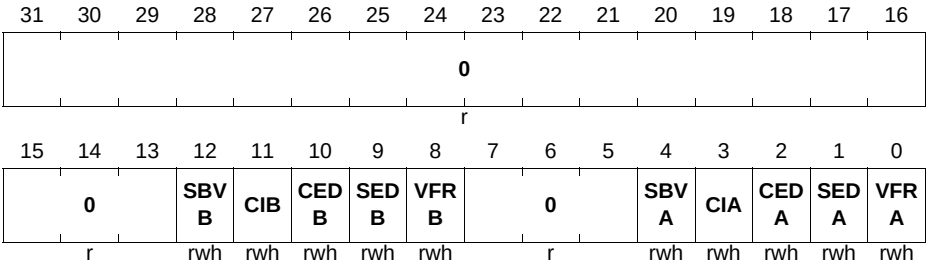
0	[31:12]	r	**Reserved** Returns 0 if read; should be written with 0.

1) MTSA and MTSB may also be changed outside “DEFAULT_CONFIG” or “CONFIG” state when the write to SUCC1 register is directly preceded by the unlock sequence as described in “Lock Register (LCK)”. This may be combined with CHI command SEND_MTS. If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000_B.

Aggregated Channel Status (ACS)

The aggregated channel status provides the Host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception. The aggregated channel status also includes status data from the symbol window and the network idle time. The status data is updated (set) after each slot and aggregated until it is reset by the Host. During startup the status data is not updated. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

ACS
Aggregated Channel Status **(0128_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
VFRA	0	rwh	**Valid Frame Received on Channel A** (vSS!ValidFrameA) One or more valid Frames were received on channel A in any static or dynamic slot during the observation period. 0_B No valid Frame received 1_B Valid Frame(s) received on channel A
SEDA	1	rwh	**Syntax Error Detected on Channel A** (vSS!SyntaxErrorA) One or more syntax errors in static or dynamic slots, symbol window, and network idle time (NIT) were observed on channel A. 0_B No syntax error observed 1_B Syntax error(s) observed on channel A
CEDA	2	rwh	**Content Error Detected on Channel A** (vSS!ContentErrorA) One or more Frames with a content error were received on channel A in any static or dynamic slot during the observation period. 0_B No Frame with content error received 1_B Frame(s) with content error received on channel A

Field	Bits	Type	Description
CIA	3	rwh	**Communication Indicator Channel A** One or more valid Frames were received on channel A in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid Frame AND had any combination of either syntax error OR content error OR slot boundary violation. 0_B No valid Frame(s) received in slots containing any additional communication 1_B Valid Frame(s) received on channel A in slots containing any additional communication
SBVA	4	rwh	**Slot Boundary Violation on Channel A** (vSS!BViolationA) One or more slot boundary violations were observed on channel A at any time during the observation period (static or dynamic slots, symbol window, and network idle time NIT). 0_B No slot boundary violation observed 1_B Slot boundary violation(s) observed on channel A
VFRB	8	rwh	**Valid Frame Received on Channel B** (vSS!ValidFrameB) One or more valid Frames were received on channel B in any static or dynamic slot during the observation period. 0_B No valid Frame received 1_B Valid Frame(s) received on channel B
SEDB	9	rwh	**Syntax Error Detected on Channel B** (vSS!SyntaxErrorB) One or more syntax errors in static or dynamic slots, symbol window, and network idle time (NIT) were observed on channel B. 0_B No syntax error observed 1_B Syntax error(s) observed on channel B
CEDB	10	rwh	**Content Error Detected on Channel B** (vSS!ContentErrorB) One or more Frames with a content error were received on channel B in any static or dynamic slot during the observation period. 0_B No Frame with content error received 1_B Frame(s) with content error received on channel B

Field	Bits	Type	Description
CIB	11	rwh	**Communication Indicator Channel B** One or more valid Frames were received on channel B in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid Frame AND had any combination of either syntax error OR content error OR slot boundary violation. 0_B No valid Frame(s) received in slots containing any additional communication 1_B Valid Frame(s) received on channel B in slots containing any additional communication
SBVB	12	rwh	**Slot Boundary Violation on Channel B** (vSS!BViolationB) One or more slot boundary violations were observed on channel B at any time during the observation period (static or dynamic slots, symbol window, and network idle time NIT). 0_B No slot boundary violation observed 1_B Slot boundary violation(s) observed on channel B
0	[7:5], [31:13]	r	**Reserved** Returns 0 if read; should be written with 0.

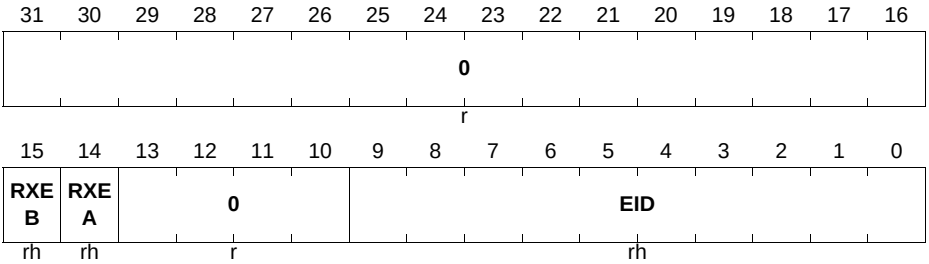
Note: The set condition of flags CIA and CIB is also fulfilled if there is only one single Frame in the slot and the slot boundary at the end of the slot is reached during the Frames channel idle recognition phase. When one of the flags SEDB, CEDB, CIB, SBVB changes from 0 to 1, service request flag EIR.EDB is set to 1.When one of the flags SEDA, CEDA, CIA, SBVA changes from 0 to 1, service request flag EIR.EDA is set to 1.

Even Sync ID [01…15] (ESIDnn)

Registers Even Sync ID nn (ESIDnn, nn=01-15) hold the Frame IDs of the SYNC Frames received in **even** communication cycles, sorted in ascending order, with register ESID01 holding the lowest received SYNC Frame ID. If the node itself transmits a SYNC Frame in an even communication cycle, register ESID01 holds the respective SYNC Frame ID as configured in Message Buffer 0 and the flags RXEA, RXEB are set. The value is updated during the network idle time (NIT) of each even communication cycle.

ESIDnn (nn = 01-15)
Even Sync ID Symbol Window nn

(012C$_H$ + nn * 4) **Reset Value: 0000 0000$_H$**



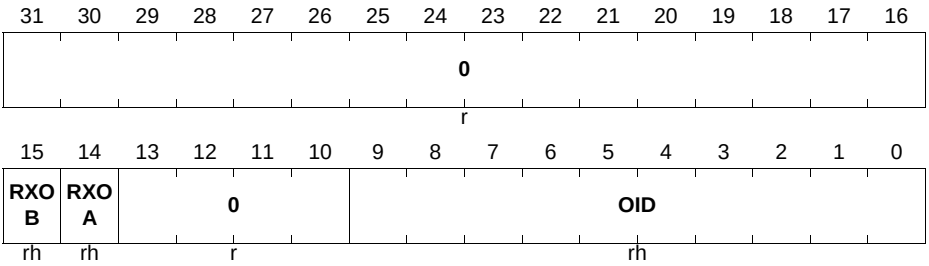
Field	Bits	Type	Description
EID	[9:0]	rh	**Even Sync ID** (vsSyncIDListA,B even) SYNC Frame ID even communication cycle.
RXEA	14	rh	**Received/Configured Even Sync ID on Channel A** Signals that a SYNC Frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot = EID (ESID1 only). 0_B SYNC Frame not received on channel A / node configured to transmit SYNC Frames 1_B SYNC Frame received on channel A/ node not configured to transmit SYNC Frames
RXEB	15	rh	**Received/Configured Even Sync ID on Channel B** Signals that a SYNC Frame corresponding to the stored even sync ID was received on channel B or that the node is configured to be a sync node with key slot = EID (ESID1 only). 0_B SYNC Frame not received on channel B / node configured to transmit SYNC Frames 1_B SYNC Frame received on channel B / node not configured to transmit SYNC Frames

Field	Bits	Type	Description
0	[13:10], [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Odd Sync ID [01…15] (OSIDnn)

he Odd Sync ID nn (OSIDnn, nn=01-15) hold the Frame IDs of the SYNC Frames received in **odd** communication cycles, sorted in ascending order, with register OSID01 holding the lowest received SYNC Frame ID. If the node itself transmits a SYNC Frame in an odd communication cycle, register OSID01 holds the respective SYNC Frame ID as configured in Message Buffer 0 and flags RXOA, RXOB are set. The value is updated during the network idle time (NIT) of each odd communication cycle.

OSIDnn (nn = 01-15)
Odd Sync ID Symbol Window nn ($016C_H$ + nn * 4) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
OID	[9:0]	rh	**Odd Sync ID** (vsSyncIDListA,B odd) SYNC Frame ID even communication cycle.
RXOA	14	rh	**Received Odd Sync ID on Channel A** Signals that a SYNC Frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = OID (OSID1 only). 0_B SYNC Frame not received on channel A/ node configured to transmit SYNC Frames 1_B SYNC Frame received on channel A/ node not configured to transmit SYNC Frames
RXOB	15	rh	**Received Odd Sync ID on Channel B** Signals that a SYNC Frame corresponding to the stored odd sync ID was received on channel B or that the node is configured to be a sync node with key slot = OID (OSID1 only) 0_B SYNC Frame not received on channel B/ node configured to transmit SYNC Frames 1_B SYNC Frame received on channel B/ node not configured to transmit SYNC Frames

Field	Bits	Type	Description
0	[13:10], [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Network Management Vector [1…3] (NMVx)

The three Network Management Vectors n (NMVx, x=1-3) registers hold the accrued Network Management (NM) vector (configurable 0 to 12 byte). The accrued Network Management (NM) vector is generated by the Communication Controller by bit-wise ORing each Network Management (NM) vector received (valid static Frames with PPI = 1) on each channel (see **"Network Management" on Page 24-213**). The Communication Controller updates the Network Management (NM) vector at the end of each communication cycle as long as the Communication Controller is either in "NORMAL_ACTIVE" or "NORMAL_PASSIVE" state. NMVx-bytes exceeding the configured Network Management (NM) vector length are not valid.

NMVx (x = 1-3)
Network Management Vector x

($01AC_H$ + x * 4) **Reset Value: $0000\ 0000_H$**

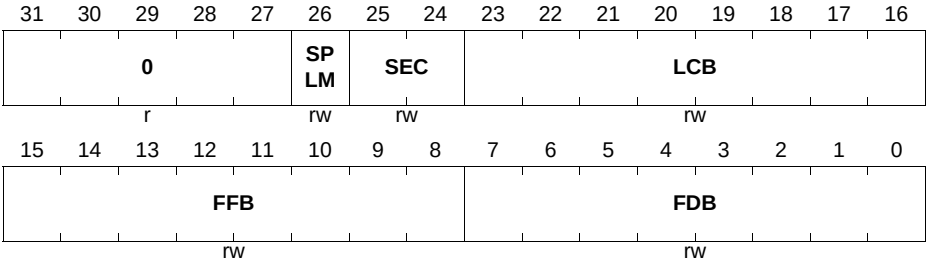
24.5.2.6 Message Buffer Control Registers

Message RAM Configuration (MRC)

The Message RAM Configuration register defines the number of Message Buffers assigned to the static segment, dynamic segment, and FIFO. The register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

MRC
Message RAM Configuration (0300_H) Reset Value: $0180\ 0000_H$



Field	Bits	Type	Description
FDB	[7:0]	rw	**First Dynamic Buffer** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_H No group of Message Buffers exclusively for the static segment configured 01_H …$7F_H$ Message Buffers 0 to FDB-1 reserved for static segment 80_H …FF_H No dynamic Message Buffers configured
FFB	[15:8]	rw	**First Buffer of FIFO** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_H …$7E_H$ Message Buffers from FFB to LCB assigned to the FIFO $7F_H$ All Message Buffers assigned to the FIFO 80_H …FF_H No Message Buffers assigned to the FIFO

Field	Bits	Type	Description
LCB	[23:16]	rw	**Last Configured Buffer** May be only modified in “DEFAULT_CONFIG” or “CONFIG” state. 01_H …$7F_H$ Number of Message Buffers is LCB + 1 80_H …FF_H No Message Buffer configured
SEC	[25:24]	rw	**Secure Buffers** Not evaluated when the Communication Controller is in “DEFAULT_CONFIG” or “CONFIG” state. For temporary unlocking see **“Host Handling of Errors” on Page 24-248**. 00_B Reconfiguration of Message Buffers enabled with numbers < FFB enabled. *Note: In nodes configured for SYNC Frame transmission or for single slot mode operation Message Buffer 0 (and if SPLM = 1, also Message Buffer 1) Reconfiguration of all Message Buffers is always locked* 01_B Reconfiguration of Message Buffers with numbers < FDB and with numbers ≥ FFB locked and transmission of Message Buffers for static segment with numbers ≥ FDB disabled 10_B Reconfiguration of all Message Buffers locked 11_B Reconfiguration of all Message Buffers locked and transmission of Message Buffers for static segment with numbers ≥ FDB disabled
SPLM	26	rw	**SYNC Frame Payload Multiplex** This bit is only evaluated if the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1). When this bit is set to 1 Message Buffers 0 and 1 are dedicated for SYNC Frame transmission with different payload data on channel A and B. When this bit is reset to 0, SYNC Frames are transmitted from Message Buffer 0 with the same payload data on both channels. Note that the channel filter configuration for Message Buffer 0 resp. Message Buffer 1 has to be chosen accordingly. 0_B Only Message Buffer 0 locked against reconfiguration 1_B Both Message Buffers 0 and 1 are locked against reconfiguration

Field	Bits	Type	Description
0	[31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

*Note: In case the node is configured as sync node (*SUCC1.*TXSY = 1) or for single slot mode operation (*SUCC1.*TSM = 1), Message Buffer 0 resp. 1 is reserved for SYNC Frames or single slot Frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation Message Buffer 0 resp. 1 is treated like all other Message Buffers.*

Table 24-6 Usage of the three Message Buffer Pointer

Message Buffer 0	⇓ Static Buffers		
Message Buffer 1			
	⇓ Static + Dynamic	⇐ **FDB**	
	Buffers		
…			FIFO configured: **FFB** > **FDB**
	⇓ FIFO	⇐ **FFB**	No FIFO configured: **FFB** ≥ 128
Message Buffer N-1			**LCB** ≥ **FDB**, **LCB** ≥ **FFB**
Message Buffer N		⇐ **LCB**	

The programmer has to ensure that the configuration defined by FDB, FFB, and LCB is valid. **The Communication Controller does not check for erroneous configurations!**

Note: The maximum number of Header Sections is 128. This means a maximum of 128 Message Buffer can be configured. The maximum length of a Data Section is 254 byte. The length of the Data Section may be configured differently for each Message Buffer. For details see ***"Message RAM" on Page 24-239****.*
In case two or more Message Buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the "Static Buffers" or at the beginning of the "Static + Dynamic Buffers" section.
The payload length configured and the length of the Data Section need to be configured identically for all Message Buffers belonging to the FIFO via WRHS2.PLC and WRHS3.DP. When the Communication Controller is not in "DEFAULT_CONFIG" or "CONFIG" state reconfiguration of Message Buffers belonging to the FIFO is locked.

FIFO Rejection Filter (FRF)

The FIFO Rejection Filter defines a user specified sequence of bits to which channel, Frame ID, and cycle count of the incoming Frames are compared. Together with the FIFO Rejection Filter Mask this register determines whether a message is rejected by the FIFO. The FRF register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

FRF
FIFO Rejection Filter **(0304_H)** **Reset Value: $0180\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0							RNF	RSS	CYF						
r							rw	rw	rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0			FID											CH	
r			rw											rw	

Field	Bits	Type	Description
CH	[1:0]	rw	**Channel Filter** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_B receive on both channels[1)] 01_B receive only on channel B 10_B receive only on channel A 11_B no reception
FID	[12:2]	rw	**Frame ID Filter** Determines the Frame ID to be rejected by the FIFO. With the additional configuration of register FRFM, the corresponding Frame ID filter bits are ignored, which results in further rejected Frame IDs. When FRFM.MFID is zero, a Frame ID filter value of zero means that no Frame ID is rejected. 000_H …$7FF_H$ Frame ID filter values

Field	Bits	Type	Description
CYF	[22:16]	rw	**Cycle Counter Filter** The 7-bit cycle counter filter determines the cycle set to which Frame ID and channel rejection filter are applied. In cycles **not** belonging to the cycle set specified by CYF, all Frames are rejected. For details about the configuration of the cycle counter filter see **“Cycle Counter Filtering” on Page 24-215**. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only.
RSS	23	rw	**Reject in Static Segment** If this bit is set, the FIFO is used only be used in dynamic segment. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B FIFO also used in static segment 1_B Reject messages for static segment
RNF	24	rw	**Reject NULL Frames** If this bit is set, received NULL Frames are not stored in the FIFO. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B NULL Frames are stored in the FIFO 1_B Reject all NULL Frames
0	[15:13], [31:25]	r	**Reserved** Returns 0 if read; should be written with 0.

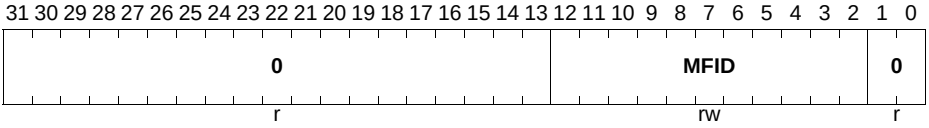
1) If reception on both channels is configured, also in static segment always both Frames (from channel A and B) are stored in the FIFO, even if they are identical.

FIFO Rejection Filter Mask (FRFM)

The FIFO Rejection Filter Mask specifies which of the corresponding Frame ID filter bits are relevant for rejection filtering. If a bit is set, it indicates that the corresponding bit in the FRF register will not be considered for rejection filtering. The FRFM register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

FRFM

FIFO Rejection Filter Mask **(0308_H)** **Reset Value: $0000\ 0000_H$**

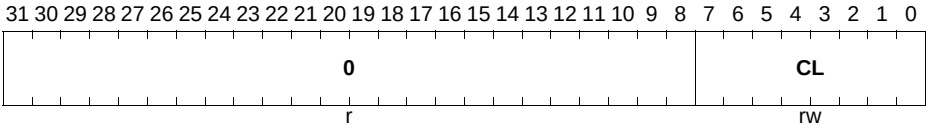


Field	Bits	Type	Description
MFID	[12:2]	rw	**Mask Frame ID Filter** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B Corresponding Frame ID filter bit is used for rejection filtering. 1_B Ignore corresponding Frame ID filter bit.
0	[1:0], [31:13]	r	**Reserved** Returns 0 if read; should be written with 0.

FIFO Critical Level (FCL)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

FCL
FIFO Critical Level **($030C_H$)** **Reset Value: $0000\ 0080_H$**



Field	Bits	Type	Description
CL	[7:0]	rw	**Critical Level** When the receive FIFO fill level FSR.RFFL is equal or greater than the critical level configured by CL, the receive FIFO critical level flag FSR.RFCL is set. If CL is programmed to values > 128, bit FSR.RFCL is never set. When FSR.RFCL changes from 0 to 1 bit **SIR.RFCL** is set to 1, and if enabled, a service request is generated.
0	[31:8]	r	**Reserved** Returns 0 if read; should be written with 0.

24.5.2.7 Message Buffer Status Registers

Message Handler Status (MHDS)

The Message Handler Status register gives the Host access to the current state of the Message Handler. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register. If one of the flags MHDS.EIBF, MHDS.EOBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2 changes from 0 to 1 EIR.EERR is set.

MHDS
Message Handler Status **(0310_H)** **Reset Value: $0000\ 0000_H$**

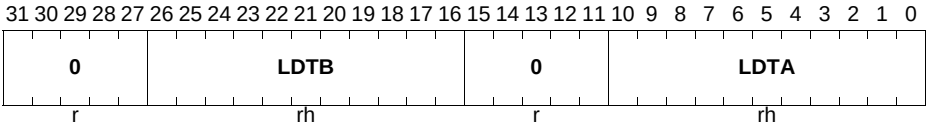
EOBF	1	rwh	**ECC Error Output Buffer RAM 1,2** 0_B No error 1_B Error occurred when reading Output Buffer RAM 1 or Output Buffer RAM 2
EMR	2	rwh	**ECC Error Message RAM** 0_B No error 1_B Error occurred when reading the Message RAM
ETBF1	3	rwh	**ECC Error Transient Buffer RAM A** 0_B No error 1_B Error occurred when reading Transient Buffer RAM A
ETBF2	4	rwh	**ECC Error Transient Buffer RAM B** 0_B No error 1_B Error occurred when reading Transient Buffer RAM B

Field	Bits	Type	Description
FMBD	5	rwh	**Faulty Message Buffer Detected** 0_B No faulty Message Buffer 1_B Message Buffer referenced by MHDS.FMB holds faulty data due to a ECC error
MFMB	6	rwh	**Multiple Faulty Message Buffers detected** 0_B No additional faulty Message Buffer 1_B Another faulty Message Buffer was detected while flag MHDS.FMBD is set
CRAM	7	rh	**Clear all internal RAM's** Signals that execution of the CHI command CLEAR_RAMS is ongoing (all bits of all internal RAM blocks are written to 0). The bit is set by CHI command CLEAR_RAMS. 0_B No execution of the CHI command CLEAR_RAMS 1_B Execution of the CHI command CLEAR_RAMS ongoing
FMB	[14:8]	rh	**Faulty Message Buffer** ECC error occurred when reading from the Message Buffer or when transferring data from Input Buffer or Transient Buffer A or Transient Buffer B to the Message Buffer referenced by MHDS.FMB. Value only valid when one of the flags MHDS.EIBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2, and flag MHDS.FMBD is set. Updated only after the Host has reset flag MHDS.FMBD.
MBT	[22:16]	rh	**Message Buffer Transmitted** Number of last successfully transmitted Message Buffer. If the Message Buffer is configured for single-shot mode, the respective TXR flag in the Transmission Request Registers TXRQ1 to TXRQ4 was reset. MBT is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.
MBU	[30:24]	rh	**Message Buffer Updated** Number of Message Buffer that was updated last. For this Message Buffer the respective NDn (n = 0-31) to NDn (n = 96-127)and / or MBCn (n = 0-31) to MBCn (n = 96-127) flag in the New Data Registers NDAT1 to NDAT4 and the Message Buffer Status Changed MBSC1 to MBSC4 registers are also set. MBU is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.
0	15, 23, 31	r	**Reserved** Returns 0 if read; should be written with 0.

Last Dynamic Transmit Slot (LDTS)

The Last Dynamic Transmit Slot Register stores the Slot Counter value at the time of the last Frame transmission in the dynamic segment. This register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state.

LDTS
Last Dynamic Transmit Slot **(0314_H)** **Reset Value: $0000\ 0000_H$**

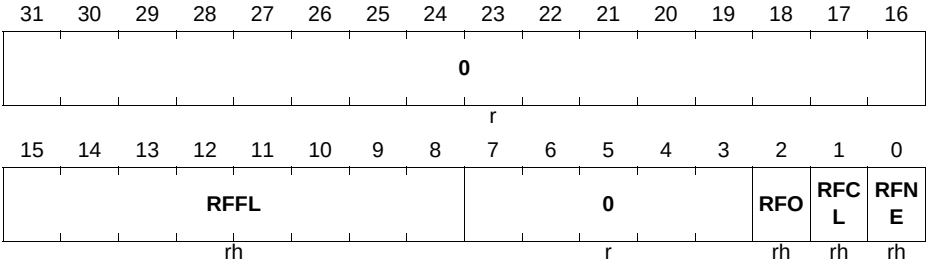


Field	Bits	Type	Description
LDTA	[10:0]	rh	**Last Dynamic Transmission Channel A** Value of (vSlotCounter[A]) at the time of the last Frame transmission on channel A in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to zero if no Frame was transmitted during the dynamic segment.
LDTB	[26:16]	rh	**Last Dynamic Transmission Channel B** Value of (vSlotCounter[B]) at the time of the last Frame transmission on channel B in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to zero if no Frame was transmitted during the dynamic segment.
0	[15:11], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

FIFO Status Register (FSR)

The register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state.

FSR
FIFO Status Register **(0318_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RFNE	0	rh	**Receive FIFO Not Empty** This flag is set by the Communication Controller when a received valid Frame (data or NULL Frame depending on rejection mask) was stored in the FIFO. In addition, service request flag SIR.RFNE is set. The bit is reset after the Host has read all message from the FIFO. 0_B Receive FIFO is empty 1_B Receive FIFO is not empty
RFCL	1	rh	**Receive FIFO Critical Level** This flag is set when the receive FIFO fill level RFFL is equal or greater than the critical level as configured by FCL.CL. The flag is cleared by the Communication Controller as soon as RFFL drops below FCL.CL. When RFCL changes from 0 to 1 bit SIR.RFCL is set to 1, and if enabled, an service request is generated. 0_B Receive FIFO below critical level 1_B Receive FIFO critical level reached

Field	Bits	Type	Description
RFO	2	rh	**Receive FIFO Overrun** The flag is set by the Communication Controller when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, service request flag EIR.RFO is set.The flag is cleared by the next FIFO read access issued by the Host. 0_B No receive FIFO overrun detected 1_B A receive FIFO overrun has been detected
RFFL	[15:8]	rh	**Receive FIFO Fill Level** Number of FIFO buffers filled up with new data not yet read by the Host. Maximum value is 128.
0	[7:3], [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Message Handler Constraints Flags (MHDF)

Some constraints exist for the Message Handler regarding f_{CLC_ERAY} frequency, Message RAM configuration, and FlexRay™ bus traffic. To simplify software development, constraints violations are reported by setting flags in the MHDF. The register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state. A flag is cleared by setting the corresponding bit position. Clearing has no effect on the flag. If any flag in MHDFL is set, interrupt flag EIR.MHF is set.

MHDF

Message Handler Constraints Flags (031C$_H$) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r							rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
SNUA	0	rwh	**Status Not Updated Channel A** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to update a Message Buffer’s status MBS with respect to channel A. 0_B No overload condition occurred when updating MBS for channel A 1_B MBS for channel A not updated
SNUB	1	rwh	**Status Not Updated Channel B** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to update a Message Buffer’s status MBS with respect to channel B. 0_B No overload condition occurred when updating MBS for channel B 1_B MBS for channel B not updated

Field	Bits	Type	Description
FNFA	2	rwh	**Find Sequence Not Finished Channel A** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching Message Buffer) with respect to channel A. 0_B No find sequence not finished for channel A 1_B Find sequence not finished for channel A
FNFB	3	rwh	**Find Sequence Not Finished Channel B** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching Message Buffer) with respect to channel B. 0_B No find sequence not finished for channel B 1_B Find sequence not finished for channel B
TBFA	4	rwh	**Transient Buffer Access Failure A** This flag is set by the Communication Controller when a read or write access to Transient Buffer A requested by PRT A could not complete within the available time. 0_B No TBF A access failure 1_B TBF A access failure
TBFB	5	rwh	**Transient Buffer Access Failure B** This flag is set by the Communication Controller when a read or write access to Transient Buffer B requested by PRT B could not complete within the available time. 0_B No Transient Buffer B access failure 1_B Transient Buffer B access failure
TNSA	6	rwh	**Transmission Not Started Channel A** This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel A at the action point of the configured slot. 0_B No transmission not started on channel A 1_B Transmission not started on channel A
TNSB	7	rwh	**Transmission Not Started Channel B** This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel B at the action point of the configured slot. 0_B No transmission not started on channel B 1_B Transmission not started on channel B

Field	Bits	Type	Description
WAHP	8	rwh	**Write Attempt to Header Partition** Outside “DEFAULT_CONFIG” and “CONFIG” state this flag is set by the Communication Controller when the message handler tries to write message data into the Header Partition of the Message RAM due to faulty configuration of a Message Buffer. The write attempt is not executed, to protect the Header Partition from unintended write accesses. 0_B No write attempt to Header Partition 1_B Write attempt to Header Partition
0	[31:9]	r	**Reserved** Returns 0 if read; should be written with 0.

Transmission Request 1 (TXRQ1)

This register reflect the state of the TXR flags of the configured Message Buffers 0 to 31. The flags are evaluated for transmit buffers only. If the number of configured Message Buffers is less than 31, the remaining TXRn flags have no meaning and are read as 0.

TXRQ1
Transmission Request Register 1 (0320_H) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
MBCn (n = 0-31)	n	rh	**Message Buffer Status Changed n (n = 0-31)** An MBC flags is set whenever the Message Handler changes on of the status flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB in the Header Section (see **“Message Buffer Status (MBS)” on Page 24-176**) of the respective Message Buffer 0 to Message Buffer 31. The flags are reset when the Header Section of the Message Buffer is reconfigured or when it has been transferred to the Output Buffer.

Message Buffer Status Changed 2 (MBSC2)

This register reflect the state of the MBC flags of all configured Message Buffers. If the number of configured Message Buffers is less than 63, the remaining MBCn flags have no meaning. The register is reset when the communication controller leaves “CONFIG” state or enters “STARTUP” state.

MBSC2

Message Buffer Status Changed 2 (0344_H) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
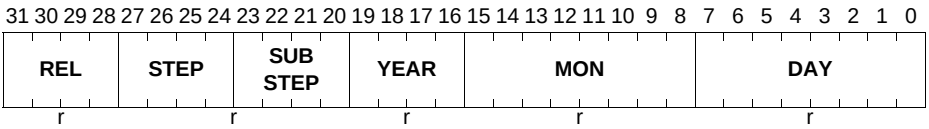
MBCn (n = 96-127)	n - 96	rh	**Message Buffer Status Changed n (n = 96-127)** An MBC flags is set whenever the Message Handler changes on of the status flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB in the Header Section (see **“Message Buffer Status (MBS)” on Page 24-176**) of the respective Message Buffer 96 to Message Buffer 127. The flags are reset when the Header Section of the Message Buffer is reconfigured or when it has been transferred to the Output Buffer.

24.5.2.8 Identification Registers

Core Release Register (CREL)

This register contains bit fields about the ERAY module identification. It is read only.

CREL
Core Release Register **($03F0_H$)** **Reset Value: $XXXX\ XXXX_H$**



Field	Bits	Type	Description
DAY	[7:0]	r	**Design Time Stamp, Day** Two digits, BCD-coded.
MON	[15:8]	r	**Design Time Stamp, Month** Two digits, BCD-coded.
YEAR	[19:16]	r	**Design Time Stamp, Year** One digit, BCD-coded.
SUBSTEP	[23:20]	r	**Sub-Step of Core Release** One digits, BCD-coded. 0_H Alpha, pre-Beta, pre-Beta-update, pre-Beta2, pre-Beta2-update, Beta, Beta2, Revision 1.0.0 1_H Beta_ct, Beta-ct-fix1, Revision 1.0.1 2_H Revision1.0RC1,Beta-ct-fix2, REVISION 1.0RC1
STEP	[27:24]	r	**Step of Core Release** One digits, BCD-coded. 0_H Revision 1.0.0 1_H Alpha 2_H pre-Beta 3_H pre-Beta-update 4_H pre-Beta2 5_H pre-Beta2-update 6_H Beta 7_H Beta2

Field	Bits	Type	Description
REL	[31:28]	r	**Core Release** One digit, BCD-coded. 0_B alpha…beta2ct 1_B Revision 1.0

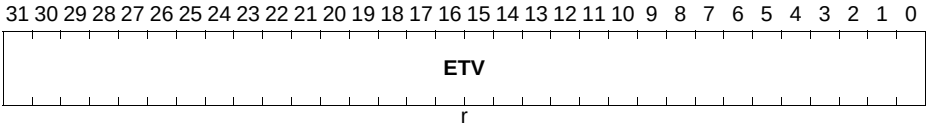
Table 24-7 Coding of releases

Release	Step	Sub-Step	Name	Release Date
0	1	0	Alpha	
0	2	0	pre-Beta	
0	3	0	pre-Beta-update	
0	4	0	pre-Beta2	
0	5	0	pre-Beta2-update	
0	6	0	Beta	
0	6	1	Beta-ct-fix1	14.10.2005
0	6	2	Beta-ct-fix2	14.12.2005
0	7	0	Beta2	03.02.2006
0	7	1	Beta2ct	24.03.2006
0	7	2	Revision 1.0RC1	07.04.2006
1	0	0	Release 1.0.0	19.05.2006
1	0	1	Release 1.0.1	2006
1	0	2	Release 1.0.2	31.10.2007

Endian Register (ENDN)

This register may be used to check, if the data of the E-Ray is handled by a host with the correct endian format. It is read only.

ENDN
Endian Register **(003F4$_H$)** **Reset Value: 8765 4321$_H$**



Field	Bits	Type	Description
ETV	[31:0]	r	**Endianness Test Value** The endianness test value.

24.5.2.9 Input Buffer

Double buffer structure consisting of Input Buffer Host and Input Buffer Shadow. While the Host can write to Input Buffer Host, the transfer to the Message RAM is done from Input Buffer Shadow. The Input Buffer holds the Header and Data Sections to be transferred to the selected Message Buffer in the Message RAM. It is used to configure the Message Buffers in the Message RAM and to update the Data Sections of transmit buffers.

When updating the Header Section of a Message Buffer in the Message RAM from the Input Buffer, the Message Buffer Status as described in **“Message Buffer Status (MBS)” on Page 24-176** is automatically reset to zero.

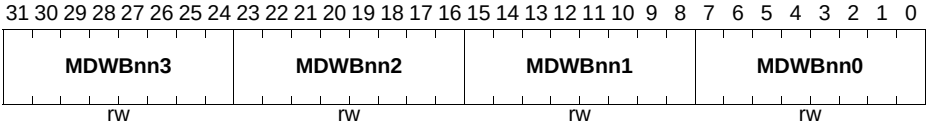
The Header Sections of Message Buffers belonging to the receive FIFO can only be (re)configured when the Communication Controller is in “DEFAULT_CONFIG” or “CONFIG” state. For those Message Buffers only the payload length configured and the data pointer need to be configured via WRHS2.PLC and WRHS2.DP. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask.

The data transfer between Input Buffer (IBF) and Message RAM is described in detail in **“Data Transfer from Input Buffer to Message RAM” on Page 24-224**.

Write Data Section [01 - 64] (WRDSnn (nn = 01-64))

The Write Data Section (WRDSnn, nn = 01-64) holds the data words to be transferred to the Data Section of the addressed Message Buffer. The data words (DW_n) are written to the Message RAM in transmission order from DW1 (byte0, byte1) to DW_{PL} (PL = number of data words as defined by the payload length configured by WRHS2.PLC).

WRDSnn (nn = 01-64)
Write Data Section nn **($03FC_H$ + nn * 4)** **Reset Value: $0000\ 0000_H$**



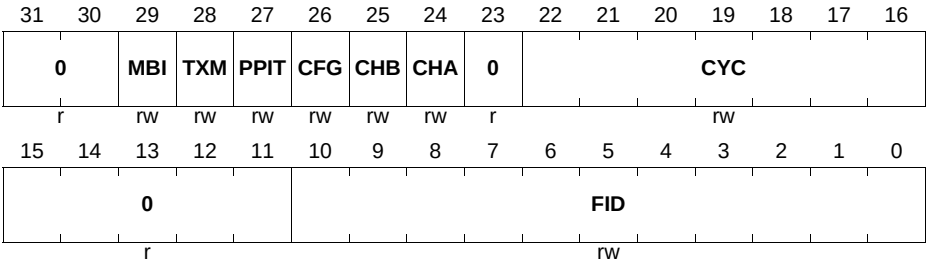
Field	Bits	Type	Description
MDWB0	[7:0]	rw	**32-Bit Word nn, Byte 0**
MDWB1	[15:8]	rw	**32-Bit Word nn, Byte 1**
MDWB2	[23:16]	rw	**32-Bit Word nn, Byte 2**
MDWB3	[31:24]	rw	**32-Bit Word nn, Byte 3**

Note: 16-bit Word 127 is located on WRDS64.MDW. In this case WRDS64.MDW is unused (no valid data). The Input Buffer RAMs are initialized to zero when leaving application reset or by CHI command CLEAR_RAMS.

Note: When writing to the WRDSnn (nn = 01-64), each 32-bit word has to be filled up by one 32-bit access OR two consecutive 16-bit accesses OR four consecutive 8-bit accesses before the transfer from the Input Buffer to the Message RAM is started by writing the number of the target Message Buffer in the Message RAM to the Input Buffer Command Request register. If a 32-bit word of the Input Buffer has been filled with less then two consecutive 16-bit accesses OR four consecutive 8-bit accesses (less then 32-bit), random data is transferred into the Input buffer for every not written 16-bit or 8-bit of a 32-bit word.

Write Header Section 1 (WRHS1)

WRHS1
Write Header Section 1 **(0500_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FID	[10:0]	rw	**Frame ID** Frame ID of the selected Message Buffer. The Frame ID defines the slot number for transmission / reception of the respective message. Message Buffers with Frame ID = 0 are considered as not valid.
CYC	[22:16]	rw	**Cycle Code** The 7-bit cycle code determines the cycle set used for cycle counter filtering. For details about the configuration of the cycle code see **Section 24.6.7.3**.
CHA	24	rw	**Channel Filter Control A** The channel filtering field A associated with the buffer serves of channel A as a filter for receive buffers, and as a control field for transmit buffers
CHB	25	rw	**Channel Filter Control B** The channel filtering field B associated with the buffer serves of channel B as a filter for receive buffers, and as a control field for transmit buffers
CFG	26	rw	**Message Buffer Direction Configuration Bit** This bit is used to configure the corresponding buffer as a transmit buffer or as a receive buffer. For Message Buffers belonging to the receive FIFO the bit is not evaluated. 0_B The corresponding buffer is configured as Receive Buffer 1_B The corresponding buffer is configured as Transmit Buffer

Field	Bits	Type	Description
PPIT	27	rw	**Payload Preamble Indicator Transmit** This bit is used to control the state of the Payload Preamble Indicator in transmit Frames. If the bit is set in a static Message Buffer, the respective Message Buffer holds Network Management information. If the bit is set in a dynamic Message Buffer the first two byte of the Payload Segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay™ Frames is not supported by the E-Ray module, but can be done by the Host. 0_B Payload Preamble Indicator not set 1_B Payload Preamble Indicator set
TXM	28	rw	**Transmission Mode** This bit is used to select the transmission mode (see **“Transmit Buffers” on Page 24-217**). 0_B Continuous mode 1_B Single-shot mode
MBI	29	rw	**Message Buffer Service Request** This bit enables the receive / transmit service request for the corresponding Message Buffer. After a dedicated receive buffer has been updated by the Message Handler, flag SIR.RXI and /or SIR.MBSI in the Status Service Request register are set. After a transmission has completed flag SIR.TXI is set. 0_B The corresponding Message Buffer service request is disabled 1_B The corresponding Message Buffer service request is enabled
0	[15:11], 23, [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: The Input Buffer RAMs are initialized to zero when leaving application reset or by CHI command CLEAR_RAMS. Note that only the currently active IBF bank is cleared. To clear the 2nd bank as well, CUST1.IBF1PAG and CUST1.IBF2PAG need to be set and command CLEAR_RAMS need to be issued again. This is required in particular after an application reset. If the 2nd bank of IBF is left unused, this procedure is not required.

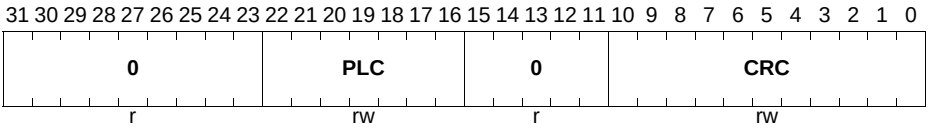
Table 24-8 Channel Filter Control Bits

CHA	CHB	Transmit Buffer transmit Frame on	Receive Buffer store Frame received from
1[1)]	1[1)]	Both Channels (static segment only)	Channel A or B (store first semantically valid Frame, static segment only)
1	0	Channel A	Channel A
0	1	Channel B	Channel B
0	0	No Transmission	Ignore Frame

1) If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

Write Header Section 2 (WRHS2)

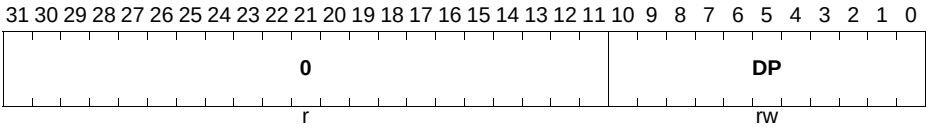
WRHS2
Write Header Section 2 **(0504_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CRC	[10:0]	rw	**Header CRC** (vRF!Header!HeaderCRC) Receive Buffer: Configuration not required Transmit Buffer: Header CRC calculated and configured by the Host. For calculation of the Header CRC the payload length of the Frame send on the bus has to be considered. In static segment the payload length of all Frames is configured by MHDC.SFDL.
PLC	[22:16]	rw	**Payload Length Configured** Length of Data Section (number of 2-byte words) as configured by the Host. During static segment the static Frame payload length as configured by MHDC.SFDL in the MHD Configuration Register defines the payload length for all static Frames. If the payload length configured by PLC is shorter than this value padding byte are inserted to ensure that Frames have proper physical length. The padding pattern is logical zero.
0	[15:11], [31:23]	r	**Reserved** Returns 0 if read; should be written with 0.

Write Header Section 3 (WRHS3)

WRHS3
Write Header Section 3 **(0508_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DP	[10:0]	rw	**Data Pointer** Pointer to the first 32-bit word of the Data Section of the addressed Message Buffer in the Message RAM.
0	[31:11]	r	**Reserved** Returns 0 if read; should be written with 0.

Input Buffer Command Mask (IBCM)

Configures how the Message Buffer in the Message RAM selected by the Input Buffer Command Request register IBCR is updated. If IBF Host and IBF Shadow are swapped, also masked bits IBCM.LHSH, IBCM.LDSH, and IBCM.STXRH are swapped with bits IBCM.LHSS, IBCM.LDSS, and IBCM.STXRS to keep them attached to the respective Input Buffer transfer.

IBCM
Input Buffer Command Mask **(0510_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0													STXRS	LDSS	LHSS
r													rh	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0													STXRH	LDSH	LHSH
r													rwh	rwh	rwh

Field	Bits	Type	Description
LHSH	0	rwh	**Load Header Section Host** 0_B Header Section is not updated 1_B Header Section selected for transfer from Input Buffer to the Message RAM
LDSH	1	rwh	**Load Data Section Host** 0_B Data Section is not updated 1_B Data Section selected for transfer from Input Buffer to the Message RAM
STXRH	2	rwh	**Set Transmission Request Host** If this bit is set to 1, the Transmission Request flag TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) for the selected Message Buffer is set in the Transmission Request Registers to release the Message Buffer for transmission. In single-shot mode the flag is cleared by the Communication Controller after transmission has completed. TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) are evaluated for transmit buffer only. 0_B Reset Transmission Request flag 1_B Set Transmission Request flag, transmit buffer released for transmission

Field	Bits	Type	Description
LHSS	16	rh	**Load Header Section Shadow** 0_B Header Section is not updated 1_B Header Section selected for transfer from Input Buffer to the Message RAM (transfer is ongoing of finalized)
LDSS	17	rh	**Load Data Section Shadow** 0_B Data Section is not updated 1_B Data Section selected for transfer from Input Buffer to the Message RAM (transfer is ongoing of finalized)
STXRS	18	rh	**Transmission Request Shadow** If this bit is set to 1, the Transmission Request flag TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) for the selected Message Buffer is set in the Transmission Request Registers to release the Message Buffer for transmission. In single-shot mode the flag is cleared by the Communication Controller after transmission has completed. TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) are evaluated for transmit buffer only. 0_B Reset Transmission Request flag 1_B Set Transmission Request flag, transmit buffer released for transmission (operation is ongoing of finalized)
0	[15:3], [31:19]	r	**Reserved** Returns 0 if read; should be written with 0.

Input Buffer Command Request (IBCR)

When the Host writes the number of the target Message Buffer in the Message RAM to IBRH in the Input Buffer Command Request register, IBF Host and IBF Shadow are swapped. In addition the Message Buffer numbers stored under IBRH and IBRS are also swapped (see also **"Data Transfer from Input Buffer to Message RAM" on Page 24-224**).

With this write operation the IBSYS bit in the Input Buffer Command Request register is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the Message Buffer in the Message RAM selected by IBRS.

While the Message Handler transfers the data from IBF Shadow to the target Message Buffer in the Message RAM, the Host may write the next message into the IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target Message Buffer number to IBRH.

If a write access to IBRH occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, IBSYH is reset to 0. IBSYS remains set to 1, and the next transfer to the Message RAM is started. In addition the Message Buffer numbers stored under IBRH and IBRS are also swapped. Any write access to an Input Buffer register while both IBSYS and IBSYH are set will cause the error flag EIR.IIBA to be set. In this case the Input Buffer will not be changed.

IBCR
Input Buffer Command Request (0514_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IBSYS	0								IBRS						
rh	r								rh						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IBSYH	0								IBRH						
rh	r								rwh						

Field	Bits	Type	Description
IBRH	[6:0]	rwh	**Input Buffer Request Host** Selects the target Message Buffer in the Message RAM for data transfer from Input Buffer. Valid values are 00_H to $7F_H$ (0…127).

Field	Bits	Type	Description
IBSYH	15	rh	**Input Buffer Busy Host** Set to 1 by writing IBRH while IBSYS is still 1. After the ongoing transfer between IBF Shadow and the Message RAM has completed, the IBSYH is set back to 0. 0_B No request pending 1_B Request while transfer between IBF Shadow and Message RAM in progress
IBRS	[22:16]	rh	**Input Buffer Request Shadow** Number of the target Message Buffer actually updated/lately updated. Valid values are 00_H to $7F_H$ (0…127).
IBSYS	31	rh	**Input Buffer Busy Shadow** Set to 1 after writing IBRH. When the transfer between IBF Shadow and the Message RAM has completed, IBSYS is set back to 0. 0_B Transfer between IBF Shadow and Message RAM completed 1_B Transfer between IBF Shadow and Message RAM in progress
0	[14:7], [30:23]	r	**Reserved** Returns 0 if read; should be written with 0.

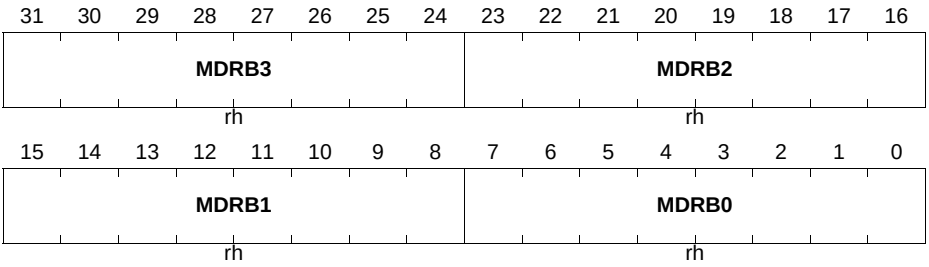
24.5.2.10 Output Buffer

Double buffer structure consisting of Output Buffer Host and Output Buffer Shadow. Used to read out Message Buffers from the Message RAM. While the Host can read from Output Buffer Host, the Message Handler transfers the selected Message Buffer from Message RAM to the respective Output Buffer Shadow. The data transfer between Message RAM and Output Buffer (OBF) is described in **"Data Transfer from Message RAM to Output Buffer" on Page 24-226**.

Read Data Section [1…64] (RDDSn)

The Read Data Section nn (RDDSnn, nn = 01-64) holds the data words read from the Data Section of the addressed Message Buffer. The data words are read from the Message RAM in reception order from DW1 (byte0, byte1) to DW_{PL} (PL = number of data words as defined by the Payload Length).

RDDSnn (nn = 01-64)
Read Data Section nn **($05FC_H$ + nn * 4)** **Reset Value: $0000\ 0000_H$**



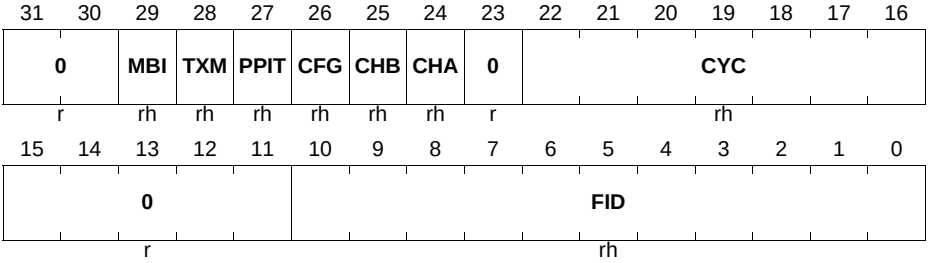
Field	Bits	Type	Description
MDRB0	[7:0]	rh	**32-Bit Word nn, Byte 0**
MDRB1	[15:8]	rh	**32-Bit Word nn, Byte 1**
MDRB2	[23:16]	rh	**32-Bit Word nn, Byte 2**
MDRB3	[31:24]	rh	**32-Bit Word nn, Byte 3**

Note: DW127 is located on RDDS64.MDW. In this case RDDS64.MDW is unused (no valid data). The Output Buffer RAMs are initialized to zero when leaving application reset or by CHI command CLEAR_RAMS.

Read Header Section 1 (RDHS1)

Values as configured by the Host via WRHS1 Register:

RDHS1
Read Header Section 1 **(0700_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FID	[10:0]	rh	**Frame ID**
CYC	[22:16]	rh	**Cycle Code**
CHA	24	rh	**Channel Filter Control A**
CHB	25	rh	**Channel Filter Control B**
CFG	26	rh	**Message Buffer Direction Configuration Bit**
PPIT	27	rh	**Payload Preamble Indicator Transmit**
TXM	28	rh	**Transmission Mode**
MBI	29	rh	**Message Buffer Service Request**
0	[15:11], 23, [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: In case that the Message Buffer read from the Message RAM belongs to the receive FIFO, FID holds the received Frame ID, while CYC, CHA, CHB, CFG, PPIT, TXM, and MBI are reset to zero.

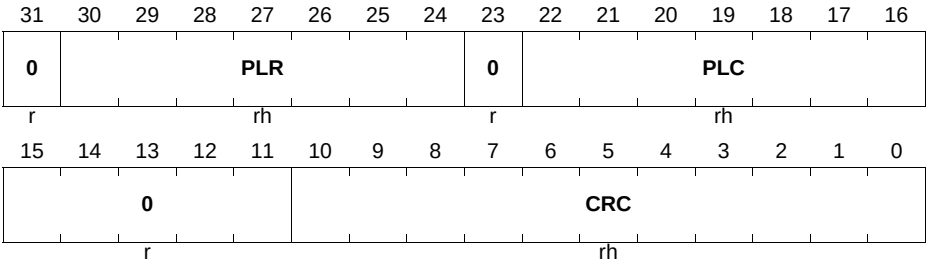
Table 24-9 Channel Filter Control Bits

CHA	CHB	Transmit Buffer transmit Frame on	Receive Buffer store Frame received from
1[1)]	1[1)]	Both Channels (static segment only)	Channel A or B (store first semantically valid Frame, static segment only)
1	0	Channel A	Channel A
0	1	Channel B	Channel B
0	0	No Transmission	Ignore Frame

1) If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

Read Header Section 2 (RDHS2)

RDHS2
Read Header Section 2 **(0704_H)** **Reset Value: $0000\ 0000_H$**



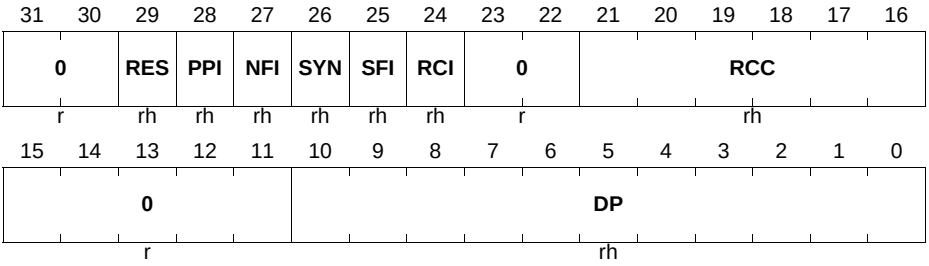
Field	Bits	Type	Description
CRC	[10:0]	rh	**Header CRC** (vRF!Header!HeaderCRC) Receive Buffer: Configuration not required. Header CRC updated from receive Data Frames. Transmit Buffer: Header CRC calculated and configured by the Host
PLC	[22:16]	rh	**Payload Length Configured** Length of Data Section (number of 2-byte words) as configured by the Host.

Field	Bits	Type	Description
PLR	[30:24]	rh	**Payload Length Received** (vRF!Header!Length) Payload length value updated from received Data Frame (exception: if Message Buffer belongs to the receive FIFO PLR is also updated from received NULL Frames). When a message is stored into a Message Buffer the following behavior with respect to payload length received and payload length configured is implemented: • **PLR > PLC:** The payload data stored in the Message Buffer is truncated to the payload length configured for even PLC or else truncated to PLC + 1. • **PLR ≤ PLC:** The received payload data is stored into the Message Buffers Data Section. The remaining data bytes of the Data Section as configured by PLC are filled with undefined data. • **PLR = 0:** The Message Buffer's Data Section is filled with undefined data. • **PLC = 0:** Message Buffer has no Data Section configured. No data is stored into the Message Buffer's Data Section.
0	[15:11], 23, 31	r	**Reserved** Returns 0 if read; should be written with 0.

Note: The Message RAM is organized in 4-byte words. When received data is stored into a Message Buffer's Data Section, the number of 2-byte data words written into the Message Buffer is PLC rounded to the next even value. PLC should be configured identical for all Message Buffers belonging to the receive FIFO. Header 2 is updated from Data Frames only.

Read Header Section 3 (RDHS3)

RDHS3
Read Header Section 3 **(0708_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DP	[10:0]	rh	**Data Pointer** Pointer to the first 32-bit word of the Data Section of the addressed Message Buffer in the Message RAM.
RCC	[21:16]	rh	**Receive Cycle Count** (vRF!Header!CycleCount) Cycle counter value updated from received Data Frame.
RCI	24	rh	**Received on Channel Indicator** (vSS!Channel) Indicates the channel from which the received Data Frame was taken to update the respective receive buffer. 0_B Frame received on channel B 1_B Frame received on channel A
SFI	25	rh	**Startup Frame Indicator** (vRF!Header!SuFIndicator) A Startup Frame is marked by the Startup Frame indicator. 0_B The received Frame is not a startup Frame 1_B The received Frame is a startup Frame
SYN	26	rh	**SYNC Frame Indicator** (vRF!Header!SyFIndicator) A SYNC Frame is marked by the SYNC Frame indicator. 0_B The received Frame is not a SYNC Frame 1_B The received Frame is a SYNC Frame
NFI	27	rh	**NULL Frame Indicator** (vRF!Header!NFIndicator) Is set to 1 after storage of the first received Data Frame. 0_B Up to now no Data Frame has been stored into the respective Message Buffer 1_B At least one Data Frame has been stored into the respective Message Buffer

Field	Bits	Type	Description
PPI	28	rh	**Payload Preamble Indicator** (vRF!Header!PPIndicator) The payload preamble indicator defines whether a Network Management vector or message ID is contained within the Payload Segment of the received Frame. 0_B The Payload Segment of the received Frame does not contain a Network Management vector nor a message ID 1_B Static segment: Network Management vector in the first part of the payload Dynamic segment: Message ID in the first part of the payload
RES	29	rh	**Reserved Bit** (vRF!Header!Reserved) Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.
0	[15:11], [23:22], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: Header 3 is updated from Data Frames only.

Message Buffer Status (MBS)

The Message Buffer status is updated by the Communication Controller with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the Message Buffer. The flags are updated only when the Communication Controller is in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state. If only one channel (A or B) is assigned to a Message Buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a Message Buffer, the channel-specific status flags of both channels are updated. The Message Buffer status is updated only when the slot counter reached the configured Frame ID and when the cycle counter filter matched. When the Host updates a Message Buffer via Input Buffer, all MBS flags are reset to zero independent of which IBCM bits are set or not. For details about receive / transmit filtering see **“Filtering and Masking” on Page 24-213**, **“Transmit Process” on Page 24-217**, and **“Receive Process” on Page 24-220**.

Whenever the Message Handler changes one of the flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB the respective Message Buffer’s MBC flag in registers MBSC1 to MBSC4 is set

MBS

Message Buffer Status **($070C_H$)** **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
VFRA	0	rh	**Valid Frame Received on Channel A** (vSS!ValidFrameA) A valid Frame indication is set if a valid Frame was received on channel A. 0_B No valid Frame received on channel A 1_B Valid Frame received on channel A
VFRB	1	rh	**Valid Frame Received on Channel B** (vSS!ValidFrameB) A valid Frame indication is set if a valid Frame was received on channel B. 0_B No valid Frame received on channel B 1_B Valid Frame received on channel B

Field	Bits	Type	Description
SEOA	2	rh	**Syntax Error Observed on Channel A** (vSS!SyntaxErrorA) A syntax error was observed in the assigned slot on channel A. 0_B No syntax error observed on channel A 1_B Syntax error observed on channel A
SEOB	3	rh	**Syntax Error Observed on Channel B** (vSS!SyntaxErrorB) A syntax error was observed in the assigned slot on channel B. 0_B No syntax error observed on channel B 1_B Syntax error observed on channel B
CEOA	4	rh	**Content Error Observed on Channel A** (vSS!ContentErrorA) A content error was observed in the assigned slot on channel A. 0_B No content error observed on channel A 1_B Content error observed on channel A
CEOB	5	rh	**Content Error Observed on Channel B** (vSS!ContentErrorB) A content error was observed in the assigned slot on channel B. 0_B No content error observed on channel B 1_B Content error observed on channel B
SVOA	6	rh	**Slot Boundary Violation Observed on Channel A** (vSS!BViolationA) A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel A. 0_B No slot boundary violation observed on channel A 1_B Slot boundary violation observed on channel A
SVOB	7	rh	**Slot Boundary Violation Observed on Channel B** (vSS!BViolationB) A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel B. 0_B No slot boundary violation observed on channel B 1_B Slot boundary violation observed on channel B
TCIA	8	rh	**Transmission Conflict Indication Channel A** (vSS!TxConflictA) A transmission conflict indication is set if a transmission conflict has occurred on channel A. 0_B No transmission conflict occurred on channel A 1_B Transmission conflict occurred on channel A

Field	Bits	Type	Description
TCIB	9	rh	**Transmission Conflict Indication Channel B** (vSS!TxConflictB) A transmission conflict indication is set if a transmission conflict has occurred on channel B. 0_B No transmission conflict occurred on channel B 1_B Transmission conflict occurred on channel B
ESA	10	rh	**Empty Slot Channel A** In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots. 0_B Bus activity detected in the assigned slot on channel A 1_B No bus activity detected in the assigned slot on channel A
ESB	11	rh	**Empty Slot Channel B** In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots. 0_B Bus activity detected in the assigned slot on channel B 1_B No bus activity detected in the assigned slot on channel B
MLST	12	rh	**Message Lost** The flag is set in case the Host did not read the message before the Message Buffer was updated from a received Data Frame. Not affected by reception of NULL Frames except for Message Buffers belonging to the receive FIFO. The flag is reset by a Host write to the Message Buffer via IBF or when a new message is stored into the Message Buffer after the Message Buffers ND flag was reset by reading out the Message Buffer via OBF. 0_B No message lost 1_B Unprocessed message was overwritten
FTA	14	rh	**Frame Transmitted on Channel A** Indicates that this node has transmitted a Data Frame in the assigned slot on channel A. 0_B No transmission transmitted on channel A 1_B Data Frame transmitted on channel A in cycle defined by CCS bit field *Note: The FlexRay™ protocol specification requires that FTA can only be reset by the Host. Therefore the Cycle Count Status CCS for these bits is only valid for the cycle where the bits are set to 1*

Field	Bits	Type	Description
FTB	15	rh	**Frame Transmitted on Channel B** Indicates that this node has transmitted a Data Frame in the assigned slot on channel B. 0_B No transmission transmitted on channel B 1_B Data Frame transmitted on channel B in cycle defined by CCS bit field *Note: The FlexRay™ protocol specification requires that FTB can only be reset by the Host. Therefore the Cycle Count Status CCS for these bits is only valid for the cycle where the bits are set to 1*
CCS	[21:16]	rh	**Cycle Count Status** Cycle Count when status (MBS register) has been updated.
RCIS	24	rh	**Received on Channel Indicator Status** (vSS!Channel) Indicates the channel on which the Frame was received. 0_B Frame received on channel B 1_B Frame received on channel A *Note: For receive buffers (CFG = 0) the RCIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
SFIS	25	rh	**Startup Frame Indicator Status** (vRF!Header!SuFIndicator) A Startup Frame is marked by the Startup Frame indicator. 0_B No Startup Frame received 1_B The received Frame is a startup Frame *Note: For receive buffers (CFG = 0) the SFIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
SYNS	26	rh	**SYNC Frame Indicator Status** (vRF!Header!SyFIndicator) A Startup Frame is marked by the Startup Frame indicator. 0_B No SYNC Frame received 1_B The received Frame is a SYNC Frame *Note: For receive buffers (CFG = 0) the SYNS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*

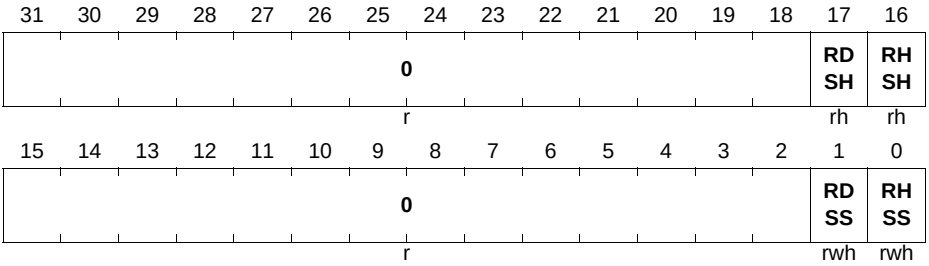
Field	Bits	Type	Description
NFIS	27	rh	**NULL Frame Indicator Status** (vRF!Header!NFIndicator) If reset to 0 the Payload Segment of the received Frame contains no usable data. 0_B Received Frame is a NULL Frame 1_B Received Frame is not a NULL Frame *Note: For receive buffers (CFG = 0) the NFIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
PPIS	28	rh	**Payload Preamble Indictor Status** (vRF!Header!PPIndicator) The payload preamble indicator defines whether a Network Management vector or message ID is contained within the Payload Segment of the received Frame. 0_B Static Segment: The Payload Segment of the received Frame does not contain a Network Management vector or a message ID Dynamic Segment: The Payload Segment of the received Frame does not contain a Network Management vector or a message ID 1_B Static Segment: Network Management vector at the beginning of the payload Dynamic Segment: Message ID at the beginning of the payload *Note: For receive buffers (CFG = 0) the PPIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
RESS	29	rh	**Reserved Bit Status** (vRF!Header!Reserved) Reflects the state of the received reserved bit. The reserved bit is transmitted as 0. *Note: For receive buffers (CFG = 0) the RESS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*

Field	Bits	Type	Description
0	13, [23:22], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Output Buffer Command Mask (OBCM)

Configures how the Output Buffer is updated from the Message Buffer in the Message RAM selected by the Output Buffer Command Request register. If OBF Host and OBF Shadow are swapped, also mask bits OBCM.RDSH and OBCM.RHSH are swapped with bits OBCM.RDSS and OBCM.RHSS to keep them attached to the respective Output Buffer transfer.

OBCM
Output Buffer Command Mask **(0710_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RHSS	0	rwh	**Read Header Section Shadow** 0_B Header Section is not read 1_B Header Section selected for transfer from Message RAM to Output Buffer
RDSS	1	rwh	**Read Data Section Shadow** 0_B Data Section is not read 1_B Data Section selected for transfer from Message RAM to Output Buffer
RHSH	16	rh	**Read Header Section Host** 0_B Header Section is not read 1_B Header Section selected for transfer from Message RAM to Output Buffer
RDSH	17	rh	**Read Data Section Host** 0_B Data Section is not read 1_B Data Section selected for transfer from Message RAM to Output Buffer
0	[15:2], [31:18]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: After the transfer of the Header Section from the Message RAM to OBF Shadow has completed, the Message Buffer status changed flag MBCn (n = 0-31) to MBCn (n = 96-127) of the selected Message Buffer in the Message Buffer Changed MBSC1 to MBSC4 registers is cleared. After the transfer of the Data Section from the Message RAM to OBF Shadow has completed, the New Data flag NDn (n = 0-31) to NDn (n = 96-127) of the selected Message Buffer in the New Data NDAT1 to NDAT4 registers is cleared.

Output Buffer Command Request (OBCR)

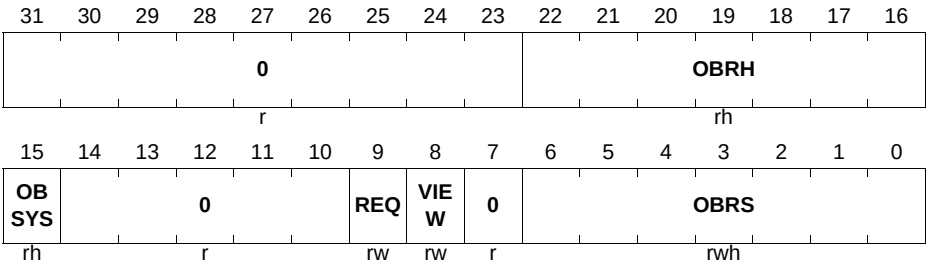
The Message Buffer selected by OBCR.OBRS is transferred from the Message RAM to the Output Buffer as soon as the Host has set OBCR.REQ. Bit OBCR.REQ can only be set while OBCR.OBSYS is 0 (see also **“Data Transfer from Message RAM to Output Buffer” on Page 24-226**).

After setting OBCR.REQ, OBCR.OBSYS is automatically set, and the transfer of the Message Buffer selected by OBCR.OBRS from the Message RAM to Output Buffer Shadow is started. When the transfer between the Message RAM and OBF Shadow has completed, this is signalled by clearing OBCR.OBSYS. By setting OBCR.VIEW while OBCR.OBSYS is 0, OBF Host and OBF Shadow are swapped. When Output Buffer Host and Output Buffer Shadow are swapped, also mask bits OBCM.RDSH and OBCM.RHSH are swapped with bits OBCM.RDSS and OBCM.RHSS to keep them attached to the respective Output Buffer transfer. Now the Host can read the transferred Message Buffer from OBF Host. In parallel the Message Handler may transfer the next message from the Message RAM to OBF Shadow if OBCR.VIEW and OBCR.REQ are set at the same time.

Any write access to an Output Buffer register while OBCR.OBSYS is set will cause the error flag EIR.IOBA to be set. In this case the Output Buffer will not be changed.

OBCR

Output Buffer Command Request (0714_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
OBRS	[6:0]	rw	**Output Buffer Request Shadow** Number of source Message Buffer to be transferred from the Message RAM to OBF Shadow. Valid values are 00_H to $7F_H$ (0 to 127). If the number of the first Message Buffer of the receive FIFO is written to this register the Message Handler transfers the Message Buffer addressed by the GET Index Register (GIDX, **"FIFO Function" on Page 24-221**) to OBF Shadow.
VIEW	8	rw	**View Shadow Buffer** Toggles between OBF Shadow and OBF Host. Only writeable while OBCR.OBSYS = 0. 0_B No action 1_B Swap OBF Shadow and OBF Host
REQ	9	rw	**Request Message RAM Transfer** Requests transfer of Message Buffer addressed by OBCR.OBRS from Message RAM to OBF Shadow. Only writeable while OBCR.OBSYS = 0. 0_B No request 1_B Transfer to OBF Shadow requested
OBSYS	15	rh	**Output Buffer Busy Shadow** Set to 1 after setting bit OBCR.REQ. When the transfer between the Message RAM and OBF Shadow has completed, OBCR.OBSYS is cleared again. 0_B No transfer in progress 1_B Transfer between Message RAM and OBF Shadow in progress

Field	Bits	Type	Description
OBRH	[22:16]	rh	**Output Buffer Request Host** Number of Message Buffer currently accessible by the Host via RDHS1 to RDHS3, MBS, and RDDSnn (nn = 01-64). By setting OBCR.VIEW OBF Shadow and OBF Host are swapped and the transferred Message Buffer is accessible by the Host. Valid values are 00_H to $7F_H$ (01 to 27).
0	7, [14:10], [31:23]	r	**Reserved** Returns 0 if read; should be written with 0.

24.6 Functional Description

This chapter describes the E-Ray implementation together with the related FlexRay™ protocol features. More information about the FlexRay™ protocol itself can be found in the FlexRay™ protocol specification v2.1.

Communication on FlexRay™ networks is based on Frames and symbols. The wakeup symbol (WUS) and the collision avoidance symbol (CAS) are transmitted outside the communication cycle to setup the time schedule. Frames and media access test symbols (MTS) are transmitted inside the communication cycle.

24.6.1 Communication Cycle

A communication cycle in FlexRay™ consists of the following elements:

- Static Segment
- Dynamic Segment
- Symbol Window
- Network Idle Time (NIT)

Static segment, dynamic segment, and symbol window form the Network Communication Time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized Macrotick.

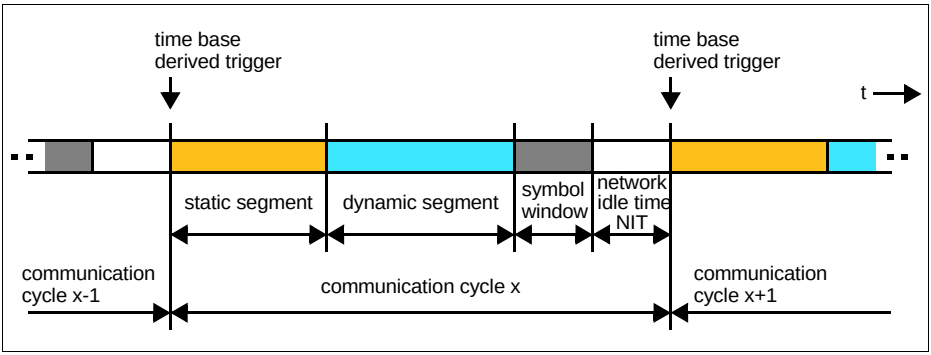


Figure 24-4 Structure of Communication Cycle

24.6.1.1 Static Segment

The Static Segment is characterized by the following features:

- Time slots of fixed length (optionally protected by bus guardian)
- Start of Frame transmission at action point of the respective static slot
- Payload length same for all Frames on both channel

Parameters: Number of Static Slots **GTUC07.NSS**, Static Slot Length **GTUC07.SSL**, Payload Length Static **MHDC.SFDL**, Action Point Offset **GTUC09.APO**.

24.6.1.2 Dynamic Segment

The Dynamic Segment is characterized by the following features:

- All controllers have bus access (no bus guardian protection possible)
- Variable payload length and duration of slots, different for both channels
- Start of transmission at minislot action point

Parameters: Number of Minislots **GTUC08.NMS**, Minislot Length **GTUC08.MSL** Minislot Action Point Offset **GTUC09.MAPO**, Start of Latest Transmit (last minislot) **MHDC.SLT**.

24.6.1.3 Symbol Window

During the symbol window only one media access test symbol (MTS) may be transmitted per channel. MTS symbols are send in “NORMAL_ACTIVE” state to test the bus guardian.

The symbol window is characterized by the following features:

- Send single symbol
- Transmission of the MTS symbol starts at the symbol windows action point

Parameters: Symbol Window Action Point Offset **GTUC09.APO** (same as for static slots), Network Idle Time Start **GTUC04.NIT**.

24.6.1.4 Network Idle Time (NIT)

During network idle time the Communication Controller has to perform the following tasks:

- Calculate clock correction terms (offset and rate)
- Distribute offset correction over multiple Macroticks
- Perform cluster cycle related tasks

Parameters: Network Idle Time Start **GTUC04.NIT**, Offset Correction Start **GTUC04.OCS**.

24.6.1.5 Configuration of Network Idle Time (NIT) Start and Offset Correction Start

The number of Macroticks per cycle (gMacroPerCycle) is assumed to be m. It is configured by programming **GTUC02.MPC** = m.

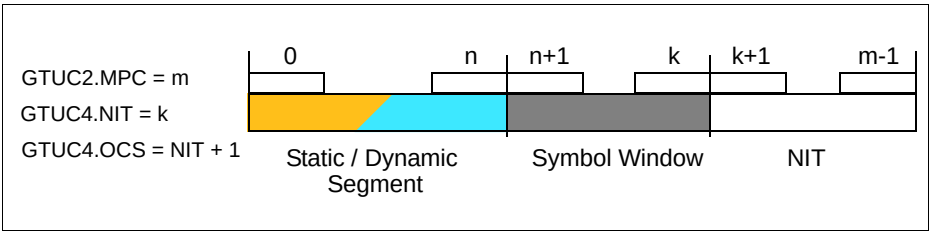

Figure 24-5 Configuration of network idle time (NIT) start and offset correction start

The static / dynamic segment starts with Macrotick 0 and ends with Macrotick n:
n = static segment length + dynamic segment offset + dynamic segment length - 1 Macrotick

n = gNumberOfStaticSlots • gdStaticSlot + dynamic segment offset
+ gNumberOfMinislots • gdMinislot - 1 Macroticks

The static segment length is configured by **GTUC07.SSL** and **GTUC07.NSS**.
The dynamic segment length is configured by **GTUC08.MSL** and **GTUC08.NMS**.

The dynamic segment offset is:

If gdActionPointOffset ≤ gdMinislotActionPointOffset:

dynamic segment offset = 0 MT

Else if gdActionPointOffset > gdMinislotActionPointOffset:

dynamic segment offset = gdActionPointOffset - gdMinislotActionPointOffset

The network idle time (NIT) starts with Macrotick k+1 and ends with the last Macrotick of cycle m-1. It has to be configured by setting **GTUC04.NIT** = k.

For the E-Ray the offset correction start is required to be

GTUC04.OCS ≥ **GTUC04.NIT** + 1 = k+1.

The length of symbol window results from the number of Macroticks between the end of the static / dynamic segment and the beginning of the NIT. It can be calculated by k - n.

24.6.2 Communication Modes

The FlexRay™ Protocol Specification v2.1 defines the Time-Triggered Distributed (TT-D) mode.

Time-triggered Distributed (TT-D)

In TT-D mode the following configurations are possible:

- **Pure static**: minimum 2 static slots + symbol window (optional)
- **Mixed static/dynamic**: minimum 2 static slots + dynamic segment + symbol window (optional)

A minimum of two coldstart nodes need to be configured for distributed time-triggered operation. Two fault-free coldstart nodes are necessary for the cluster startup. Each Startup Frame must be a SYNC Frame, therefore all coldstart nodes are sync nodes.

24.6.3 Clock Synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received SYNC Frames from other nodes.

24.6.3.1 Global Time

Activities in a FlexRay™ node, including communication, are based on the concept of a global time, even though each individual node maintains its own view of it. It is the clock synchronization mechanism that differentiates the FlexRay™ cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (Macrotick counter).

Cluster specific:

- Macrotick = basic unit of time measurement in a FlexRay™ network, a Macrotick consists of an integer number of Microticks
- Cycle length = duration of a communication cycle in units of Macroticks

24.6.3.2 Local Time

Internally, nodes time their behavior with Microtick resolution. Microticks are time units derived from the oscillator clock tick of the specific node. Therefore Microticks are controller-specific units. They may have different duration in different controllers. The precision of a node's local time difference measurements is a Microtick.

Node specific:

- Oscillator clock → prescaler → Microtick
- Microtick = basic unit of time measurement in a Communication Controller, clock correction is done in units of Microticks
- Cycle counter + Macrotick counter = nodes local view of the global time

24.6.3.3 Synchronization Process

Clock synchronization is performed by means of SYNC Frames. Only preconfigured nodes (sync nodes) are allowed to send SYNC Frames. In a two-channel cluster a sync node has to send its SYNC Frame on both channels.

For synchronization in FlexRay™ the following constraints have to be considered:

- Max. one SYNC Frame per node in one communication cycle
- Max. 15 SYNC Frames per cluster in one communication cycle
- Every node has to use all available SYNC Frames for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of SYNC Frames received during the static segment, valid on both channels (two-channel cluster), is measured. The calculation of correction terms is done during network idle time (NIT) (offset: every cycle, rate: odd cycle) by using a FTA / FTM algorithm. For details see FlexRay™ protocol specification v2.1, chapter 8.

Offset (phase) Correction

- Only deviation values measured and stored in the current cycle used
- For a two channel node the smaller value will be taken
- Calculation during network idle time (NIT) of **every** communication cycle, value may be negative
- Offset correction value calculated in even cycles used for error checking only
- Checked against limit values (violation: “NORMAL_ACTIVE” → “NORMAL_PASSIVE” → “HALT”)
- Correction value is an integer number of Microticks
- Correction done in **odd** numbered cycles, distributed over the Macroticks beginning at offset correction start up to cycle end (end of network idle time (NIT)) to shift nodes next start of cycle (Macroticks lengthened / shortened)

Rate (frequency) Correction

- Pairs of deviation values measured and stored in even / odd cycle pair used
- For a two channel node the average of the differences from the two channels is used
- Calculated during network idle time (NIT) of **odd** numbered cycles, value may be negative
- Cluster drift damping is performed using global damping value

- Checked against limit values
- Correction value is a signed integer number of Microticks
- Distributed over Macroticks comprising the next **even / odd** cycle pair (Macroticks lengthened / shortened)

Synchronization Process

Clock synchronization is performed by means of SYNC Frames. Only preconfigured nodes (sync nodes) are allowed to send SYNC Frames. In a two-channel cluster a sync node has to send its SYNC Frame on both channels.

For synchronization in FlexRay™ the following constraints have to be considered:

- Max. one SYNC Frame per node in one communication cycle
- Max. 15 SYNC Frames per cluster in one communication cycle
- Every node has to use all available SYNC Frames for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of SYNC Frames received during the static segment, valid on both channels (two-channel cluster), is measured. The calculation of correction terms is done during network idle time (NIT) (offset: every cycle, rate: odd cycle) by using a FTA / FTM algorithm. For details see FlexRay™ protocol specification v2.1, chapter 8.

SYNC Frame Transmission

SYNC Frame transmission is only possible from buffer 0 and 1. Message Buffer 1 may be used for SYNC Frame transmission in case that SYNC Frames should have different payloads on the two channels. In this case bit **MRC.SPLM** has to be programmed to 1.

Message Buffers used for SYNC Frame transmission have to be configured with the key slot ID and can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only. For nodes transmitting SYNC Frames **SUCC1.TXSY** must be set to 1.

24.6.3.4 External Clock Synchronization

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

- External offset / rate correction value is a signed integer
- External offset / rate correction value is added to calculated offset / rate correction value
- Aggregated offset / rate correction term (external + internal) is not checked against configured limits

24.6.4 Error Handling

The implemented error handling concept is intended to ensure that in case of a lower layer protocol error in a single node communication between non-affected nodes can be maintained. In some cases, higher layer program command activity is required for the Communication Controller to resume normal operation. A change of the error handling state will set bit **EIR.PEMC** in the Error Service Request Register and may trigger an service request to the Host if enabled. The actual error mode is signalled by **CCEV.ERRM** in the Communication Controller Error Vector register.

Table 24-10 Error Modes of the POC (Degradation Model)

Error Mode	Activity
ACTIVE (green)	**Full operation**, State: “NORMAL_ACTIVE” The Communication Controller is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers **EIR** and **SIR**.
PASSIVE (yellow)	**Reduced operation**, State: “NORMAL_PASSIVE”, Communication Controller self rescue allowed The Communication Controller stops transmitting Frames and symbols, but received Frames are still processed. Clock synchronization mechanisms are continued based on received Frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers **EIR** and **SIR**.
COMM_HALT (red)	**Operation halted**, State: “HALT”, Communication Controller self rescue not allowed The Communication Controller stops Frame and symbol processing, clock synchronization processing, and the Macrotick generation. The host has still access to error and status information by reading the error and status interrupt flags from registers **EIR** and **SIR**. The bus drivers are disabled.

24.6.4.1 Clock Correction Failed Counter

When the Clock Correction Failed Counter reaches the maximum “without clock correction passive” limit defined by **SUCC3.WCP**, the POC transits from “NORMAL_ACTIVE” to “NORMAL_PASSIVE” state. When it reaches the “maximum without clock correction fatal” limit defined by **SUCC3.WCF**, it transits “NORMAL_ACTIVE” or “NORMAL_PASSIVE” to the “HALT” state. Both limits are defined in the SUC Configuration Register 3.

The Clock Correction Failed Counter **CCEV.CCFC** allows the Host to monitor the duration of the inability of a node to compute clock correction terms after the Communication Controller passed protocol startup phase. It will be incremented by one at the end of any **odd** numbered communication cycle where either the Missing Offset Correction signal **SFS.MOCS** nor the Missing Rate Correction signal **SFS.MRCS** flag is set. The two flags are located in the SYNC Frame Status register, while the Clock Correction Failed Counter is located in the Communication Controller Error Vector register.

The Clock Correction Failed Counter is reset to zero at the end of an **odd** communication cycle if neither the Missing Offset Correction signal **SFS.MOCS** nor the Missing Rate Correction signal **SFS.MRCS** flag is set.

The Clock Correction Failed Counter stops incrementing when the “maximum without clock correction fatal” value **SUCC3.WCF** as defined in the SUC Configuration Register 3 is reached (i.e. incrementing the counter at its maximum value will not cause it to “wraparound” back to zero). The Clock Correction Failed Counter is initialized to zero when the Communication Controller enters “READY” state or when “NORMAL_ACTIVE” state is entered.

24.6.4.2 Passive to Active Counter

The passive to active counter controls the transition of the POC from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. **SUCC1.PTA** in the SUC Configuration Register 1 defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the Communication Controller is allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. If **SUCC1.PTA** is reset to zero the Communication Controller is not allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state.

24.6.4.3 HALT Command

In case the Host wants to stop FlexRay™ communication of the local node it can bring the Communication Controller into “HALT” state by asserting the HALT command. This can be done by writing **SUCC1.CMD** = 0110_B in the SUC Configuration Register 1. When called in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state the POC transits to “HALT” state at the end of the current cycle. When called in any other state **SUCC1.CMD** will be reset to 0000_B = “COMMAND_NOT_ACCEPTED” and bit **EIR.CNA** in the Error Service Request Register is set to 1. If enabled an service request to the Host is generated.

24.6.4.4 FREEZE Command

In case the Host detects a severe error condition it can bring the Communication Controller into “HALT” state by asserting the FREEZE command. This can be done by writing **SUCC1.CMD** = 0111_B in the SUC Configuration Register 1. The FREEZE

command triggers the entry of the “HALT” state immediately regardless of the actual POC state.

The POC state from which the transition to HALT state took place can be read from **CCSV.PSL**.

24.6.5 Communication Controller States

This chapter introduces the states of the Communication Controller.

24.6.5.1 Communication Controller State Diagram

State transitions are controlled by externals the application reset or RXDA/B, by the POC state machine, and by the CHI Command Vector **SUCC1.CMD** located in the SUC Configuration Register 1.

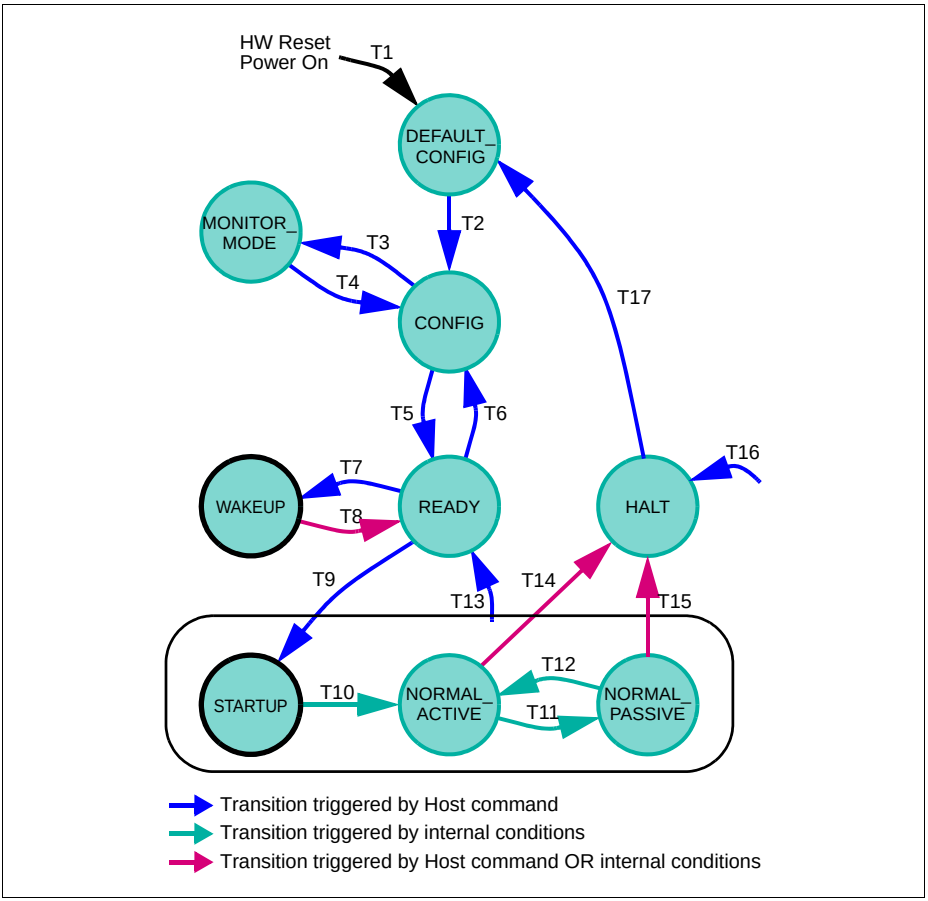

Figure 24-6 Overall State Diagram of E-Ray Communication Controller

The Communication Controller exits from all states to “HALT” state after application of the FREEZE command (SUCC1.CMD = 0111_B).

Table 24-11 State Transitions of E-Ray Overall State Machine

T#	Condition	From	To
1	application reset	HW Reset	DEFAULT_CONFIG
2	Command CONFIG, SUCC1.CMD = 0001_B	DEFAULT_CONFIG	CONFIG
3	Unlock sequence followed by command MONITOR_MODE, SUCC1.CMD = 1011_B	CONFIG	MONITOR_MODE
4	Command CONFIG, SUCC1.CMD = 0001_B	MONITOR_MODE	CONFIG
5	Unlock sequence followed by command READY, SUCC1.CMD = 0010_B	CONFIG	READY
6	Command CONFIG, SUCC1.CMD = 0001_B	READY	CONFIG
7	Command WAKEUP, SUCC1.CMD = 0011_B	READY	WAKEUP
8	Complete, non-aborted transmission of wakeup pattern OR received WUP OR received Frame Header OR command READY, SUCC1.CMD = 0010_B	WAKEUP	READY
9	Command RUN, SUCC1.CMD = 0100_B	READY	STARTUP
10	Successful startup	STARTUP	NORMAL_ACTIVE
11	Clock Correction Failed counter reached Maximum Without Clock Correction Passive limit configured by WCP in SUC Configuration Register 3	NORMAL_ACTIVE	NORMAL_PASSIVE
12	Number of valid correction terms reached the Passive to Active limit configured by PTA in SUC Configuration Register 1	NORMAL_PASSIVE	NORMAL_ACTIVE
13	Command READY, SUCC1.CMD = 0010_B	STARTUP, NORMAL_ACTIVE, NORMAL_PASSIVE	READY

Table 24-11 State Transitions of E-Ray Overall State Machine (cont'd)

T#	Condition	From	To
14	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by WCF in SUC Configuration Register 3 AND bit HCSE in the SUC Configuration Register 1 set to 1 OR command HALT, SUCC1.CMD = 0110_B	NORMAL_ACTIVE	HALT
15	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by WCF in SUC Configuration Register 3 AND bit HCSE in the SUC Configuration Register 1 set to 1 OR command HALT, SUCC1.CMD = 0110_B	NORMAL_PASSIVE	HALT
16	Command FREEZE, SUCC1.CMD = 0111_B	All States	HALT
17	Command CONFIG, SUCC1.CMD = 0001_B	HALT	DEFAULT_CONFIG

24.6.5.2 DEFAULT_CONFIG State

In "DEFAULT_CONFIG" state, the Communication Controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The Communication Controller enters this state

- When leaving application reset
- When exiting from "HALT" state

To leave "DEFAULT_CONFIG" state the Host has to write SUCC1.CMD = 0001_B in the SUC Configuration Register 1. The Communication Controller transits to "CONFIG" state.

CONFIG State

In "CONFIG" state, the Communication Controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the Communication Controller configuration.

The Communication Controller enters this state

- When exiting from “DEFAULT_CONFIG” state
- When exiting from “MONITOR_MODE” or “READY” state

When the state has been entered via “HALT” and “DEFAULT_CONFIG” state, the Host can analyze status information and configuration. Before leaving “CONFIG” state the Host has to assure that the configuration is fault-free.

To leave “CONFIG” state, the Host has to perform the unlock sequence as described on **“LCK” on Page 24-30**. Directly after unlocking the “CONFIG” state the Host has to write **SUCC1.CMD** in the SUC Configuration Register 1 to enter the next state.

Internal counters and the Communication Controller status flags are reset when the Communication Controller leaves “CONFIG”.

*Note: The Message Buffer Status Registers (**MHDS**, **TXRQ1** to **TXRQ4**, **NDAT1** to **NDAT4**, **MBSC1** to **MBSC4**) and status data stored in the Message RAM and are not affected by the transition of the POC from “CONFIG” to “READY” state.*

When the Communication Controller is in “CONFIG” state it is also possible to bring the Communication Controller into a power saving mode by halting the module clocks (f_{SCLK}, f_{CLC_ERAY}). To do this the Host has to assure that all Message RAM transfers have finished before turning off the clocks.

24.6.5.3 MONITOR_MODE

After unlocking “CONFIG” state and writing **SUCC1.CMD** = 0011_B the Communication Controller enters “MONITOR_MODE”. In this mode the Communication Controller is able to receive FlexRay™ Frames and to detect wakeup pattern. The temporal integrity of received Frames is not checked, and therefore cycle counter filtering is not supported. It is not possible to distinguish between static and dynamic frames, because limited functions in Monitor Mode (FRF.RSS will be ignored, filtering not functional).This mode can be used for debugging purposes in case e.g. that startup of a FlexRay™ network fails. After writing **SUCC1.CMD** = 0001_B the Communication Controller transits back to “CONFIG” state.

In MONITOR_MODE the pick first valid mechanism is disabled. This means that a receive Message Buffer may only be configured to receive on one channel. Received Frames are stored into Message Buffers according to Frame ID and receive channel. NULL Frames are handled like Data Frames. After Frame reception only status bits **MBS.VFRA**, **MBS**, **MBS.MLST**, **MBS.RCIS**, **MBS.SFIS**, **MBS.SYNS**, **MBS.NFIS**, **MBS.PPIS**, **MBS.RESS** have valid value.

In “MONITOR_MODE” the Communication Controller is not able to distinguish between CAS and MTS symbols. In case one of these symbols is received on one or both of the two channels, the flags **SIR.MTSA** resp. **SIR.MTSB** are set. **SIR.CAS** has no function in “MONITOR_MODE”.

24.6.5.4 READY State

After unlocking “CONFIG” state and writing **SUCC1.CMD** = 0010_B the Communication Controller enters “READY” state. From this state the Communication Controller can transit to WAKEUP state and perform a cluster wakeup or to “STARTUP” state to perform a coldstart or to integrate into a running communication.

The Communication Controller enters this state

- When exiting from “CONFIG”, “WAKEUP”, “STARTUP”, “NORMAL_ACTIVE”, or “NORMAL_PASSIVE” state by writing **SUCC1.CMD** = 0010_B (READY command).

The Communication Controller exits from this state

- To “CONFIG” state by writing **SUCC1.CMD** = 0001_B (CONFIG command)
- To “WAKEUP” state by writing **SUCC1.CMD** = 0011_B (WAKEUP command)
- To “STARTUP” state by writing **SUCC1.CMD** = 0100_B (RUN command)

Internal counters and the Communication Controller status flags are reset when the Communication Controller enters “STARTUP” state.

*Note: Status bits **MHDS**, registers **TXRQ1** to **TXRQ4**, and status data stored in the Message RAM are not affected by the transition of the POC from “READY” to “STARTUP” state.*

24.6.5.5 WAKEUP State

The description below is intended to help configuring wakeup for the E-Ray IP-module. A detailed description of the wakeup procedure together with the respective SDL diagrams can be found in the FlexRay™ protocol specification v2.1, section 7.1.

The Communication Controller enters this state

- When exiting from “READY” state by writing **SUCC1.CMD** = 0011_B (WAKEUP command).

The Communication Controller exits from this state to “READY” state

- After complete non-aborted transmission of wakeup pattern
- After WUP reception
- After detecting a WUP collision
- After reception of a Frame Header
- By writing **SUCC1.CMD** = 0010_B (READY command)

The cluster wakeup must precede the communication startup in order to ensure that all mechanisms defined for the startup work properly. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an **external** wakeup source.

The Host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the Communication Controller and configures bus guardian

(if available) and Communication Controller to perform the cluster wakeup. The Communication Controller provides to the Host the ability to transmit a special wakeup pattern on each of its available channels separately. The Communication Controller needs to recognize the wakeup pattern only during “WAKEUP” state.

Wakeup may be performed on only one channel at a time. The Host has to configure the wakeup channel while the Communication Controller is in “CONFIG” state by writing bit **SUCC1.WUCS** in the SUC Configuration Register 1. The Communication Controller ensures that ongoing communication on this channel is not disturbed. The Communication Controller cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup the Communication Controller returns to “READY” state and signals the change of the wakeup status to the Host by setting bit **SIR.WST** in the Status Service Request Register. The wakeup status vector can be read from the Communication Controller Status Vector register **CCSV.WSV**. If a valid wakeup pattern was received also either flag **SIR.WUPA** or flag **SIR.WUPB** in the Status Service Request Register is set.

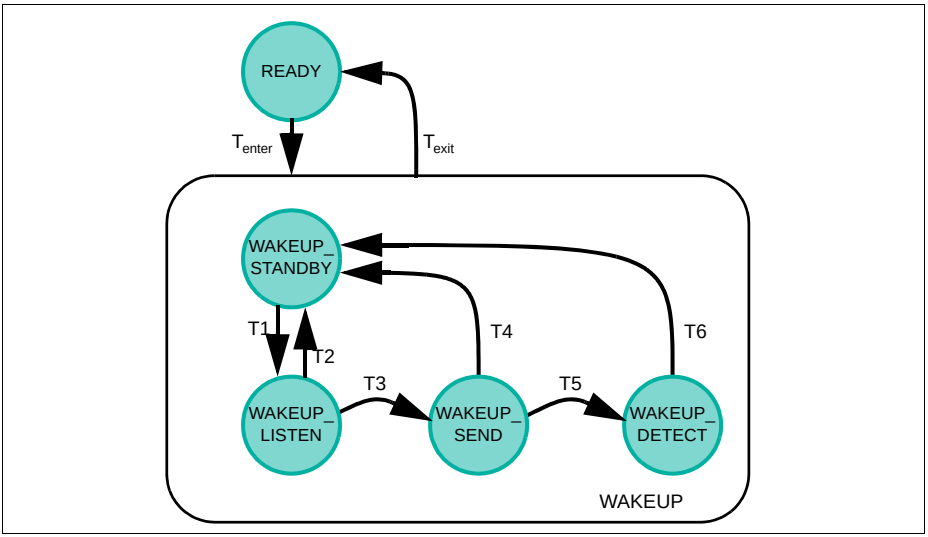

Figure 24-7 Structure of POC State WAKEUP

Table 24-12 State Transitions WAKEUP

T#	Condition	From	To
enter	Host commands change to “WAKEUP” state by writing **SUCC1.CMD** = 0011_B (WAKEUP command)	READY	WAKEUP
1	CHI command WAKEUP triggers wakeup FSM to transit to “WAKEUP_LISTEN” state	WAKEUP_ STANDBY	WAKEUP_ LISTEN
2	Received WUP on wakeup channel selected by flag **SUCC1.WUCS** in the SUC Configuration Register 1 OR Frame Header on either available channel	WAKEUP_ LISTEN	WAKEUP_ STANDBY
3	Timer event	WAKEUP_ LISTEN	WAKEUP_ SEND
4	Complete, non-aborted transmission of wakeup pattern	WAKEUP_ SEND	WAKEUP_ STANDBY

Table 24-12 State Transitions WAKEUP (cont'd)

T#	Condition	From	To
5	Collision detected	WAKEUP_ SEND	WAKEUP_ DETECT
6	Wakeup timer expired OR WUP detected on wakeup channel selected by flag **SUCC1.WUCS** in the SUC Configuration Register 1 OR Frame Header received on either available channel	WAKEUP_ DETECT	WAKEUP_ STANDBY
exit	Wakeup completed (after T2 or T4 or T6) OR Host commands change to "READY" state by writing **SUCC1.CMD** = 0010_B (READY command). This command also resets the wakeup FSM to "WAKEUP_STANDBY" state	WAKEUP	READY

The "WAKEUP_LISTEN" state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters listen time-out **SUCC2.LT** and listen time-out noise **SUCC2.LTN**. Both values can be configured in the SUC Configuration Register 2. listen time-out enables a fast cluster wakeup in case of a noise free environment, while listen time-out noise enables wakeup under more difficult conditions regarding noise interference.

In "WAKEUP_SEND" state the Communication Controller transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the Host has to bring the Communication Controller into "STARTUP" state by CHI command RUN.

In "WAKEUP_DETECT" state the Communication Controller attempts to identify the reason for the wakeup collision detected in "WAKEUP_SEND" state. The monitoring is bounded by the expiration of listen time-out as configured by **SUCC2.LT** in the SUC Configuration Register 2. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a Frame Header indication existing communication, causes the direct transition to "READY" state. Otherwise WAKEUP_DETECT is left after expiration of listen time-out; in this case the reason for wakeup collision is unknown.

The Host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay™ Protocol Specification v2.1 recommends that two different Communication Controllers shall awake the two channels.

Host activities

The host must coordinate the wakeup of the two channels and must decide whether, or not, to wake a specific channel. The sending of the wakeup pattern is initiated by the Host and generated by the Communication Controller. The wakeup pattern is detected by the remote BDs and signalled to their local Hosts.

Wakeup procedure controlled by Host (single-channel wakeup):

- Configure the Communication Controller in “CONFIG” state
  - Select wakeup channel by programming bit **SUCC1.WUCS**
- Check local BDs whether a WUP was received
- Activate BD of selected wakeup channel
- Command Communication Controller to start wakeup on the configured channel by writing **SUCC1.CMD** = 0011_B
  - Communication Controller enters “WAKEUP
  - Communication Controller returns to “READY” state and signals status of wakeup attempt to Host
- Wait predefined time to allow the other nodes to wakeup and configure themselves
- Coldstart node: wait for WUP on the other channel
  - In a dual channel cluster wait for WUP on the other channel
  - Reset coldstart inhibit flag **CCSV.CSI** by writing **SUCC1.CMD** = 1001_B (ALLOW_COLDSTART command))
- Reset Coldstart Inhibit flag **CCSV.CSI** in the CCSV register by writing **SUCC1.CMD** = 1001_B (ALLOW_COLDSTART command), coldstart node only
- Command Communication Controller to enter startup by writing **SUCC1.CMD** = 0100_B (RUN command)

Wakeup procedure triggered by BD:

- Wakeup recognized by BD
- BD triggers power-up of Host (if required)
- BD signals wakeup event to Host
- Host configures its local Communication Controller
- If necessary Host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves
- Host commands Communication Controller to enter “STARTUP” state by writing **SUCC1.CMD** = 0100_B (RUN command)

Wakeup pattern (WUP)

The wakeup pattern is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by the PRT Configuration Registers **PRTC1** and **PRTC2**.

- Single channel wakeup, wakeup symbol may not be sent on both channels at the same time

- Wakeup symbol collision resilient for up to two sending nodes (two overlapping wakeup symbols still recognizable)
- Wakeup symbol must be configured identical in all nodes of a cluster
- Wakeup symbol transmit low time configured by **PRTC2.TXL**
- Wakeup symbol idle time used to listen for activity on the bus, configured by **PRTC2.TXI**
- A wakeup pattern composed of at least two Tx-wakeup symbols needed for wakeup
- Number of repetitions configurable by **PRTC1.RWP** (2 to 63 repetitions)
- Wakeup symbol receive window length configured by **PRTC1.RXW**
- Wakeup symbol receive low time configured by **PRTC2.RXL**
- Wakeup symbol receive idle time configured by **PRTC2.RXI**

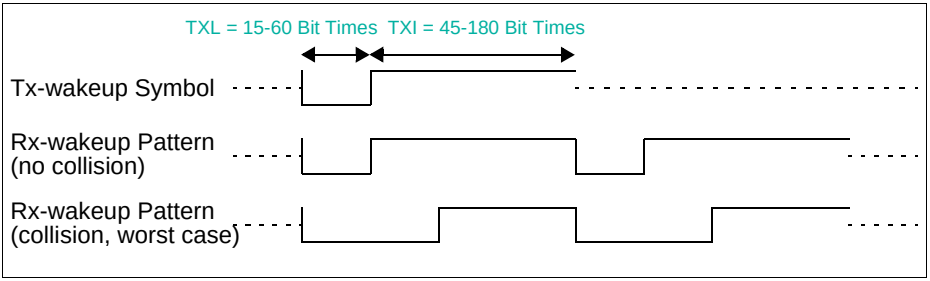

Figure 24-8 Timing of Wakeup Pattern

24.6.5.6 STARTUP State

The description below is intended to help configuring startup for the E-Ray IP-module. A detailed description of the startup procedure together with the respective SDL diagrams can be found in the FlexRay™ protocol specification v2.1, section 7.2.

Any node entering “STARTUP” state that has coldstart capability should assure that both channels attached have been awakened before initiating coldstart.

It cannot be assumed that all nodes and stars need the same amount of time to become completely awake and to be configured. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup Frames.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter “NORMAL_ACTIVE” state via (see **Figure 24-9**):

- Coldstart path initiating the schedule synchronization (leading coldstart node)
- Coldstart path joining other coldstart nodes (following coldstart node)
- Integration path integrating into an existing communication schedule (all other nodes)

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that had transmitted the CAS transmits Frames in the first four cycles after the CAS, it is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

A coldstart node has the Transmit SYNC Frame in Key Slot bits **SUCC1.TXST** and **SUCC1.TXSY** in the SUC Configuration Register 1 set to 1. The Message Buffer 0 holds the key slot ID which defines the slot number where the Startup Frame is send. In the Frame Header of the Startup Frame the Startup Frame indicator bit is set.

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each Startup Frame must also be a SYNC Frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by **SUCC1.CSA** in the SUC Configuration Register 1.

A non-coldstart node requires at least two startup Frames from distinct nodes for integration. It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start passive integration via the integration path as soon as they receive SYNC Frames from which to derive the TDMA schedule information. During integration the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.

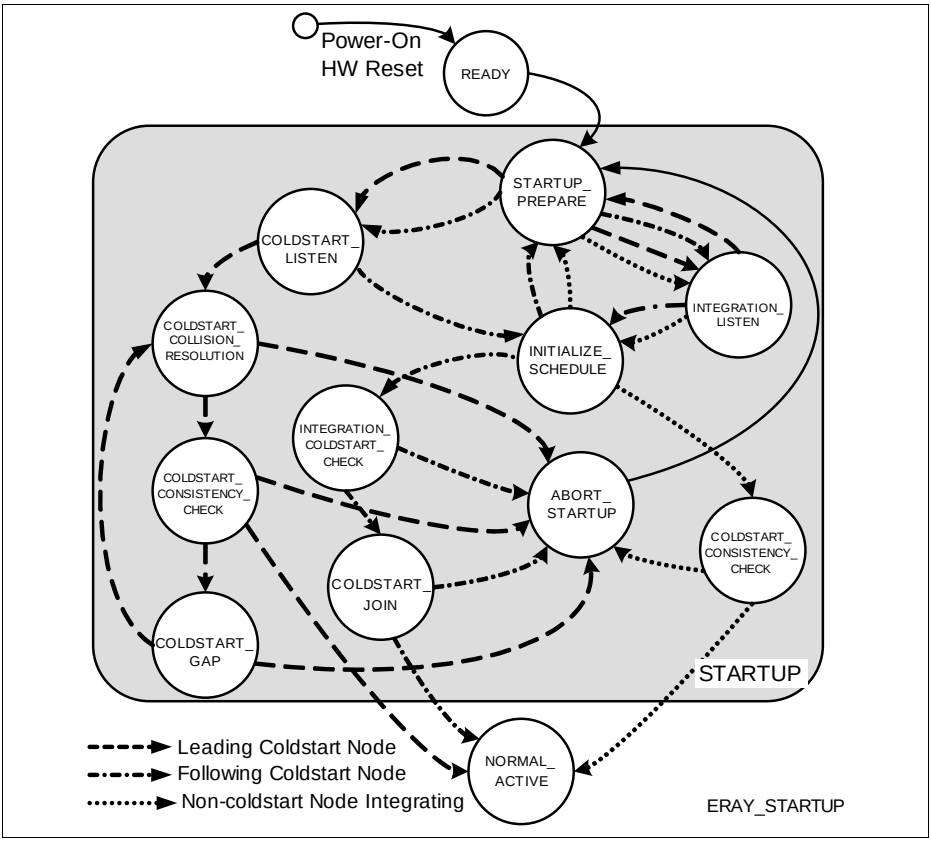

Figure 24-9 State Diagram Time-Triggered Startup

Coldstart Inhibit Mode

In coldstart inhibit mode the node is prevented from initializing the TDMA communication schedule. If bit **CCSV.CSI** in the Communication Controller Status Vector register is set, the node is not allowed to initialize the cluster communication, i.e. entering the coldstart path is prohibited. The node is allowed to integrate to a running cluster or to transmit startup Frames after another coldstart node started the initialization of the cluster communication.

The coldstart inhibit bit **CCSV.CSI** is set whenever the POC enters “READY” state. The bit has to be cleared under control of the Host by CHI command ALLOW_COLDSTART (**SUCC1.CMD** = 1001_B)

24.6.5.7 Startup Time-outs

The Communication Controller supplies two different Microtick timers supporting two time-out values, startup time-out and startup noise time-out. The two timers are reset when the Communication Controller enters the “COLDSTART_LISTEN” state. The expiration of either of these timers causes the node to leave the initial sensing phase (“COLDSTART_LISTEN” state) with the intention of starting up communication.

*Note: The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values **SUCC2.LT** and **SUCC2.LTN** from the SUC Configuration Register 2.*

Startup Time-out

The startup time-out limits the listen time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others.

The startup timer is configured by programming **SUCC2.LT** (pdListenTimeout) in the SUC Configuration Register 2.

The startup timer is restarted upon:

- Entering the “COLDSTART_LISTEN” state
- Both channels reaching idle state while in “COLDSTART_LISTEN” state

The startup timer is stopped:

- If communication channel activity is detected on one of the configured channels while the node is in the “COLDSTART_LISTEN” state
- When the “COLDSTART_LISTEN” state is left

Once the startup time-out expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

Startup Noise Time-out

At the same time the startup timer is started for the first time (transition from “STARTUP_PREPARE” state to “COLDSTART_LISTEN” state), the startup noise timer is started. This additional time-out is used to improve reliability of the startup procedure in the presence of noise.

The startup noise timer is configured by programming **SUCC2.LTN** (gListenNoise - 1) in the SUC Configuration Register 2 (see **“SUC Configuration Register 2 (SUCC2)” on Page 24-87**).

The startup noise time-out is:
pdListenTimeout • ´gListenNoise = **SUCC2.LT** • (**SUCC2.LTN** + 1)

The startup noise timer is restarted upon:

- Entering the “COLDSTART_LISTEN” state
- Reception of correctly decoded Headers or CAS symbols while the node is in “COLDSTART_LISTEN” state

The startup noise timer is stopped when the “COLDSTART_LISTEN” state is left.

Once the startup noise time-out expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer won’t be restarted when random channel activity is sensed, this time-out defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

24.6.5.8 Path of leading Coldstart Node (initiating coldstart)

When a coldstart node enters “COLDSTART_LISTEN”, it listens to its attached channels.

If no communication is detected, the node enters the “COLDSTART_COLLISION_RESOLUTION” state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number zero.

From cycle zero on, the node transmits its startup Frame. Since each coldstart node is allowed to perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a Frame Header during these four cycles, it re-enters the “COLDSTART_LISTEN” state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup Frames.

After four cycles in “COLDSTART_COLLISION_RESOLUTION” state, the node that initiated the coldstart enters the “COLDSTART_CONSISTENCY_CHECK” state. It collects all startup Frames from cycle four and five and performs the clock correction. If the clock correction does not deliver any errors and it has received at least one valid Startup Frame pair, the node leaves “COLDSTART_CONSISTENCY_CHECK” and enters “NORMAL_ACTIVE” state.

The number of coldstart attempts that a node is allowed to perform is configured by **SUCC1.CSA** in the SUC Configuration Register 1. The number of remaining coldstarts attempts **CCSV.RCA** can be read from Communication Controller Status Vector register. The number of remaining attempts is reduced by one for each attempted coldstart. A node may enter the “COLDSTART_LISTEN” state only if this value is larger than one and it may enter the “COLDSTART_COLLISION_RESOLUTION” state only if this value is larger than zero. If the number of coldstart attempts is one, coldstart is inhibited but integration is still possible.

Path of following Coldstart Node (responding to leading Coldstart Node)

When a coldstart node enters the “COLDSTART_LISTEN” state, it tries to receive a valid pair of startup Frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid Startup Frame has been received the “INITIALIZE_SCHEDULE” state is entered. If the clock synchronization can successfully receive a matching second valid Startup Frame and can derive a schedule from this startup Frames, the “INTEGRATION_COLDSTART_CHECK” state is entered.

In “INTEGRATION_COLDSTART_CHECK” state it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still available. The node collects all SYNC Frames and performs clock correction in the following double-cycle. If clock correction does not signal any errors and if the node continues to receive sufficient Frames from the same node it has integrated on, the “COLDSTART_JOIN” state is entered.

In “COLDSTART_JOIN” state integrating coldstart nodes begin to transmit their own startup Frames. Thereby the node that initiated the coldstart and the nodes joining it can check if their schedules agree to each other. If for the following three cycles the clock correction does not signal errors and at least one other coldstart node is visible, the node leaves “COLDSTART_JOIN” state and enters “NORMAL_ACTIVE” state. Thereby it leaves “STARTUP” at least one cycle after the node that initiated the coldstart.

Path of Non-coldstart Node

When a non-coldstart node enters the INTEGRATION_LISTEN state, it listens to its attached channels and tries to receive FlexRay™ Frames.

As soon as a valid Startup Frame has been received the “INITIALIZE_SCHEDULE” state is entered. If the clock synchronization can successfully receive a matching second valid Startup Frame and derive a schedule from this, the INTEGRATION_CONSISTENCY_CHECK state is entered.

In “INTEGRATION_CONSISTENCY_CHECK” state it is verified that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) send startup Frames that agree to the nodes own schedule. Clock correction is activated, and if any errors are signalled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup Frames or the Startup Frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid Startup Frame pairs or the Startup Frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

If after the first double-cycle less than two valid startup Frames are received within an even cycle, or less than two valid Startup Frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to see two valid Startup Frame pairs for two consecutive double-cycles each to be allowed to leave STARTUP and enter NORMAL_OPERATION. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

24.6.5.9 NORMAL_ACTIVE State

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering “STARTUP” via coldstart path) and one additional node have entered the “NORMAL_ACTIVE” state, the startup phase for the cluster has finished. In the “NORMAL_ACTIVE” state, all configured messages are scheduled for transmission. This includes all Data Frames as well as the SYNC Frames. Rate and offset measurement is started in all even cycles (even/odd cycle pairs required).

In “NORMAL_ACTIVE” state the Communication Controller supports regular communication functions

- The Communication Controller performs transmissions and reception on the FlexRay™ bus as configured
- Clock synchronization is running
- The Host interface is operational

The Communication Controller exits from that state to

- “HALT” state by writing **SUCC1.CMD** = 0110_B (HALT command, at the end of the current cycle)
- “HALT” state by writing **SUCC1.CMD** = 0111_B (FREEZE command, immediately)
- “HALT” state due to change of the error state from “ACTIVE” to “COMM_HALT”
- “NORMAL_PASSIVE” state due to change of the error state from “ACTIVE” to “PASSIVE”
- “READY” state by writing **SUCC1.CMD** = 0010_B (READY command)

24.6.5.10 NORMAL_PASSIVE State

“NORMAL_PASSIVE” state is entered from “NORMAL_ACTIVE” state when the error state changes from ACTIVE (green) to PASSIVE (yellow).

In “NORMAL_PASSIVE” state, the node is able to receive all Frames (node is fully synchronized and performs clock synchronization). In comparison to the “NORMAL_ACTIVE” state the node does not actively participate in communication, i.e. neither symbols nor Frames are transmitted.

In “NORMAL_PASSIVE” state

- The Communication Controller performs reception on the FlexRay™ bus
- The Communication Controller does not transmit any Frames or symbols on the FlexRay™ bus
- Clock synchronization is running
- The Host interface is operational

The Communication Controller exits from this state to

- “HALT” state by writing **SUCC1.CMD** = 0110_B (HALT command, at the end of the current cycle)
- “HALT” state by writing **SUCC1.CMD** = 0111_B (FREEZE command, immediately)
- “HALT” state due to change of the error state from “PASSIVE” to “COMM_HALT”
- “NORMAL_ACTIVE” state due to change of the error state from “PASSIVE” to “ACTIVE”. The transition takes place when **CCEV.PTAC** from the Communication Controller Error Vector register equals **SUCC1.PTA** - 1.
- “READY” state by writing **SUCC1.CMD** = 0010_B (READY command)

24.6.5.11 HALT State

In this state all communication (reception and transmission) is stopped.

The Communication Controller enters this state

- By writing **SUCC1.CMD** = 0110_B (HALT command) while the Communication Controller is in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state
- By writing **SUCC1.CMD** = 0111_B (FREEZE command) from all states
- When exiting from “NORMAL_ACTIVE” state because the clock correction failed counter reached the “maximum without clock correction fatal” limit
- When exiting from “NORMAL_PASSIVE” state because the clock correction failed counter reached the “maximum without clock correction fatal” limit

The Communication Controller exits from this state to “CONFIG” state

- By writing **SUCC1.CMD** = 0001_B (DEFAULT_CONFIG command)

When the Communication Controller enters “HALT” state, all configuration and status data is maintained for analyzing purposes.

When the Host writes **SUCC1.CMD** = 0110_B (HALT command) in the SUC Configuration Register 1 to 1, the Communication Controller sets bit **CCSV.HRQ** in the Communication Controller Status Vector register and enters “HALT” state after the current communication cycle has finished.

When the Host writes **SUCC1.CMD** = 0111_B (FREEZE command) in the SUC Configuration Register to 1, the Communication Controller enters “HALT” state immediately and sets the **CCSV.FSI** bit in the Communication Controller Status Vector register.

The POC state from which the transition to HALT state took place can be read from **CCSV.PSL**.

24.6.6 Network Management

The accrued Network Management (NM) vector is located in the Network Management Register 1 to Network Management Register 3 (**NMVx (x = 1-3)**). The Communication Controller performs a logical OR operation over all Network Management (NM) vectors out of all received valid Network Management (NM) Frames with the Payload Preamble Indicator (PPI) bit set. Only a static Frame may be configured to hold Network Management (NM) information. The Communication Controller updates the Network Management (NM) vector at the end of each cycle.

The length of the Network Management (NM) vector can be configured from 0 to 12 byte by NML in the NEM Configuration Register. The Network Management (NM) vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay™ Frames with the PPI bit set, the PPIT bit in the Header Section of the respective transmit buffer has to be set via **WRHS1.PPIT**. In addition the Host has to write the Network Management (NM) information to the Data Section of the respective transmit buffer.

The evaluation of the Network Management (NM) vector has to be done by the application running on the Host.

*Note: In case a Message Buffer is configured for transmission / reception of Network Management Frames, the payload length configured in Header 2 of that Message Buffer should be equal or greater than the length of the NM Vector configured by **NEMC.NML**.*

When the Communication Controller transits to “HALT” state, the cycle count is not incremented and therefore the NM Vector is not updated. In this case NMV1 to NMV3 holds the value from the cycle before.

24.6.7 Filtering and Masking

Filtering is done by checking specific fields in a received Frame against the corresponding configuration constants of the valid Message Buffers and the actual slot and cycle counter values (acceptance filtering), or by comparing the configuration constants of the valid Message Buffers against the actual slot and cycle counter values (transmit filtering). A Message Buffer is only updated / transmitted if the required matches occur.

Filtering is done on the following fields:

- Channel ID
- Frame ID
- Cycle Counter

The following filter combinations for acceptance / transmit filtering are allowed:

- Frame ID + Channel ID
- Frame ID + Channel ID + Cycle Counter

In order to store a received message in a Message Buffer all configured filters must match.

Note: For the FIFO the acceptance filter is configured by the FIFO Rejection Filter and the FIFO Rejection Filter Mask.

A message will be transmitted in the time slot corresponding to the configured Frame ID on the configured channel(s). If cycle counter filtering is enabled the configured cycle filter value must also match.

24.6.7.1 Frame ID Filtering

Every transmit and receive buffer contains a Frame ID stored in the Header Section. This Frame ID is used differently for receive and transmit buffers.

Receive Buffers

A received message is stored in the first receive buffer where the received Frame ID matches the configured Frame ID, provided channel ID and cycle counter criteria are also met.

Transmit Buffers

For transmit buffers the configured Frame ID is used to determine the appropriate slot for message transmission. The Frame will be transmitted in the time slot corresponding to the configured Frame ID, provided channel ID and cycle counter criteria are also met.

24.6.7.2 Channel ID Filtering

There is a 2-bit channel filtering field (CHA, CHB) located in the Header Section of each Message Buffer in the Message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers (see **Table 24-13**).

Table 24-13 Channel Filtering Configuration

CHA	CHB	Transmit Buffer transmit Frame	Receive Buffer store valid receive Frame
1	1	on both channels (static segment only)	received on channel A or B (store first semantically valid Frame, static segment only)
1	0	on channel A	received on channel A
0	1	on channel B	received on channel B
0	0	no transmission	ignore Frame

Note: If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

Receive Buffers

Valid received Frames are stored if they are received on the channels specified in the channel filtering field. Only in static segment a receive buffer may be setup for reception on both channels (CHA and CHB set). Other filtering criteria must also be met.

If a valid Header Segment was stored, the respective MBC flag in the Message Buffer Status Changed register is set. If a valid Payload Segment was stored, the respective **NDn (n = 0-31)** to **NDn (n = 96-127)** flag in the New Data **NDAT1** to **NDAT4** register is set. In both cases, if bit **RDHS1.MBI** in the Header Section of the respective Message Buffer is set, the RXI flag in the Status Service Request Register is set to 1. If enabled an service request is generated.

Transmit Buffers

The content of the buffer is transmitted only on the channels specified in the channel filtering field when the Frame ID filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be setup for transmission on both channels (CHA and CHB set). After transmission has completed, and if bit **WRHS1.MBI** in the Header Section of the respective Message Buffer is set, the TXI flag in the Status Service Request Register is set to 1. If enabled an service request is generated.

24.6.7.3 Cycle Counter Filtering

Cycle counter filtering is based on the notion of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in the Header Section of each Message Buffer.

If Message Buffer 0 is configured to hold the startup / SYNC Frame or the single slot Frame by bits TXST, TXSY, and TSM in the SUC Configuration Register 1, cycle counter filtering for Message Buffer 0 should be disabled.

*Note: Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay™ network is **not** allowed.*

The set of cycle numbers belonging to a cycle set is determined as described in **Table 24-14**.

Table 24-14 Definition of Cycle Set

Cycle Code	Matching Cycle Counter Values		
$000000x_B$	all Cycles		
$000001c_B$	every second Cycle	at (Cycle Count)mod2	= c
$00001cc_B$	every fourth Cycle	at (Cycle Count)mod4	= cc
$0001ccc_B$	every eighth Cycle	at (Cycle Count)mod8	= ccc
$001cccc_B$	every sixteenth Cycle	at (Cycle Count)mod16	= cccc
$01ccccc_B$	every thirty-second Cycle	at (Cycle Count)mod32	= ccccc
$1cccccc_B$	every sixty-fourth Cycle	at (Cycle Count)mod64	= cccccc

Table 24-15 below gives some examples for valid cycle sets to be used for cycle counter filtering:

Table 24-15 Examples for Valid Cycle Sets

Cycle Code	Matching Cycle Counter Values
0000011_B	1-3-5-7- ….-63 ↵
0000100_B	0-4-8-12- ….-60 ↵
0001110_B	6-14-22-30- ….-62 ↵
0011000_B	8-24-40-56 ↵
0100011_B	3-35 ↵
1001001_B	9 ↵

Receive Buffers

The received message is stored only if the received cycle counter matches an element of the receive buffer's cycle set. Channel ID and Frame ID criteria must also be met.

Transmit Buffers

The content of the buffer is transmitted on the configured channels when an element of the cycle set matches the current cycle counter value and the Frame ID matches the slot counter value.

24.6.7.4 FIFO Filtering

For FIFO filtering there is one rejection filter and one rejection filter mask available. The FIFO rejection filter consists of 20 bits for **Channel** (2 bits), **Frame ID** (11 bits), and **Cycle Code** (7 bits). Rejection filter and rejection filter mask can be configured in

DEFAIULT_CONGIF or “CONFIG” state only. The filter configuration in the Header Sections of Message Buffers belonging to the FIFO is ignored.

A valid received Frame is stored in the FIFO if channel ID, Frame ID, and cycle counter are not rejected by the configured rejection filter and rejection filter mask, and if there is no matching dedicated receive buffer.

24.6.8 Transmit Process

The transmit process is described in the following sections.

24.6.8.1 Static Segment

For the static segment, if there are several messages pending for transmission, the message with the Frame ID corresponding to the next sending slot is selected for transmission.

The Data Section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

24.6.8.2 Dynamic Segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest Frame ID) is selected next. Only Frame ID’s which are higher than the largest static Frame ID are allowed for the dynamic segment.

In the dynamic segment different slot counter sequences are possible (concurrent sending of different Frame ID’s on both channels). Therefore pending messages are selected according to their Frame ID and their channel configuration bit.

The Data Section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

The start of latest transmit configured by SLT in the MHD Configuration Register 1 defines the maximum minislot value allowed before inhibiting new Frame transmission in the dynamic segment of the current cycle.

24.6.8.3 Transmit Buffers

A portion of the E-Ray Message Buffers can be configured as transmit buffers by programming bit CFG in the Header Section of the respective Message Buffer to 1. This can be done via the Write Header Section 1 register.

There exist the following possibilities to assign a transmit buffer to the Communication Controller channels:

- Static segment: channel A **or** channel B, channel A **and** channel B

- Dynamic segment: channel A **or** channel B

Message Buffer 0 is dedicated to hold the startup Frame, the SYNC Frame, or the designated single slot Frame as configured by TXST, TXSY, and TSM in the SUC Configuration Register 1. In this case it can be reconfigured in “DEFAULT_CONFIG” or “CONFIG” state only. This ensures that any node transmits at most one startup / SYNC Frame per communication cycle. Transmission of startup / SYNC Frames from other Message Buffers is not possible.

All other Message Buffers configured for transmission in static or dynamic segment are reconfigurable during runtime. Due to the organization of the Data Partition in the Message RAM (reference by data pointer), reconfiguration of the configured payload length and the data pointer in the Header Section of a Message Buffer may lead to erroneous configurations. If a Message Buffer is reconfigured during runtime it may happen that this Message Buffer is not send out in the respective communication cycle.

The Communication Controller does not have the capability to calculate the Header CRC. The Host is supposed to provide the Header CRCs for all transmit buffers. If Network Management is required the Host has to set the PPIT bit in the Header Section of the respective Message Buffer to 1 and write the Network Management information to the Data Section of the Message Buffer (see **Section 24.6.6**).

The payload length field configures the data payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by SFDL in the Message Handler Configuration Register 1, the Communication Controller generates padding byte to ensure that Frames have proper physical length. The padding pattern is logical zero.

Each transmit buffer provides a transmission mode flag TXM that allows the Host to configure the transmission mode for the transmit buffer in the static segment. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode. In dynamic segment the transmitter always works in single-shot mode.

If a Message Buffer is configured in the continuous mode, the Communication Controller does not reset the transmission request flag TXR after successful transmission. In this case a Frame is sent out each time the Frame ID and cycle counter filter match. The TXR flag can be reset by the Host by writing the respective Message Buffer number to the Input Buffer Command Request register while bit **STXRH** in the Input Buffer Command Mask register is reset to 0.

If two or more transmit buffers are configured with the same Frame ID **and** cycle counter filter value, the transmit buffer with the lowest Message Buffer number will be transmitted in the respective slot.

24.6.8.4 Frame Transmission

To prepare a transmit buffer for transmission the following steps are required:

- Configure the Message Buffer as transmit buffer by writing bit CFG = 1 in the Write Header Section 1 register
- Write transmit message (Header and Data Section) to the Input Buffer.
- To transfer a transmit message from Input Buffer to the Message RAM proceed as described on **“Data Transfer from Input Buffer to Message RAM” on Page 24-224**.
- If configured in the Input Buffer Command Mask register the Transmission Request flag for the respective Message Buffer will be set as soon as the transfer has completed, and the Message Buffer is ready for transmission.
- Check whether the Message Buffer has been transmitted by checking the TXR bits (TXR = 0) in the Transmission Request 1,2 registers (single-shot mode only).

In single-shot mode the Communication Controller resets the TXR flag after transmission has been completed. Now the Host may update the transmit buffer with the next message. The Communication Controller does not transmit the message before the Host has indicated that the update is completed by setting the Transmission Request flag TXR again. The Host can check the actual state of the TXR flags of all Message Buffers by reading the Transmission Request registers. After successful transmission, if bit **WRHS1.MBI** in the Header Section of the respective Message Buffer is set, the transmit service request flag in the Status Service Request Register is set (TXI = 1). If enabled an service request is generated.

24.6.8.5 NULL Frame Transmission

If in static segment the Host does not set the transmission request flag before transmit time, and if there is no other transmit buffer with matching filter criteria (matching Frame ID and cycle counter filter), the Communication Controller transmits a NULL Frame with the NULL Frame indication bit reset to 0 and the payload data reset to zero.

In the following cases the Communication Controller transmits a NULL Frame with the NULL Frame indication bit reset to 0, and the rest of the Frame Header and the Frame length unchanged (payload data is reset to zero):

- All transmit buffers configured for the slot have cycle counter filters that do not match the current cycle
- There are matching Frame ID’s and cycle counter filters, but none of these transmit buffers has the transmission request flag TXR set

NULL Frames are not transmitted in the dynamic segment.

24.6.9 Receive Process

The receive process is described in the following sections.

24.6.9.1 Frame Reception

To prepare or change a Message Buffer for reception the following steps are required:

- Configure the Message Buffer as receive buffer by writing bit CFG = 0 in the Write Header Section 1 register
- Configure the receive buffer by writing the configuration data (Header Section) to the Input Buffer
- Transfer the configuration from Input Buffer to the Message RAM by writing the number of the target Message Buffer to the Input Buffer Command Request register.

Once these steps are performed, the Message Buffer functions as an active receive buffer and participates in the internal acceptance filtering process, which takes place every time the Communication Controller receives a message. The first matching receive buffer is updated from the received message. If the Message Buffer holds an unprocessed Data Section (ND = 1) it is overwritten with the new message and the MLST bit in the respective Message Buffer Status register is set.

If the payload length of a received Frame PLC is longer than the value programmed by PLC in the Header Section of the respective Message Buffer, the data field stored in the Message Buffer is truncated to that length.

If no Frame, a NULL Frame, or a corrupted Frame is received in a slot, the Data Section of the Message Buffer configured for this slot is not updated. In this case only the flags in the Message Buffer Status register are updated to signal the cause of the problem. In addition the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set.

When the Data Section of a receive buffer has been updated from a received Frame, the respective New Data **NDn (n = 0-31)** to **NDn (n = 96-127)** flag in the New Data **NDAT1** to **NDAT4** registers is set. When the Message Handler has updated the Message Buffer status, the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set. If bit **RDHS1.MBI** in the Header Section of the respective Message Buffer is set, the receive service request flag in the Status Service Request Register is set (RXI = 1). If enabled an service request is generated.

To read a receive buffer from the Message RAM via the Output Buffer proceed as described on **“Data Transfer from Message RAM to Output Buffer” on Page 24-226**.

Note: The ND and MBC flags are automatically cleared by the Message Handler when the received message has been transferred to the Output Buffer.

24.6.9.2 NULL Frame reception

The Payload Segment of a received NULL Frame is **not** copied into the matching receive buffer. If a NULL Frame has been received, the Header Section of the matching Message Buffer is updated from the received NULL Frame. The NULL Frame indication bit in the Header Section 3 of the respective Message Buffer is reset (NFI = 0) and the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set.

In case that bit ND and / or MBC were already set before this event because the Host did not read the last received message, bit MLST in the Message Buffer Status register of the respective Message Buffer is also set.

24.6.10 FIFO Function

A group of the Message Buffers can be configured as a cyclic First-In-First-Out (FIFO). The group of Message Buffers belonging to the FIFO is contiguous in the register map starting with the Message Buffer referenced by FFB and ending with the Message Buffer referenced by LCB in the Message RAM Configuration register. Up to 128 Message Buffers can be assigned to the FIFO.

24.6.10.1 Description

Every valid incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case Frame ID, payload length, receive cycle count, and the status bits of the addressed FIFO Message Buffer are overwritten with Frame ID, payload length, receive cycle count, and the status from the received message and can be read by the Host for message identification. Bit RFNE in the Status Service Request Register shows that the FIFO is not empty, bit RFF in the Status Service Request Register is set when the last available Message Buffer belonging to the FIFO is written, bit RFO in the Error Service Request Register shows that a FIFO overrun has been detected. If enabled, service requests are generated.

There are two index registers associated with the FIFO. The PUT Index Register (PIDX) is an index to the next available location in the FIFO. When a new message has been received it is written into the Message Buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available Message Buffer. If the PIDX register is incremented past the highest numbered Message Buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) Message Buffer in the FIFO chain. The GET Index Register (GIDX) is used to address the next Message Buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a Message Buffer belonging to the FIFO to the Output Buffer. The PUT Index Register and the GET Index Register are not accessible by the Host.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message

overwrites the oldest message in the FIFO. This will set FIFO overrun flag RFO in the Error Service Request Register.

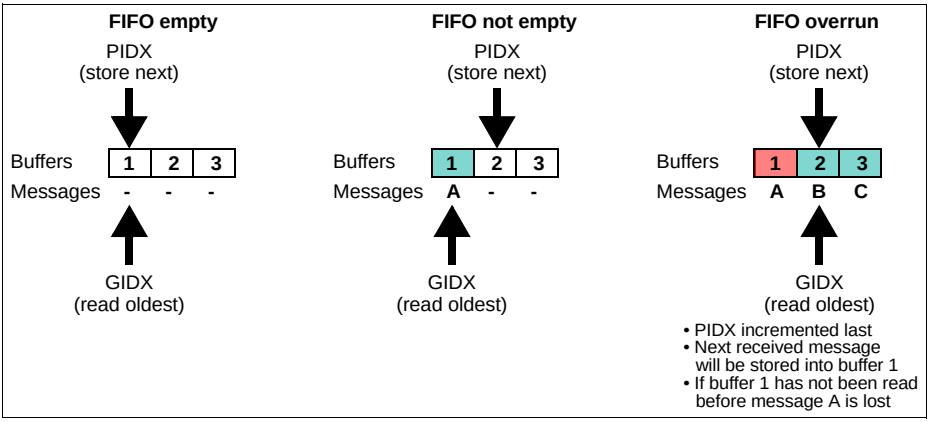

Figure 24-10 FIFO Status: Empty, Not Empty, Overrun

A FIFO non empty status is detected when the PUT index (PIDX) differs from the GET index (GIDX). In this case flag RFNE is set. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty, and the FIFO overrun states are explained in **Figure 24-10** for a three Message Buffer FIFO.

There is a programmable FIFO rejection filter for the FIFO. The FIFO Rejection Filter register (FRF) defines a filter pattern for messages to be rejected. The FIFO rejection filter consists of channel filter, Frame ID filter, and cycle counter filter. If bit RSS is set to 1 (default), all messages received in the static segment are rejected by the FIFO. If bit RNF is set to 1 (default), received NULL Frames are not stored in the FIFO.

The FIFO Rejection Filter Mask register (FRFM) specifies which bits of the Frame ID filter in the FIFO Rejection Filter register are marked “don’t care” for rejection filtering.

24.6.10.2 Configuration of the FIFO

For all Message Buffers belonging to the FIFO the data pointer to the first 32-bit word of the Data Section of the respective Message Buffer in the Message RAM has to be configured via the Write Header Section 3 register. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask and needs not be configured in the Header Sections of the Message Buffers belonging to the FIFO.

When programming the data pointers for the Message Buffers belonging to the FIFO, the payload length of all Message Buffers should be programmed to the same value.

*Note: It is recommended to program the MBI bits of the Message Buffers belonging to the FIFO to 0 via **WRHS1.MBI** to avoid generation of RX interrupts.*
*If the payload length of a received Frame is longer than the value programmed by **WRHS2.PLC** in the Header Section of the respective Message Buffer, the data field stored in a Message Buffer of the FIFO is truncated to that length.*

24.6.10.3 Access to the FIFO

To read from the FIFO the Host has to trigger a transfer from the Message RAM to the Output Buffer by writing the number of the first Message Buffer of the FIFO (referenced by FFB) to the Output Buffer Command Request register. The Message Handler then transfers the Message Buffer addressed by the GET Index Register (GIDX) to the Output Buffer. After this transfer the GET Index Register (GIDX) is incremented.

24.6.11 Message Handling

The Message Handler controls data transfers between the Input / Output Buffer and the Message RAM and between the Message RAM and the two Transient Buffer RAMs. All accesses to the internal RAM's are 32 bit accesses.

Access to the Message Buffers stored in the Message RAM is done under control of the Message Handler state machine. This avoids conflicts between accesses of the two protocol controllers and the Host to the Message RAM.

Frame IDs of Message Buffers assigned to the static segment have to be in the range from 1 to NSS as configured in the GTU Configuration Register 7. Frame IDs of Message Buffers assigned to the dynamic segment have to be in the range from NSS + 1 to 2047.

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

24.6.11.1 Host access to Message RAM

The message transfer between Input Buffer and Message RAM as well as between Message RAM and Output Buffer is triggered by the Host by writing the number of the target / source Message Buffer to be accessed to the Input or Output Buffer Command Request register.

The Input / Output Buffer Command Mask registers can be used to write / read Header and Data Section of the selected Message Buffer separately. If bit **STXRS** in the Input Buffer Command Mask register is set (**STXRS** = 1), the transmission request flag TXR of the selected Message Buffer is automatically set after the Message Buffer has been updated.

If bit **STXRS** in the Input Buffer Command Mask register is reset (**STXRS** = 0), the transmission request flag TXR of the selected Message Buffer is reset. This can be used to stop transmission from Message Buffers operated in continuous mode.

Input Buffer (IBF) and the Output Buffer (OBF) are build up as a double buffer structure. One half of this double buffer structure is accessible by the Host (IBF Host / OBF Host), while the other half (IBF Shadow / OBF Shadow) is accessed by the Message Handler for data transfers between IBF / OBF and Message RAM.

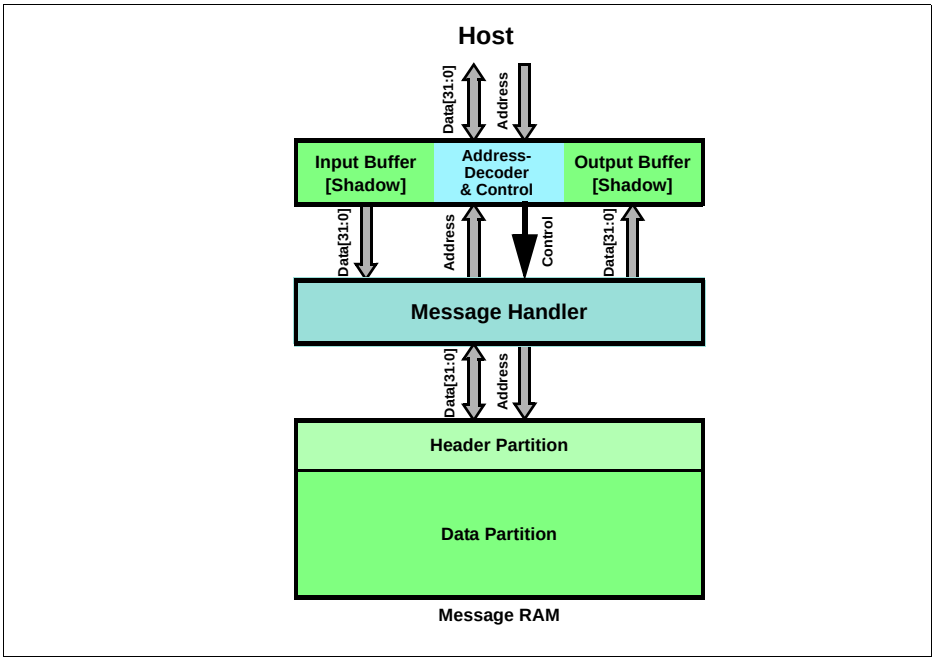

Figure 24-11 Host Access to Message RAM

Data Transfer from Input Buffer to Message RAM

To configure / update a Message Buffer in the Message RAM, the Host has to write the data to **WRDSnn (nn = 01-64)** and the Header to **WRHS1**, **WRHS2**, **WRHS3**. Two sets of **WRDSnn (nn = 01-64)** are available in parallel and selected by **CUST1.IBF1PAG**and **CUST1.IBF2PAG**. **CUST1.IBFS** shows which Input Buffer is currently used as Input Shadow Buffer and which as Input Host Buffer. **WRHS1**, **WRHS2**, and **WRHS2** does only exist once. The specific action is selected by configuring the Input Buffer Command Mask **IBCM**.

When the Host writes the number of the target Message Buffer in the Message RAM to IBRH in the Input Buffer Command Request register **IBCR**, IBF Host and IBF Shadow are swapped (see **Figure 24-12**).

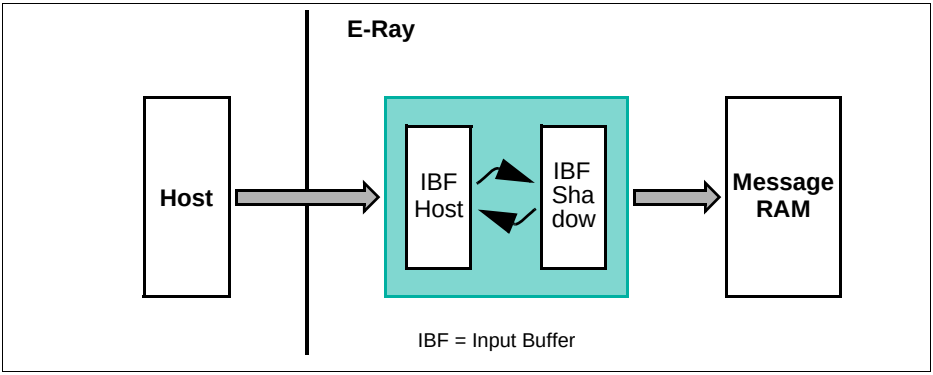

Figure 24-12 Double Buffer Structure Input Buffer

In addition the bits in the Input Buffer Command Mask and Input Buffer Command Request registers are also swapped to keep them attached to the respective IBF section (see **Figure 24-13**).

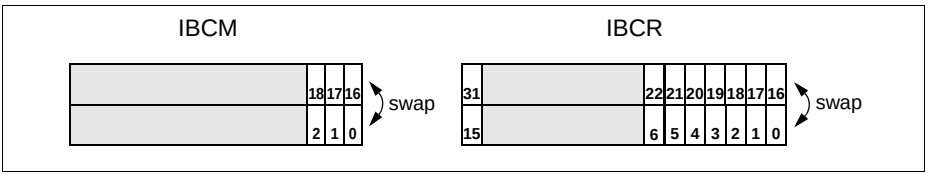

Figure 24-13 Swapping of IBCM and IBCR Bit

With this write operation the IBSYS bit in the Input Buffer Command Request register is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the Message Buffer in the Message RAM selected by IBRS.

While the Message Handler transfers the data from IBF Shadow to the target Message Buffer in the Message RAM, the Host may write the next message to IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target Message Buffer number to IBRH in the Input Buffer Command Request register.

If a write access to IBRH occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, IBSYH is reset to 0, IBSYS remains set to 1, and the next transfer

to the Message RAM is started. In addition the Message Buffer numbers stored under IBRH and IBRS and the Command Mask flags are also swapped.

Table 24-16 Assignment of Input Buffer Command Mask Bit

Pos.	Access	Bit	Function
18	rh	**STXRS**	Set Transmission Request Shadow
17	rh	**LDSS**	Load Data Section Shadow
16	rh	**LHSS**	Load Header Section Shadow
2	rw	**STXRH**	Set Transmission Request Host
1	rw	**LDSH**	Load Data Section Host
0	rw	**LHSH**	Load Header Section Host

Table 24-17 Assignment of Input Buffer Command Request Bit

Pos.	Access	Bit	Function
31	rh	IBSYS	**IBF Busy Shadow,** signals ongoing transfer from IBF Shadow to Message RAM
21–16	rh	IBRS	**IBF Request Shadow,** number of Message Buffer currently / last updated
15	rh	IBSYH	**IBF Busy Host,** transfer request pending for Message Buffer referenced by IBRH
5-0	rwh	IBRH	**IBF Request Host,** number of Message Buffer to be updated next

Data Transfer from Message RAM to Output Buffer

To read a Message Buffer from the Message RAM, the Host has to write to Command Request register **OBCR** to trigger the data transfer as configured in Output Buffer Command Mask **OBCM** register. After the transfer has completed, the Host can read the transferred data from **RDDSnn (nn = 01-64)**, **RDHS1**, **RDHS2**, **RDHS2**, and **MBS**.

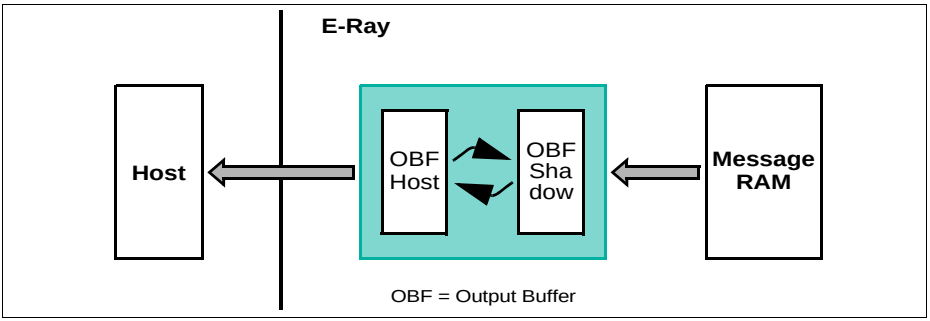

Figure 24-14 Double Buffer Structure Output Buffer

OBF Host and OBF Shadow as well as bits **OBCM.RHSS**, **OBCM.RDSS**, **OBCM.RHSH**, **OBCM.RDSH** and bits **OBCR.OBRS**, **OBCR.OBRH** are swapped under control of bits **OBCR.VIEW** and **OBCR.REQ**.

Writing bit **OBCR.REQ** to 1 copies bits **OBCM.RHSS**, **OBCM.RDSS** and bits **OBCR.OBRS** to an internal storage (see **Figure 24-15**).

After setting **OBCR.REQ** to 1, **OBCR.OBSYS** is set to 1, and the transfer of the Message Buffer selected by **OBCR.OBRS** from the Message RAM to OBF Shadow is started. After the transfer between the Message RAM and OBF Shadow has completed, the **OBCR.OBSYS** bit is set back to 0. Bits **OBCR.REQ** and **OBCR.VIEW** can only be set to 1 while **OBCR.OBSYS** is 0.

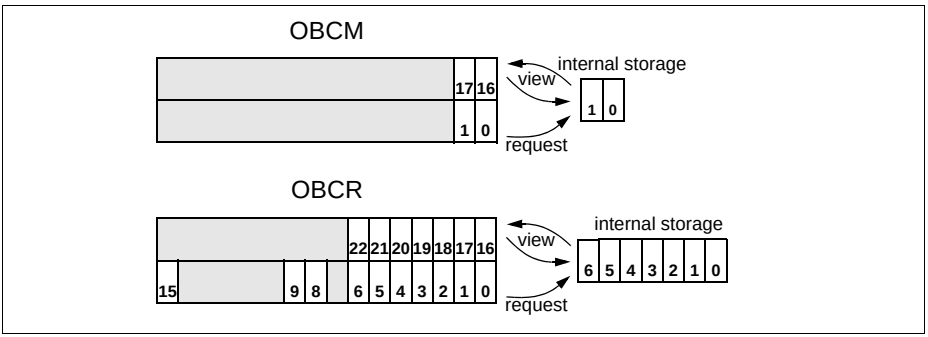

Figure 24-15 Swapping of OBCM and OBCR Bit

OBF Host and OBF Shadow are swapped by setting bit **OBCR.VIEW** to 1 while bit **OBCR.OBSYS** is 0 (see **Figure 24-14**).

In addition bits **OBCR.OBRH** and bits **OBCM.RHSH**, **OBCM.RDSH** are swapped with the registers internal storage thus assuring that the Message Buffer number stored in

OBCR.OBRH and the mask configuration stored in **OBCM.RHSH**, **OBCM.RDSH** matches the transferred data stored in OBF Host (see **Figure 24-15**).

Now the Host can read the transferred Message Buffer from OBF Host while the Message Handler may transfer the next message from the Message RAM to OBF Shadow.

Table 24-18 Assignment of Output Buffer Command Mask Bit

Pos.	Access	Bit	Function
17	rh	RDSH	Data Section available for Host access
16	rh	RHSH	Header Section available for Host access
1	rw	RDSS	Read Data Section Shadow
0	rw	RHSS	Read Header Section Shadow

Table 24-19 Assignment of Output Buffer Command Request Bit

Pos.	Access	Bit	Function
22–16	rh	OBRH	**OBF Request Host,** number of Message Buffer available for Host access
15	rh	OBSYS	**OBF Busy Shadow,** signals ongoing transfer from Message RAM to OBF Shadow
9	rw	REQ	**Request Transfer from Message RAM to OBF Shadow**
8	rwh	VIEW	**View OBF Shadow, swap OBF Shadow, and OBF Host**
6–0	rwh	OBRS	**OBF Request Shadow,** number of Message Buffer for next request

24.6.11.2 Data Transfers between IBF / OBF and Message RAM

This document uses the following terms and abbreviations:

Table 24-20 Terms and Abbreviations

Term	Meaning
MHD	Message Handler
IBF	Input Buffer 1 or 2 RAM
OBF	Output Buffer 1 or 2 RAM
MBF	Message Buffer RAM
TBF	Transient Buffer RAM Channel A (TBF1) or Channel B (TBF2)

Table 24-20 Terms and Abbreviations (cont'd)

IBF ⇒ MBF	Transfer from IBF to MBF
MBF ⇒ OBF	Transfer from MBF to OBF
MBF ⇒ TBF	Transfer from MBF to TBF
TBF ⇒ MBF	Transfer from TBF to MBF
SS	Slot Status
SS ⇒ MBF	Transfer SS to MBF

Message Handler functionality

The MHD controls the access to the MBF. It manages data-transfer between MBF and IBF, OBF, TBF1, TBF2. The data-path are shown in Figure 24-16.

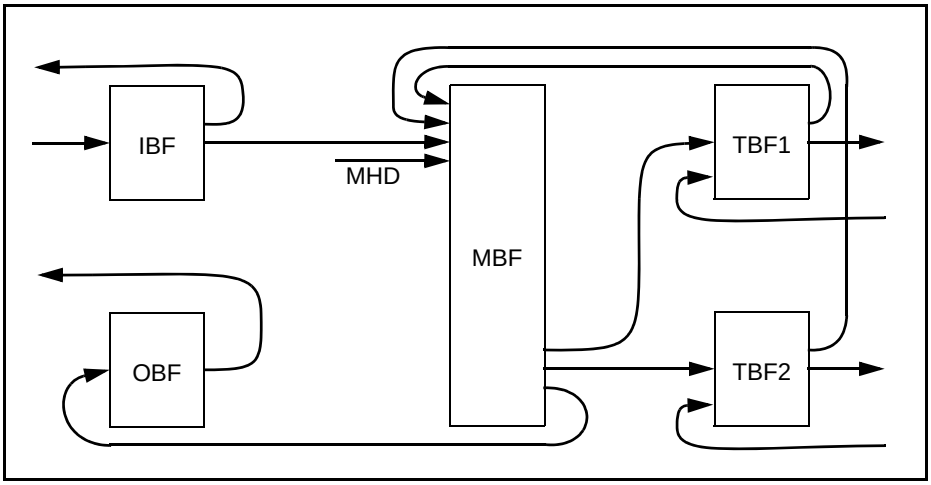

Figure 24-16 Interconnection of RAMs

Furthermore a search-algorithm allows to find the next valid message object in the MBF for transmission or reception.

Each transfer consists of a setup-time, four time steps to transfer the Header-section and a payload-length-dependent number of time steps to transfer the data-section. The internal data-busses have a width of 32 bits. Thereby it is possible to transfer two 2-byte words in one time step. If the payload consists of an odd number of 2-byte words the last time step of the data-section contains only 16 bit of valid data. If the Payload-Length (PL) is e.g. 7, the data-section consists of 4 time steps.

The maximum length for the data-section is 64 time steps, the minimum length is zero time steps.

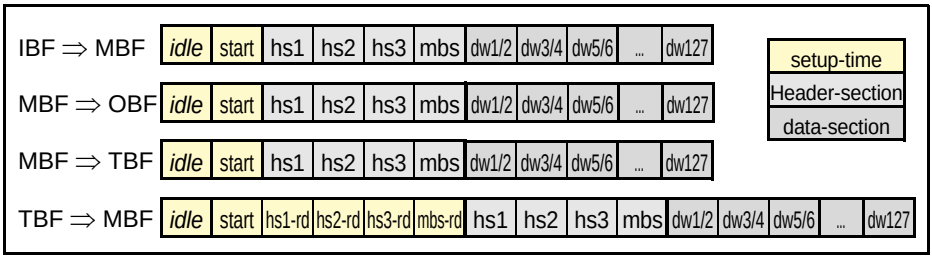

Figure 24-17 Different Possible Buffer Transfers

The update of the Slot-Status consists of a setup-time and one time-step to write the new Slot-Status.

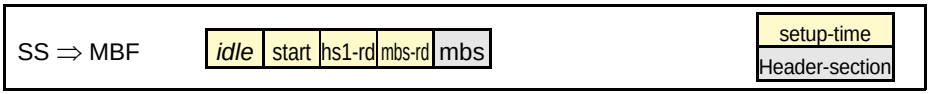

Figure 24-18 Update of Slot Status

The length of a time step depends on the number of concurrent tasks.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and MBF
- Data transfer between TBF1 and MBF, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and MBF, search next TX / RX Message Buffer CHB

Thereby the time step length can vary between one and three f_{CLC_ERAY} periods.

Under certain conditions it is possible that a transfer is stopped or interrupted for a number of time steps until it is continued.

When a IB F⇒ MBF is started short after a TBF ⇒ MBF or SS ⇒ MBF the transfer from IBF has to wait until the setup-time of the internal transfer has finished (see Figure 24-19)

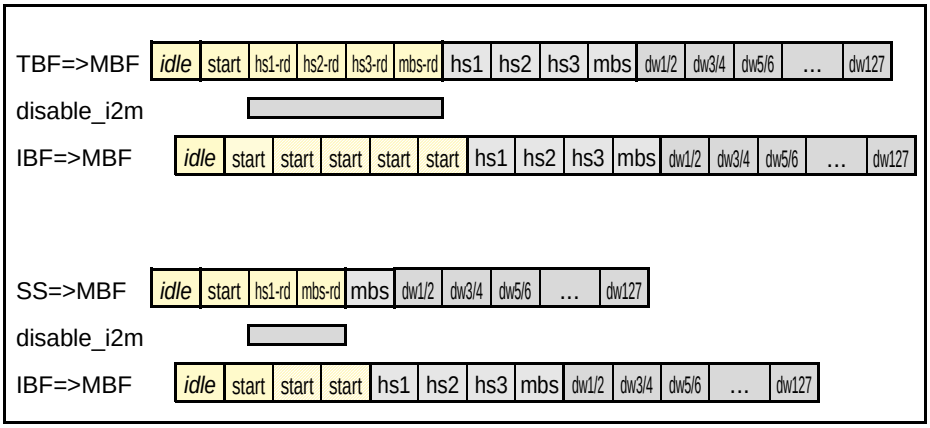

Figure 24-19 Delay start of IBF⇒MBF

The internal signal “disable_i2m” is always active when the TBF ⇒ MBF is in state “hs1-rd”, “hs2-rd”, “hs3-rd” or “mbs-rd” and when the SS ⇒ MBF is in state “hs1-rd” or “mbs-rd”.

The IBF ⇒ MBF is hold in state “start” until the internal signal “disable_i2m” gets inactive.

These additional time-steps are independent of any address-counter-values. This means, the IBF ⇒ MBF has to wait even if it writes to another buffer than the internal transfer.

Multiple requests of transfers between IBF/OBF and Message RAM

The time required to transfer the contents of a Message Buffer between IBF / OBF and Message RAM depends on the number of 4-byte words to be transferred, the number of concurrent tasks to be managed by the Message Handler, and in special cases the type and address range of the internal transfer. The number of 4-byte words varies from 4 (Header Section only) to 68 (Header + maximum Data Section) plus a short setup time to start the first transfer, while the number of concurrent task varies from one to three. The 4 Header words have to be included in calculation even if only the Data Section is requested for transfer.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and MBF
- Data transfer between TBF1 and MBF, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and MBF, search next TX / RX Message Buffer CHB

Transfers between IBF and MBF respectively MBF and OBF can only be handled one after another. In case that e.g. a IBF ⇒ MBF has been started shortly before a

MBF ⇒ OBF is requested, the MBF ⇒ OBF has to wait until the IBF ⇒ MBF has completed.

In case that e.g. a second IBF⇒MBF is requested, a MBF⇒OBF is requested and a IBF⇒MBF is ongoing, the MBF⇒OBF has to wait until the first IBF⇒IBF has completed. The second IBF=MBF has to wait until the MBF⇒OBF has completed (see figure 24-20) independent whether MBF⇒OBF or second IBF⇒MBF is requested first.

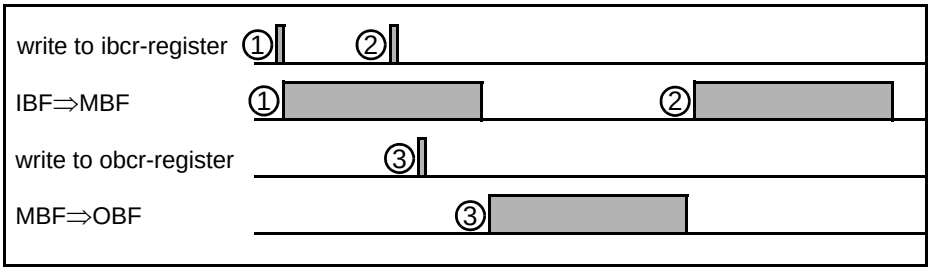

Figure 24-20 Multiple IBF/OBF Request

Worst case for single request

When a message with a large payload length is received the TBF⇒MBF is started at the begin of the next slot (n+1). If the next slot is a dynamic slot without transmission/reception (minislot), it may happen that the TBF⇒MBF has not finished until begin of the next but one slot (n+2). In this case the TBF⇒MBF will be service requested (break) to start a transmission in the next but one slot (MBF⇒TBF) and/or to update the slot status (SS⇒MBF) for the RX-buffer corresponding with next slot (n+1). After this interruption the TBF⇒MBF is continued.

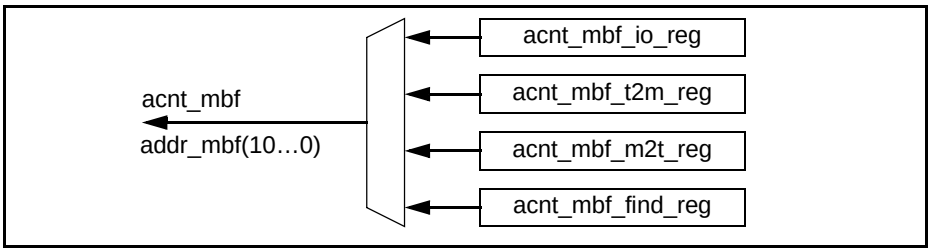

Figure 24-21 Address Counter Scheme of Message RAM (simplified)

For the transfers IBF⇒MBF / MBF⇒OBF, TBF⇒MBF and MBF⇒TBF separate address-counter are implemented (see Figure 24-21).

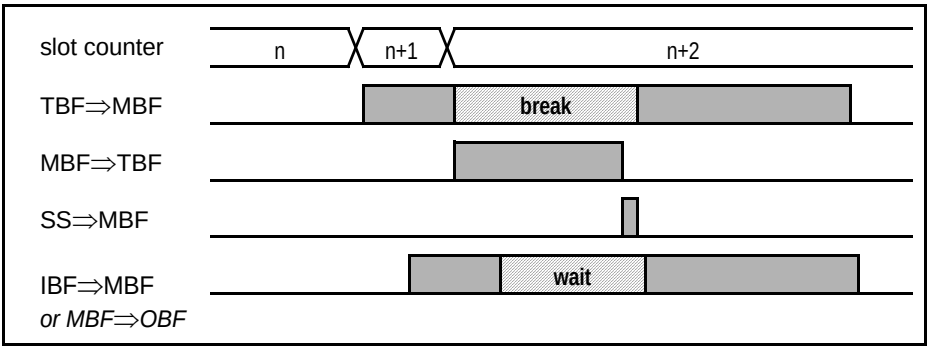

Figure 24-22 interruption of TBF⇒MBF

If the address-counter for IBF⇒MBF / MBF⇒OBF (acnt_mbf_io_reg) reaches the address of the interrupted TBF=>MBF (acnt_mbf_t2m_reg) the IBF⇒MBF / MBF⇒OBF has to wait until the TBF⇒MBF is continued (see Figure 24-22).

The relative time is measured in f_{CLC_ERAY} cycles. Absolute time depends on the actual f_{CLC_ERAY} cycle period.

tbf_to_mbf_break time$_{max}$ = (setup time + mbf_to_tbf time$_{max}$) + (setup time + ss_to_mbf)

cycles$_{req}$ = (number of concurrent tasks) × ((setup time+ (number of 4-byte words)$_{req}$) + tbf_to_mbf_break time)

setup time = 2 f_{CLC_ERAY} cycles

Worst case for one IBF⇒MBF or MBF⇒OBF:

Max. break time: tbf_to_mbf_break time$_{max}$ = (2+68) + (4+1) = 75

Max. number of f_{CLC_ERAY} cycles: cycles$_{req}$ = 3 × (6 + 68 + 75) = 435

Worst case for multiple transfers

If a second IBF⇒MBF and a MBF⇒OBF (see Figure 24-20) is requested directly after the first IBF⇒MBF has started following worst case timing could appear:

cycles$_{trans}$ = (remaining cycles of transfer running)
+ (cycles of second requested transfer)
+ (cycles of third requested transfer)

cycles$_{trans}$ = cycles$_{rem}$ + cycles$_{req_2}$+ cycles$_{req_3}$

Max. number of f_{CLC_ERAY} cycles: cycles$_{trans}$ = 447 + 435 + 447 = 1329

24.6.11.3 Minimum f_{CLC_ERAY}

To calculate the minimum f_{CLC_ERAY} the worst case scenario has to be considered.

The worst case scenario depends on the following parameters

- maximum payload length
- minimum minislot length
- number of configured Message Buffers (excluding FIFO)
- used channels (single/dual channel)

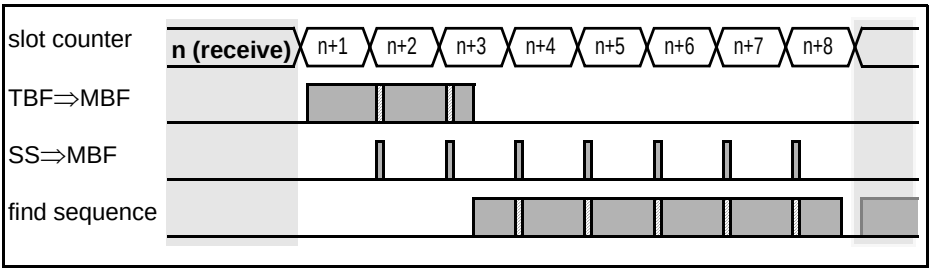

Figure 24-23 worst case scenario

Worst case scenario:

- reception of message with a maximum payload length in Slot n (n is 7,15,23,31,39,…)
- slot n+1 to n+7 are empty dynamic slots (minislot) and configured as receive buffer
- the find-sequence (usually started in slot 8,16,24,32,40,…) has to scan the maximum number of configured buffers
- the number of concurrent tasks has its maximum value of three

The find-sequence is executed each 8 Slots (slot 8,16,24,32,40,…). It has to be finished until the next find-sequence is requested.

The length of a TBF⇒MBF varies from 4 (Header Section only) to 68 (Header + maximum Data Section) time step plus a setup time of 6 time steps.

$$cycles_{t2m} = \frac{f_{CLC\_ERAY}}{\text{number of concurrent tasks}) \times (\text{setup time}_{t2m} + (\text{number of 4-byte words})_{t2m})}$$

A SS⇒MBF has a fixed length of 1 time steps plus a setup time of 4 time steps.

$$cycles_{ss2m} = \frac{f_{CLC\_ERAY}}{(\text{number of concurrent tasks}) \times 5}$$

The find sequence has a maximum length of 128 (maximum number of buffers) time steps plus a setup time of 2 time steps.

$$cycles_{find} = \frac{f_{CLC\_ERAY}}{(\text{number of concurrent tasks}) \times (\text{setup time}_{find} + (\text{number of configured buffers}))}$$

A minislot has a length of 2 to 63 Macrotick (gdMinislot). The minimum nominal Macrotick period (cdMinMTNom) is 1 µs. A sequence of 8 minislots has a length of

$$time_{8minislots} = 8 \times gdMinislot \times cdMinMTNom$$

The maximum period $T_{CLC\_ERAY} = 1/f_{CLC\_ERAY}$ can be calculated as followed:

$$time_{8minislots} \geq (f_{CLC\_ERAY}\ \text{period in}\ \mu s) \times (\ (f_{CLC\_ERAY}\ cycles_{t2m}) + 7 \times (f_{CLC\_ERAY}\ cycles_{ss2m}) + (f_{CLC\_ERAY}\ cycles_{find}))$$

$$f_{CLC\_ERAY}\ \text{period in ms} \leq \frac{time_{8mnislots}}{(\ cycles_{t2m}) + 7 \times (cycles_{ss2m}) + (cycles_{find})}$$

minimum $time_{8minislots}$ = $8 \times 2 \times 1\ \mu s = 16\ \mu s$

maximum $f_{CLC\_ERAY}\ cycles_{t2m}$ = $3 \times (6 + 68) = 222$

maximum $f_{CLC\_ERAY}\ cycles_{ss2m}$ = $3 * 5 = 15$

maximum $f_{CLC\_ERAY}\ cycles_{find}$ = $3 * (2 + 128) = 390$

$$f_{CLC\_ERAY}\ \text{period in ms} \leq \frac{16\mu s}{222 + 7 \times 15 + 390} = 22.315\ldots ns$$

The minimum f_{CLC_ERAY} frequency for this worst case scenario is 44.8125 MHz.

A too low f_{CLC_ERAY} frequency can cause a malfunction of the E-Ray.

The E-Ray can detect several malfunctions and reports this by setting the corresponding flag in the Message Handler Constraints Flags (**MHDF**) register.

Minimum f_{CLC_ERAY} for various maximum payload length

Table 24-21 summarizes the minimum required f_{CLC_ERAY} frequency for various maximum payload length assuming:

- a minimum minislot length of 2µs.
- a maximum of 128 configured Message Buffers.
- dual channels in use.

Table 24-21 Minimum f_{CLC_ERAY} for different maximum payload length

Maximum payload length of 32 bit words	4	8	16	32	64
minimum f_{CLC_ERAY}	32,82 MHz	33,57 MHz	35,07 MHz	38,07 MHz	44,1 MHz

Minimum f_{CLC_ERAY} for various minimum minislot length

Table 24-22 summarizes the minimum required f_{CLC_ERAY} frequency for various minimum minislot length assuming:

- a maximum payload length of 254 bytes / 64 four-byte-words.
- a maximum 128 configured Message Buffers.
- dual channels in use.

Table 24-22 Minimum f_{CLC_ERAY} for different minimum minislot length

gdMinislot at dMinMTNom = 1 µs	2 µs	3 µs	4 µs	7 µs	8 µs
minimum f_{CLC_ERAY}	44,82 MHz	29,88 MHz	22,412 MHz	12,8 MHz	9,96 MHz

Minimum f_{CLC_ERAY} for various amount of configured Message Buffers

Table 24-23 summarizes the minimum required f_{CLC_ERAY} frequency for various amount of configured Message Buffers assuming:

- a maximum payload length of 254 bytes / 64 four-byte-words.
- a minimum minislot length of 2 µs.
- dual channels in use.

Table 24-23 Minimum f_{CLC_ERAY} for different amount of configured Message Buffers

Configured maximum amount of Message Buffers	128	64	32
minimum f_{CLC_ERAY}	44,82 MHz	32,82 MHz	26,82 MHz

Minimum f_{CLC_ERAY} for a typical configuration

´The minimum required f_{CLC_ERAY} frequency for various assuming the following typical E-Ray configuration:

- a maximum payload length of 32 bytes / 8 four-byte-words.
- a minimum minislot length of 7 µs.
- a maximum 128 configured Message Buffers.
- dual channels in use

The minimum f_{CLC_ERAY} frequency for this typical example would be 10 MHz.

24.6.11.4 FlexRay™ Protocol Controller access to Message RAM

The two Transient Buffer RAMs (TBF 1, TBF 2) are used to buffer the data for transfer between the two FlexRay™ Protocol Controllers and the Message RAM.

Each Transient Buffer RAM is build up as a double buffer, able to store two complete FlexRay™ messages. There is always one buffer assigned to the corresponding Protocol Controller while the other one is accessible by the Message Handler.

If e.g. the Message Handler writes the next message to be send to Transient Buffer Tx, the FlexRay™ Channel Protocol Controller can access Transient Buffer Rx to store the message it is actually receiving. During transmission of the message stored in Transient Buffer Tx, the Message Handler transfers the last received message stored in Transient Buffer Rx to the Message RAM (if it passes acceptance filtering) and updates the respective Message Buffer.

Data transfers between the Transient Buffer RAMs and the shift registers of the FlexRay™ Channel Protocol Controllers are done in words of 32 bit. This enables the use of a 32 bit shift register independent of the length of the FlexRay™ messages.

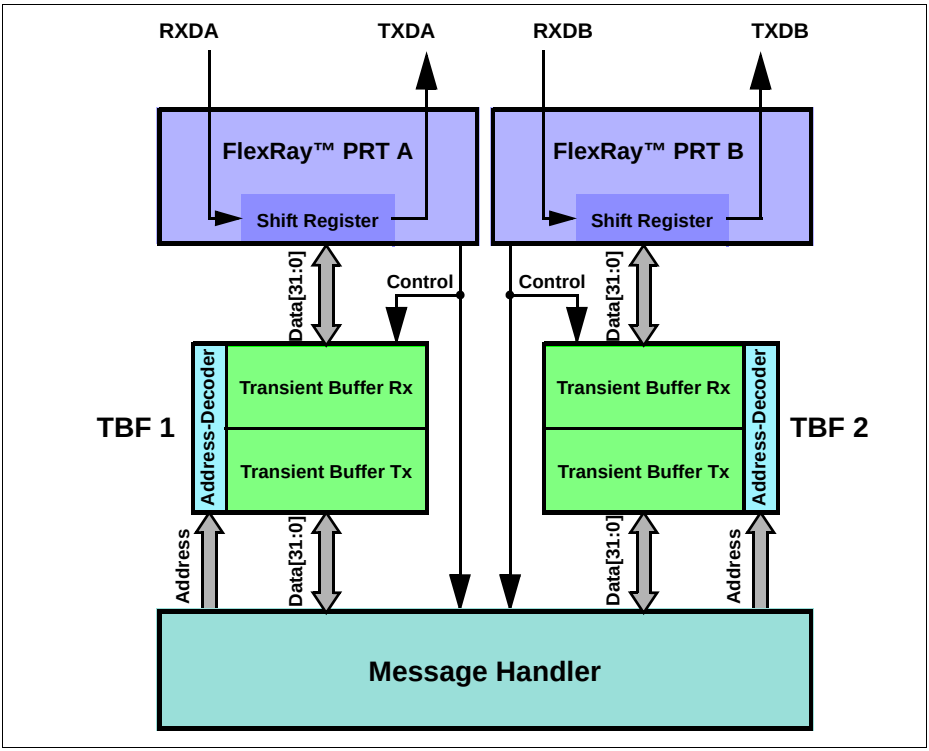

Figure 24-24 Access to Transient Buffer RAMs

24.6.12 Message RAM

To avoid conflicts between Host access to the Message RAM and FlexRay™ message reception / transmission, the Host cannot directly access the Message Buffers in the Message RAM. These accesses are handled via the Input and Output Buffers. The Message RAM is able to store up to 128 Message Buffers depending on the configured payload length.

The Message RAM is organized 2048 x 32. To achieve the required flexibility with respect to different numbers of data byte per FlexRay™ Frame (0 to 254), the Message RAM has a structure as shown in **Figure 24-25**.

The Data Partition is allowed to start at Message RAM word number: (MRC.LCB + 1) • 4

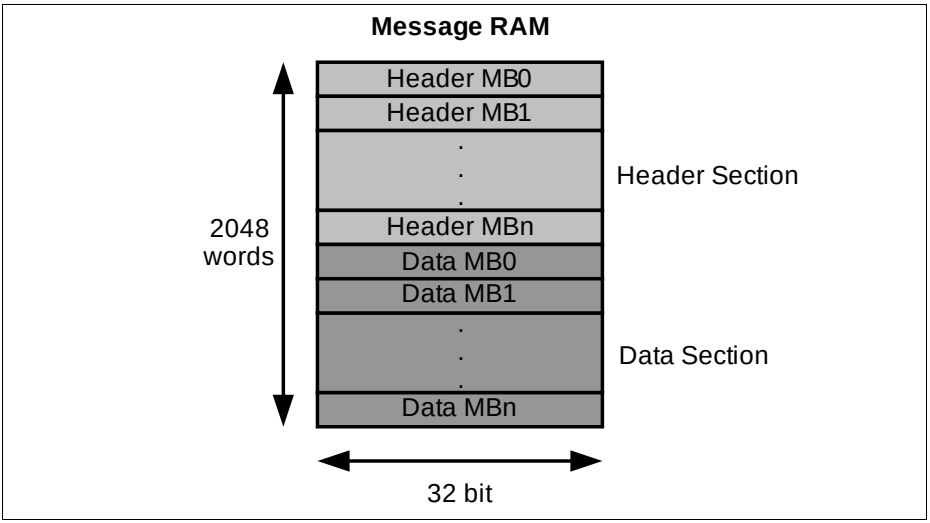

Figure 24-25 Structure of Message RAM

Header Partition

Stores Header Segments of FlexRay™ Frames:

- Supports a maximum of 128 Message Buffers
- Each Message Buffer has a Header of four 32 bit words
- Header 3 of each Message Buffer holds the11 bit pointer to the respective Data Section in the Data Partition

Data Partition

Flexible storage of Data Sections with different length. Some maximum values are:

- 30 Message Buffers with 254 byte Data Section each
- Or 56 Message Buffers with 128 byte Data Section each
- Or 128 Message Buffers with 48 byte Data Section each

Restriction: Header Partition + Data Partition may not occupy more than 2048 32-bit words.

24.6.12.1 Header Partition

The Header of each Message Buffer occupies four 32-bit words in the Header Partition of the Message RAM. The Header of Message Buffer 0 starts with the first word in the Message RAM.

For transmit buffers the Header CRC has to be calculated by the Host.

Payload Length Received **PLR**, Receive Cycle Count **RCC**, Received on Channel Indication **RCI**, Startup Frame Indication bit **SFI**, Sync bit **SYN**, NULL Frame Indication bit **NFI**, Payload Preamble Indication bit **PPI**, and Reserved bit **RES** are only updated from received valid Frames (including valid NULL Frames).

Header word 4 of each configured Message Buffer holds the respective Message Buffer Status **MBS** information.

Table 24-24 Header Section of a Message Buffer in the Message RAM

Bit Word	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1			MBI	TXM	NME	CFG	CHB	CHA		Cycle Code												Frame ID										
2		Payload Length Received								Payload Length Configured												Tx Buffer: Header CRC Configured Rx Buffer: Header CRC Received										
3			RES	PPI	NFI	SYN	SFI	RCI		Receive Cycle Count												Data Pointer										
4			RESS	PPIS	NFIS	SYNS	SFIS	RCIS		Cycle Count Status							TFB	FTY		MLST	ESB	ESA	TCIB	TCIA	SVOB	SVOA	CEOB	CEOA	SEOB	SEOA	VFRB	VFRA

- Frame Configuration
- Filter Configuration
- Message Buffer Control
- Message RAM Configuration
- Updated from received Frame
- Message Buffer Status
- unused

Header 1 (word 0)

Write access via **WRHS1**, read access via **RDHS1**:

- Frame ID: Slot counter filtering configuration
- Cycle Code: Cycle counter filtering configuration
- CHA, CHB: Channel filtering configuration
- CFG: Message Buffer configuration: receive / transmit
- PPIT: Payload Preamble Indicator Transmit
- XMI: Transmit mode configuration: single-shot / continuous
- MBI: Message Buffer receive / transmit service request enable

Header 2 (word 1)

Write access via **WRHS2**, read access via **RDHS2**:

- Header CRC
  - Transmit Buffer: Configured by the Host (calculated from Frame Header Segment)
  - Receive Buffer: Updated from received Frame
- Payload Length Configured
  - Length of Data Section (2-byte words) as configured by the Host
- Payload Length Received
  - Length of Payload Segment (2-byte words) stored from received Frame

Header 3

Write access via **WRHS3**, read access via **RDHS3**:

- Data Pointer
  - Pointer to the beginning of the corresponding Data Section in the Data Partition

Read access via **RDHS3**, valid for receive buffers only, updated from received Frames:

- Receive Cycle Count: Cycle count from received Frame
- RCI: Received on Channel Indicator
- SFI: Startup Frame Indicator
- SYN: SYNC Frame Indicator
- NFI: NULL Frame Indicator
- PPI: Payload Preamble Indicator
- RES: Reserved bit

Message Buffer Status MBS (word 3)

Read access via MBS, updated by the Communication Controller at the end of the configured slot.

- VFRA: Valid Frame Received on channel A
- VFRB: Valid Frame Received on channel B
- SEOA: Syntax Error Observed on channel A
- SEOB: Syntax Error Observed on channel B
- CEOA: Content Error Observed on channel A
- CEOB: Content Error Observed on channel B
- SVOA: Slot boundary Violation Observed on channel A
- SVOB: Slot boundary Violation Observed on channel B
- TCIA: Transmission Conflict Indication channel A
- TCIB: Transmission Conflict Indication channel B
- ESA: Empty Slot Channel A
- ESB: Empty Slot Channel B
- MLST: Message LoST
- FTA: Frame Transmitted on Channel A
- FTA: Frame Transmitted on Channel B
- Cycle Count Status: Actual cycle count when status was updated
- RCIS: Received on CHannel Indicator Status
- SFIS: Startup Frame Indicator Status
- SYNS: SYNC Frame Indicator Status
- NFIS: NULL Frame Indicator Status
- PPIS: Payload Preamble Indicator Status
- RESS: Reserved Bit Status

24.6.12.2 Data Partition

The Data Partition of the Message RAM stores the Data Sections of the Message Buffers configured for reception / transmission as defined in the Header Partition. The number of data bytes for each Message Buffer can vary from 0 to 254. To optimize the data transfer between the shift registers of the two FlexRay™ Protocol Controllers and the Message RAM as well as between the Host interface and the Message RAM, the physical width of the Message RAM is set to 4 bytes.

The Data Partition starts after the last word of the Header Partition. When configuring the Message Buffers in the Message RAM the programmer has to assure that the data pointers point to addresses within the Data Partition. **Table 24-25** below shows an example how the Data Sections of the configured Message Buffers can be stored in the Data Partition of the Message RAM.

The beginning and the end of a Message Buffer's Data Section is determined by the data pointer and the payload length configured in the Message Buffer's Header Section,

respectively. This enables a flexible usage of the available RAM space for storage of Message Buffers with different data length.

If the size of the Data Section is an odd number of 2-byte words, the remaining 16 bits in the last 32-bit word are unused (see **Table 24-25** below)

Table 24-25 Example for Structure of the Data Section in the Message RAM

Bit Word	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

24.6.12.3 ECC Check

There is an ECC checking mechanism implemented in the E-Ray module to assure the integrity of the data stored in the seven RAM blocks of the module. The RAM blocks have an ECC generator / checker attached as shown in **Figure 24-26**. When data is written to a RAM block, the local ECC generator generates the ECC data. The ECC data is stored together with the respective data word. The ECC data is checked each time a data word is read from any of the RAM blocks.

If an ECC error is detected, the respective error flag is set. The ECC error flags **MHDS.EIBF**, **MHDS.EOBF**, **MHDS.EMR**, **MHDS.ETBF1**, **MHDS.ETBF2**, and the faulty Message Buffer indicators **MHDS.FMBD**, **MHDS.MFMB**, **MHDS.FMB** are located in the Message Handler Status register. These error flags control the error interrupt flag **EIR.EERR**.

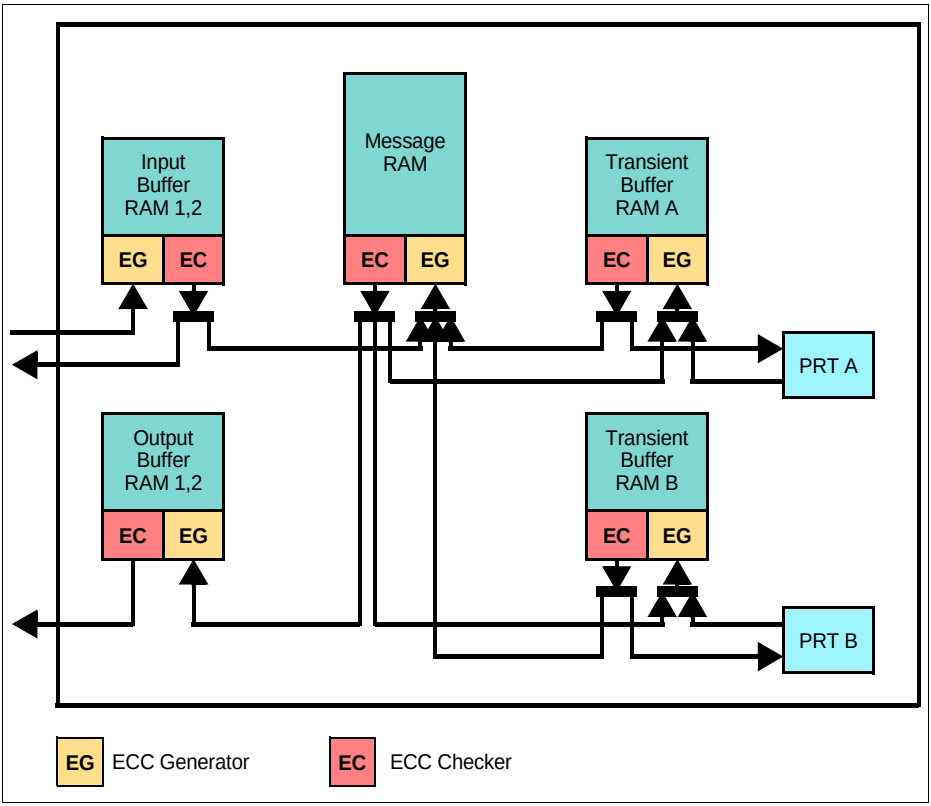

Figure 24-26 ECC Generation and Check

When an ECC error has been detected the following actions will be performed:

In all cases

- The respective ECC error flag in the Message Handler Status **MHDS** register is set
- The ECC error flag **EIR.EERR** in the Error Service Request Register is set, and if enabled, a module service request to the Host will be generated.

Additionally in specific cases

1. ECC error in data transfer from Input Buffer RAM 1,2 ⇒ Message RAM (Transfer of Header and Data Section)
   a) **MHDS.EIBF** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** has been updated
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) Transmit buffer: Transmission request for the respective Message Buffer is not set
2. ECC error in data transfer from Input Buffer RAM 1,2 ⇒ Message RAM (Transfer of Data Section only)
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) The Data Section of the respective Message Buffer is not updated
   e) Transmit buffer: Transmission request for the respective Message Buffer is not set
3. ECC error during host reading Input Buffer RAM
   a) • **MHDS.EIBF** bit is set
4. ECC error during scan of Header Sections in Message RAM
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) Ignore Message Buffer (Message Buffer is skipped)
5. ECC error during data transfer from Message RAM ⇒ Transient Buffer RAM A, B
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) Frame not transmitted, Frames already in transmission are invalidated by setting the Frame CRC to zero
6. ECC error during data transfer from Transient Buffer RAM A, B ⇒ Protocol Controller 1, 2
   a) **MHDS.ETBF1**, **MHDS.ETBF2** bit is set
7. ECC error in data transfer from Transient Buffer RAM A, B ⇒ Message RAM (ECC error when reading Header Section of respective Message Buffer from Message RAM)
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) The Data Section of the respective Message Buffer is not updated

8. ECC error in data transfer from Transient Buffer RAM A, B ⇒ Message RAM (ECC error when reading Transient Buffer RAM A, B)
   a) **MHDS.ETBF1**, **MHDS.ETBF2** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
9. ECC error during data transfer from Message RAM ⇒ Output Buffer RAM
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
10. ECC error during Host reading Output Buffer RAM
    a) • **MHDS.EOBF** bit is set
11. ECC error during data read of Transient Buffer RAM A, B

If an ECC error occurs while the Message Handler reads a Frame with Network Management information (PPI = 1) from the Transient Buffer RAM A, B the corresponding Network Management vector registers NMV1 to NMV3 are not updated from that Frame.

24.6.13 Host Handling of Errors

An ECC error caused by transient bit flips can be fixed by:

24.6.13.1 Self-Healing

ECC errors located in

- Input Buffer RAM 1,2
- Output Buffer RAM 1,2
- Data Section of Message RAM
- Transient Buffer RAM A
- Transient Buffer RAM B

are overwritten with the next write access to the disturbed bit(s) caused by Host access or by FlexRay communication.

24.6.13.2 CLEAR_RAMS Command

When called in DEFAULT_CONFIG or CONFIG state POC command CLEAR_RAMS initializes all module-internal RAMs to zero.

24.6.13.3 Temporary Unlocking of Header Section

An ECC error in the header section of a locked message buffer can be fixed by a transfer from the Input Buffer to the locked buffer Header Section. For this transfer, the write-

access to the IBCR (specifying the message buffer number) must be immediately preceded by the unlock sequence normally used to leave CONFIG state (see **“Lock Register (LCK)” on Page 24-30**).

For that single transfer the respective message buffer header is unlocked, regardless whether it belongs to the FIFO or whether its locking is controlled by MRC.SEC[1:0], and will be updated with new data.

24.7 Module Service Request

In general, service requests provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the controller, a Frame is received or transmitted, a configured timer service request is activated, or a stop watch event occurred. This enables the Host to react very quickly on specific error conditions, status changes, or timer events. On the other hand too many service requests can cause the Host to miss deadlines required for the application. Therefore the Communication Controller supports disable / enable controls for each individual service request source separately.

An service request may be triggered when

- An error was detected
- A status flag is set
- A timer reaches a preconfigured value
- A message transfer from Input Buffer to Message RAM or from Message RAM to Output Buffer has completed
- A stop watch event occurred

Tracking status and generating service requests when a status change or an error occurs are two independent tasks. Regardless of whether an service request is enabled or not, the corresponding status is tracked and indicated by the Communication Controller. The Host has access to the actual status and error information by reading the Error Service Request Register **EIR** and the Status Service Request **SIR** Register.

Table 24-26 Module Service Request Flags and Service Request Line Enable

Register	Bit	Function
SIR	WST	Wakeup Status
	CAS	Collision Avoidance Symbol
	CYCS	Cycle Start Service Request
	TXI	Transmit Service Request
	RXI	Receive Service Request
	RFNE	Receive FIFO not Empty
	RFF	Receive FIFO Full
	NMVC	Network Management Vector Changed
	TI0	Timer Service Request 0
	TI1	Timer Service Request 1
	TIBC	Transfer Input Buffer Completed
	TOBC	Transfer Output Buffer Completed
	SWE	Stop Watch Event
	SUCS	Startup Completed Successfully
	MBSI	Message Buffer Status Interrupt
	SDS	Start of Dynamic Segment
	WUPA	Wakeup Pattern Channel A
	MTSA	MTS Received on Channel A
	WUPB	Wakeup Pattern Channel B
	MTSB	MTS Received on Channel B
ILE	EINT0	Enable Service Request Line 0
	EINT1	Enable Service Request Line 1
EIR	PEMC	Protocol Error Mode Changed
	CNA	Command Not Valid
	SFBM	SYNC Frames Below Minimum
	SFO	SYNC Frame Overflow
	CCF	Clock Correction Failure
	CCL	CHI Command Locked
	EERR	ECC Error
	RFO	Receive FIFO Overrun

Table 24-26 Module Service Request Flags and Service Request Line Enable

Register	Bit	Function
EIR	EFA	Empty FIFO Access
	IIBA	Illegal Input Buffer Access
	IOBA	Illegal Output Buffer Access
	MHF	Message Handler Constraints Flag
	EDA	Error Detected on Channel A
	LTVA	Latest Transmit Violation Channel A
	TABA	Transmission Across Boundary Channel A
	EDB	Error Detected on Channel B
	LTVB	Latest Transmit Violation Channel B
	TABB	Transmission Across Boundary Channel B

The interrupt lines to the Host TINT0SR and TINT1SR are controlled by the enabled interrupts. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit ILE.EINT0/INT0SRC.SRE and ILE.EINT1/ INT1SRC.SRE.

The interrupt lines to the Host NDAT0SR and NDAT1SR are controlled by the enabled new data interrupts (**NDIC1** to **NDIC4**). In addition each of the two interrupt lines can be enabled / disabled separately by programming bit NDAT0SRC.SRE and NDAT1SRC.SRE.

The interrupt lines to the Host MBSC0SR and MBSC1SR are controlled by the enabled new data interrupts (**MSIC1** to **MSIC4**). In addition each of the two interrupt lines can be enabled / disabled separately by programming bit MBSC0SRC.SRE and MBSC1SRC.SRE.

The two timer service requests generated by service request timer 0 and 1 are available on pins TINT0SR and TINT1SR. They can be configured via the Timer 0 and Timer 1 Configuration register. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit TINT0SRC.SRE and TINT1SRC.SRE.

A stop watch event may be triggered via input pin STPWn.

The status of the data transfer between IBF / OBF and the Message RAM is signalled on signals IBUSY and OBUSY. When a transfer has completed bit **SIR.TIBC** or **SIR.TOBC** is set.

24.8 Restrictions

The following restrictions have to be considered when programming the E-Ray IP-module. A violation of these restrictions may lead to an erroneous behavior of the E-Ray IP-module.

24.8.1 Message Buffers with the same Frame ID

If two or more Message Buffers are configured with the same Frame ID, and if they have a matching cycle counter filter value for the same slot, then the Message Buffer with the lowest Message Buffer number is used.

Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay™ network is **not** allowed.

24.8.2 Data Transfers between IBF / OBF and Message RAM

The time required to transfer the contents of a Message Buffer between IBF / OBF and Message RAM depends on the setup time to start the first transfer, the number of 4-byte words to be transferred, and the number of concurrent tasks to be managed by the Message Handler. The number of 4-byte words varies from 4 (Header Section only) to 68 (Header + maximum Data Section) while the number of concurrent task varies from one to three.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and Message RAM
- Data transfer between TBF1 and Message RAM, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and Message RAM, search next TX / RX Message Buffer CHB

Transfers between IBF and Message RAM respectively Message RAM and OBF can only be handled one after another. In case that e.g. a transfer between IBF and Message RAM has been started shortly before a transfer between Message RAM and OBF is requested, the OBF transfer has to wait until the IBF transfer has completed.

The relative time is measured in f_{CLC_ERAY} cycles. Absolute time depends on the actual f_{CLC_ERAY} cycle period.

cyclestrans = (remaining cycles of transfer running) + (cycles of requested transfer)

cyclestrans = cyclesrem + cyclesreq

cyclesrem = (number of concurrent tasks) * (setup time + (number of 4-byte words)rem)

cyclesreq = (number of concurrent tasks) * (setup time + (number of 4-byte words)req)

setup time = 2 f_{CLC_ERAY} cycles

Under worst case conditions a transfer is requested directly after the previous transfer started:

Max. number of f_{CLC_ERAY} cycles: cyclestrans = (3 * (2 + 68)) + (3 * (2 + 68)) = 420

Worst case timing: timetrans(40MHz) = 420 * 25ns = 10.5 ms

24.9 E-Ray Module Implementation

This section describes the E-Ray interfaces as implemented in TC27x with the clock control, port and DMA connections, interrupt control, and address decoding.

Figure 24-27 shows a detailed view of the E-Ray interface.

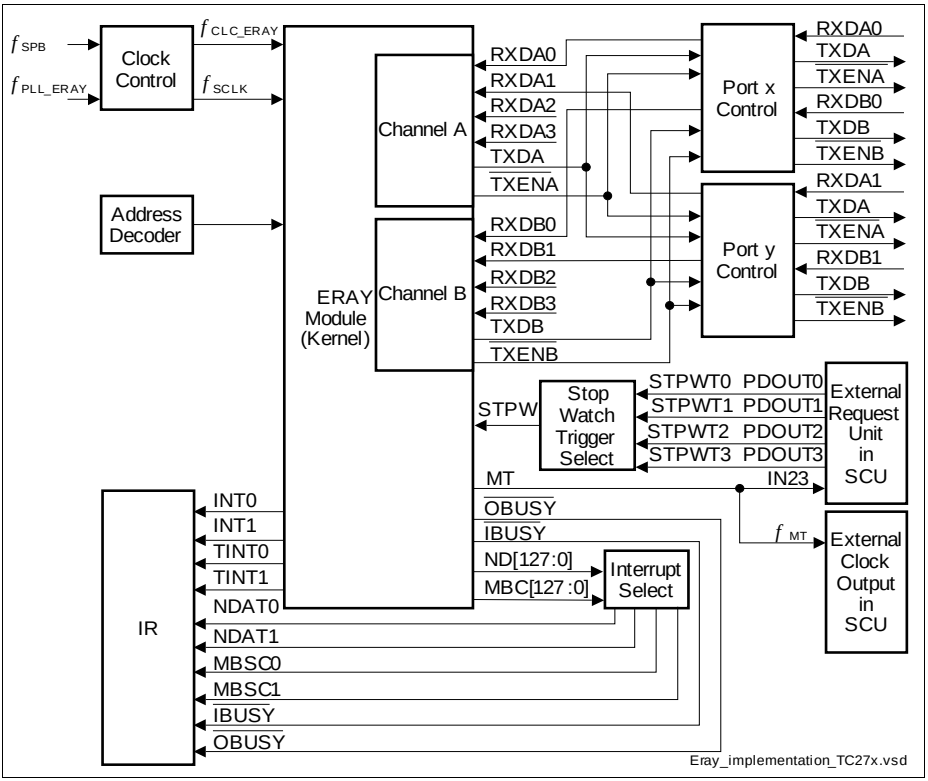

Figure 24-27 Detailed Block Diagram of the E-Ray Interface

24.9.1 Interconnections of the E-Ray Module

The E-Ray module has 2 FlexRay™ communication channels, channel A and channel B. Each channel provides a set of signals to drive a bus driver. The E-Ray module requires two different clocks, a sampling clock of the FlexRay™ bus f_{SCLK}. f_{SCLK} has to be 8 times the baud rate of the FlexRay™ communication. A second clock f_{CLC_ERAY} is

used for the main protocol controller state machine and the customer interface logic. To enable deactivation of the E-Ray Module, f_{CLC_ERAY} and f_{SCLK} may be disabled (clock gated) by the **CLC.DISR** Enable E-Ray (Clock Gating) bit.The following items are described in this section:

- E-Ray module (kernel) external registers
- Port control and connections
  - I/O port line assignment
  - I/O function selection
  - Pad driver characteristics selection
- On-chip connections
  - SCU Connections
  - DMA connections
- Module clock generation
- Interrupt registers
- E-Ray address map

24.9.2 Port Control and Connections

This section describes the I/O connections of the E-Ray module.

24.9.2.1 Input/Output Function Selection

Table 24-27 shows how bits and bit fields must be programmed for the required I/O functionality of the E-Ray I/O lines. This table also shows the values of the peripheral input select registers.

Table 24-27 E-Ray **I/O Control Selection and Setup**

24.9.3 On-Chip Connections

This section describes all on-chip interconnections of the E-Ray modules except the connections to I/O ports (see).

24.9.3.1 E-Ray Connections with IR

The E-Ray module of the TC27x has several on-chip interconnections to the IR. **Table 24-28** shows these interconnections. These enable the IR to handle different service request of E-Ray module via the DMA or Interrupt Service Routine.

Table 24-28 Request Assignment for IR

Line #	ERAY Output Signal	IR Request Input Line
00	INT0	SRC_ERAYINT0
01	INT1	SRC_ERAYINT1
02	TINT0	SRC_ERAYTINT0
03	TINT1	SRC_ERAYTINT1
04	NDAT0	SRC_ERAYNDAT0
05	NDAT1	SRC_ERAYNDAT1
06	MBSC0	SRC_ERAYMBSC0
07	MBSC1	SRC_ERAYMBSC1
08	OBUSY	SRC_ERAYOBUSY
09	IBUSY	SRC_ERAYIBUSY

24.9.3.2 E-Ray Connections with SMU

The E-Ray module of the TC27x provides to the SMU the following alarms (ALMx): SRAM ECC single bit correction, SRAM ECC uncorrectable error, SRAM address error, SRAM buffer address error..

24.9.3.3 E-Ray Connections with the External Request Unit of SCU

The E-Ray module of the TC27x has several on-chip interconnections to the External Request Unit (ERU) in the SCU to externally trigger stop watch events and to provide a global time e.g. to the on chip timers. **Table 24-29** and **Table 24-30** show these interconnections.

Table 24-29 External Stop Watch Request Assignment

ERAY Input Signal	ERU Request Output Line	Selected by
STPWT0	ERU_PDOUT0	**CUST1.STPWTS** = 00_B
STPWT1	ERU_PDOUT1	**CUST1.STPWTS** = 01_B
STPWT2	ERU_PDOUT2	**CUST1.STPWTS** = 10_B
STPWT3	ERU_PDOUT3	**CUST1.STPWTS** = 11_B

Table 24-30 Global Macrotick Connection to ERU

ERAY Output Signal	ERU Request Input Line	Selected by
MT	ERU_IN23	ERU_EICR1.EXIS0 = 11_B

24.9.3.4 E-Ray Connections to GTM

The E-Ray module of the TC27x has several on-chip interconnections to the Generic Timer Module (GTM). **Table 24-31** show these interconnection s.

Table 24-31 Global Macrotick Connection to GTM

ERAY Output Signal	TIM Input Line
MT	TIM0_7
MT	TIM1_7
MT	TIM2_7
MT	TIM3_7

24.9.3.5 E-Ray Connections with the External Clock Output of SCU

The E-Ray module of the TC27x has one on-chip interconnections to the External Clock Output Unit in the SCU to distribute externally as also internally the Macro Tick as time base for distributed system control. **Table 24-32** shows this interconnection.

Table 24-32 Global Macrotick Connection to External Clock Output

ERAY Output Signal	External Clock Output	Selected by
MT0	f_{MT0}	SCU_EXTCON.SEL0 = 1111_B

24.9.4 OCDS Trigger Bus (OTGB) Interface

The E-Ray module has two 16 bit and one 32 bit Trigger Sets (**Table 24-33**) which are selected with the **OTSS** register.

Table 24-33 E-Ray Trigger Sets

Trigger Set	Details
TS16_SEP Service Requests, Errors and POC State	Table 24-35
TS16_MC Macrotick Counter	Table 24-36
TS32_SCSC State, Cycle and Slot Counter	Table 24-37

Table 24-34 shows all possible Trigger Set mapping options. If OTGB0 and/or OTGB1 is not used for E-Ray, Trigger Sets of other sources can be added in the OTGM module.

Table 24-34 Trigger Set Mapping Options

Width	OTGB0	OTGB1	OTGB2
32 Bit	TS16_SEP/MC		
		TS16_SEP/MC	
	TS16_SEP/MC	TS16_SEP/MC	
64 Bit			TS32_SCSC
	TS16_SEP/MC		TS32_SCSC
		TS16_SEP/MC	TS32_SCSC
	TS16_SEP/MC	TS16_SEP/MC	TS32_SCSC

Table 24-35 TS16_SEP Service Requests, Errors and POC State

Bits	Description
0	Interrupt 0 Service Request (INT0SRC)
1	Interrupt 1 Service Request (INT1SRC)
2	Timer Interrupt 0 Service Request (TINT0SRC)
3	Timer Interrupt 1 Service Request (TINT1SRC)
4	New Data 0 Service Request (NDAT0SRC)
5	New Data 1 Service Request (NDAT1SRC)
6	Message Buffer Status Changed 0 Service Request (MBSC0SRC)
7	Message Buffer Status Changed 1 Service Request (MBSC1SRC)

Table 24-35 TS16_SEP Service Requests, Errors and POC State (cont'd)

Bits	Description
8	Output Buffer Busy Service Request (OBUSYSRC)
9	Input Buffer Busy Service Request (IBUSYSRC)
10	Reserved
11	Error on Channel A (EIR.EDA)
12	Error on Channel B (EIR.EDB)
[15:13]	POC State bits[2:0] (CCSV.POCS)

Table 24-36 TS16_MC Macrotick Counter

Bits	Description
[13:0]	Macrotick Value (MTCCV.MTV)
[15:14]	Reserved

Table 24-37 TS32_SCSC State, Cycle and Slot Counter

Bits	Description
[10:0]	Slot Counter Channel A (SCV.SCCA)
[22:12]	Slot Counter Channel B (SCV.SCCB)
[29:24]	Cycle Counter Value (MTCCV.CCV)
30	Transfer Input Buffer Completed (SIR.TIBC)
31	Transfer Output Buffer Completed (SIR.TOBC)
11,23	Reserved

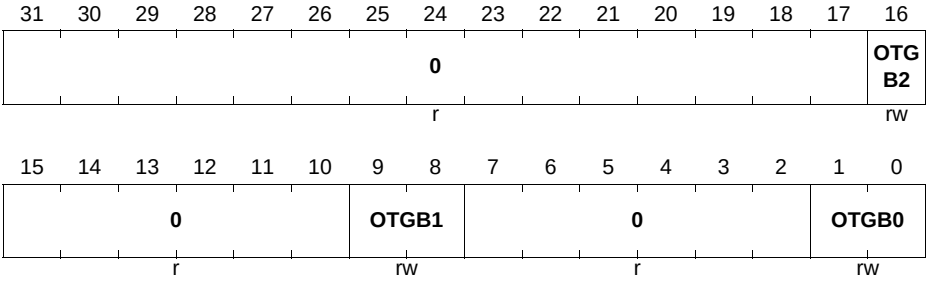
TS32_SCSC becomes valid (posedge on otgb2_valid_o) on a change of any Slot Counter or Transfer Buffer state. This covers also the Cycle Counter which will always change with a slower rate.

24.9.5 OTGB E-Ray Registers

24.9.5.1 OCDS Trigger Bus (OTGB)

The OTGB control register is cleared by Debug Reset. Write access is 32 bit wide only and requires Supervisor Mode.

OTSS
OCDS Trigger Set Select **(0870_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
OTGB0	[1:0]	rw	**Trigger Set for OTGB0** 0_D No Trigger Set selected 1_D Trigger Set TS16_SEP (**Table 24-35**) 2_D Trigger Set TS16_MC (**Table 24-36**) 3_D reserved

0	[7:2], [15:10], [31:17]	r	**Reserved** Read as 0; must be written with 0.

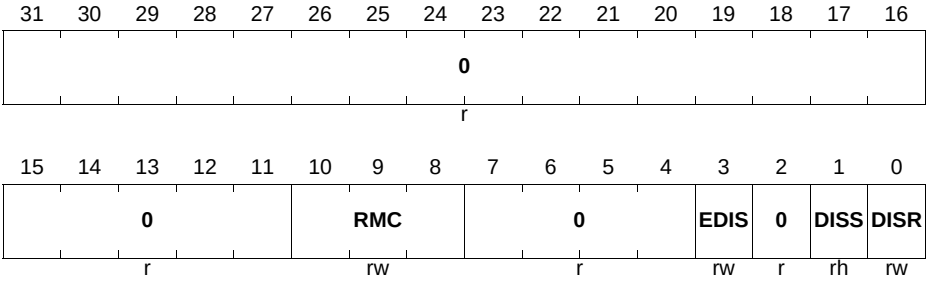
24.9.6 BPI_FPI Module Registers

Note: Register bits marked "r" in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock, sleep mode and disable mode for the module.

CLC
Clock Control Register **(0000_H)** **Reset Value: 0000 0003_H**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. *Note: This bit disables the kernel clocks f_{CLC_ERAY} and the sampling clock f_{SCLK}.*
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**External Sleep Mode Request Disable Bit** Used to control module's sleep mode. *Note: If this bit is cleared the kernel clock f_{CLC_ERAY} and the sampling clock f_{SCLK} are disabled during System Sleep Mode.*

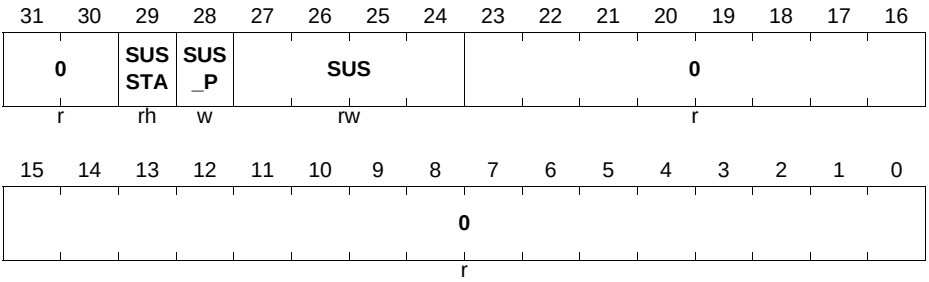
Field	Bits	Type	Description
RMC	[10:8]	rw	**Clock Divider in Run Mode** 000_B No clock signal f_{CLC_ERAY} generated (default after reset) 001_B Clock $f_{CLC\_ERAY} = f_{SPB}$ selected 010_B Clock $f_{CLC\_ERAY} = f_{SPB}$ /2 selected 011_B Clock $f_{CLC\_ERAY} = f_{SPB}$ /3 selected 100_B Clock $f_{CLC\_ERAY} = f_{SPB}$ /4 selected 101_B Clock $f_{CLC\_ERAY} = f_{SPB}$ /5 selected 110_B Clock $f_{CLC\_ERAY} = f_{SPB}$ /6 selected 111_B Clock $f_{CLC\_ERAY} = f_{SPB}$ /7 selected *Note: This bit field is not affected by an application reset.* *Note: This bit field only controls the kernel clock f_{CLC_ERAY} and not the sampling clock f_{SCLK}.*
0	[31:16], [15:11], [7:4], 2	r	**Reserved** Read as 0; should be written with 0.

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency, which is selected via bit field RMC in the CLC register. Therefore, increasing CLC.RMC may result in a longer FPI Bus read cycle access time for kernel registers and can also slow down the write throughput to the kernel registers.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status **($08E8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clocks f_{CLC_ERAY} and the sampling clock f_{SCLK} are switched off immediately. No read or write access to any registers. 2_H Soft suspend. This bit forces the module into freeze state. **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

ACCEN0

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

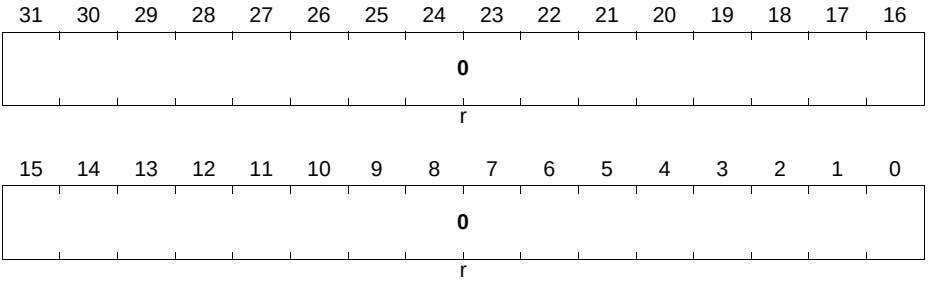
Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ACCEN1
Access Enable Register 1 **($08F8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

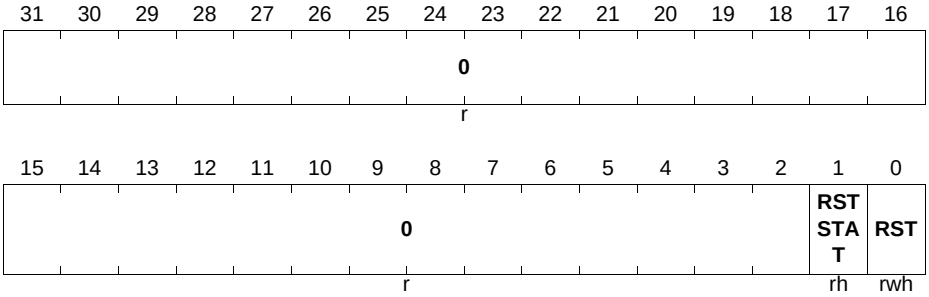
Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **(08F4$_H$)** **Reset Value: 0000 0000$_H$**

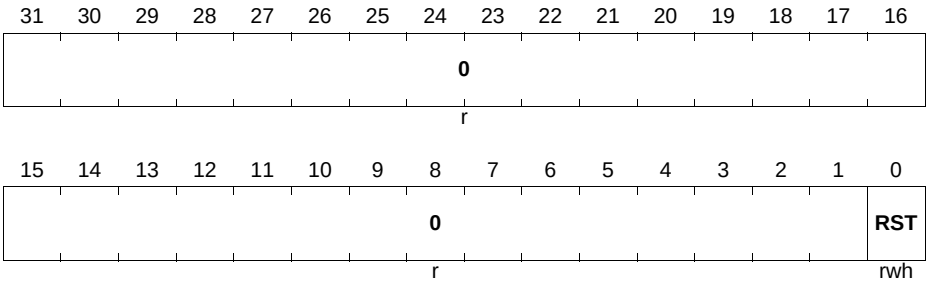


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rw	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers (KRSTx1.RST and KRSTx0.RST) related to the module kernel that should be reset (kernel 0 or kernel 1). The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **(08F0$_H$)** **Reset Value: 0000 0000$_H$**

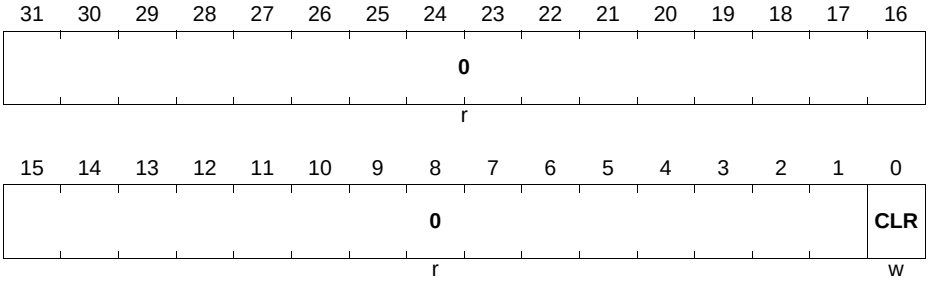


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR
Kernel Reset Status Clear Register (08EC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

24.9.7 Interrupt Registers

Two different type of Interrupt Registers are described within this chapter.
The Interrupt Control register enable the selection of the Service Request used to signal an event. The Interrupt Control registers **NDIC1** to **NDIC4** select the service request node used for New Data Events.The Interrupt Control registers **MSIC1** to **MSIC4** select the service request node used for Message Buffer Status Changed Events.
The Interrupt Service Request Control Registers control the eight service request nodes.

New Data Interrupt Control 1 (NDIC1)

This New Data Interrupt Control register controls the interrupt that becomes active (NDAT0SRC or NDAT1SRC) on a ND flag turning active of all configured Message Buffers 0 to Message Buffers 31.

NDIC1
New Data Interrupt Control 1 ($03A8_H$) Reset Value: $0000\ 0000_H$

24.10 Revision History

This User's Manual is based on the IP Specification: **Revision 1.2.6**.

Table 24-38 Revision History

Version Number	Changes to Previous Version
Rev_0.1	First Draft
Rev_0.2	Adapted to PWD 0.8
Rev_0.3	Chapters 3, 5, 6 completed
Rev_0.4	Adapted to actual state of protocol development
Rev_0.5	Adapted to actual state of protocol development
Rev_0.51	Adapted to actual state of protocol development
Rev_0.52	Adapted to actual state of protocol development
Rev_0.53	Adapted to actual state of protocol development
Rev_0.6	Adapted to actual state of protocol development
Rev_0.61	Adapted to actual state of protocol development
Rev_0.62	Adapted to actual state of protocol development
Rev_1.0	First complete revision
Rev_1.01	Message Buffer Status bits PLE, MLST, ES replaced by bits ESA, ESB, MLST
Rev_1.02	IBCR, IBCM, OBCR, OBCM: addresses changed HDC2: register removed MHDC1: renamed to MHDC Message Buffer 0 dedicated to hold key slot ID SFS: description updated ESIDn, OSIDn: description updated EIR: bit SCE removed EILS: bit SCEL removed EIES, EIER: bit SCEE removed

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.2	IDEFAULT_CONFIG added to POC working CCSV: assignment of states to $_{\text{POCS changed:}}$ $_{\text{POCS}}$ = 00 0000_B = "DEFAULT_CONFIG" POCS = 00 1111_B = "CONFIG" CCSV: bit DCREQ removed SIR: bit MBSI added SILS: bit MBSIL added SIES, SIER: bit MBSIE added Register BGSC removed EIR: bits SMEB, SMEA removed EILS: bits SMEBL, SMEAL removed EIES, EIER: bits SMEBE, SMEAE removed Registers TXRQ3, TXRQ4, NDAT3, NDAT4,MBSC3, MBSC4 added Bus guardian related pins eray_arm, eray_bgt, eray_mt, eray_bge1, and eray_bge2 have no function PRTC1: Configuration parameter CASM added WRHS1: Bit NME changed to PPIT RDHS1: Bit NME changed to PPIT Pin eray_scanmode for scan mode control added
Rev_1.3	Changed "r" bits into "rh" bits. Made ACS Register writable. Included Reserved Bits into EIES and EIER Changed access write from "rw" to "rwh" for Register CUST1.IEN. Changed access type of unused bits (0) to "rw". Changed access type of CUST1.INT0 to rwh. Changed Reset value of CUST0 to C104 0105_H Updated the "Known Limitations of E-Ray IP-Module", revision 4.07.2005.

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.4	Updated the "Errata of E-Ray IP-Module", revision 1.0 30.06.2006. Renamed from "Interrupt Flag Interface" to "Internal Signal and Flag Interface" With this revision it is possible to use Message Buffer 1for SYNC Frame transmission in addition to Message Buffer 0 if SYNC Frames should have different payloads on channel A and B TEST1: Bit ELBE for control of internal / external loop back mode added, description of internal loop back added EIR: Handling of bits PERR and RFO same as for other bits, bit MHF added SIR: Bit RFF renamed to RFCL, handling of bits RFNE, RFCL same as for other bits EILS: Bit MHFL added, SILS: Bit RFFL renamed to RFCLL EIES, EIER: Bit MHFE added SIES, SIER: Bit RFFE renamed to RFCLE Register STPW renamed to STPW1 STPW2: Register added CCSV: Bits PSL added SWNIT: Bits MTSA, MTSB added MRC: Bit SPLM added FCL: Register added FSR: Register added MHDF: Register added MBSC1/2/3/4: Naming of bits changed from MBS to MBC to distinguish between Message Buffer status flag (MBC) and Message Buffer status register (MBS) CREL: Register added ENDN: Register added Message Buffers in Message RAM: Header 2 and 3 updated from received Data Frames only MBS: Bits FTA, FTB, CCS, RCIS, SFIS, SYNS,NFIS, PPIS, RESS added Description Asynchronous Transmit Mode, added: …This write operation has to be directly preceded by two consecutive write accesses to the Configuration LockKey (unlock sequence)… Description Loop Back Mode, added: …This write operation has to be directly preceded by two consecutive write accesses to the Configuration LockKey (unlock sequence).

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.4 (cont'd)	Description LCK.CLK, corrected: To leave CONFIG state by writing SUCC1.CMD (commands READY, MONITOR_MODE, ATM,LOOP_BACK), …Third write: SUCC1.CMD Description EIR.MHF, added: The flag signals a Message Handler constraints violation condition. It is set whenever one of the flags MHDF.SNUA, MHDF.SNUB, MHDF.FNFA, MHDF.FNFB,MHDF.TBFA, MHDF.TBFB, MHDF.WAHP changes from 0 to 1. Description SIR.CAS, added: This flag is set by the Communication Controller during STARTUP state when a CAS or a potential CAS was received. 1 = Bit pattern matching the CAS symbol received 0 = No bit pattern matching the CAS symbol received. Description SIR.MBSI, corrected: This flag is set by the Communication Controller when the Message Buffer status MBS has changed if bit MBI of that Message Buffer is set. Description T0C, added: Note: The configuration of timer 0 is compared against the Macrotick counter value, there is no separate counter for timer 0… Description SUCC1.CMD, modified: Note included into description of CHI command CLEAR_RAMS. …Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMS… Description SUCC1.TSM, changed: …The key slot ID is configured in the Header Section of Message Buffer 0 respectively Message Buffers 0 and 1 depending on bit MRC.SPLM. In case TSM = 1, Message Buffer 0 respectively Message Buffers 0,1 can be (re)configured in "DEFAULT_CONFIG" or "CONFIG" state only. In ALL slot mode the Communication Controller may transmit in all slots. TSM is a configuration bit which can only be set / reset by the Host. The bit can be written in "DEFAULT_CONFIG" or "CONFIG" state only. The Communication COntroller changes to ALL slot mode when the Host successfully applied the ALL_SLOTS command by writing CMD = "0101" in POC states "NORMAL_ACTIVE" or "NORMAL_PASSIVE"... Description PRTC1.SPP, added: Note: The current revision 2.1 of the FlexRay™ protocol requires that SPP = "00". The alternate strobe point positions could be used to compensate for asymmetries in the physical layer. Description CCSV.CSNI, corrected: …Reset by CHI command RESET_STATUS_INDICATORS or by transition from "HALT" to "DEFAULT_CONFIG" state or from "READY" to "STARTUP" state.

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.4 (cont'd)	Description CCSV.CSAI, corrected: …Reset by CHI command RESET_STATUS_INDICATORS or by transition from "HALT" to "DEFAULT_CONFIG" state or from "READY" to "STARTUP" state. Description CCSV.WSV, corrected: …Reset by CHI command RESET_STATUS_INDICATORS or by transition from "HALT" to "DEFAULT_CONFIG" state or from "READY" to "STARTUP" state. Description SFS.VSAE, modified: Holds the number of valid SYNC Frames received on channel A in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one… Description SFS.VSAO, modified: Holds the number of valid SYNC Frames received on channel A in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one… Description SFS.VSBE, modified: Holds the number of valid SYNC Frames received on channel B in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one… Description SFS.VSBO, modified: Holds the number of valid SYNC Frames received on channel B in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one… Description ACS, added: Note: The set condition of flags CIA and CIB is also fulfilled if there is only one single Frame in the slot and the slot boundary at the end of the slot is reached during the Frames channel idle recognition phase… Description MRC.SEC1:0, changed: …Exception: In nodes configured for SYNC Frame transmission or for single slot mode operation Message Buffer 0 (and if SPLM = 1, also Message Buffer 1) is always locked Description MRC.SPLM, changed: This bit is only evaluated if the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1)… Description MRC.SPLM, changed: Note: In case the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1), Message Buffer 0 resp. 1 is reserved for SYNC Frames or single slot Frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation Message Buffer 0 resp. 1 is treated like all other Message Buffers.

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.4 (cont'd)	Description Parity Check, changed: …When a parity error occurs when the Message Handler reads a Frame with Network Management information (PPI = 1) from the Transient Buffer RAM A, B the corresponding Network Management vector register NMV1…3 is not updated from that Frame. Included TC1797 O Ports the Physical Layer Interface is connected to. Description MBS.MLST, added: The flag is set in case the Host did not read the message before the Message Buffer was updated from a received Data Frame… …The flag is reset by a Host write to the Message Buffer via IBF or when a new message is stored into the Message Buffer after the Message Buffers ND flag was reset by reading out the Message Buffer via OBF. Description MBS, corrected: Note: The FlexRay™ protocol specification requires that FTA, and FTB can only be reset by the Host… Description NULL Frame Transmission, changed: …In this case, no Message Buffer status MBS is updated.
Rev_1.5	Included BPI Register (Service Request Nodes: INT0SRC, INT1SRC, TINT0SRC, TINT1SRC, NDAT0SRC, NDAT0SRC, MBSC0SRC, MBSC1SRC, CLC). Included for New Data and Message Buffer Status Changed Flags eight Interrupt Select Register (NDIC0, NDIC1, NDIC2, NDIC3, MSIC0, MSIC1, MSIC2, MSIC3) Included new address range for TC1797. Included into CUST1 Register Control (IBF1PAG, IBF1PAG) and Status Bits (IBS) for multiple buffer control. Included for TC1797 the IO Ports the Physical Layer Interface is connected to. Included into CUST1 1 out of 4 multiplexer Select Input Control for RXA (CUST1.RISA), RXB (CUST1.RISB) and STPWT (CUST1.STPWTS). Included DMA Trigger connections for TC1797.
Rev_1.6	Included a description of the Delayed Write Scheme to OBF and IBF. Corrected an erroneous description of IBF1PAG and IBF2PAG concerning the write access for specific values of IBFS. Included a verification scheme to verify correct polarity of IBFS and logic for IBF1PAG and IBF2PAG.
Rev_1.7	Changed P6.7 to P6.10 to use only p6.PDR1 only. Included table summarizing access wait states.
Rev_1.8	Included a description of registering the reset when E-Ray module is disabled and executing the reset when it is enabled hereafter.

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.9	Included IP Specification changes of Revision 1.2.3. **DescriptionTEST1, added**: When the E-Ray IP is operated in one of its test modes that requires WRTEN to be set (RAM Test Mode, I/O Test Mode, Asynchronous Transmit Mode, and Loop Back Mode) only the selected test mode functionality is available. The test functions are not available in addition to the normal operational mode functions, they change the functions of parts of the E-Ray module. Therefore normal operation as specified outside this chapter and as required by the FlexRay™ protocol specification and the FlexRay™ conformance test is not possible. Test mode functions may not be combined with each other or with FlexRay™ protocol functions. The test mode features are intended for hardware testing or for FlexRay™ bus analyzer tools. They are not intended to be used in FlexRay™ applications. **Description TEST1.ELBE, modified:** …Bit ELBE is evaluated only when POC is in loop back mode and test multiplexer control is in non-multiplexing mode TMC = 00. **Description TEST1.TMC, modified:** TMC Test Multiplexer Control 00, 11= Normal signal path (default); 01 = RAM Test Mode - Internal busses are multiplexed to make all RAM blocks of the E-Ray module directly accessible by the Host… **Description Loop Back Mode, corrected:** …Reading CCSV.POCS will return "00 1101" while the E-Ray module is in loop back mode… **Description Loop Back mode, completed:** …When the CC is in loop back mode, a loop back test is started by the Host writing a message to the Input Buffer and requesting the transmission by writing to register IBCR… **Description LCK.CLK, corrected:** …If the write sequence below is interrupted by other write accesses between the second write to the Configuration Lock Key and the write access to the SUCC1 register, the Communication Controller remains in CONFIG state and the sequence has to be repeated. **Description LCK.TMK, corrected:** …If the write sequence below is interrupted by other write accesses between the second write to the Test Mode Key and the write access to the TEST1 register, TEST1.WRTEN is not set to '1' and the sequence has to be repeated. **Description EIR.CCL, corrected:** The flag signals that the write access to the CHI command vector SUCC1.CMD was not successful because the execution of the previous CHI command has not yet completed… **Description SIR.MTSA,B, modified:** Media Access Test symbol received on channel A,B during the preceding symbol window…

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.9 (cont'd)	**Description T1C, removed:** … In case the configured Macrotick count is not within the valid range, timer 1 will not start… **Description SUCC1.CMD, corrected:** …In case the previous CHI command has not yet completed, EIR.CCL is set to 1 together with EIR.CNA; the CHI command needs to be repeated. Except for HALT state, a POC state change command applied while the CC is already in the requested POC state will be ignored. **Description SUCC1.CMD, added:** ALLOW_COLDSTART; …When called in states DEFAULT_CONFIG, CONFIG, HALT, or MONITOR_MODE, CMD will be reset to 0000 = command_not_accepted… D**escription SUCC1.CMD, completed:** RESET_STATUS_ INDICATORS; …Flags internally evaluated in the actual POC state are not reset… **Description SUCC1.CMD, corrected:** MONITOR_MODE; …In this mode the CC is able to receive FlexRay™ Frames and wakeup pattern… **Description SUCC1.CMD, added:** Table added which references the CHI commands from the FlexRay™ Protocol Specification v2.1 (section 2.2.1.1, Table 2-2) to the E-Ray CHI command vector CMD. **Description CCSV.RCA, completed:** …The READY command resets this counter to the maximum number of coldstart attempts as configured by SUCC1.CSA. **Description SWNIT.MTSA,B, modified:** Media Access Test symbol received on channel A,B during the preceding symbol window… **Description ESID[1…15].RXEA,B completed:** …sorted in ascending order, … …If the node transmits a SYNC Frame in an even communication cycle by itself, register ESID1 holds the respective SYNC Frame ID as configured in Message Buffer 0 and flags RXEA, RXEB are set… RXEA,B Received / Configured Even Sync ID on Channel A,B Signals that a SYNC Frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot = EID (ESID1 only). 1 = SYNC Frame received on channel A / node configured to transmit SYNC Frames; 0 = No SYNC Frame received on channel A / node not configured to transmit SYNC Frames.

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.9 (cont'd)	**Description OSID[1…15].RXOA,B completed:** … sorted in ascending order, … …If the node transmits a SYNC Frame in an odd communication cycle by itself, register OSID1 holds the respective SYNC Frame ID as configured in Message Buffer 0 and flags RXOA, RXOB are set…RXOA,B Received / Configured Odd Sync ID on Channel A,B Signals that a SYNC Frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = OID(OSID1 only). 1 = SYNC Frame received on channel A / node configured to transmit SYNC Frames;0 = No SYNC Frame received on channel A / node not configured to transmit SYNC Frames **Description FRF.FID, modified:** Determines the Frame ID to be rejected by the FIFO. With the additional configuration of register FRFM, the corresponding Frame ID filter bits are ignored, which results in further rejected Frame IDs. When FRFM.MFID is zero, a Frame ID filter value of zero means that no Frame ID is rejected. **Description MHDF.WAHP, added:** Outside DEFAULT_CONFIG and CONFIG state this flag is set by the CC when the message handler tries to write message data into the Header Partition of the Message RAM due to faulty configuration of a Message Buffer… **Description MONITOR_MODE, completed:** …In this mode the CC is able to receive FlexRay™ Frames and to detect wakeup pattern… **Modified the description of CUST1.POBFEN to:** Parity Error Reporting of Output Buffer (OBF1/OBF1) RAMs Enable/Test Disable; 0_B: Parity error in Output Buffer (OBF1,OBF2) RAMs is not reported to SCU nor to OBF1, OBF2 RAM wrapper.1_B: The parity error reporting and thus the activation of error signals to SCU as also to OBF1 and OBF2 RAM wrapper is enabled. **Modified the description of CUST1.PMBFEN to:** Parity Error Reporting of Message Buffer (MBF) RAMs Enable/Test Disable; 0_B: Parity error in Message Buffer (MBF) RAMs is not reported to SCU nor to MBF RAM wrapper.1_B: The parity error reporting and thus the activation of error signals to SCU as also to MBF RAM wrapper is enabled. **Modified the description of CUST1.PITBFEN to:** Parity Error Reporting of Message Buffer (IBF1, IBF2, TBF1, TBF2) RAMs Enable/Test Disable; 0_B: Parity error in Input Buffer and Transient Buffer (IBF1, IBF2, TBF1, TBF2) RAMs is not reported to SCU nor to IBF1, IBF2, TBF1, and TBF2 RAM wrapper.1_B: The parity error reporting and thus the activation of error signals to SCU as also to IBF1, IBF2, TBF1, and TBF2 RAM wrapper is enabled

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_2.0	Modified the address of INT0SRC, INT1STC, TINT0SRC, TINT1SRC, NDIC1…NDIC4, MSIC1…MSIC4, NDAT_NDAT0SRC, NDAT1SRC, MBSC0SRC, MBSC1SRC. Cleared up the Index entries. Changed Address Range from to 00000000_H …$00007FFF_H$ to $F0010000_H$ …$F0017FFF_H$
Rev_2.1	Inserted additional information on the minimal eray_bclk required to work properly. Corrected some Typos in the port implementation. Renamed the Interrupt Control Registers due to some problems extracting register names by automatic tools. Changed in Figure 2-1 the names of the clock signals. Changed the Long Name of Register ACS to Aggregated Channel Status Register. Included Message Handler Timing Details. Modified the Clock Signal Names in Figure 2-37.
Rev_2.2	Modified the Pinning of TC1797: TXDA: P0.14, RXDA:P0.9; TXENA: P0.10; TXDB: P0.12; RXDB: P0.12; TXENB: P0.11. Changed the name of the Bit RFCLL in SILS Register.
Rev_2.3	Included IP Specification changes of Revision 1.2.3. Description write access to Data Section of IBF, changed: …If not all bytes of a 32-bit word have been written by the Host (8/16-bit access only), WRDSn holds partly undefined data. Description SIR.WST, completed: This flag is set when the wakeup status vector CCSV.WSV is changed by a protocol event. Description SIR.SWE, modified: This flag is set after a stop watch activation when the actual cycle counter and Macrotick value are stored in the Stop Watch register (see section Stop Watch Register 1 (STPW1)). Description STPW1.ESWT, corrected: …In single-shot mode this bit is reset to 0 after the actual cycle counter and Macrotick value are stored in the Stop Watch register. Description SUCC1.CMD3:0, changed: RESET_STATUS_INDICATORS Resets status flags CCSV.CSNI, CCSV.CSAI, and CCSV.WSV to their default values. May be called in POC state "READY". When called in any other state, CMD will be reset to 0000_B = command_not_accepted. Description CCSV.POC, added: …101011_B = STARTUP_SUCCESS state 101100_B … 111111_B = reserved

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_2.3	Description SUCC1.MTSA,B, added: Note: MTSA,B may also be changed outside "DEFAULT_CONFIG" or "CONFIG" state when the write to SUCC1 register is directly preceded by the unlock sequence as described in chapter Lock Register (LCK). This may be combined with CHI command SEND_MTS… Description Communication Controller Status Registers, added: …The status vector may change faster than the Host can poll the status vector, depending on eray_bclk frequency. Description Communication Controller Status Registers, removed: …All internal counters and the Communication Controller status flags are reset when the Communication Controller transits from "CONFIG" to "READY" state. Description CCSV.FSI, changed: …Reset by transition from HALT to "DEFAULT_CONFIG" state. Description CCSV.HRQ, changed: …Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state. Description CCSV.SLM, changed: …Set to the value defined by SUCC1. TSM when entering "READY", "CONFIG", or "DEFAULT_CONFIG" state. Description CCSV.CSI, completed: …The flag is set whenever the POC enters READY state due to CHI command READY. Description CCSV.WSV, modified: …000_B = UNDEFINED. Wakeup not yet executed by the Communication Controller… Description CCSV.RCA, corrected: …The "RUN" command resets this counter to the maximum number of coldstart attempts as configured by SUCC1.CSA. Description Communication Controller Status Registers, removed: …Note: CHI command "RESET_STATUS_INDICATORS" (SUCC1.CMD = 1010_B) resets flags FSI, HRQ, CSNI, CSAI, the slot mode SLM, and the wakeup status WSV. Description CC Error Vector, changed: Reset by transition from "HALT" to "DEFAULT_CONFIG" state or when entering "READY" state... Description MONITOR_MODE, added: …In "MONITOR_MODE" the Communication Controller is not able to distinguish between CAS and MTS symbols. In case one of these symbols is received on one or both of the two channels, the flags SIR.MTSA resp. SIR.MTSB are set. SIR.CAS has no function in "MONITOR_MODE". Inserted remark to negate eray_ibusy and eray_obusy signal to simplify the usage for DMA requesting and interrupt triggering. Corrected Typo in CMD field of SUCC1.

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_2.4	Updated ERAY Kernel Errata List (Bosch Errata List from November 24th, 2006: "Errata_E-Ray_R1.0_20061124")
Rev_2.5	**Modified RISA: Receive Input Select Channel A** 00_B Channel A receiver input RXDA0 selected 01_B Channel A receiver input RXDA1 selected 10_B Channel A receiver input RXDA2 selected 11_B Channel A receiver input RXDA3 selected **Modified RISB: Receive Input Select Channel B** 00_B Channel B receiver input RXDB0 selected 01_B Channel B receiver input RXDB1 selected 10_B Channel B receiver input RXDB2 selected 11_B Channel B receiver input RXDB3 selected Description MONITOR_MODE, removed: …In "MONITOR_MODE" the receive FIFO is not available. Description Message RAM Configuration Register, added: … Note: … In case two or more Message Buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the "Static Buffers" or at the beginning of the "Static + Dynamic Buffers" section… Description CCSV.POC[5:0], added: …101011_B = "STARTUP_SUCCESS" state 101100_B…111111_B = reserved. Inserted text condition to commonly cover IP revision 1.0.0 and IP revision 1.0.1. Updated ERAY Kernel Errata List (Bosch Errata List from December 20th, 2006: "Errata_E-Ray_R1.0.0_20061220"). Included IP Specification changes of Revision 1.2.5. Description EIR.SFO, changed: Set when either the number of SYNC Frames received during the last communication cycle or the total number of SYNC Frames received during the last double cycle exceeds the maximum number of SYNC Frames as defined by GTUC2.SNM. Description SUCC1.CMD[3:0], changed: RESET_STATUS_INDICATORS … May be called in POC states "READY" and "STARTUP"…

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_2.6	Description CCSV.SLM, changed: Indicates the actual slot mode of the POC in states "READY", "STARTUP", "NORMAL_ACTIVE", and "NORMAL_PASSIV"E. Default is SINGLE. Changes to ALL, depending on SUCC1.TSM. In "NORMAL_ACTIVE" or "NORMAL_PASSIVE" state the CHI command ALL_SLOTS will change the slot mode from SINGLE over ALL_PENDING to ALL. Set to SINGLE in all other states. Description SFS.VSAE, removed: … (vSyncFramesEvenA) Description SFS.VSAO, removed: … (vSyncFramesOddA) Description SFS.VSBE[3:0], removed:… (vSyncFramesEvenB) Description SFS.VSBO[3:0], removed: …(vSyncFramesOddB) Description MBS.RCIS, MBS.SFIS, MBS.SYNS, MBS.NFIS, MBS.PPIS, MBS.RESS, completed: For receive buffers (CFG = 0) the following status bits are updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored. Description Network Management, added: Note: …When the Communication Controller transits to "HALT" state, the cycle count is not incremented and therefore the NM Vector is not updated. In this case NMV1…3 holds the value from the cycle before. Description Configuration of the FIFO, added: Note: It is recommended to program the MBI bits of the Message Buffers belonging to the FIFO to 0 via WRHS1.MBI to avoid generation of RX interrupts… Updated the CLC reset value to 0000 0100_H. Included the ERAY trigger signals to the DMA channels 10 -17. Modified the stop watch clock input. Shifted them from GOUT to PDOUT. Removed a description of the non implemented fractional divider. Updated ERAY Kernel Errata List (Bosch Errata List from February 19th, 2007: "E-Ray_Errata_Sheet_20070219"). Connected Macrotick signal to ERU input IN23. Modified the DMA connection. Included IBUSY and OBUSY and TINT0. Included Service Request node for IBUSY and OBUSY. Modified the addresses of NDIC1, NDIC2, NDIC3, NDIC4, MSIC1, MSIC2, MSIC3, and MSIC4 to have a continues address range for the new service request registers OBUSYSRC and IBUSYSRC.
Rev_2.7	Removed Parity Bit generation and checking Added ECC generation and checking Wording and typos correction Signal name clean up (e.g. clock signals, ERAY internal signals etc.) CLC is endinit protected

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_3.0	Included IP Specification changes of Revision 1.2.6 Inserted text condition to commonly cover IP revision 1.0.0, IP revision 1.0.1 and IP revision 1.0.2. It is not possible to change the Stop Watch Mode (STPW1.SWMS) during enabled stop watch trigger (STPW1.ESWT) Implemented AI00042258. It is not possible to distinguish between static and dynamic frames, because limited functions in Monitor Mode (FRF.RSS will be ignored, filtering not functional). Added note in TEST1L/H register about the change of TEST1H.CERA/B if accessing TEST1H or L Reset value for KSCFG changed to $0x0001_h$. Was the initial value $0x0000_h$. ECC control and status registers added (SEC_CON, SED_CON, DED_CON, ECCR, ECCW) Removed ECC control form CUST1 Removed ECC test description from Register TEST2 Address space enlarged from 2k to 4k Figure E-Ray Register Map contains the new registers
Rev_3.1	ECC control and status registers renamed (SEC_CON -> SECCON, SED_CON -> SEDCON, DED_CON -> DEDCON Corrected RDHS3H.0 length field Renamed STPW1, 2, 3, 4 to STPWT0, 1, 2, 3 16-Bit: Detailed KSCFG functionality MT connected to ERU_3B2 (was ERU_3A2 in V3.0 16-Bit: KSCFG moved to 0x0000h 16-Bit: MT connected to ERU_3B2 (was ERU_3A2 in V3.0) Completed Register Table with page numbers Corrected address spaces that are reserved for customer specific purposes
Rev_3.2	16-bit: "Implement DEDCON registers" "Description of register SECCONL, SEDCON, DEDCON": changed TBFA/B to TBF1/2 implemented individual ECC control over each RAM + implement KSCFG register

Rev_3.7	Markers for key-word -index reduced to 3 levels
Rev_3.8	port mapping added 32-bit: CLC description corrected: "requesting the HW to ~~clear~~ set bit CLC.DISS" 32-bit: added hint about initial value of CLC 16-bit: ERU_3B2 used for FR_MT and not ERU3A2 corrected IOCR settings in Table of Port connections.
Rev_3.9	32-bit: added BPI Protection and Module Reset 32-bit: removed SRCs
Rev_3.10	32-bit: added trace interface 32-bit: added tagging
Rev_3.11	32-bit: updated BPI Registers Chapter
Rev_3.12	32-bit: changed MHDS.CRAM reset value to '0' added: Reset Value CUST1.IBFS changes after 2 clock cycles from '0' to '1'. added: Reset Value SUCC1.PBUSY changed from '1' to '0' changed base address to F001C000
Rev_3.13	32-bit: added port mapping added IR wiring, added SMU interconnection
Rev_3.14	32-bit: added 2nd Kernel (ERAY0 and ERAY1).
Rev_3.15	32-bit: added: MT output connection to GTM

Table 24-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_3.16	32-bit: removed OCS.TGS, TGB, TB_P. Changed OCS description to current implementation. Removed OTSS and OTGB description.
Rev_3.17	32-bit: updated pin out description (typo fix)

25 Generic Timer Module (GTM)

25.1 Introduction

This document is based on the GTM_IP Specification version 1.5.5.1 (Released on 20.06.2013) of the Robert Bosch GmbH.

25.1.1 Overview

This document is the specification for the Generic Timer Module (GTM). It contains a module framework with submodules of different functionality. These submodules can be combined in a configurable manner to form a complex timer module that serves different application domains and different classes within one application domain. Because of this scalability and configurability the timer is called generic.

The scalability and configurability is reached with an architecture philosophy where dedicated hardware submodules are located around a central routing unit (called Advanced Routing Unit (ARU)). The ARU can connect the submodules in a flexible manner. The connectivity is software programmable and can be configured during runtime.

Nevertheless, the GTM is designed to unload the CPU or a peripheral core from a high interrupt load. Most of the tasks inside the GTM can run -once setup by an external CPU- independent and in parallel to the software. There may be special situations, where the CPU has to take action but the goal of the GTM design was to reduce these situations to a minimum.

The hardware submodules have dedicated functionalities, e.g. there are timer input modules where incoming signals can be captured and characterized together with a notion of time. By combination of several submodules through the ARU complex functions can be established. E.g. the signals characterized at an input module can be routed to a signal processing unit where an intermediate value about the incoming signal frequency can be calculated.

The modules that help to implement such complex functions are called infrastructural components further on. These components are present in all GTM variants.

Other submodules have a more general architecture and can fulfil typical timer functions, e.g. there are PWM generation units. The third class of submodules are those fulfilling a dedicated functionality for a certain application domain, e.g. the DPLL serves engine management applications. A fourth group of submodules is responsible for supporting the implementation of safety functions to fulfil a defined safety level. The module ICM is responsible for interrupt services and defines the fifth group.

Each GTM is build up therefore with submodules coming from those four groups. The application class is defined by the amount of components of those submodules integrated into the implemented GTM.

25.1.2 Document Structure

The structure of this document is motivated out of the aforementioned submodule classes. **Section 25.2** describes the dedicated GTM implementation this specification is written for. It gives an overview about the implemented submodules.

Section 25.3 up to **Section 25.9** deal with the so called infrastructural components for routing, clock management and common time base functions. **Section 25.10** to **Section 25.12** describe the signal input and output modules while the following **Section 25.13** explains the signal processing and generation submodule. **Section 25.14** outlines a memory configuration module for the described signal processing and generation submodule. The next sections provide a detailed description of application specific and safety related modules like the MAP, DPLL, SPE, CMP and MON submodules. **Section 25.18** describes a module that bundles several interrupts coming from the other submodules and connect them to the outside world.

These submodule groups are shown in the following table:

Table 25-1 Submodule groups

Section	Submodule	Group
Section 25.3	Advanced Routing Unit (ARU)	Infrastructural components
Section 25.4	Broadcast Module (BRC)	Infrastructural components
Section 25.5	First In First Out Module (FIFO)	Infrastructural components
Section 25.6	AEI-to-FIFO Data Interface (AFD)	Infrastructural components
Section 25.7	FIFO-to-ARU Interface (F2A)	Infrastructural components
Section 25.8	Clock Management Unit (CMU)	Infrastructural components
Section 25.9	Time Base Unit (TBU)	Infrastructural components
Section 25.10	Timer Input Module (TIM)	IO Modules
Section 25.11	Timer Output Module (TOM)	IO Modules
Section 25.12	ARU-connected Timer Output Module (ATOM)	IO Modules
Section 25.13	Multi Channel Sequencer (MCS)	Signal generation and processing

Table 25-1 Submodule groups (cont'd)

Section	Submodule	Group
Section 25.14	Memory Configuration Module (MCFG)	Infrastructural component for MCS
Section 25.15	TIM0 Input Mapping Module (MAP)	Dedicated
Section 25.16	Digital PLL (DPLL)	Dedicated
Section 25.17	Sensor Pattern Evaluation Module (SPE)	BLDC support
Section 25.18	Interrupt Concentrator Module (ICM)	Interrupt services
Section 25.19	Output Compare Unit (CMP)	Safety features
Section 25.20	Monitoring Unit (MON)	Safety features

25.2 GTM Architecture

25.2.1 Overview

As already mentioned in **Section 25.1** the GTM forms a generic timer platform that serves different application domains and different classes within these application domains. Depending on these multiple requirements of application domains multiple device configurations with different count of submodules (i.e. ATOM, BRC, MCS, PSM, SPE, TIM, TOM) are possible. In this section the GTM realization is outlined. The architecture of the GTM is depicted in.

25.2.1.1 GTM Architecture Block Diagram

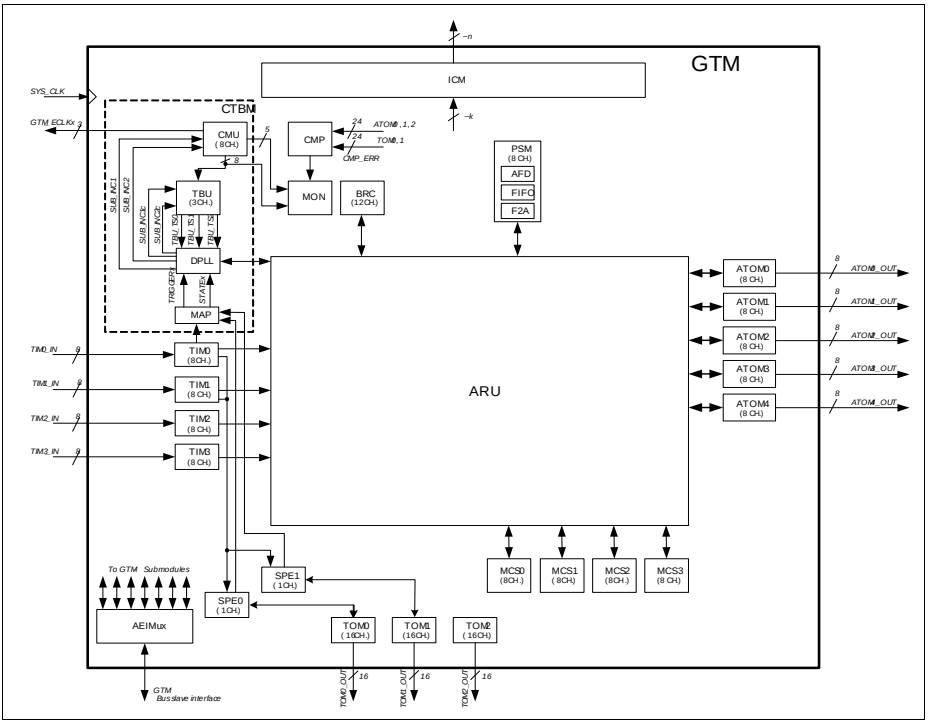

Figure 25-1 GTM Architecture Block Diagram

The central component of the GTM is the Advanced Routing Unit (ARU) where most of the submodules are located around and connected to. This ARU forms together with the Broadcast (BRC) and the Parameter Storage Module (PSM) the infrastructural part of the GTM. The ARU is able to route data from a connected source submodule to a connected destination submodule. The routing is done in a deterministic manner with a round-robin scheduling scheme of connected channels which receive data from ARU and with a worst case round-trip time.

The routed data word size of the ARU is 53 bit. The data word can logically be split into three parts. These parts are shown in **Figure 25-2**. Bits 0 to 23 and bits 24 to 47 typically hold data for the operation registers of the GTM. This can be for example the duty cycle and period duration of a measured PWM input signal or the output characteristic of an output PWM to be generated. Another possible content of Data0 and Data1 can be two 24 bit values of the GTM time bases TBU_TS0, TBU_TS1 and TBU_TS2. Bits 48 to 52 can contain control bits to send control information from one submodule to another. These ARU Control Bits (ACB) can have a different meaning for different submodules.

It is also possible to route data from a source to a destination and the destination can act later on as source for another destination. These routes through the GTM are further on called data streams. For a detailed description of the ARU submodule please refer to **Section 25.3**.

25.2.1.2 ARU Data Word Description

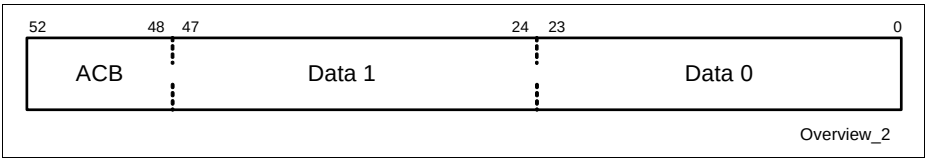

Figure 25-2 ARU Data Word Description

The BRC is able to distribute data from one source module to more than one destination modules connected to the ARU. The PSM submodule consists of three subunits, the AEI-to-FIFO Data Interface (AFD), FIFO-to-ARU Interface (F2A) and the FIFO itself. The PSM can serve as a data storage for incoming data characteristics or as parameter storage for outgoing data. This data is stored in a RAM that is logically located inside the FIFO subunit. The AFD subunit is the interface between the FIFO and the GTM system bus interface AEI (please see **Section 25.2.2.1** for detailed discussion). The F2A subunit is the interface between the FIFO subunit and the ARU.

Signals are transferred into the GTM at the Timer Input Modules (TIM). These modules are able to filter the input signals and annotate additional information. Each channel is for example able to measure pulse high or low times and the period of a PWM signal in

parallel and route the values to ARU for further processing. The internal operation registers of the TIM submodule are 24 bits wide.

The Clock Management Unit (CMU) serves up to 13 different clocks for the GTM and up to three external clock pins GTM_ECLK0…2. It acts as a clock divider for the system clock. The counters implemented inside other submodules are typically driven from this submodule. Please note, that the CMU clocks are implemented as enable signals for the counters while the whole system runs with the GTM global clock SYS_CLK. This global clock typically corresponds to the microcontroller bus clock the GTM is connected to.

The TBU provides up to three independent common time bases for the GTM. Two of these time bases can also be clocked with the digital PLL (DPLL) sub_inc1c and sub_inc2c outputs. The DPLL generates the higher frequent clock signals sub_inc1, sub_inc2, sub_inc1c and sub_inc2c on behalf of the frequencies of up to two input signals. These two input signals can be selected out of six incoming signals from the TIM0 submodule. In this submodule the incoming signals are filtered and transferred to the MAP submodule where two of these six signals are selected for further processing inside the DPLL.

Signal outputs are generated with the Timer Output Modules (TOM) and the ARU-connected TOMs (ATOM). Each TOM channel is able to generate a PWM signal at its output. Because of the integrated shadow register even the generation of complex PWM outputs is possible with the TOM channels by serving the parameters with the CPU. It is possible to trigger TOM channels for a successor TOM submodule through a trigger line between TOM(x)_CH(15) and TOM(x+1)_CH(0). But to avoid long trigger paths the trigger signal is registered at the TOM submodule output, resulting in one SYS_CLK cycle delay of the trigger signal.

In addition each TOM submodule can integrate functions to drive one BLDC engine. This BLDC support is established together with the TIM and Sensor Pattern Evaluation (SPE) submodule.

The ATOMs offer the additional functionality to generate complex output signals without CPU interaction by serving these complex waveform characteristics by other submodules that are connected to the ARU like the PSM or Multi Channel Sequencer (MCS). While the internal operation and shadow registers of the TOM channels are 16 bit wide, the operation and shadow registers of the ATOM channels are 24 bit wide to have a higher resolution and to have the opportunity to compare against time base values coming from the TBU.

It is possible to trigger ATOM channels for a successor ATOM submodule through a trigger line between ATOM(x)_CH(7) and ATOM(x+1)_CH(0). But to avoid long trigger paths the trigger signal is registered at each second ATOM submodule in the trigger line, resulting in one SYS_CLK cycle delay of the trigger signal between each second ATOM submodule.

Together with the MCS the ATOM is able to generate an arbitrary predefined output sequence at the GTM output pins. The output sequence is defined by instructions

located in RAM connected to the MCS submodule. The instructions define the points were an output signal should change or to react on other signal inputs. The output points can be one or two time stamps (or even angle stamp in case of an engine management system) provided by the TBU. Since the MCS is able to read data from the ARU it is also able to operate on incoming data routed from the TIM. Additionally, the MCS can process data that is located in its connected RAMs. The MCS RAM is located logically inside the MCS while the silicon vendor has to implement its own RAM technology there.

The two modules Compare Module (CMP) and Monitor Module (MON) implement safety related features. The CMP compares two output channels of an ATOM or TOM and sends the result to the MON submodule were the error is signalled to the CPU. The MON module is also able to monitor the ARU and CMU activities.

In the described implementation the submodules of the GTM have a huge amount of different interrupt sources. These interrupt sources are grouped and concentrated by the Interrupt Concentrator Module (ICM) to form a much easier management bunch of interrupts that are visible outside of the GTM.

On the GTM toplevel there are some configurable signal connections from the signal output of the TOM, ATOM modules to the input signals of the TIM modules.

25.2.1.3 GTM signal multiplex

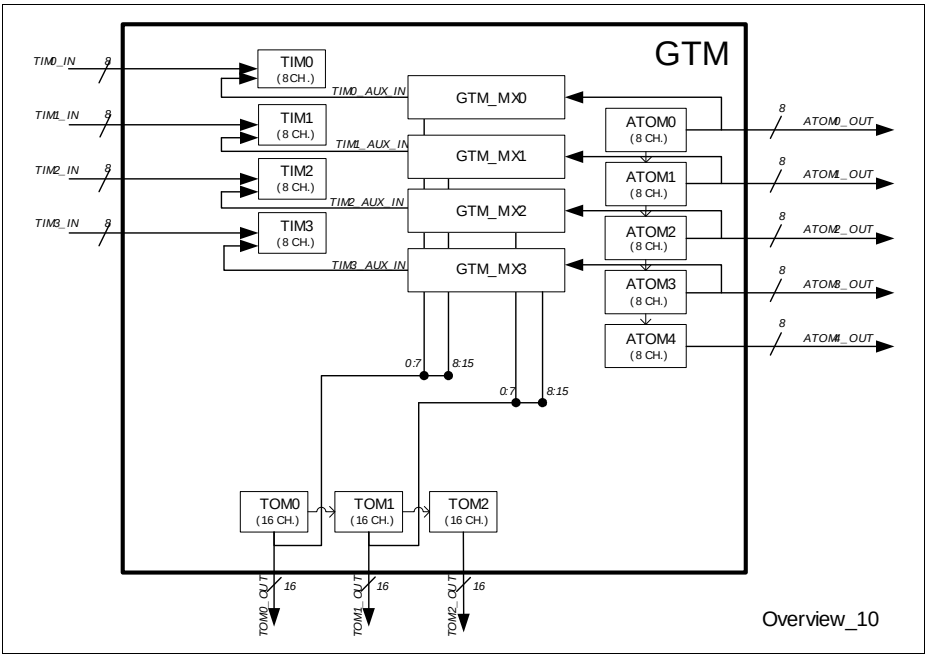

Figure 25-3 GTM Signal Multiplexer

The next diagram gives an overview of the connectivity. The source selection is defined with the bit SRXx in the register GTM_TIM[y]_AUX_IN_SRC.

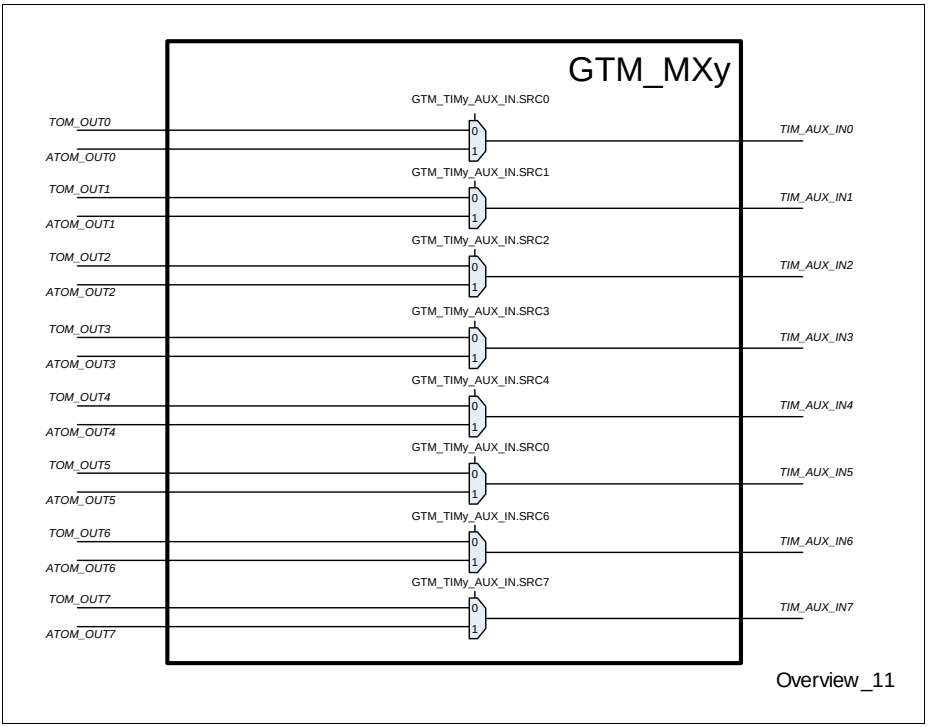

Figure 25-4 GTM TOM / ATOM to TIM Multiplexer

25.2.2 GTM Interfaces

In general the GTM can be divided into four interface groups. Two interface groups represent the ports of the GTM where incoming signals are assembled and outgoing signals are created. These interfaces are therefore connected to the GTM input submodule TIM and to the GTM output submodules TOM and ATOM.

Another interface is the bus interface where the GTM can be connected to the SoC system bus. This generic bus interface is described in more detail in **Section 25.2.2.1**. The last interface is the interrupt controller interface. The GTM provides several interrupt lines coming from the various submodules. These interrupt lines are concentrated inside the ICM and have to be adapted to the dedicated microcontroller environment where each interrupt handling can look different. The interrupt concept is described in more detail in **Section 25.2.5**.

25.2.2.1 GTM Generic Bus Interface (AEI)

The GTM is equipped with a generic bus interface that can be widely adapted to different SoC bus systems. This generic bus interface is called AE-Interface (AEI). The adaptation of the AEI to SoC buses is done with a bridge module translating the AEI signals to the SPB bus signals. The AEI bus signals are depicted in the following table:

Table 25-2 AEI Bus Signals

Signal name	I/O	Description	Bit width
AEI_SEL	I	GTM select line	1
AEI_ADDR	I	GTM address	32
AEI_PIPE	I	AEI Address phase signal	1
AEI_W1R0	I	Read/Write access	1
AEI_WDATA	I	Write data bus	32
AEI_RDATA	O	Read data bus	32
AEI_READY	O	Data ready signal	1
AEI_STATUS	O	AEI Access status	2

The AEI Status Signal may drive on of the following values:

Table 25-3 AEI Status Options

AEI_STATUS	Description
00	No Error
01	Illegal Byte Addressing
10	Illegal Address Access
11	Unsupported Address

The signal value "00" is driven if no error occurred during AEI access.

The signal value "01" is driven if the bus address is not an integer multiple of 4 (byte addressing).

The signal value "11" is driven if the address is not handled in the GTM.

The signal value "10" is driven if an illegal write access to one of the following register is performed

a) register is protected (e.g. protected by bit RF_PROT).

In case of an illegal write access signaled by status “10” the register will not be modified.

Reading registers will never return status “10”.

Write access to following addresses returns status “10” under special conditions:

ARU_IRQ_FORCINT
ATOMi_CHx_CM0
ATOMi_CHx_CM1
ATOMi_CHx_SR0

25.2.2.2 GTM Multi-master and multi-tasking support

To support multi-master and multi-task access to the registers of the GTM a dedicated write-access scheme is used for critical control bits inside the GTM that need such a mechanism. This can be for example a shared register where more than one channel can be controlled globally by one register write access. Such register bits are implemented inside the GTM with a double bit mechanism, where the writing of '00' and '11' has no effect on the register bit and where '01' sets the bit and '10' resets the bit. If the CPU wants to read the status of the bit it always gets a '00' if the bit is reset and it gets a '11' if the bit is set.

Note: CPU accesses have to consider the configured SPB to SYS_CLK ratio if SPB > SYSCLK.

25.2.3 ARU Routing Concept

One central concept of the GTM is the routing mechanism of the ARU submodule for data streams. Each data word transferred between the ARU and its connected submodule is 53 bit wide. It is important to understand this concept in order to use the resources of the GTM effectively. Each module that is connected to the ARU may provide an arbitrary number of ARU write channels and an arbitrary number of ARU read channels. In the following, the ARU write channels are named data sources and the ARU read channels are named data destinations.

The concept of the ARU intends to provide a flexible and resource efficient way for connecting any data source to an arbitrary data destination. In order to save resource costs, the ARU does not implement a switch matrix, but it implements a data router with serialized connectivity providing the same interconnection flexibility. **Figure 25-5** shows the ARU data routing principle. Data sources are marked with a green rectangle and the data destinations are marked with yellow rectangles. The dashed lines in the ARU depict

the configurable connections between data sources and data destinations. A connection between a data source and a data destination is also called a data stream.

25.2.3.1 Principle of data routing using ARU

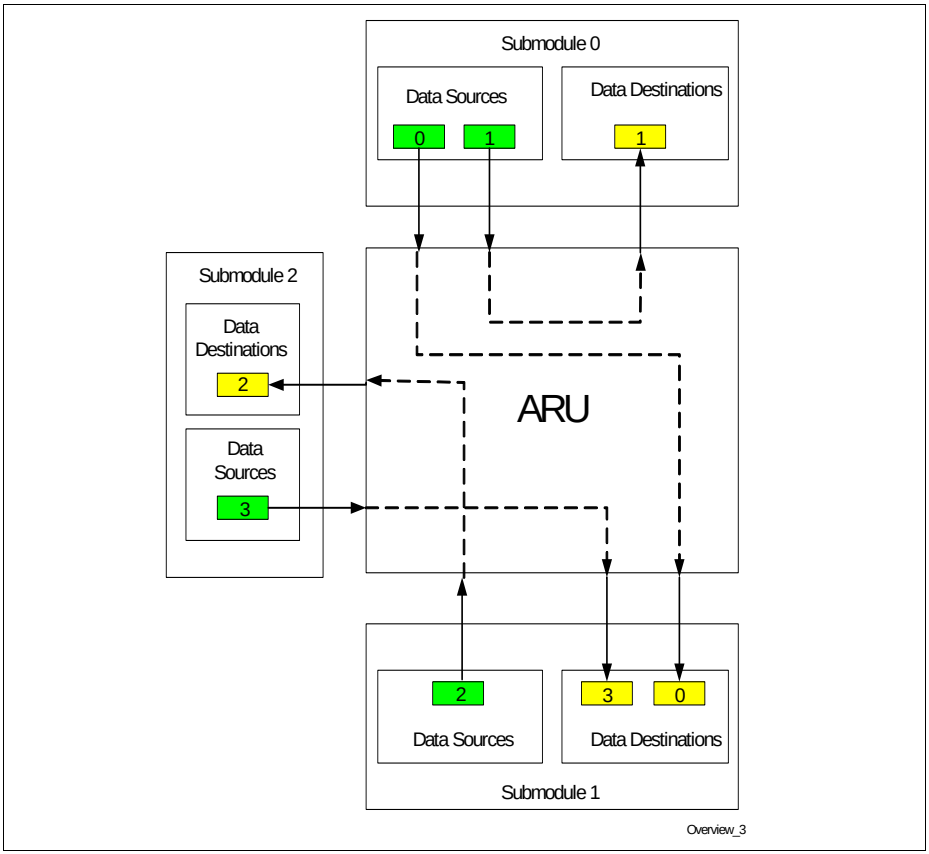

Figure 25-5 ARU Data Routing Principle

The configuration of the data streams is realized according to the following manner: Each data source has its fixed and unique source address: The fixed address of each data source is pointed out by the numbers in the green boxes of **Figure 25-5**. The address definitions of all available data sources in the GTM can be obtained from **Table 25.21.1**. The connection from a specific data source to a specific data destination is defined by configuring the corresponding address of a data source in the desired data destination. The configured address of each data destination is pointed out by the numbers in the yellow boxes of **Figure 25-5**.

Normally, the destination is idle and waits for data from the source. If the source offers new data, the destination does a destructive read, processes the data and goes idle again. The same data is never read twice.

There is one submodule for which this destructive read access does not hold. This is the BRC submodule configured in Maximal Throughput Mode. For a detailed description of this module please refer to **Section 25.4**.

The functionality of the ARU is as follows: The ARU sequentially polls the data destinations of the connected modules in a round-robin order. If a data destination requests new data from its configured data source and the data source has data available, the ARU delivers the data to the destination and it informs both, the data source and destination that the data is transferred. The data source marks the delivered ARU data as invalid which means that the destination consumed the data.

It should be noted that each data source should only be connected to a single data destination. This is because the destinations consume the data. If two destinations would reference the same source one destination would consume the data before the other destination could consume it. Since the data transfers are blocking, the second destination would block until it receives new data from the source. If a data source should be connected to more than one data destination the submodule Broadcast (BRC) has to be used. On the other hand, the transfer from a data source to the ARU is also blocking, which means that the source channel can only provide new data to the ARU when an old data word is consumed by a destination. In order to speed up the process of data transfers, the ARU handles two different data destinations in parallel. Therefore, a transfer between source and destination takes two cycles, but since the transfers are pipelined these two cycles have only effect for one round trip of the ARU.

Table 25-4 gives an overview about the number of channels for the GTM.

Table 25-4 ARU Channels

Submodule	Number of data sources	Number of data destinations
ARU	1	0
DPLL	24	24
TIM 0-3	32	0
MCS 0-3	96	32
BRC	22	12
TOM	0	0
ATOM 0-4	40	40
PSM 0	8	8
ICM	0	0
CMP	0	0

Table 25-4 ARU Channels (cont'd)

Submodule	Number of data sources	Number of data destinations
MON	0	0
Total	223	116

25.2.3.2 ARU Round Trip Time

The ARU uses a round-robin arbitration scheme with a fixed round trip time for all connected data destinations. This means that the time between two adjacent read requests resulting from a data destination channel always takes the round trip time, independently if the read request succeeds or fails.

The worst case round-trip time is defined as 73 *SYS_CLC of the GTM input system clock. Since the round-trip time depends on the number of destinations the ARU has to ensure that the round-trip time never exceeds the defined time.

25.2.3.3 ARU Blocking Mechanism

Another important concept of the ARU is its blocking mechanism that is implemented for transferring data from a data source to a data destination. This mechanism is used by ARU connected submodules to synchronize the submodules to the routed data streams. **Figure 25-6** explains the blocking mechanism.

Graphical representation of ARU blocking mechanism

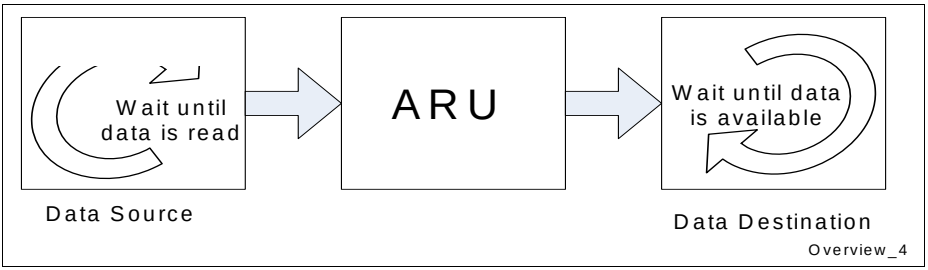

Figure 25-6 Graphical representation of ARU blocking mechanism

If a data destination requests data from a data source over the ARU but the data source does not have any data yet, it has to wait until the data source provides new data. In this case the submodule that owns the data destination may perform other tasks. When a data source produces new data faster than a data destination can consume the data the source raises an error interrupt and signals that the data could not be delivered in time. The new data is marked as valid for further transfers and the old data is overwritten.

In any case the round trip time for the ARU is always fixed.

One exception is the BRC submodule when configured in Maximal Throughput Mode. Please refer to **Section 25.4** for a detailed description.

25.2.4 GTM Clock and Time Base Management (CTBM)

Inside the GTM several subunits are involved in the clock and time base management of the whole GTM. **Figure 25-7** shows the connections and subblocks involved in these tasks. The subblocks involved are called Clock and Time Base Management (CTBM) modules further on.

25.2.4.1 GTM Clock and time base management architecture

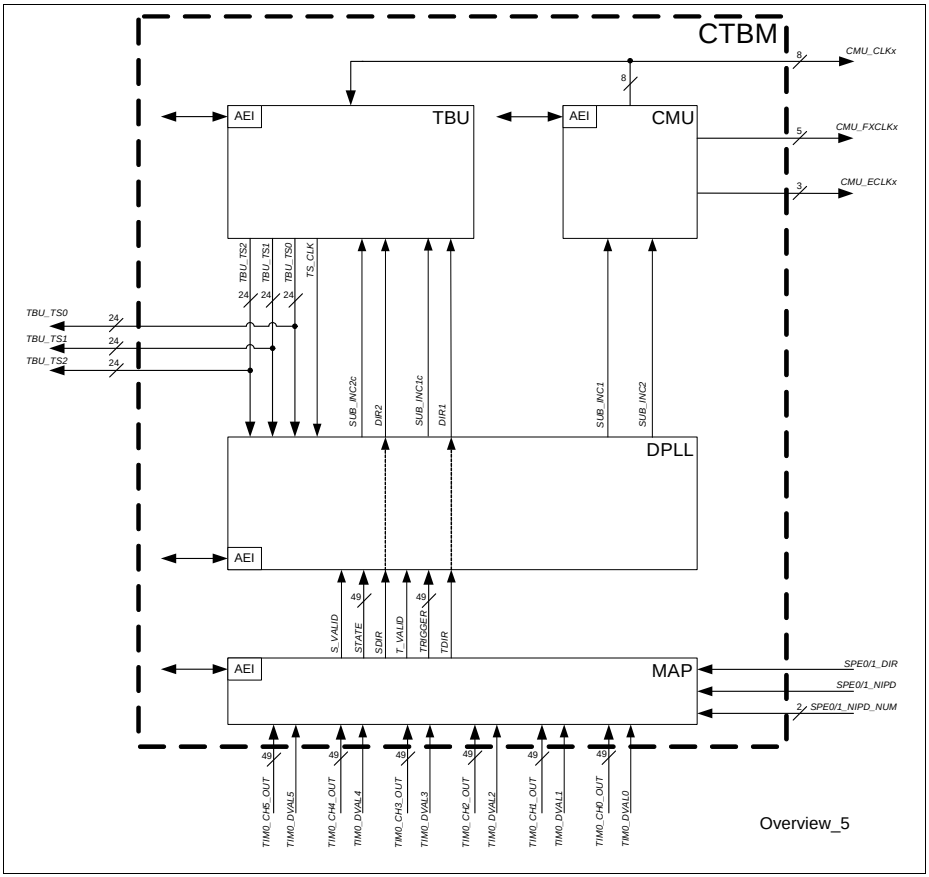

Figure 25-7 GTM Clock and time base management architecture

One important module of the CTBM is the Clock Management Unit (CMU) which generates up to 13 clocks for the submodules of the GTM and up to three GTM external clocks CMU_ECLK[z] (z: 0…2). For a detailed description of the CMU functionality and clocks please refer to **Section 25.8**.

The five (5) CMU_FXCLK[y] (y: 0…4) clocks are used by the TOM submodule for PWM generation. A maximum of eight (8) CMU_CLK[x] (x: 0…7) clocks are used by other submodules of the GTM for signal generation.

Inside the Time Base Unit (TBU) one of these maximum eight clocks is used per channel to generate a common time base for the GTM. Besides the CMU_CLK[x] signals, the TBU can use the compensated SUB_INC[i]c (i: 1,2) signals coming from the DPLL

submodule for time base generation. This time base then typically represents an angle clock for an engine management system. For the meaning of compensated (SUB_INC[i]c) and uncompensated (SUB_INC[i]) DPLL signals please refer to the DPLL **Section 25.16**. The SUB_INC[i]c signals in combination with the two direction signal lines DIR[i] the TBU time base can be controlled to run forwards or backwards. The TBU functionality is described in **Section 25.9**.

The TBU submodule generates the three time base signals TBU_TS0, TBU_TS1 and TBU_TS2 which are widely used inside the GTM as common time bases for signal characterization and generation.

As stated before, the DPLL submodule provides the four clock signals SUB_INC[i] and SUB_INC[i]c which can be seen as a clock multiplier generated out of the two input signal vectors TRIGGER and STATE coming from the MAP submodule. For a detailed description of the DPLL functionality please refer to **Section 25.16**.

The MAP submodule is used to select the TRIGGER and STATE signals for the DPLL out of six input signals coming from TIM0 submodule. Besides this, the MAP submodule is able to generate a TDIR (TRIGGER Direction) and SDIR (STATE Direction) signal for the DPLL and TBU coming from the SPE0 and SPE1 signal lines. The direction signals are generated out of a defined input pattern. For a detailed description of the MAP submodule please refer to **Section 25.15**.

25.2.5 GTM Interrupt Concept

The submodules of the GTM can generate thousands of interrupts on behalf of internal events. This high amount of interrupts is combined inside the Interrupt Concentrator Module (ICM) into interrupt groups. In this interrupt groups the GTM submodule interrupt signals are bundled to a smaller set of interrupts. Out of these interrupt sets a smaller amount of interrupt signals is created and signalled outside of the GTM as a signal GTM_<MOD>_IRQ, where as <MOD> identifies the name of the corresponding GTM submodule.

The controlling of the individual interrupts is done inside the submodules. If a submodule consists of several submodule channels that are most likely to work independent from each other (like TIM, PSM, MCS, TOM, and ATOM), each submodule channel has its own interrupt control and status register set, named as interrupt set in the following. Other submodules (SPE, ARU, DPLL, BRC, CMP and global GTM functionality) have a common interrupt set for the whole submodule.

The interrupt set consists of four registers: The IRQ_EN register, the IRQ_NOTIFY register, the IRQ_FORCINT register, and the IRQ_MODE register. While the registers IRQ_EN, IRQ_NOTIFY, and IRQ_FORCINT signalize the status and allow controlling of each individual interrupt source within an interrupt set, the register IRQ_MODE configures the interrupt mode that is applied to all interrupts that belong to the same interrupt set.

In order to support a wide variety of microcontroller architectures and interrupt systems with different interrupt signal output characteristics and internal interrupt handling the following four modes can be configured:

Level mode

Pulse mode

Pulse-Notify mode

Single-Pulse mode

It is recommended to use the Pulse-Notify mode as interrupt mode.

These interrupt modes are described in more details in the following subsections.

The register IRQ_EN allows the enabling and disabling of an individual interrupt within an interrupt set. Independent of the configured mode, only enabled interrupts can signalize an interrupts on its signal GTM_<MOD>_IRQ.

The register IRQ_NOTIFY collects the occurrence of interrupt events.The behaviour for setting a bit in this register depends on the configured mode and thus it is described later on in the mode descriptions.

Independent of the configured mode any write access with value '1' to a bit in the register IRQ_NOTIFY always clears the corresponding IRQ_NOTIFY bit.

Moreover, the enabling of a disabled interrupt sources with a write access to the register IRQ_EN also clears the corresponding bit in the IRQ_NOTIFY register but only if the error interrupt source EIRQ_EN is disabled. However, if the enabling of a disabled interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register IRQ_NOTIFY is not cleared.

Additionally, each write access to the register IRQ_MODE, clears all bits in the IRQ_NOTIFY register. It should be notified that the clearing of IRQ_NOTIFY is applied independently of the written data (e.g. no mode change).

Thus, a secure way for reconfiguring the interrupt mode of an interrupt set, is to disable all interrupts of the interrupt set with the register IRQ_EN, define the new interrupt mode by writing register IRQ_MODE, followed by enabling the desired interrupts with the register IRQ_EN.

Thus, a secure way for reconfiguring the interrupt mode of an error interrupt set, is to disable all error interrupts of the error interrupt set with the register EIRQ_EN, define the new interrupt mode by writing register IRQ_MODE, followed by enabling the desired error interrupts with the register EIRQ_EN.

The register IRQ_FORCINT is used by software for triggering individual interrupts with a write access with value '1'. Since a write access to IRQ_FORCINT only generates a single pulse, IRQ_FORCINT is not implemented as a true register and thus any read access to IRQ_FORCINT always results with a value of '0'.

It should be noted, that the mechanism for triggering interrupts with IRQ_FORCINT is globally disabled after reset. It has to be explicitly enabled by clearing the bit RF_PROT in the register GTM_CTRL (see **Section 25.2.9.3**)

For the modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE and CMP each interrupt may configured to raise instead of the normal interrupt an error interrupt if enabled by the corresponding error interrupt enable bit in register EIRQ_EN.

Note, it is possible for one source to enable the normal interrupt and the error interrupt in parallel. Because of both interrupt clear signals could reset the notify bit this is expected to cause problems in a system and therefore it is strongly recommended to not enable both interrupt types at the same point in time.

Similar to enabling an interrupt, the enabling of a disabled error interrupt source with a write access to the register EIRQ_EN also clears the corresponding bit in the IRQ_NOTIFY register only if the interrupt source is disabled. However, if the enabling of a disabled error interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register IRQ_NOTIFY is not cleared.

All enabled error interrupts are or-combined inside the ICM and assigned to the dedicated GTM port gtm_err_irq.

To be able to detect the module source of the error interrupt the ICM provides the register ICM_IRQG_MEI.

The error interrupt causing channel can be determined for the modules FIFO, TIM and MCS by evaluating the ICM register ICM_IRQG_CEI0 to ICM_IRQG_CEI4.

25.2.5.1 Level interrupt mode

The default interrupt mode is the Level Interrupt Mode. In this mode each occurred interrupt event is collected in the register IRQ_NOTIFY, independent of the corresponding enable bit of register IRQ_EN and EIRQ_EN.

An interrupt event, which is defined as a pulse on the signal Int_out of **Figure 25-8**, may be triggered by the interrupt source of the submodule or by software performing a write access to the corresponding register IRQ_FORCINT, with a disabled bit RF_PROT in register GTM_CTRL.

Level interrupt mode scheme

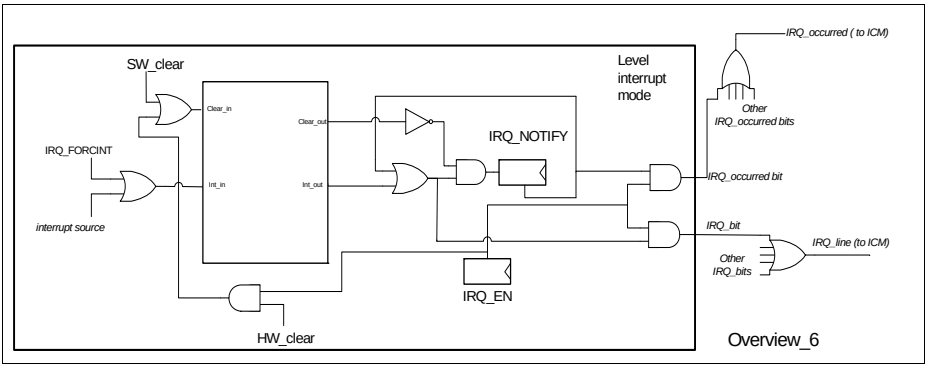

Figure 25-8 Level interrupt mode scheme

A collected interrupt bit in register IRQ_NOTIFY may be cleared by a clear event, which is defined as a pulse on signal Clear_out of **Figure 25-8**. A clear event can be performed with a write access with value '1' to the corresponding bit in the register IRQ_NOTIFY leading to a pulse on signals SW_clear. A clear event may also result from an externally connected signal GTM_<MOD>_IRQ_CLR, which is routed to the signal HW_clear of **Figure 25-8**. However, the hardware clear mechanism is only possible, if the corresponding interrupt is enabled by register IRQ_EN.

As the **Table 25-5** shows, interrupt events are dominant in the case of a simultaneous interrupt event and clear event.

Table 25-5 IRQ_NOTIFY behaviour

Int_in	Clear_in	Int_out	Clear_out
0	0	0	0
0	1	0	1
1	0	1	0
1	1	1	0

Priority of Interrupt Events and Clear Events

As it can be seen from the **Figure 25-8** an occurred interrupt event is signaled as a constant signal level with value 1 to the signal IRQ_bit, if the corresponding interrupt is enabled in register IRQ_EN.

With exception of the submodules ARU and DPLL, the signal IRQ_bit is OR-combined with the neighboring IRQ_bit signals of the same interrupt set and they are routed as a single signal IRQ_line to the interrupt concentrator module (ICM). The interrupt signals IRQ_bit of the submodules DPLL and ARU are routed directly as a signal IRQ_line to the submodule ICM. In some cases (submodules TOM and ATOM) the ICM may further OR-

combine several IRQ_line signals to an outgoing interrupt signal GTM_<MOD>_IRQ. In the other cases the IRQ_line signals are directly connected to the outgoing signals GTM_<MOD>_IRQ. within the submodule ICM.

The signal IRQ_occurred is connected in a similar way as the signal IRQ_line, however this signal is used for monitoring the interrupt state of the register IRQ_NOTIFY in the registers of the ICM.

The additional error interrupt enable mechanism for level interrupt is shown below.

Level interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

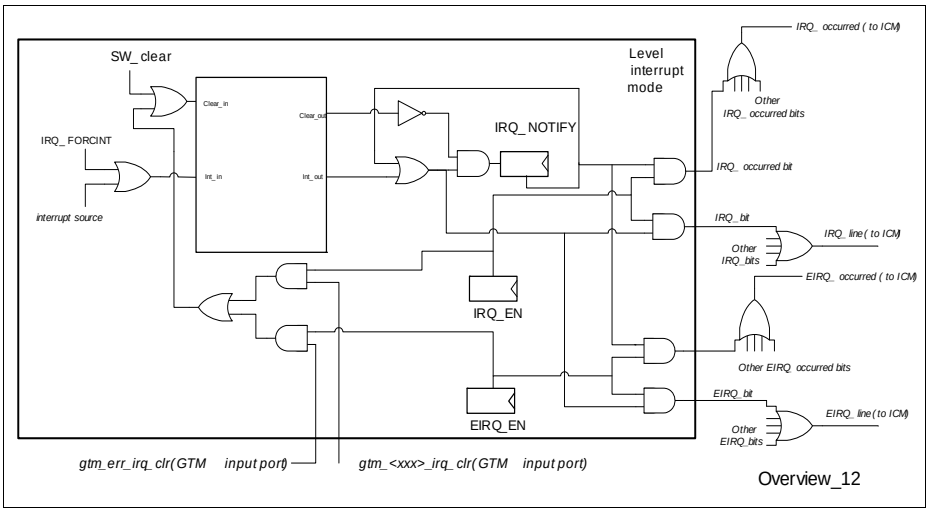

Figure 25-9 Level interrupt scheme

A collected interrupt bit in register IRQ_NOTIFY may be cleared by a clear event, which is defined as a pulse on signal Clear_out of **Figure 25-8**. A clear event can be performed with a write access with value '1' to the corresponding bit in the register IRQ_NOTIFY leading to a pulse on signals SW_clear. A clear event may also result from externally connected signal gtm_<xxx>_irq_clr or gtm_err_irq_clr, which is routed as a HW_clear to Clear_in of **Figure 25-8**. However, the hardware clear mechanism is only possible, if the corresponding interrupt or error interrupt is enabled by register IRQ_EN or EIRQ_EN.

As it can be seen from the **Figure 25-9** an occurred interrupt event is signalled as a constant signal level with value 1 to the signal IRQ_bit, if the corresponding interrupt is enabled in register IRQ_EN.

25.2.5.2 Pulse interrupt mode

The Pulse interrupt mode behaviour can be observed from **Figure 25-10**.

Pulse interrupt mode scheme

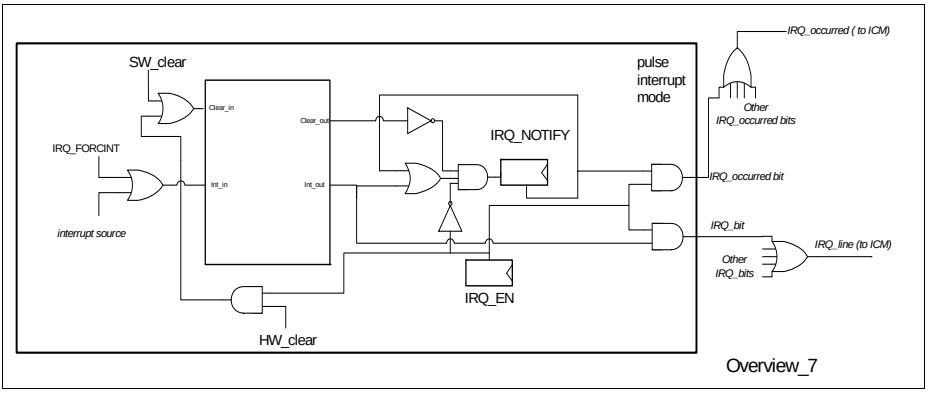

Figure 25-10 Pulse interrupt mode scheme

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the IRQ_bit signal if IRQ_EN is enabled.

As it can be seen from the figure, the interrupt bit in IRQ_NOTIFY register is always cleared if IRQ_EN or IRQ_EN are enabled.

However, if an interrupt is disabled in the register IRQ_EN, an occurred interrupt event is captured in the register IRQ_NOTIFY, in order to allow polling for disabled interrupts by software.

Disabled interrupts may be cleared by an interrupt clear event.

In Pulse interrupt mode, the signal IRQ_occurred is always 0.

The additional error interrupt enable mechanism for pulse interrupt is shown below.

Pulse interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

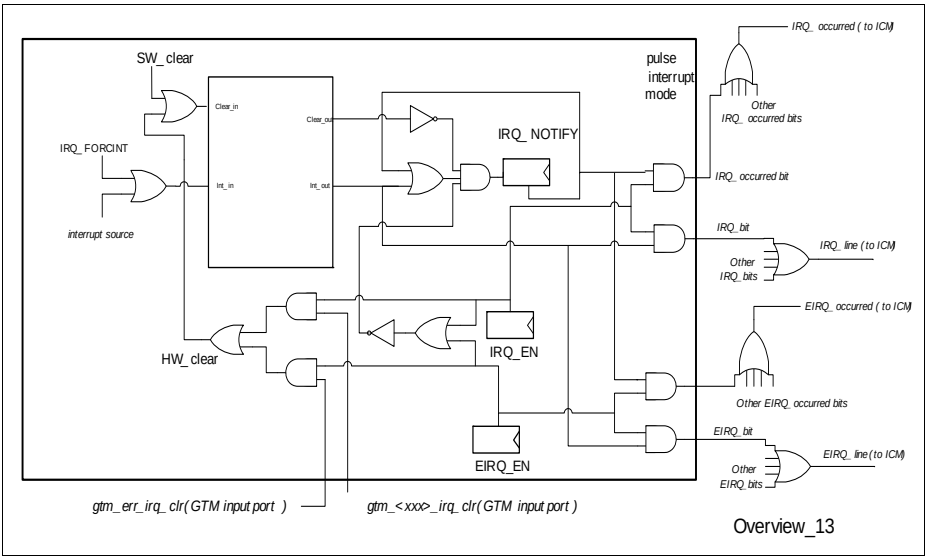

Figure 25-11 Pulse interrupt scheme

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the EIRQ_bit signal if EIRQ_EN is enabled.

As it can be seen from the figure, the interrupt bit in IRQ_NOTIFY register is always cleared if EIRQ_EN is enabled.

However, if an error interrupt is disabled in the register EIRQ_EN, an occurred error interrupt event is captured in the register IRQ_NOTIFY, in order to allow polling for disabled error interrupts by software.

Disabled error interrupts may be cleared by an error interrupt clear event.

In Pulse interrupt mode, the signal EIRQ_occurred is always 0.

25.2.5.3 Pulse-notify interrupt mode

In Pulse-notify Interrupt mode, all interrupt events are captured in the register IRQ_NOTIFY. If an interrupt is enabled by the register IRQ_EN, each interrupt event will also generate a pulse on the IRQ_bit signal. The signal IRQ_occurred will be high if interrupt is enabled in register IRQ_EN and the corresponding bit of register IRQ_NOTIFY is set. The Pulse-notify interrupt mode is shown in **Figure 25-12**.

Pulse-notify interrupt mode scheme

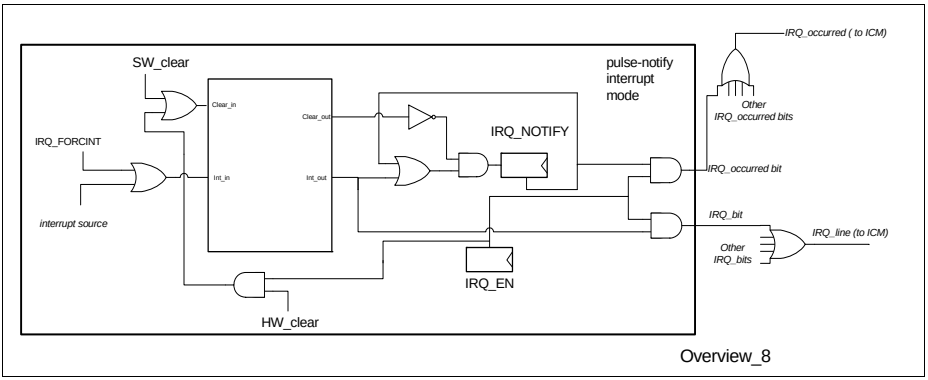

Figure 25-12 Pulse-notify interrupt mode scheme

The additional error interrupt enable mechanism for pulse-notify interrupt is shown below

Pulse-notify interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

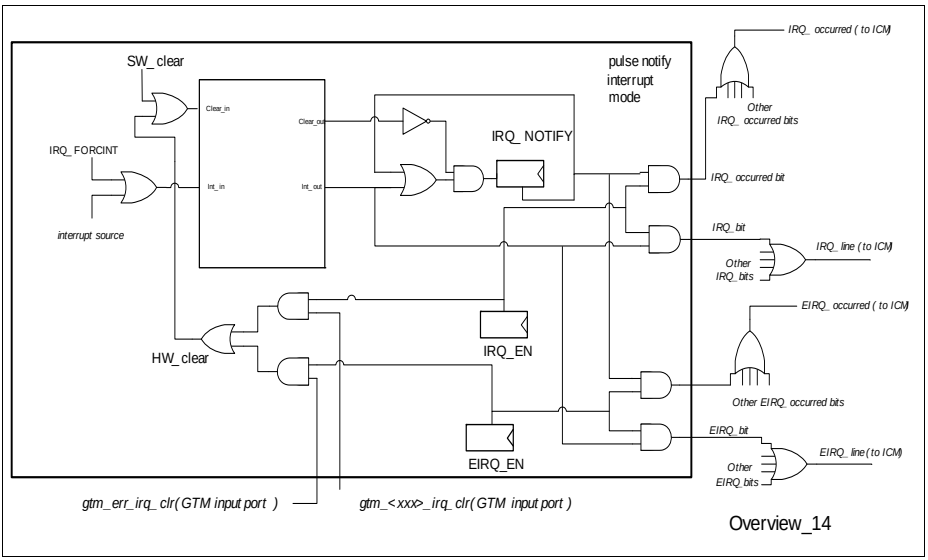

Figure 25-13 Pulse-notify interrupt scheme

In Pulse-notify Interrupt mode, all error interrupt events are captured in the register IRQ_NOTIFY. If an error interrupt is enabled by the register EIRQ_EN, each error interrupt event will also generate a pulse on the EIRQ_bit signal. The signal EIRQ_occurred will be high if error interrupt is enabled in register EIRQ_EN and the corresponding bit of register IRQ_NOTIFY is set. The Pulse-notify interrupt mode for error interrupts is shown in figure 2.5.3.2.

25.2.5.4 Single-pulse interrupt mode

In Single-pulse Interrupt Mode, an interrupt event is always captured in the register IRQ_NOTIFY, independent of the state of IRQ_EN. However, only the first interrupt event of an enabled interrupt within an common interrupt set is forwarded to signal IRQ_line. Additional interrupt events of the same interrupt set cannot generate pulses on the signal IRQ_line, until the corresponding bits in register IRQ_NOTIFY of enabled interrupts are cleared by a clear event. The IRQ_occurred signal line will be high, if the IRQ_EN and the IRQ_NOTIFY register bits are set. The Single-pulse interrupt mode is shown in **Figure 25-14**.

The only exceptions are the modules ARU and DPLL. In these modules the IRQ_occurred bit of each interrupt is directly connected (without OR-conjunction of neighboring IRQ_occurred bits) to the inverter for suppressing further interrupt pulses.

Single-pulse interrupt mode scheme

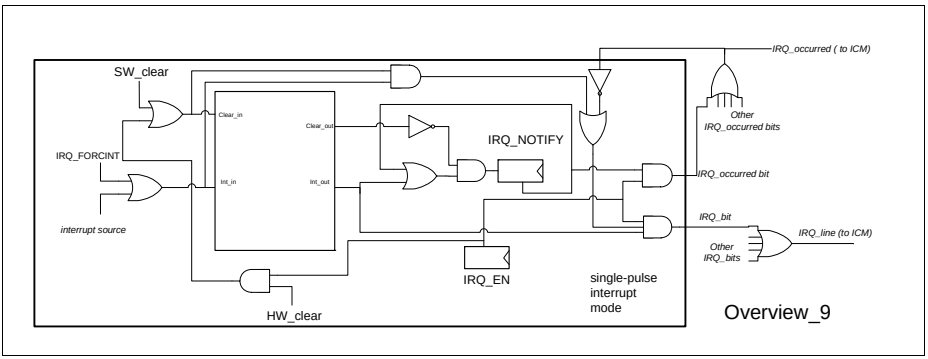

Figure 25-14 Single-pulse interrupt mode scheme

To avoid unexpected IRQ behaviour in the single pulse mode, all desired interrupt sources should be enabled by a single write access to IRQ_EN and the notification bits should be cleared by a single write access to the register IRQ_NOTIFY.

The additional error interrupt enable mechanism for single-pulse interrupt is shown below

Single-pulse interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

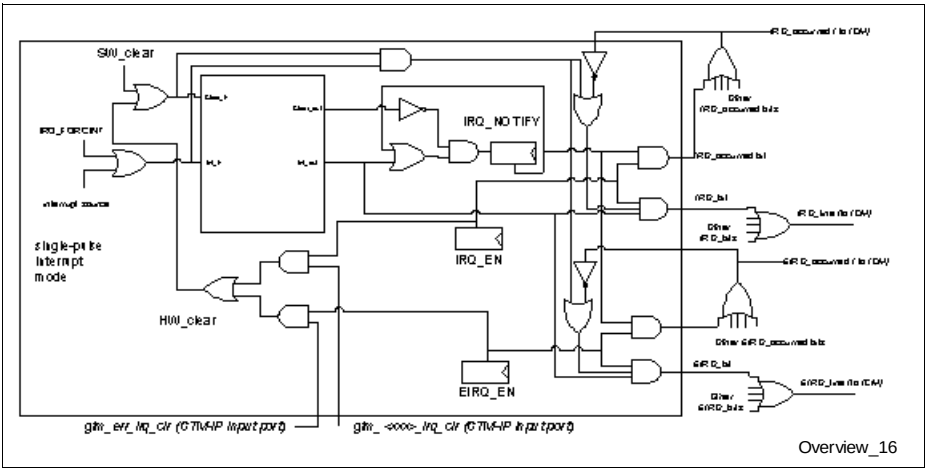

Figure 25-15 Single-pulse interrupt mode scheme

In Single-pulse Interrupt Mode, an error interrupt event is always captured in the register IRQ_NOTIFY, independent of the state of EIRQ_EN. However, only the first error interrupt event of an enabled error interrupt within a common error interrupt set is forwarded to signal EIRQ_line. Additional error interrupt events of the same error interrupt set cannot generate pulses on the signal EIRQ_line, until the corresponding bits in register IRQ_NOTIFY of enabled error interrupts are cleared by a clear event. The EIRQ_occurred signal line will be high, if the EIRQ_EN and the IRQ_NOTIFY register bits are set. The Single-pulse interrupt mode for error interrupts is shown in figure 2.5.4.2.

To avoid unexpected EIRQ behaviour in the single pulse mode, all desired error interrupt sources should be enabled by a single write access to EIRQ_EN and the notification bits should be cleared by a single write access to the register IRQ_NOTIFY.

The only exceptions are the modules ARU and DPLL. In these modules the EIRQ_occured bit of each error interrupt is directly connected (without OR-conjunction of neighboring EIRQ_occurred bits) to the inverter for suppressing further error interrupt pulses.

25.2.5.5 GTM Interrupt concentration method

Because of the grouping of interrupts inside the ICM, it can be necessary for the software to access the ICM submodule first to determine the interrupt set that is responsible for an interrupt. A second access to the responsible register IRQ_NOTIFY is then necessary to identify the interrupt source, serve it and to reset the interrupt flag in register IRQ_NOTIFY afterwards. The interrupt flags are never reset by an access to the ICM. For a detailed description of the ICM submodule please refer to **Chapter 25.18**.

25.2.6 GTM Software Debugger Support

For software debugger support the GTM comes with several features. E.g. status register bits must not be altered by a read access from a software debugger. To avoid this behaviour to reset a status register bit by software, the CPU has to write a '1' explicitly to the register bit to reset its content.

The **Table 25-6** describes the behaviour of some GTM registers with special functionality on behalf of read accesses from the AEI bus interface.

25.2.6.1 Register behaviour in case of Software Debugger accesses

Table 25-6 Register behaviour in case of Software Debugger accesses

Module	Register	Description
AFD	AFDi_CHx_BUFFACC	The FIFO read access pointers are not altered on behalf of a debugger read access to this register.
TIM	TIMi_CHx_GPR0 / 1	The overflow bit is not altered in case of a debugger read access to this register.
ATOM	ATOMi_CHx_SR0 / 1	In SOMC mode a read access to this register by the debugger does not release the channel for a new compare / match event.

Further on, some important states inside the GTM submodule have to be signalled to the outside world, when reached and should for example trigger the software debugger to stop program execution. For this internal state signalling please refer to the GTM module integration guide.

The GTM provides an external signal gtm_halt, which disables clock signal SYS_CLK for debugging purposes. If SYS_CLK is disabled, a connected debugger can read any GTM related register and the GTM internal RAMs using AEI. Moreover, the debugger can also perform write accesses to the internal RAMs and to several GTM related registers in order to enable advanced debugging features (e.g. modifications of register contents in single step mode).

25.2.7 GTM Programming conventions

To serve different application domains the GTM is a highly configurable module with many configuration modes. In principle the submodules of the GTM are intended to be configured at system startup to fulfil certain functionality for the application domain the microcontroller runs in.

For example, a TIM input channel can be used to monitor an application specific external signal, and this signal has to be filtered. Therefore, the configuration of the TIM channel filter mode will be specific to the external signal characteristic. While it can be necessary to adapt the filter thresholds during runtime an adaptation of the filter mode during runtime is not reasonable. Thus, the change of the filter mode during runtime can lead to an unexpected behaviour.

In general, the programmer has to be careful when reprogramming configuration registers of the GTM submodules during runtime. It is recommended to disable the channels before reconfiguration takes place to avoid unexpected behaviour of the GTM.

25.2.8 GTM TOP-Level Configuration Registers Overview

GTM TOP-level contains following configuration registers:

Table 25-7 GTM TOP-Level Configuration Registers Overview

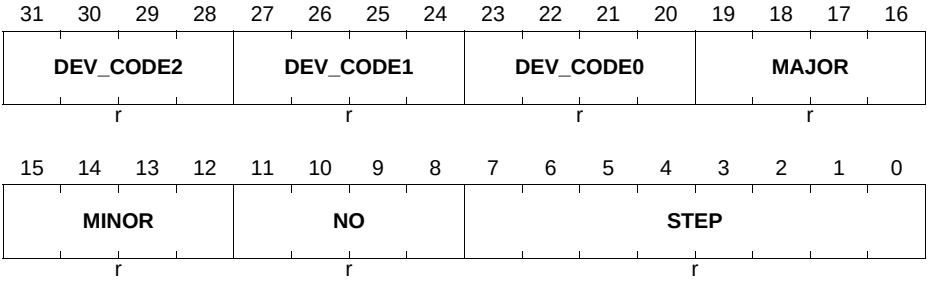
Register name	Description	Details in Section
GTM_REV	GTM Version control register	Section 25.2.9.1
GTM_RST	GTM Global reset register	Section 25.2.9.2
GTM_CTRL	GTM Global control register	Section 25.2.9.3
GTM_AEI_ADDR_XPT	GTM AEI Timeout exception address register	Section 25.2.9.4
GTM_IRQ_NOTIFY	GTM Interrupt notification register	Section 25.2.9.5
GTM_IRQ_EN	GTM Interrupt enable register	Section 25.2.9.6
GTM_IRQ_EIRQ_EN	GTM Error interrupt generation register	Section 25.2.9.12
GTM_IRQ_FORCINT	GTM Software interrupt generation register	Section 25.2.9.7
GTM_IRQ_MODE	GTM top level interrupts mode selection. Please note that this mode selection is only valid for the three interrupts described in Section 25.2.9.5	Section 25.2.9.8
GTM_TIMi_AUX_IN_SRC (i= 0…n)	GTM-IP TIMi module AUX_IN source selection register	Section 25.2.9.13

25.2.9 GTM TOP-Level Configuration Registers Description

All of the following registers are 32-bit only accessible.

25.2.9.1 Register GTM_REV

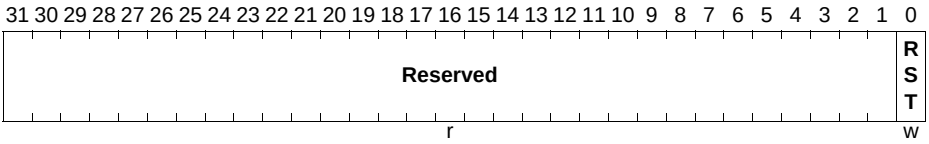
GTM_REV
GTM Version Control Register (00000_H) Reset Value: $103155A1_H$



Field	Bits	Type	Description
STEP	[7:0]	r	**Release Step**
NO	[11:8]	r	**Define delivery number of GTM specification**
MINOR	[15:12]	r	**Define minor version number of GTM specification**
MAJOR	[19:16]	r	**Define major version number of GTM specification**
DEV_CODE0	[23:20]	r	**Device encoding digit 0**
DEV_CODE1	[27:24]	r	**Device encoding digit 1**
DEV_CODE2	[31:28]	r	**Device encoding digit 2** Note: The numbers are encoded in BCD. Values “A” - “F” are chapters.

25.2.9.2 Register GTM_RST

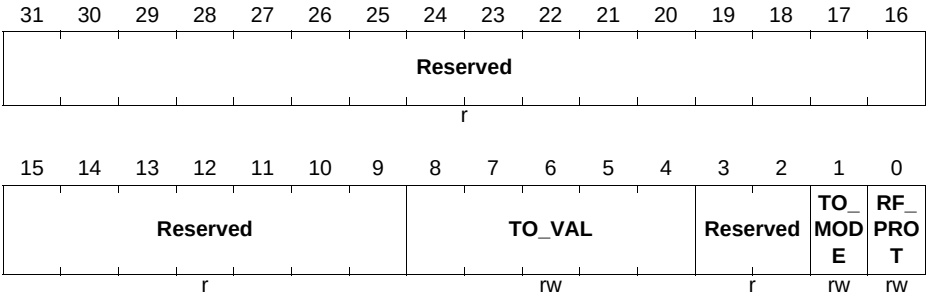
GTM_RST
GTM Global Reset Register (00004_H) Reset Value: 00000000_H



Field	Bits	Type	Description
RST	0	w	**GTM Reset** 0_B No reset action 1_B Initiate reset action for all submodules Note: This bit is automatically cleared by hardware after it was written. Therefore, the register is always read as zero (0) by the software. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
Reserved	[31:1]	r	**Reserved** Read as zero, should be written as zero

25.2.9.3 Register GTM_CTRL

GTM_CTRL
GTM Global Control Register (00008_H) Reset Value: 00000001_H

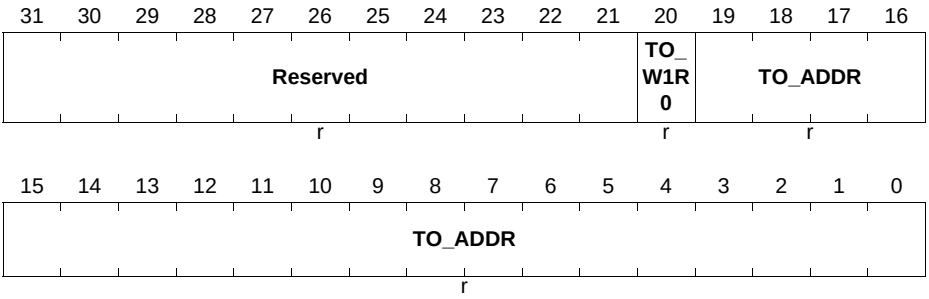


Field	Bits	Type	Description
RF_PROT	0	rw	**RST and FORCINT protection** 0_B SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is enabled 1_B SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is disabled
TO_MODE	1	rw	**AEI Timeout mode** 0_B Observe: If timeout_counter=0 the address and rw signal in addition with timeout flag will be stored to the GTM_AEI_ADDR_XPT register. Following timeout_counter=0 accesses will not overwrite the first entry in the aei_addr_timeout register. Clearing the timeout flag/aei_status error_code will reenable the storing of a next faulty access. 1_B Abort: In addition to observe mode the pending access will be aborted by signalling an illegal module access on aei_status and sending ready. In case of a read deliver as data 0 by serving of next AEI accesses.
Reserved	[3:2]	r	**Reserved** Read as zero, should be written as zero

Field	Bits	Type	Description
TO_VAL	[8:4]	rw	**AEI Timeout value** Note: These bits define the number of cycles after which a timeout event occurs. When TO_VAL equals zero (0) the AEI timeout functionality is disabled.
Reserved	[31:9]	r	**Reserved** Read as zero, should be written as zero

25.2.9.4 Register GTM_AEI_ADDR_XPT

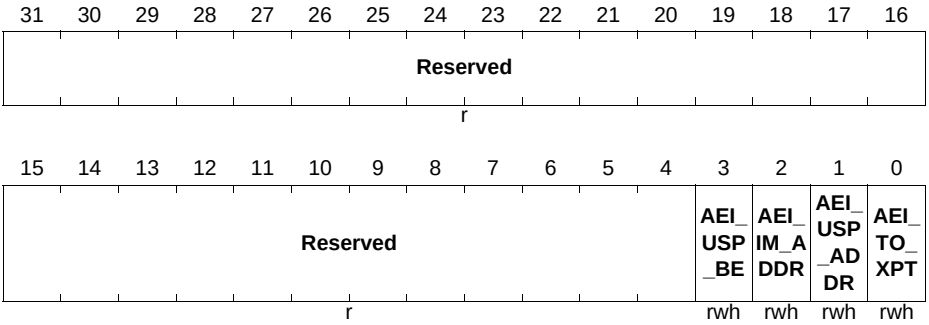
GTM_AEI_ADDR_XPT
GTM AEI Timeout Exception Address Register
(0000C$_H$) **Reset Value: 00000000$_H$**



Field	Bits	Type	Description
TO_ADDR	[19:0]	r	**AEI Timeout address** Note: This bit field defines the AEI address for which the AEI timeout event occurred.
TO_W1R0	20	r	**AEI Timeout Read/Write flag** Note: This bit defines the AEI Read/Write flag for which the AEI timeout event occurred.
Reserved	[31:21]	r	**Reserved** Read as zero, should be written as zero

25.2.9.5 Register GTM_IRQ_NOTIFY

GTM_IRQ_NOTIFY
GTM Interrupt Notification Register (00010_H) **Reset Value: 00000000_H**

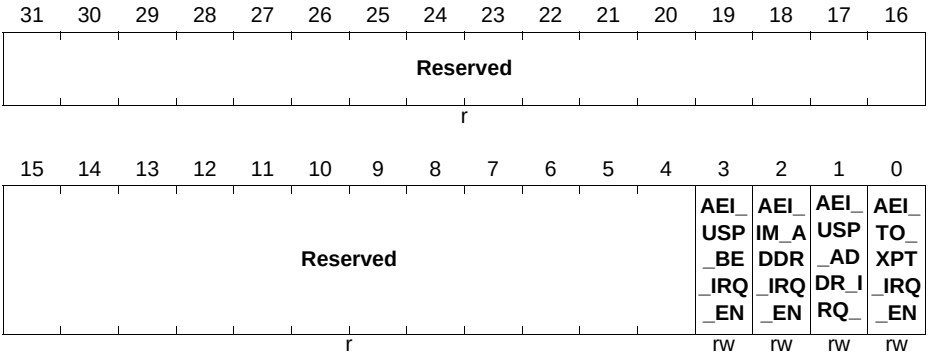


Field	Bits	Type	Description
AEI_TO_XPT	0	rwh	**AEI Timeout exception occurred** 0_B No interrupt occurred 1_B AEI_TO_XPT interrupt was raised by the AEI Timeout detection unit Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
AEI_USP_ADDR	1	rwh	**AEI Unsupported address interrupt** 0_B No interrupt occurred 1_B AEI_USP_ADDR interrupt was raised by the AEI interface Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
AEI_IM_ADDR	2	rwh	**AEI Illegal Module address interrupt** 0_B No interrupt occurred 1_B AEI_IM_ADDR interrupt was raised by the AEI interface Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Field	Bits	Type	Description
AEI_USP_BE	3	rwh	**AEI Unsupported byte enable interrupt** 0_B No interrupt occurred 1_B AEI_USP_BE interrupt was raised by the AEI interface Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

25.2.9.6 Register GTM_IRQ_EN

GTM_IRQ_EN
GTM Interrupt Enable Register (00014_H) Reset Value: 00000000_H



Field	Bits	Type	Description
AEI_TO_XPT_IRQ_EN	0	rw	**AEI_TO_XPT_IRQ interrupt enable.** 0_B Disable interrupt, interrupt is not visible outside GTM 1_B Enable interrupt, interrupt is visible outside GTM
AEI_USP_ADDR_IRQ_EN	1	rw	**AEI_USP_ADDR_IRQ interrupt enable.** 0_B Disable interrupt, interrupt is not visible outside GTM 1_B Enable interrupt, interrupt is visible outside GTM

Field	Bits	Type	Description
AEI_IM_ADDR_IRQ_EN	2	rw	**AEI_IM_ADDR_IRQ interrupt enable.** 0_B Disable interrupt, interrupt is not visible outside GTM 1_B Enable interrupt, interrupt is visible outside GTM
AEI_USP_BE_IRQ_EN	3	rw	**AEI_USP_BE_IRQ interrupt enable.** 0_B Disable interrupt, interrupt is not visible outside GTM 1_B Enable interrupt, interrupt is visible outside GTM
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

25.2.9.7 Register GTM_IRQ_FORCINT

GTM_IRQ_FORCINT
GTM Software Interrupt Generation Register
(00018_H) **Reset Value: 00000000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

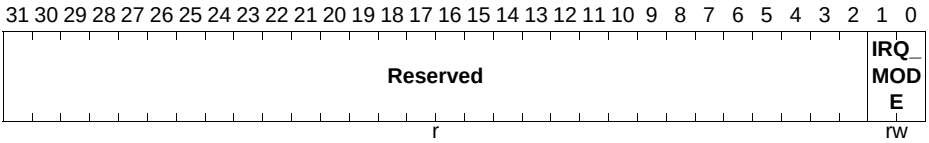
r												w	w	w	w

Field	Bits	Type	Description
TRG_AEI_TO_XPT	0	w	**Trigger AEI_TO_XPT_IRQ interrupt by software.** 0_B No interrupt triggering 1_B Assert AEI_TO_XPT_IRQ interrupt for one clock cycle Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.

Field	Bits	Type	Description
TRG_AEI_USP_ADDR	1	w	**Trigger AEI_USP_ADDR_IRQ interrupt by software.** 0_B No interrupt triggering 1_B Assert AEI_USP_ADDR_IRQ interrupt for one clock cycle Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
TRG_AEI_IM_ADDR	2	w	**Trigger AEI_IM_ADDR_IRQ interrupt by software.** 0_B No interrupt triggering 1_B Assert AEI_IM_ADDR_IRQ interrupt for one clock cycle Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
TRG_AEI_USP_BE	3	w	**Trigger AEI_USP_BE_IRQ interrupt by software.** 0_B No interrupt triggering 1_B Assert AEI_USP_BE_IRQ interrupt for one clock cycle Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

25.2.9.8 Register GTM_IRQ_MODE

GTM_IRQ_MODE
GTM Top Level Interrupts Mode Selection
($0001C_H$) **Reset Value: 00000000_H**

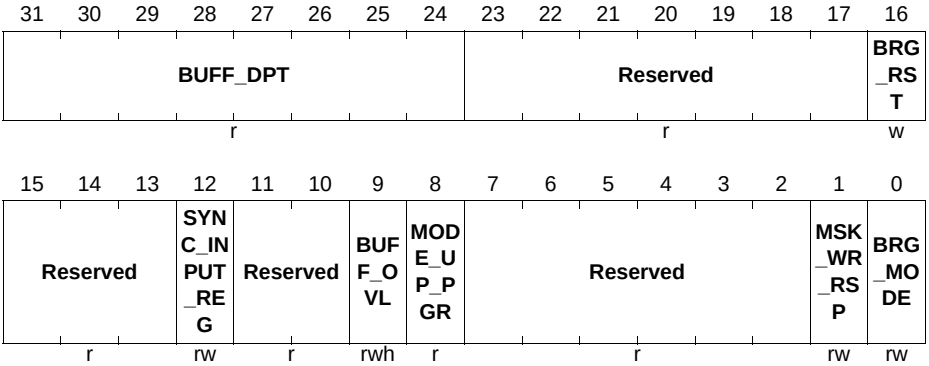


Field	Bits	Type	Description
IRQ_MODE	[1:0]	rw	**Interrupt strategy mode selection for the AEI timeout and address monitoring interrupts** 00_B Level mode 01_B Pulse mode 10_B Pulse-Notify mode 11_B Single-Pulse mode Note: The interrupt modes are described in **Section 25.2.5**.
Reserved	[31:2]	r	**Reserved** Read as zero, should be written as zero

25.2.9.9 Register GTM_BRIDGE_MODE

Note: The content of this register should never be changed.

GTM_BRIDGE_MODE
GTM to SPB BRIDGE MODE **(00030_H)** **Reset Value: 04001001_H**

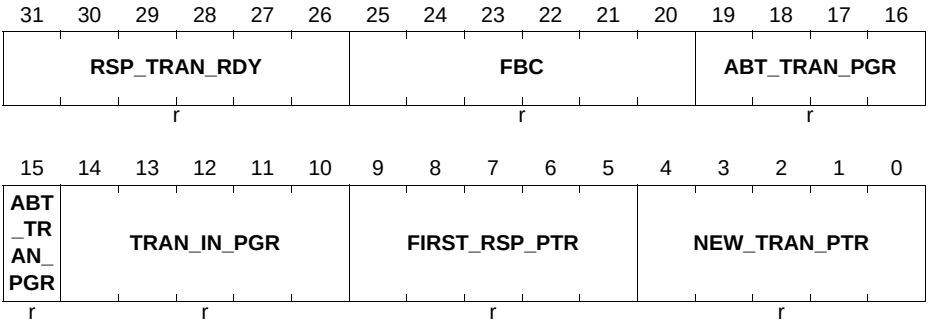


Field	Bits	Type	Description
BRG_MODE	0	rw	**Defines the operation mode for the AEI bridge** 0_B AEI bridge operates in sync_bridge mode 1_B AEI bridge operates in async_bridge mode
MSK_WR_RSP	1	rw	**Mask write response** 0_B Do not mask the write response 1_B Mask write response
Reserved	[7:2]	r	**Reserved** Read as zero, should be written as zero
MODE_UP_PGR	8	r	**Mode update in progress** 0_B No update in progress. 1_B Update in progress.
BUFF_OVL	9	rwh	**Buffer overflow register** 0_B No buffer overflow occurred. 1_B Buffer overflow occurred. Note: A buffer overflow can occur while multiple aborts are issued by the external bus or a pipelined instruction is started while FBC = 0 (see GTM_BRIDGE_PTR1 register). This bit always read as zero.

Field	Bits	Type	Description
Reserved	[11:10]	r	**Reserved** Read as zero, should be written as zero.
SYNC_INPUT_REG	12	rw	**Additional Pipeline Stage in Synchronous Bridge Mode** 0_B No additional pipeline stage implemented 1_B Additional pipeline stage implemented. All accesses in synchronous mode will be increased by one clock cycle.
Reserved	[15:13]	r	**Reserved** Read as zero, should be written as zero.
BRG_RST	16	w	**Bridge software reset** 0_B No bridge reset request. 1_B Bridge reset request. Note: This bit is cleared automatically after write. This bit always read as zero.
BUFF_DPT	[31:24]	r	**Buffer depth of AEI bridge** Signals the buffer depth of the GTM AEI bridge implementation.
Reserved	[23:17]	r	**Reserved** Read as zero, should be written as zero

25.2.9.10 Register GTM_BRIDGE_PTR1

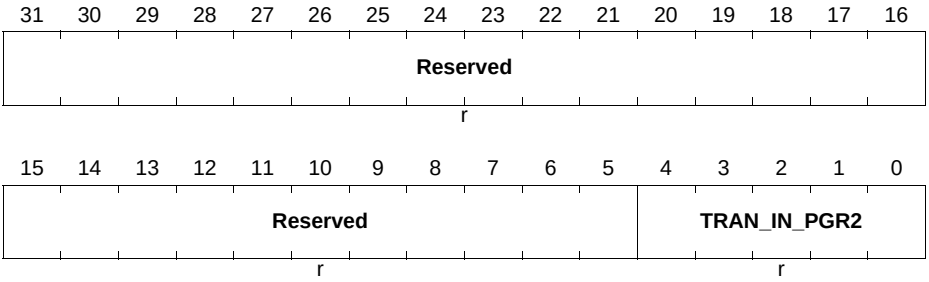
GTM_BRIDGE_PTR1
GTM to SPB BRIDGE PTR1 **(00034_H)** **Reset Value: $00X00000_H$**



Field	Bits	Type	Description
NEW_TRAN_PTR	[4:0]	r	**New transaction pointer** Signals the actual value of the new transaction pointer.
FIRST_RSP_PTR	[9:5]	r	**First response pointer** Signals the actual value of first response pointer.
TRAN_IN_PGR	[14:10]	r	**Transaction in progress pointer (acquire)** Transaction in progress pointer.
ABT_TRAN_PGR	[19:15]	r	**Aborted transaction in progress pointer** Aborted transaction in progress pointer.
FBC	[25:20]	r	**Free buffer count** Number of free buffer entries.
RSP_TRAN_RDY	[31:26]	r	**Response transactions ready** Amount of ready response transactions. Note: This register operates on the AEI_CLK domain.

25.2.9.11 Register GTM_BRIDGE_PTR2

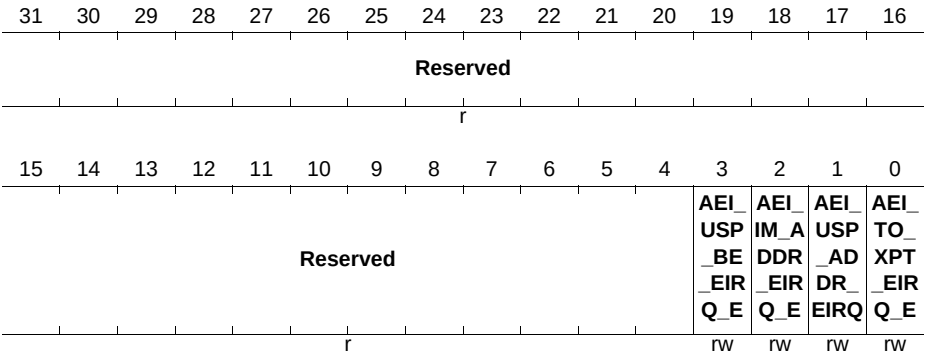
GTM_BRIDGE_PTR2
GTM to SPB BRIDGE PTR2 **(00038_H)** **Reset Value: 00000000_H**



Field	Bits	Type	Description
TRAN_IN_PGR2	[4:0]	r	**Transaction in progress pointer (aquire2)** Transaction in progress pointer 2.
Reserved	[31:5]	r	**Reserved** Read as zero, should be written as zero *Note: This register operates on the GTM_CLK domain*

25.2.9.12 Register GTM_EIRQ_EN

GTM_EIRQ_EN
GTM Error Interrupt Enable Register (00020_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
AEI_TO_XPT_EIRQ_EN	0	rw	**AEI_TO_XPT_EIRQ error interrupt enable** 0_B Disable error interrupt, interrupt is not visible outside GTM 1_B Enable error interrupt, interrupt is visible outside GTM
AEI_USP_ADDR_EIRQ_EN	1	rw	**AEI_USP_ADDR_EIRQ error interrupt enable** 0_B Disable error interrupt, interrupt is not visible outside GTM 1_B Enable error interrupt, interrupt is visible outside GTM
AEI_IM_ADDR_EIRQ_EN	2	rw	**AEI_IM_ADDR_EIRQ error interrupt enable** 0_B Disable error interrupt, interrupt is not visible outside GTM 1_B Enable error interrupt, interrupt is visible outside GTM
AEI_USP_BE_EIRQ_EN	3	rw	**AEI_USP_BE_EIRQ error interrupt enable** 0_B Disable error interrupt, interrupt is not visible outside GTM 1_B Enable error interrupt, interrupt is visible outside GTM

Field	Bits	Type	Description
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

25.2.9.13 Register GTM_TIMi_AUX_IN_SRC (i= 0…n)

GTM_TIMi_AUX_IN_SRC (i=0-3)

GTM TIMi AUX_IN_SRC **(00040_H+i*04_H)** **Reset Value: 00000000_H**

Field	Bits	Type	Description
SRC_CH0	0	rw	**Defines AUX_IN source of TIMi channel 0 x=0** 0_B TOM Output selected TOM[a] channel [b] with a= (i* 8 +x) div 16; b=(i* 8 +x) mod 16; 1_B ATOM Output selected ATOMi channel x
SRC_CH1	1	rw	**Defines AUX_IN source of TIMi channel 1 x=1, see bit 0**
SRC_CH2	2	rw	**Defines AUX_IN source of TIMi channel 2 x=2, see bit 0**
SRC_CH3	3	rw	**Defines AUX_IN source of TIMi channel 3 x=3, see bit 0**
SRC_CH4	4	rw	**Defines AUX_IN source of TIMi channel 4 x=4, see bit 0**
SRC_CH5	5	rw	**Defines AUX_IN source of TIMi channel 5 x=5, see bit 0**
SRC_CH6	6	rw	**Defines AUX_IN source of TIMi channel 6 x=6, see bit 0**
SRC_CH7	7	rw	**Defines AUX_IN source of TIMi channel 7 x=7, see bit 0**
Reserved	[31:8]	r	**Reserved** Read as zero, should be written as zero

25.3 Advanced Routing Unit (ARU)

25.3.1 Overview

The Advanced Routing Unit (ARU) is a flexible infrastructure component for transferring 53 bit wide data (five control bits and two 24 bit values) between several submodules of the GTM core in a configurable manner.

Since the concept of the ARU has already been described in **Section 25.2.3**, this section only describes additional ARU features that can be used by the software for configuring and debugging ARU related data streams.

Also the definition of 'streams' and 'channels' in the ARU context is done in **Section 25.2.3**.

25.3.2 Special Data Sources

Besides the addresses of the submodule related data sources as described in **Table 25.21.1**, the ARU provides two special data sources that can be used for the configuration of data streams. These data sources are defined as follows:

Address 0x1FF: Data source that provides always a 53 bit data word with zeros. A read access to this memory location will never block a requesting data destination.

Address 0x1FE: Data source that never provides a data word. A read access to this memory location will always block a requesting data destination. This is the reset value of the read registers inside the data destinations.

Address 0x000: This address is reserved and can be used to bring data through the ARU registers ARU_DATA_H and ARU_DATA_L into the system by writing the write address 0x000 into the ARU_ACCESS register. This means that software test data can be brought into the GTM by the CPU.

25.3.3 ARU Access via AEI

Besides the data transfer between the connected submodules, there are two possibilities to access ARU data via the AEI.

25.3.3.1 Default ARU Access

The default ARU access incorporates the registers ARU_ACCESS, which is used for initiation of a read or write request and the registers ARU_DATA_H and ARU_DATA_L that provide the ARU data word to be transferred.

The status of a read or write transfer can be determined by polling specific bits in register ARU_ACCESS. Furthermore the acc_ack bit in the interrupt notify register is set after the read or write access is performed to avoid data loss e.g. on access cancelation.

A pending read or write request may also be cancelled by clearing the associated bit.

In the case of a read request, the AEI access behaves as a read request initiated by a data destination of a module. The read request is served by the ARU immediately when no other destination has a pending read request. This means, that an AEI read access does not take part in the scheduling of the destination channels and that the time between two consecutive read accesses is not limited by the round trip time.

On the other hand, the AEI access has the lowest priority behind the ARU scheduler that serves the destination channels. Thus, in worst case, the read request is served after one round trip of the ARU, when all destination channels would request data at the same point in time.

In the case of the write request, the ARU provides the write data at the address defined by the ADDR bit field inside the ARU_ACCESS register.

To avoid data loss, the reserved ARU address 0x0 has to be used to bring data into the system. Otherwise, in case the address specified inside the ADDR bit field is defined for another submodule that acts as a source at the ARU data loss may occur and no deterministic behaviour is guaranteed.

This is because the regular source submodule is not aware that its address is used by the ARU itself to provide data to a destination.

It is guaranteed that the ARU write data is send to the destination in case of both modules want to provide data at the same time.

Configuring both read and write request bits results in a read request, if the write request bit inside the register isn't already set. The following table describes the important cases of the bit 12 (RREQ) and bit 13 (WREQ) of the ARU_ACCESS register:

Table 25-8 ARU_ACCESS behaviour

AEI write access: aei_wdata(13:12)	actual value of ARU_ACCESS [13:12]	next value of ARU_ACCESS [13:12]	comment
00_B	01_B	00_B	cancel read request
00_B	10_B	00_B	cancel write request
01_B	10_B	10_B	unchanged register
10_B	01_B	01_B	unchanged register
11_B	00_B	01_B	both read and write request results in a read request
11_B	10_B	10_B	as before but WREQ bit is already set -> unchanged register

25.3.3.2 Debug Access

The debug access mode enables to inspect routed data of configured data streams during runtime.

The ARU provides two independent debug channels, whereas each is configured by a dedicated ARU read address in register ARU_DBG_ACCESS0 and ARU_DBG_ACCESS1 respectively.

The registers ARU_DBG_DATA0_H and ARU_DBG_DATA0_L (ARU_DBG_DATA1_H and ARU_DBG_DATA1_L) provide read access to the latest data word that the corresponding data source sent through the ARU.

Any time when data is transferred through the ARU from a data source to the destination requesting the data the interrupt signal ARU_NEW_DATA0_IRQ (ARU_NEW_DATA1_IRQ) is raised.

For advanced debugging purposes, the interrupt signal can also be triggered by software using the register ARU_IRQ_FORCINT.

Please note, that the debug mechanism should not be used by the application, when a HW-Debugger is used to trace the ARU communication. In that case, the debug registers are used by the HW-Debugger to specify the ARU streams that should be traced.

25.3.4 ARU Interrupt Signals

The following table describes ARU interrupt signals:

Table 25-9 ARU interrupt signals

Signal	Description
ARU_NEW_DATA0_IRQ	Indicates that data is transferred through the ARU using debug channel ARU_DBG_ACCESS0.
ARU_NEW_DATA1_IRQ	Indicates that data is transferred through the ARU using debug channel ARU_DBG_ACCESS1.
ACC_ACK_IRQ	ARU access acknowledge IRQ.

25.3.5 ARU Configuration Registers Overview

The following table shows a conclusion of configuration registers address offsets and initial values.

Table 25-10 ARU Configuration Registers Overview

Register name	Description	Details in Section
ARU_ACCESS	ARU access register	Section 25.3.6.1
ARU_DATA_H	ARU access register upper data word	Section 25.3.6.2

Table 25-10 ARU Configuration Registers Overview (cont'd)

Register name	Description	Details in Section
ARU_DATA_L	ARU access register lower data word	Section 25.3.6.3
ARU_DBG_ACCESS0	Debug access channel 0	Section 25.3.6.4
ARU_DBG_DATA0_H	Debug access 0 transfer register upper data word	Section 25.3.6.5
ARU_DBG_DATA0_L	Debug access 0 transfer register lower data word	Section 25.3.6.6
ARU_DBG_ACCESS1	Debug access channel 0	Section 25.3.6.7
ARU_DBG_DATA1_H	Debug access 1 transfer register upper data word	Section 25.3.6.8
ARU_DBG_DATA1_L	Debug access 1 transfer register lower data word	Section 25.3.6.9
ARU_IRQ_NOTIFY	ARU Interrupt notification register	Section 25.3.6.10
ARU_IRQ_EN	ARU Interrupt enable register	Section 25.3.6.11
ARU_IRQ_FORCINT	Register for forcing the ARU_NEW_DATA_IRQ interrupt	Section 25.3.6.12
ARU_IRQ_MODE	IRQ mode configuration register	Section 25.3.6.13

25.3.6 ARU Configuration Registers Description

All of the following registers are 32-bit only accessible.

25.3.6.1 Register ARU_ACCESS

GTM_ARU_ACCESS
ARU Access Register **(00280_H)** **Reset Value: $000001FE_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved		WREQ	RREQ	Reserved			ADDR								
r		rwh	rwh	r			rw								

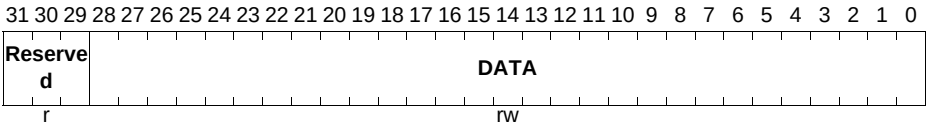
Field	Bits	Type	Description
ADDR	[8:0]	rw	**ARU address** Define the ARU address used for transferring data Note: For an ARU write request, the preferred address 0x0 have to be used. Note: A write request to the address 0x1FF (always full address) or 0x1FE (always empty address) are ignored and doesn't have any effect. Note: ARU address bits ADDR are only writable if RREQ and WREQ bits are zero
Reserved	[11:9]	r	**Reserved** Read as zero, should be written as zero
RREQ	12	rwh	**Initiate read request** 0_B No read request is pending 1_B Set read request to source channel addressed by ADDR Note: This bit is cleared automatically after transaction. Moreover, it can be cleared by software to cancel a read request. Note: RREQ bit is only writable if WREQ bit is zero, so to switch from RREQ to WREQ a cancel request has to be performed before. Note: Configuring both RREQ and WREQ bits results in a read request, so RREQ bit will be set if the WREQ bit of the register isn't already set. Note: The ARU read request on address ADDR is served immediately when no other destination has actually a read request when the RREQ bit is set by CPU. In a worst case scenario, the read request is served after one round trip of the ARU, but this is only the case when every destination channel issues a read request at consecutive points in time.

Field	Bits	Type	Description
WREQ	13	rwh	**Initiate write request** 0_B No write request is pending 1_B Mark data in registers ARU_DATA_H and ARU_DATA_L as valid Note: This bit is cleared automatically after transaction. Moreover, it can be cleared by software to cancel a write request. Note: WREQ bit is only writable if RREQ bit is zero, so to switch from WREQ to RREQ a cancel request has to be performed before. Note: Configuring both WREQ and RREQ bits result in a read request, so WREQ bit will not be set. Note: The data is provided at address ADDR. This address has to be programmed as the source address in the destination submodule channel. In worst case, the data is provided after one full ARU round trip. Note: It is strongly recommended that an address ADDR is used that is not reserved for another source submodule inside the GTM, for example the reserved address 0x000. Otherwise, data from another source submodule, that provides his data at the specified address ADDR may be lost. This can be avoided when the reserved ARU write address 0x0 is specified inside the ADDR bit field.
Reserved	[31:14]	r	**Reserved** Read as zero, should be written as zero Note: The register ARU_ACCESS can be used either for reading or for writing at the same point in time.

25.3.6.2 Register ARU_DATA_H

GTM_ARU_DATA_H
ARU Access Register Upper Data Word

(00284_H) **Reset Value: 00000000_H**

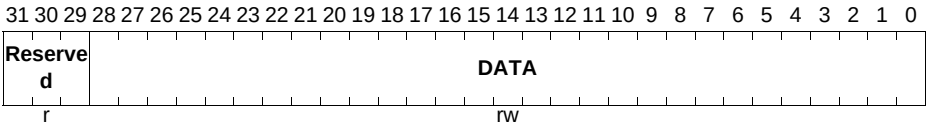


Field	Bits	Type	Description
DATA	[28:0]	rw	**Upper ARU data word** Note: Transfer upper ARU data word addressed by ADDR. The data bits 24 to 52 of an ARU word are mapped to the data bits 0 to 28 of this register
Reserved	[31:29]	r	**Reserved** Read as zero, should be written as zero

25.3.6.3 Register ARU_DATA_L

GTM_ARU_DATA_L
ARU Access Register Lower Data Word

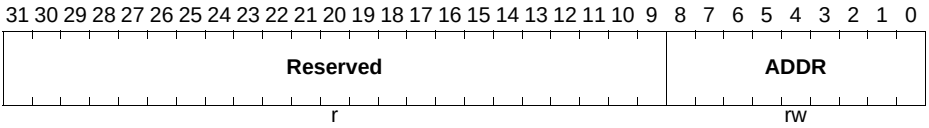
(00288_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
DATA	[28:0]	rw	**Lower ARU data word** Note: Transfer lower ARU data word addressed by ADDR. The data bits 0 to 23 of an ARU word are mapped to the data bits 0 to 23 of this register and the data bits 48 to 52 of an ARU word are mapped to the data bits 24 to 28 of this register when data is read by the CPU. Note: For writing data into the ARU by the CPU the bits 24 to 28 are not transferred to bit 48 to 52 of the ARU word. Only bits 0 to 23 are written to bits 0 to 23 of the ARU word
Reserved	[31:29]	r	**Reserved** Read as zero, should be written as zero

25.3.6.4 Register ARU_DBG_ACCESS0

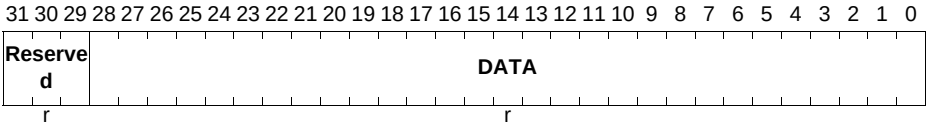
GTM_ARU_DBG_ACCESS0
Debug Access Channel 0 ($0028C_H$) Reset Value: $000001FE_H$



Field	Bits	Type	Description
ADDR	[8:0]	rw	**ARU debugging address** Note: Define address of ARU debugging channel 0.
Reserved	[31:9]	r	**Reserved** Read as zero, should be written as zero

25.3.6.5 Register ARU_DBG_DATA0_H

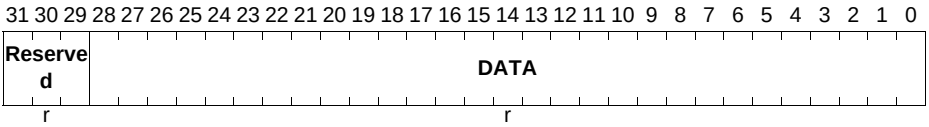
GTM_ARU_DBG_DATA0_H
Debug Access 0 Transfer Register Upper Data Word
(00290_H) Reset Value: 00000000_H



Field	Bits	Type	Description
DATA	[28:0]	r	**Upper debug data word** Note: Transfer upper ARU data word addressed by register DBG_ACCESS0. The data bits 24 to 52 of an ARU word are mapped to the data bits 0 to 28 of this register Note: The interrupt ARU_NEW_DATA0_IRQ is raised if a new data word is available.
Reserved	[31:29]	r	**Reserved** Read as zero, should be written as zero

25.3.6.6 Register ARU_DBG_DATA0_L

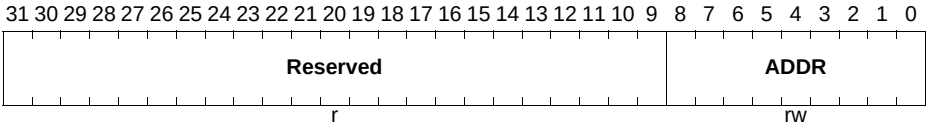
GTM_ARU_DBG_DATA0_L
Debug Access 0 Transfer Register Lower Data Word
(00294_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
DATA	[28:0]	r	**Lower debug data word** Note: Transfer lower ARU data word addressed by register DBG_ACCESS0.The data bits 0 to 23 of an ARU word are mapped to the data bits 0 to 23 of this register and the data bits 48 to 52 of an ARU word is mapped to the data bits 24 to 28 of this register. Note: The interrupt ARU_NEW_DATA0_IRQ is raised if a new data word is available.
Reserved	[31:29]	r	**Reserved** Read as zero, should be written as zero

25.3.6.7 Register ARU_DBG_ACCESS1

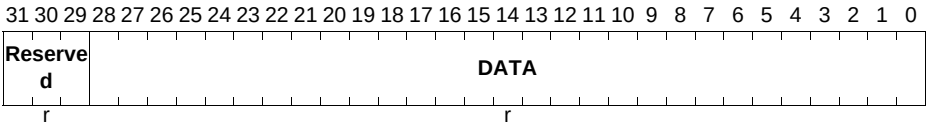
GTM_ARU_DBG_ACCESS1
Debug Access Channel 0 **(00298_H)** **Reset Value: $000001FE_H$**



Field	Bits	Type	Description
ADDR	[8:0]	rw	**ARU debugging address** Note: Define address of ARU debugging channel 1.
Reserved	[31:9]	r	**Reserved** Read as zero, should be written as zero

25.3.6.8 Register ARU_DBG_DATA1_H

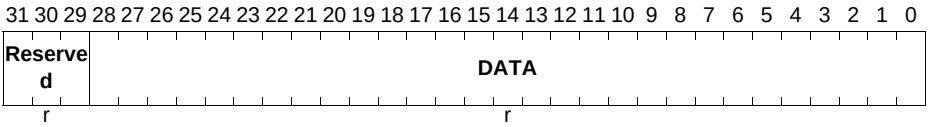
GTM_ARU_DBG_DATA1_H
Debug Access 1 Transfer Register Upper Data Word
($0029C_H$) **Reset Value: 00000000_H**



Field	Bits	Type	Description
DATA	[28:0]	r	**Upper debug data word** Note: Transfer upper ARU data word addressed by register DBG_ACCESS1. The data bits 24 to 52 of an ARU word are mapped to the data bits 0 to 28 of this register Note: The interrupt ARU_NEW_DATA1_IRQ is raised if a new data word is available.
Reserved	[31:29]	r	**Reserved** Read as zero, should be written as zero

25.3.6.9 Register ARU_DBG_DATA1_L

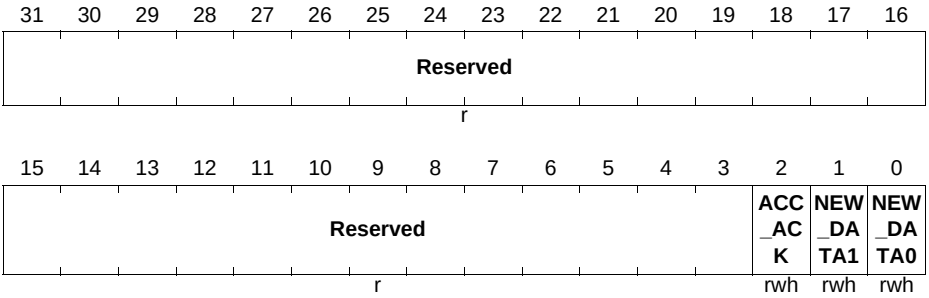
GTM_ARU_DBG_DATA1_L
Debug Access 1 Transfer Register Lower Data Word
($002A0_H$) **Reset Value: 00000000_H**



Field	Bits	Type	Description
DATA	[28:0]	r	**Lower debug data word** Note: Transfer lower ARU data word addressed by register DBG_ACCESS1.The data bits 0 to 23 of an ARU word are mapped to the data bits 0 to 23 of this register and the data bits 48 to 52 of an ARU word is mapped to the data bits 24 to 28 of this register. Note: The interrupt ARU_NEW_DATA1_IRQ is raised if a new data word is available.
Reserved	[31:29]	r	**Reserved** Read as zero, should be written as zero

25.3.6.10 Register ARU_IRQ_NOTIFY

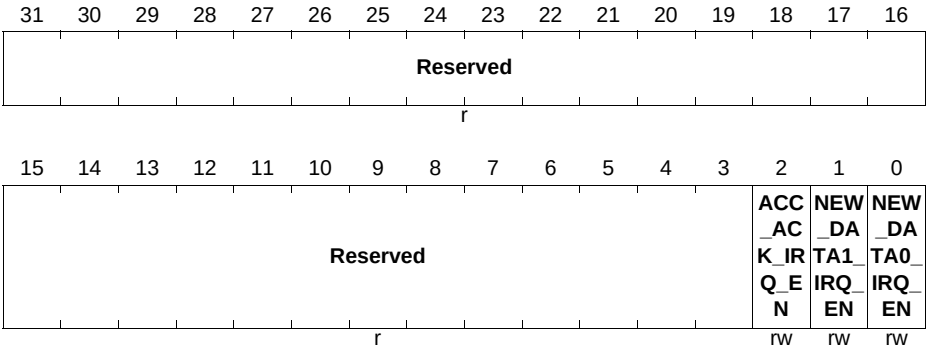
GTM_ARU_IRQ_NOTIFY
ARU Interrupt Notification Register (002A4$_H$) **Reset Value: 00000000$_H$**



Field	Bits	Type	Description
NEW_DATA0	0	rwh	**Data was transferred for addr ARU_DBG_ACCESS0** 0_B No interrupt occurred 1_B ARU_NEW_DATA0_IRQ interrupt was raised by the ARU Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
NEW_DATA1	1	rwh	**Data was transferred for addr ARU_DBG_ACCESS1** 0_B No interrupt occurred 1_B ARU_NEW_DATA1_IRQ interrupt was raised by the ARU Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
ACC_ACK	2	rwh	**AEI to ARU access finished, on read access data are valid** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
Reserved	[31:3]	r	**Reserved** Read as zero, should be written as zero

25.3.6.11 Register ARU_IRQ_EN

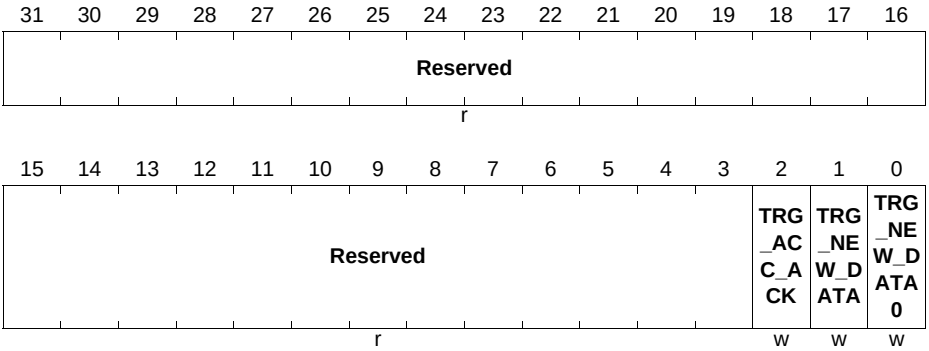
GTM_ARU_IRQ_EN
ARU Interrupt Enable Register (002A8$_H$) Reset Value: 00000000$_H$



Field	Bits	Type	Description
NEW_DATA0_IRQ_EN	0	rw	**ARU_NEW_DATA0_IRQ interrupt enable** 0_B Disable interrupt, interrupt is not visible outside GTM 1_B Enable interrupt, interrupt is visible outside GTM
NEW_DATA1_IRQ_EN	1	rw	**ARU_NEW_DATA1_IRQ interrupt enable** 0_B Disable interrupt, interrupt is not visible outside GTM 1_B Enable interrupt, interrupt is visible outside GTM
ACC_ACK_IRQ_EN	2	rw	**ACC_ACK_IRQ interrupt enable** 0_B Disable interrupt, interrupt is not visible outside GTM 1_B Enable interrupt, interrupt is visible outside GTM
Reserved	[31:3]	r	**Reserved** Read as zero, should be written as zero

25.3.6.12 Register ARU_IRQ_FORCINT

GTM_ARU_IRQ_FORCINT
ARU_NEW_DATA_IRQ Forcing Interrupt Register
(002AC$_H$) **Reset Value: 00000000$_H$**

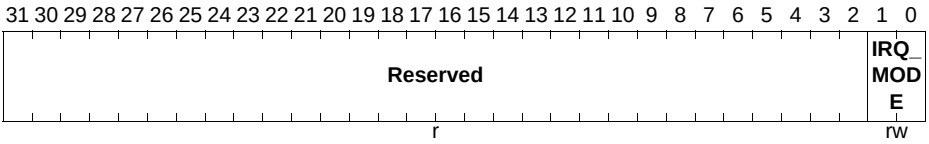


Field	Bits	Type	Description
TRG_NEW_DATA0	0	w	**Trigger new data 0 interrupt** 0_B corresponding bit in status register will not be forced 1_B Assert corresponding field in ARU_IRQ_NOTIFY register Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
TRG_NEW_DATA	1	w	**1 Trigger new data 1 interrupt** 0_B corresponding bit in status register will not be forced 1_B Assert corresponding field in ARU_IRQ_NOTIFY register Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.

Field	Bits	Type	Description
TRG_ACC_ACK	2	w	**Trigger ACC_ACK interrupt** 0_B corresponding bit in status register will not be forced 1_B Assert corresponding field in ARU_IRQ_NOTIFY register Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
Reserved	[31:3]	r	**Reserved** Read as zero, should be written as zero

25.3.6.13 Register ARU_IRQ_MODE

GTM_ARU_IRQ_MODE
IRQ Mode Configuration Register (002B0$_H$) **Reset Value: 00000000$_H$**



Field	Bits	Type	Description
IRQ_MODE	[1:0]	rw	**IRQ mode selection** 00_B Level mode 01_B Pulse mode 10_B Pulse-Notify mode 11_B Single-Pulse mode Note: The interrupt modes are described in **Section 25.2.5**.
Reserved	[31:2]	r	**Reserved** Read as zero, should be written as zero

25.4 Broadcast Module (BRC)

25.4.1 Overview

Since each write address for the submodule channels of the GTM that are able to write to the ARU can only be read by a single module, it is impossible to provide a data stream to different modules in parallel (This statement holds not for sources, which do not invalidate their data after the data were read by any consumer, e.g. DPLL).

To overcome this issue for regular modules, the submodule Broadcast (BRC) enables to duplicate data streams multiple times.

The BRC submodule provides 12 input channels as well as 22 output channels.

In order to clone an incoming data stream, the corresponding input channel can be mapped to zero or more output channels.

When mapped to zero no channel is read.

To destroy an incoming data stream, the EN_TRASHBIN bit inside the BRC_SRCx_DEST register has to be set.

The total number of output channels that are assigned to a single input channel is variable. However, the total number of assigned output channels must be less than or equal to 22.

25.4.2 BRC Configuration

As it is the case with all other submodules connected to the ARU, the input channels can read arbitrary ARU address locations and the output channels provide the broadcast data to fixed ARU write address locations.

The associated write addresses for the BRC submodule are fixed and can be obtained from **Section 25.21**.

The read address for each input channel is defined by the corresponding register BRC_SRCx_ADDR (x: 0…1).

The mapping of an input channel to several output channels is defined by setting the appropriate bits in the register BRC_SRCx_DEST (x: 0…11). Each output channel is represented by a single bit in the register BRC_SRCx_DEST. The address of the output channel is defined in **Section 25.21**.

If no output channel bit is set within a register BRC_SRCx_DEST, no data is provided to the corresponding ARU write address location from the defined read input specified by BRC_SRCx_ADDR. This means that the channel does not broadcast any data and is disabled (reset state).

Besides the possibility of mapping an input channel to several output channels, the bit EN_TRASHBIN of register BRC_SRCx_DEST may be set, which results in dropping an

incoming data stream. In this case the data of an input channel defined by BRC_SRCx_ADDR is consumed by the BRC module and not routed to any succeeding submodule. In consequence, the output channels defined in the register BRC_SRCx_DEST are ignored. Therefore, the bits 0 to 21 are set to zero (0) when trash bin functionality is enabled.

In general, the BRC submodule can work in two independent operation modes. In the first operation mode the data consistency is guaranteed since a BRC channel requests only new data from a source when all destination channels for the BRC have consumed the old data value. This mode is called Data Consistency Mode (DCM).

In a second operation mode the BRC channel always requests data from a source and distributes this data to the destination regardless whether all destinations have already consumed the old data. This mode is called Maximum Throughput Mode (MTM).

MTM ensures, that always the newest available data is routed through the system, while it is not guaranteed data consistency since some of the destination channels can be provided with the old data while some other destination channels are provided with the new data. If this is the case, the Data Inconsistency Detected Interrupt BRC_DID_IRQ[x] is raised but the channel continues to work.

Furthermore in MTM mode it is guaranteed that it is not possible to read a data twice by a read channel. This is blocked.

The channel mode can be configured inside the BRC_SRCx_ADDR register.

To avoid invalid configurations of the registers BRC_SRCx_DEST, the BRC also implements a plausibility check for these configurations. If the software assigns an already used output channel to a second input channel, BRC performs an auto correction of the lastly configured register BRC_SRCx_DEST and it triggers the interrupt BRC_DEST_ERR.

Consider the following example for clarification of the auto correction mechanism. Assume that the following configuration of the 22 lower significant bits for the registers BRC_SRCx_DEST:

BRC_SRC_0_DEST: 00 0000 0000 1000 1000 0000 (binary)

BRC_SRC_1_DEST: 00 0000 0000 0100 0000 0100 (binary)

BRC_SRC_2_DEST: 00 0000 0000 0001 0100 0010 (binary)

BRC_SRC_3_DEST: 00 0000 0000 0010 0001 1001 (binary)

If the software overwrites the value for register BRC_SRC_2_DEST with

BRC_SRC_2_DEST: 00 0000 0000 1001 0010 0010 (binary)

(changed bits are underlined), then the BRC releases a BRC_DEST_ERR interrupt since bit 11 is already assigned in register BRC_SRC_0_DEST. The auto correction forces bit 11 to be cleared. The modifications of the bits 5 and 6 are accepted, since there is no violation with previous configurations. So the result of the write access mentioned above results in the following modified register configuration:

BRC_SRC_2_DEST: 00 0000 0000 0001 0010 0010 (binary)

For debug purposes, the interrupt BRC_DEST_ERR can also be released by writing to register BRC_IRQ_FORCINT. Nevertheless, the interrupt has to be enabled to be visible outside of the GTM.

25.4.3 BRC Interrupt Signals

Interrupt signals are defined in following table:

Table 25-11 BRC Interrupts

Signal	Description
BRC_DEST_ERR_IRQ	Indicating configuration errors for BRC module
BRC_DID_IRQ[x]	Data inconsistency occurred in MTM mode (x=0-11)

25.4.4 BRC Configuration Registers Overview

Following table shows a conclusion of configuration registers address offsets and initial values.

Table 25-12 BRC Registers

Register Name	Description	Details in Section
BRC_SRCx_ADDR	Read address for input channel x (x=0-11)	Section 25.4.5.1
BRC_SRCx_DEST	Destination channels for input channel x (x=0-11)	Section 25.4.5.2
BRC_IRQ_NOTIFY	BRC Interrupt notification register	Section 25.4.5.3
BRC_IRQ_EN	BRC Interrupt enable register	Section 25.4.5.4
BRC_IRQ_EIRQ_EN	BRC Error interrupt enable register	Section 25.4.5.8
BRC_IRQ_FORCINT	Register for forcing the BRC_DEST_ERR interrupt	Section 25.4.5.5
BRC_RST	Software reset	Section 25.4.5.7
BRC_IRQ_MODE	IRQ mode configuration register	Section 25.4.5.6

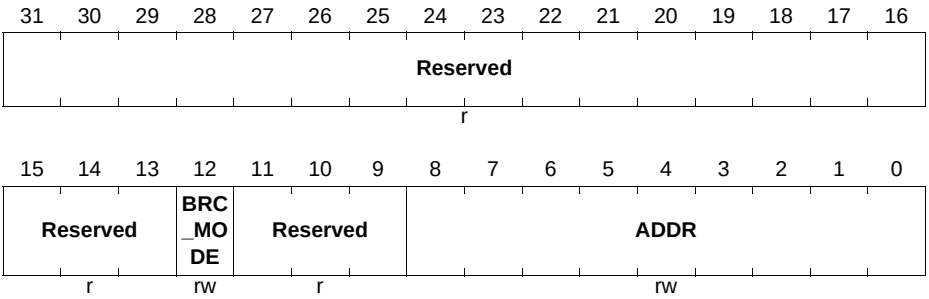
25.4.5 BRC Configuration Registers Description

All of the following registers are 32-bit only accessible.

25.4.5.1 Register BRC_SRCx_ADDR (x=0-11)

GTM_BRC_SRCx_ADDR (x=0-11)
Read Address For Input Channel x

(00400_H+x*08_H) **Reset Value: $000001FE_H$**



Field	Bits	Type	Description
ADDR	[8:0]	rw	**Source ARU address** Define an ARU read address used as data source for input channel x (x011)
Reserved	[11:9]	r	**Reserved** Read as zero, should be written as zero
BRC_MODE	12	rw	**BRC Operation mode select** 0_B Consistency Mode (DCM) selected 1_B Maximum Throughput Mode (MTM) selected Note: this bit field is only writable if channel is disabled.
Reserved	[31:13]	r	**Reserved** Read as zero, should be written as zero

25.4.5.2 Register BRC_SRCx_DEST (x:0…11)

GTM_BRC_SRCx_DEST (x=0-11)
Destination Channels For Input Channel x

(00404_H+x*08_H) **Reset Value: 00000000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved									EN_TRASHBIN	EN_DEST21	EN_DEST20	EN_DEST19	EN_DEST18	EN_DEST17	EN_DEST16

DID_ENx (x = 0-11)	x+1	rw	**BRC_DIDx_EIRQ error interrupt enable** 0_B Disable error interrupt, error interrupt is not visible outside GTM 1_B Enable error interrupt, error interrupt is visible outside GTM
Reserved	[31:13]	r	**Reserved** Read as zero, should be written as zero

25.5 First In First Out Module (FIFO)

25.5.1 Overview

The FIFO unit is the storage part of the FIFO submodule. The F2A described in **Section 25.7** and the AFD described in **Section 25.6** implement the interface part of the FIFO submodule to the ARU and the AEI bus. Each FIFO unit embeds eight logical FIFOs. These logical FIFOs are configurable in the following manner:

- FIFO size (defines start and end address)
- FIFO operation modes (normal mode or ring buffer operation mode)
- Fill level control / memory region read protection

Each logical FIFO represents a data stream between the submodules of the GTM and the microcontroller connected to AFD submodule (see **Section 25.6**). The FIFO RAM counts 1K words, where the word size is 29 bit. This gives the freedom to program or receive 24 bit of data together with the five control bits inside an ARU data word.

The FIFO unit provides three ports for accessing its content. One port is connected to the F2A interface, one port is connected to the AFD interface and one port has its own AEI bus interface.

The AFD interface has always the highest priority. Accesses to the FIFO from AFD interface and direct AEI interface in parallel - which means at the same time - is not possible, because both interfaces are driven from the same AEI bus interface of the GTM.

The priority between F2A and direct AEI interface can be defined by software. This can be done by using the register FIFO0_CHx_CTRL for all FIFO channels of the submodule.

The FIFO is organized as a single RAM that is also accessible through the FIFO AEI interface connected to one of the FIFO ports. To provide the direct RAM access, the RAM is mapped into the address space of the microcontroller.

After reset, the FIFO RAM isn't initialized.

The FIFO channels can be flushed individually. Each of the eight FIFO channels can be used whether in normal FIFO operation mode or in ring buffer operation mode.

Beside the possibility of flushing each FIFO channel directly, a write access to FIFOi_CHx_END_ADDR or to FIFOi_CHx_START_ADDR will also flush the regarding channel which means that the read and write pointer and also the fill level of the regarding channel will be reset. In consequence of this existing data in the concerned FIFO channel are not longer valid- thereafter the channel is empty.

25.5.2 Operation Modes

25.5.2.1 Normal Operation Mode

In normal FIFO operation mode the content of the FIFO is written and read in first-in first-out order, where the data is destroyed after it is delivered to the system bus or the F2A submodule (see **Section 25.7**).

The upper and lower watermark registers (registers FIFO0_CHx_UPPER_WM and FIFO0_CHx_LOWER_WM) are used for controlling the FIFO's fill level. If the fill level declines the lower watermark or it exceeds the upper watermark, an interrupt signal is triggered by the FIFO submodule if enabled inside the FIFO0_IRQ_EN.

The interrupt signals are sending to the Interrupt Concentrator Module (ICM) (see **Section 25.18**). The ICM can also initiate specific DMA transfers.

25.5.2.2 Ring Buffer Operation Mode

The ring buffer mode is a powerful tool to provide a continuous data or configuration stream to the other GTM submodules without CPU interaction. In ring buffer mode the FIFO provides a continuous data stream to the F2A submodule. The first word of the FIFO is delivered first and after the last word is provided by the FIFO to the ARU, the first word can be obtained again.

If in ring buffer mode the read pointer reaches the write pointer it will be set again to the configured start address. So the read pointer always rotates cyclic between the configured start address of the regarding FIFO channel (first written data) and the write pointer which points to the last written data of the channel.

It is possible to add data via the AEI to FIFO interface (AFD) to the FIFO channel while running in ring buffer mode. The new written data will be added in the next ring buffer cycle.

It is recommended to fill the FIFO channel first before enabled the data stream in the FIFO to ARU interface (F2A).

There could be the requirement that the user must be able to change some data inside the continuous data stream to the GTM submodules or system bus. This is possible through direct memory access provided by the FIFO AEI interface.

25.5.3 FIFO Interrupt Signals

Interrupt signals are defined in following table:

Table 25-13 FIFO Interrupt Signals

Signal	Description
FIFOi_CH[x]_EMPTY	Indicating empty FIFOi x (x:0…7) was reached
FIFOi_CH[x]_FULL	Indicating full FIFOi x (x:0…7) was reached
FIFOi_CHx_LOWER_WM	Indicating FIFOi x (x:0…7) reached lower watermark.
FIFOi_CHx_UPPER_WM	Indicating FIFOi x (x:0…7) reached upper watermark.

25.5.4 FIFOi Configuration Registers Overview

The following table shows a conclusion of configuration registers address offsets and initial values:

Table 25-14 FIFOi Configuration Registers Overview

Register Name	Description	Details in Section
FIFOi_CHx_CTRL	FIFOi Channel x control register (x: 0…7)	Section 25.5.5.1
FIFOi_CHx_END_ADDR	FIFOi Channel x end address register (x: 0…7)	Section 25.5.5.2
FIFOi_CHx_START_ADDR	FIFOi Channel x start address register (x: 0…7)	Section 25.5.5.3
FIFOi_CHx_UPPER_WM	FIFOi Channel x upper watermark register (x: 0…7)	Section 25.5.5.4
FIFOi_CHx_LOWER_WM	FIFOi Channel x lower watermark register (x: 0…7)	Section 25.5.5.5
FIFOi_CHx_STATUS	FIFOi Channel x status register (x: 0…7)	Section 25.5.5.6
FIFOi_CHx_FILL_LEVEL	FIFOi Channel x fill level register (x: 0…7)	Section 25.5.5.7
FIFOi_CHx_WR_PTR	FIFOi Channel x write pointer register (x: 0…7)	Section 25.5.5.8
FIFOi_CHx_RD_PTR	FIFOi Channel x read pointer register (x: 0…7)	Section 25.5.5.9
FIFOi_CHx_IRQ_NOTIFY	FIFOi x interrupt notification register (x: 0…7)	Section 25.5.5.10

Table 25-14 FIFOi Configuration Registers Overview (cont'd)

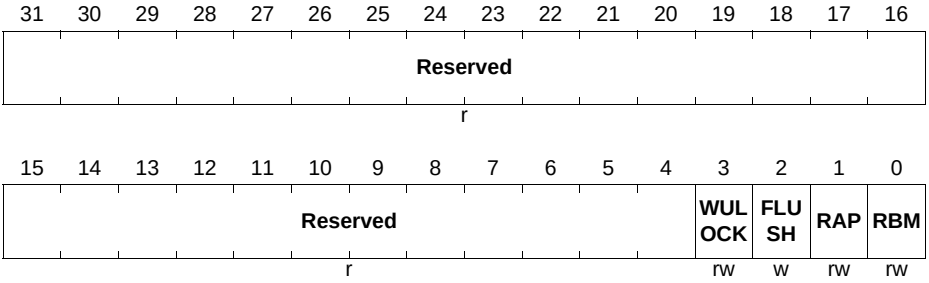
Register Name	Description	Details in Section
FIFOi_CHx_IRQ_EN	FIFOi x interrupt enable register (x: 0…7)	Section 25.5.5.11
FIFOi_CHx_EIRQ_EN	FIFO x Error interrupt enable register	Section 25.5.5.14
FIFOi_CHx_IRQ_FORCINT	FIFOi x register to force interrupt by software (x: 0…7)	Section 25.5.5.12
FIFOi_CHx_IRQ_MODE	FIFOi x IRQ mode control register (x: 0…7)	Section 25.5.5.13

25.5.5 FIFOi Configuration Registers Description

All of the following registers are 32-bit only accessible.

25.5.5.1 Register FIFOi_CHx_CTRL (x:0…7)

GTM_FIFO0_CHx_CTRL (x=0-7)
FIFO0 Channel x Control Register(18400_H+x*40_H) **Reset Value: 00000000_H**



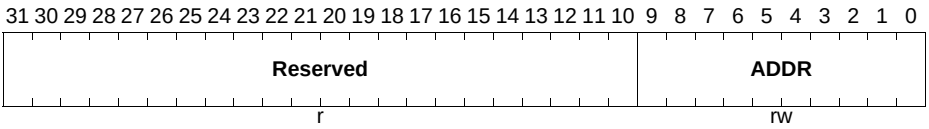
Field	Bits	Type	Description
RBM	0	rw	**Ring buffer mode enable** 0_B Normal FIFO operation mode 1_B Ring buffer mode
RAP	1	rw	**RAM access priority** 0_B FIFO ports have higher access priority than AEI-IF 1_B AEI-IF has higher access priority than FIFO ports Note: RAP bit is only functional in register FIFOi_CHx_CTRL. The priority is defined for all FIFO channels there
FLUSH	2	w	**FIFO Flush control** 0_B Normal operation 1_B Execute FIFO flush (bit is automatically cleared after flush). Note: A FIFO Flush operation resets the FIFOi_CHx_FILL_LEVEL, FIFOi_CHx_WR_PTR and FIFOi_CHx_RD_PTR registers to their initial values.

Field	Bits	Type	Description
WULOCK	3	rw	**RAM write unlock Enable/disable direct RAM write access to the memory mapped FIFO region** 0_B Direct RAM write access disabled 1_B Direct RAM write access enabled Note: Only the bit WULOCK of register FIFOi_CH0_CTRL enables/disables the direct RAM write access for all FIFO channels (whole FIFO RAM). The WULOCK bits of the other channels are writable but have no effect.
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

25.5.5.2 Register FIFOi_CHx_END_ADDR (x:0…7)

GTM_FIFO0_CHx_END_ADDR (x=0-7)
FIFO0 Channel x End Address Register

(18404_H+x*40_H) **Reset Value: 00000XXX$_H$**

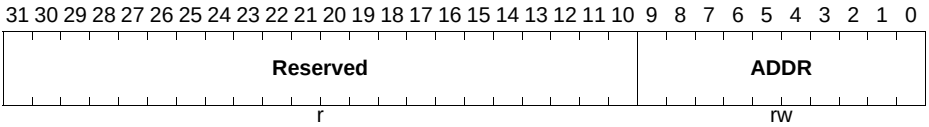


Field	Bits	Type	Description
ADDR	[9:0]	rw	**End address for FIFOi channel x, (x:0…7)** *Note: Note: value for ADDR is calculated as ADDR = 128*(x+1)−1.* *Note: A write access will flush the regarding channel.*
Reserved	[31:10]	r	**Reserved** Read as zero, should be written as zero

25.5.5.3 Register FIFOi_CHx_START_ADDR (x:0…7)

GTM_FIFO0_CHx_START_ADDR (x=0-7)
FIFO0 Channel x Start Address Register

(18408_H+x*40_H) **Reset Value: 00000XXX$_H$**

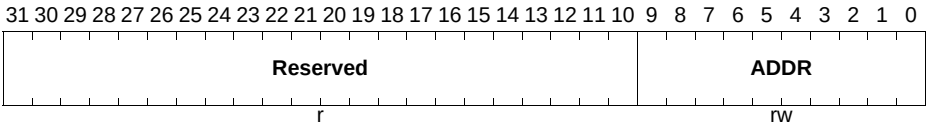


Field	Bits	Type	Description
ADDR	[9:0]	rw	**Start address for FIFOi channel x, (x07)** *Note: Note: Initial value for ADDR is calculated as ADDR = 128*x* *Note: A write access will flush the regarding channel.*
Reserved	[31:10]	r	**Reserved** Read as zero, should be written as zero

25.5.5.4 Register FIFOi_CHx_UPPER_WM (x:0…7)

GTM_FIFO0_CHx_UPPER_WM (x=0-7)
FIFO0 Channel x Upper Watermark Register

($1840C_H$+x*40_H) **Reset Value: 00000060$_H$**

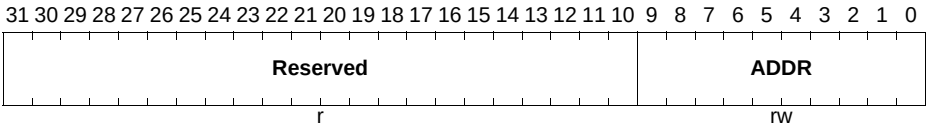


Field	Bits	Type	Description
ADDR	[9:0]	rw	**Upper watermark address** Note: The upper watermark is configured as a relative fill level of the FIFOi. ADDR must be in range: 0 <= ADDR <= FIFOi_CHx_END_ADDR − FIFOi_CHx_START_ADDR. Initial value for ADDR is defined as ADDR = 0x60.

Field	Bits	Type	Description
Reserved	[31:10]	r	**Reserved** Read as zero, should be written as zero

25.5.5.5 Register FIFOi_CHx_LOWER_WM (x:0…7)

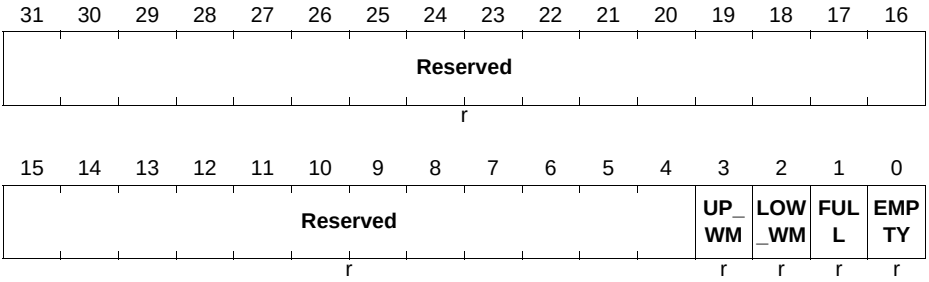
GTM_FIFO0_CHx_LOWER_WM (x=0-7)
FIFO0 Channel x Lower Watermark Register
(18410_H+x*40_H) **Reset Value: 00000020_H**



Field	Bits	Type	Description
ADDR	[9:0]	rw	**Lower watermark address** Note: The lower watermark is configured as a relative fill level of the FIFOi. ADDR must be in range: 0 <= ADDR <= FIFOi_CHx_END_ADDR − FIFOi_CHx_START_ADDR. Initial value for ADDR is defined as ADDR = 0x20.
Reserved	[31:10]	r	**Reserved** Read as zero, should be written as zero

25.5.5.6 Register FIFOi_CHx_STATUS (x:0…7)

GTM_FIFO0_CHx_STATUS (x=0-7)
FIFO0 Channel x Status Register (18414_H+x*40_H) **Reset Value: 00000005_H**

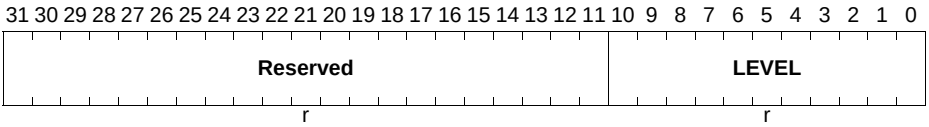


Field	Bits	Type	Description
EMPTY	0	r	**FIFO is empty** 0_B Fill level > 0 1_B Fill level = 0 Note: Bit only applicable in normal mode
FULL	1	r	**FIFO is full** 0_B Fill level < FIFOi_CHx_END_ADDR − FIFOi_CHx_START_ADDR + 1 1_B Fill level = FIFOi_CHx_END_ADDR − FIFOi_CHx_START_ADDR + 1 Note: Bit only applicable in normal mode
LOW_WM	2	r	**Lower watermark reached** 0_B Fill level > lower watermark 1_B Fill level <= lower watermark Note: Bit only applicable in normal mode
UP_WM	3	r	**Upper watermark reached** 0_B Fill level < upper watermark 1_B Fill level >= upper watermark Note: Bit only applicable in normal mode
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

25.5.5.7 Register FIFOi_CHx_FILL_LEVEL (x:0…7)

GTM_FIFO0_CHx_FILL_LEVEL (x=0-7)
FIFO0 Channel x Fill Level Register

(18418_H+x*40_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
LEVEL	[10:0]	r	**Fill level of the current FIFO** Note: LEVEL is in range: 0 ≤ LEVEL ≤ FIFOi_CHx_END_ADDR − FIFOi_CHx_START_ADDR + 1. Register content is compared to the upper and lower watermark values for this channel to detect watermark over- and underflow.
Reserved	[31:11]	r	**Reserved** Read as zero, should be written as zero

25.5.5.8 Register FIFOi_CHx_WR_PTR (x:0…7)

GTM_FIFO0_CHx_WR_PTR (x=0-7)
FIFO0 Channel x Write Pointer Register

($1841C_H$+x*40_H) **Reset Value: 00000XXX$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																						ADDR									
r																						r									

Field	Bits	Type	Description
ADDR	[9:0]	r	**Position of the write pointer** Note: ADDR must be in range 0 ≤ ADDR ≤ 1023. Initial value for ADDR is defined as ADDR = FIFOi_CHx_START_ADDR
Reserved	[31:10]	r	**Reserved** Read as zero, should be written as zero

25.5.5.9 Register FIFOi_CHx_RD_PTR (x:0…7)

GTM_FIFO0_CHx_RD_PTR (x=0-7)
FIFO0 Channel x Read Pointer Register

(18420_H+x*40_H) **Reset Value: 00000XXX$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																						ADDR									
r																						r									

Field	Bits	Type	Description
ADDR	[9:0]	r	**Position of the read pointer** Note: ADDR must be in range 0 ≤ ADDR ≤ 1023. Initial value for ADDR is defined as ADDR = FIFOi_CHx_START_ADDR
Reserved	[31:10]	r	**Reserved** Read as zero, should be written as zero

25.5.5.10 Register FIFOi_CHx_IRQ_NOTIFY (x:0…7)

GTM_FIFO0_CHx_IRQ_NOTIFY (x=0-7)
FIFO0 Channel x Interrupt Notification Register

(18424_H+x*40_H) **Reset Value: 00000005_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

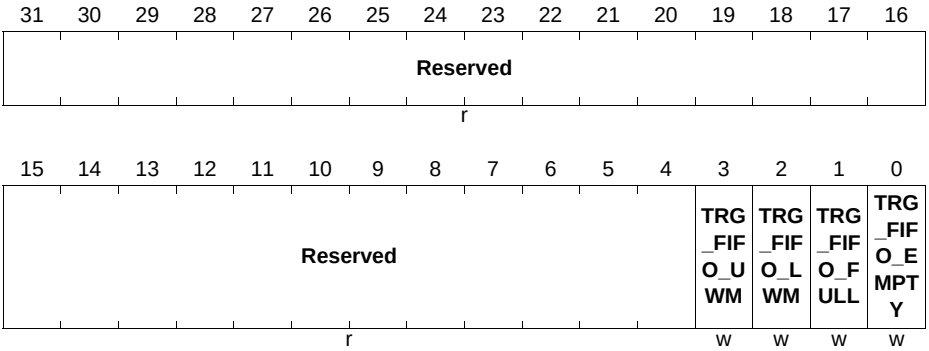
r												rw	rw	rw	rw

Field	Bits	Type	Description
FIFO_EMPTY_IRQ_EN	0	rw	**interrupt enable** 0_B Disable interrupt, interrupt is not visible outside GTM. 1_B Enable interrupt, interrupt is visible outside GTM.
FIFO_FULL_IRQ_EN	1	rw	**interrupt enable** See bit 0
FIFO_LWM_IRQ_EN	2	rw	**interrupt enable** See bit 0
FIFO_UWM_IRQ_EN	3	rw	**interrupt enable** See bit 0
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

25.5.5.12 Register FIFOi_CHx_IRQ_FORCINT

GTM_FIFO0_CHx_IRQ_FORCINT (x=0-7)
FIFO0 Channel x Force Interrupt By Software Register
(1842C$_H$+x*40$_H$) **Reset Value: 00000000$_H$**

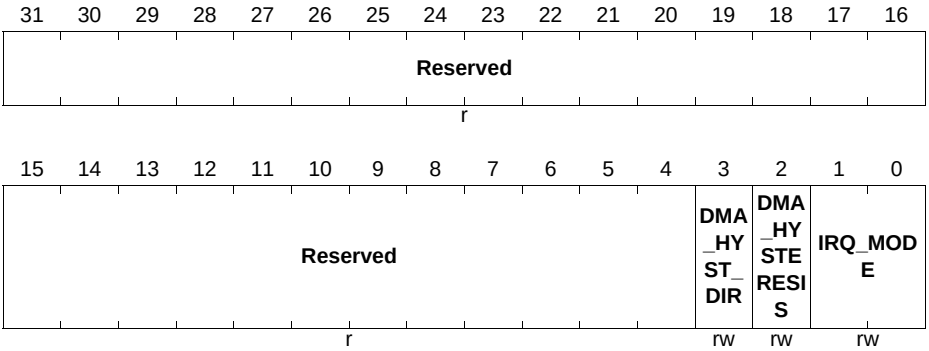


Field	Bits	Type	Description
TRG_FIFO_EMPTY	0	w	**Force interrupt of FIFO empty status** 0_B corresponding bit in status register will not be forced 1_B Assert corresponding field in FIFOi_CHi_IRQ_NOTIFY register Note: This bit is cleared automatically after write.
TRG_FIFO_FULL	1	w	**Force interrupt of FIFO full status** See bit 0
TRG_FIFO_LWM	2	w	**Force interrupt of lower watermark** See bit 0
TRG_FIFO_UWM	3	w	**Force interrupt of upper watermark** See bit 0
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

25.5.5.13 Register FIFOi_CHx_IRQ_MODE

GTM_FIFO0_CHx_IRQ_MODE (x=0-7)
FIFO0 Channel x IRQ Mode Control Register

(18430_H+x*40_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
IRQ_MODE	[1:0]	rw	**IRQ mode selection** 00_B Level mode 01_B Pulse mode 10_B Pulse-Notify mode 11_B Single-Pulse mode Note: The interrupt modes are described in Section 25.2.5.
DMA_HYSTERESIS	2	rw	**Enable DMA hysteresis mode** 0_B Disable FIFO hysteresis for DMA access. 1_B Enable FIFO hysteresis for DMA access.

Field	Bits	Type	Description
DMA_HYST_DIR	3	rw	**DMA direction in hysteresis mode** 0_B DMA direction read in hysteresis mode. 1_B DMA direction write in hysteresis mode. Note: In the case of DMA writing data to a FIFO the DMA requests must be generated by the lower watermark. If the DMA hysteresis is enabled, the FIFO does not generate a new DMA request until the upper watermark is reached. Note: In the case of DMA reading data from FIFO the DMA requests must be generated by the upper watermark. If the DMA hysteresis is enabled, the FIFO does not generate a new DMA request until the lower watermark is reached.
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

25.5.5.14 Register FIFOi_CHx_EIRQ_EN (x:0…7)

GTM_FIFO0_CHx_EIRQ_EN (x=0-7)
FIFO0 Channel x Error Interrupt Enable Register
(18434_H+x*40_H) **Reset Value: 00000000_H**

FIFO_UWM_EIRQ_EN	3	rw	**Interrupt enable** See bit 0
Reserved	[31:4]	r	**reserved** Note: read as zero, should be written as zero

25.6 AEI to FIFO Data Interface (AFD)

25.6.1 Overview

The AFD submodule implements a data interface between the AEI bus and the FIFO submodule, which consists of eight logical FIFO channels.

The AFD submodule provides one buffer registers that are dedicated to the logical channels of the FIFO. Access to the corresponding FIFO channel is given by reading or writing this buffer registers AFD0_CHx_BUF_ACC.

An AEI write access to the buffer register where the corresponding FIFO channel is full will be ignored. The data will be lost.

An AEI read access to the buffer register where the corresponding FIFO channel is empty will be served with zero data.

25.6.2 AFD Register overview

Following table shows a conclusion of configuration registers address offsets and initial values.

Table 25-15 AFD Register overview

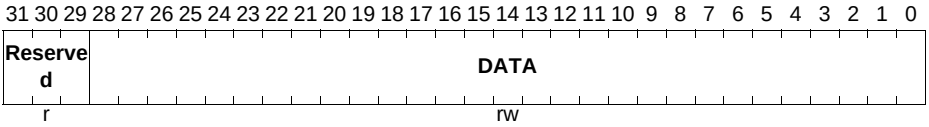
Register Name	Description	Details in Section
AFD0_CHx_BUF_ACC	AFD FIFO x buffer access register (x: 0…7)	Section 25.6.3.1

25.6.3 AFD Register description

All of the following registers are 32-bit only accessible.

25.6.3.1 Register AFD0_CHx_BUF_ACC (x:0...7)

GTM_AFD0_CHx_BUF_ACC (x=0-7)
AFD0 FIFO0 Channel x Buffer Access Register
(18080_H+x*10_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
DATA	[28:0]	rw	**Read/write data from/to FIFO**
Reserved	[31:29]	r	**Reserved** Read as zero, should be written as zero

25.7 FIFO to ARU Unit (F2A)

25.7.1 Overview

The F2A is the interface between the ARU and the FIFO submodule. Since the data width of the ARU (ARU word) is 53 bit (two 24 bit values and five control bits) and the data width of the FIFO is only 29 bit, the F2A has to distribute the data from and to the FIFO channels in a configurable manner.

The data transfer between FIFO and ARU is organized with eight different streams that are connected to the eight different channels of the corresponding FIFO module. A stream represents a data flow from/to ARU to/from the FIFO via the F2A.

The general definition of 'channels' and 'streams' in the ARU context is done in **Section 25.2.3**.

Each FIFO channel can act as a write stream (data flow from FIFO to ARU) or as a read stream (data flow from ARU to FIFO).

Within these streams the F2A can transmit/receive the lower, the upper or both 24 bit values of the ARU together with the ARU control bits according to the configured transfer modes as described in **Section 25.7.2**

25.7.2 Transfer modes

The F2A unit provides several transfer modes to map 29 bit data of the FIFO from/to 53 bit data of the ARU. E.g. it is configurable that the 24 bit FIFO data is written to the lower ARU data entry (means bits 0 to 23) or to the higher 24 bit ARU data entry (means bits 24 to 47). Bits 24 to 28 of the FIFO data entry (the five control bits) are written/read in both cases to/from bits 48 to 52 of the ARU entry.

When both values of the ARU have to be stored in the FIFO the values are stored behind each other inside the FIFO if the FIFO is not full.

If there is only space for one 24 bit data word plus the five control bits, the F2A transfers one part of the 53 bits first and than waits for transferring the second part before new data is requested from the ARU.

When two values from the FIFO have to be written to one ARU location the words have to be located behind each other inside the FIFO.

The transfer to ARU is only established when both parts could be read out of the FIFO otherwise if only one 29 bit word was provided by the FIFO the F2A waits until the second part is available before the data is made available at the ARU.

Figure 25-16 shows the data ordering of the FIFO when both ARU values must be transferred between ARU and FIFO.

When reading from the ARU the F2A first writes the lower word to the FIFO.

In case of writing to the ARU the F2A reads the lower word first from the FIFO, thus the lower word must be written first to the FIFO through the AFD interface.

Please note, that the five control bits (bits 48 to 52 of the ARU data word) are duplicated as bit 24 to 28 of both FIFO words in case of reading from ARU.

In the case of writing to the ARU, bits 24 to 28 of the last written FIFO word (the higher ARU word) are copied to bits 48 to 52 of the corresponding ARU location.

The transfer modes can be configured with the TMODE bits of registers F2A0_CHx_STR_CFG (x: 0…7).

25.7.2.1 Data transfer of both ARU words between ARU and FIFO

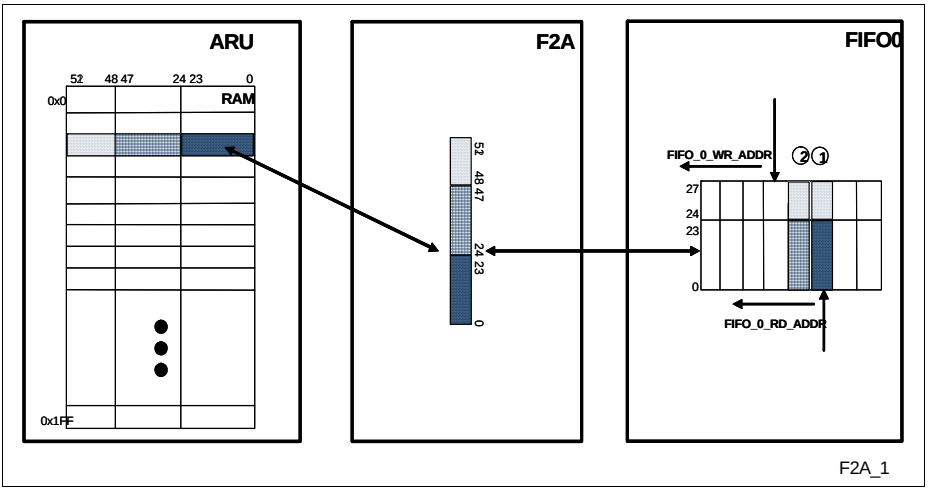


Figure 25-16 Data transfer of both ARU words between ARU and FIFO

25.7.3 F2A Configuration Registers Overview

The following table shows a conclusion of configuration registers address offsets and initial values.

Table 25-16 F2A Configuration Registers Overview

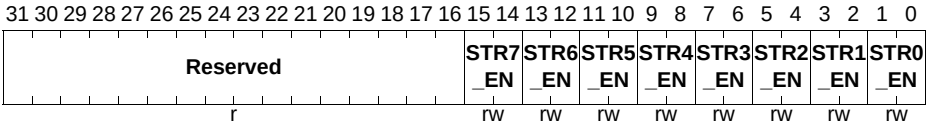
Register name	Description	Details in Section
F2Ai_ENABLE	F2A stream activation register	Section 25.7.4.1
F2Ai_CHx_ARU_RD_FIFO	F2A read channel address register (x: 0…7)	Section 25.7.4.2
F2Ai_CHx_STR_CFG	F2A stream x configuration register (x: 0…7)	Section 25.7.4.3

25.7.4 F2A Configuration Registers description

All of the following registers are 32-bit only accessible.

25.7.4.1 Register F2Ai_ENABLE

GTM_F2A0_ENABLE
F2A0 Stream Activation Register (18040_H) Reset Value: 00000000_H



Field	Bits	Type	Description
STR0_EN	[1:0]	rw	**Enable/disable stream 0** Write of following double bit values is possible: 00_B Don't care, bits 1:0 will not be changed 01_B Stream 0 is disabled and internal states are reset 10_B Stream 0 is enabled 11_B Don't care, bits 1:0 will not be changed Read of following double values means: 00_B Stream disabled 11_B Stream enabled
STR1_EN	[3:2]	rw	**Enable/disable stream 1** See bits 1:0

Field	Bits	Type	Description

DIR	18	rw	**Data transfer direction** 0_B Transport from ARU to FIFO 1_B Transport from FIFO to ARU Note: This bit is only writable if the corresponding enable bit STRx_EN of register F2A_ENABLE is cleared.
Reserved	[31:19]	r	**Reserved** Read as zero, should be written as zero

25.8 Clock Management Unit (CMU)

25.8.1 Overview

The Clock Management Unit (CMU) is responsible for clock generation of the counters and of the GTM. The CMU consists of three subunits that generate different clock sources for the whole GTM. **Figure 25-17** shows a block diagram of the CMU.

The Configurable Clock Generation (CFGU) subunit provides eight dedicated clock sources for the following GTM submodules: TIM, ATOM, TBU, and MON. Each instance of such a submodule can choose an arbitrary clock source, in order to specify wide-ranging time bases.

The Fixed Clock Generation (FXU) subunit generates predefined non-configurable clocks CMU_FXCLK[y] (y: 0…4) for the TOM submodules and the MON submodule. The CMU_FXCLK[y] signals are derived from the CMU_GCLK_EN signal generated by the Global Clock Divider. The dividing factors are defined as 2^0, 2^4, 2^8, 2^{12}, and 2^{16}.

The External Clock Generation (EGU) subunit is able to generate up to three GTM external clock signals visible at CMU_ECLK[z] (z: 0…2) with a duty cycle of about 50%.

The clock source signals CMU_CLK[x] (x: 0…7) and CMU_FXCLK[y] are implemented in form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use the SYS_CLK signal.

The four configurable clock signals CMU_CLK0, CMU_CLK1, CMU_CLK6 and CMU_CLK7 are connected to the TIM filter counters.

25.8.1.1 CMU Block Diagram

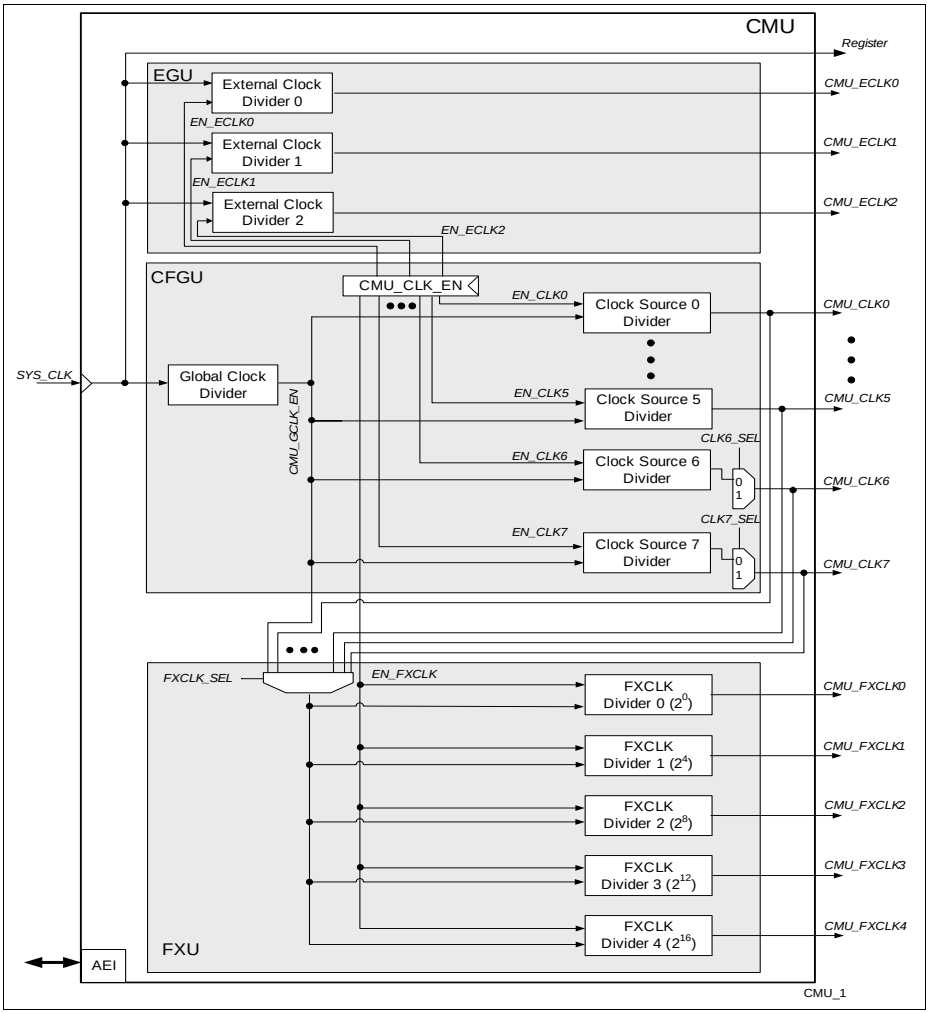

Figure 25-17 CMU Block Diagram

25.8.2 Global Clock Divider

The subblock Global Clock Divider can be used to divide the GTM global input clock signal SYS_CLK into a common subdivided clock signal.

The divided clock signal of the subblock Global Clock Divider is implemented as an enable signal that enables dedicated clocks from the SYS_CLK signal to generate the user specified divided clock frequency.

The resulting fractional divider (Z/N) specified through equation:

TCMU_GCLK_EN=(Z/N)*TSYS_CLK

is implemented according the following algorithm

(Z: CMU_GCLK_NUM(23:0); N: CMU_GCLK_DEN(23:0); Z,N >0):

(1) Set remainder (r), operand1 (OP1) and operand2 (OP2) register during init-phase (with implicit conversion to signed):

r=Z, OP1=N, OP2=N-Z;

(2) After leaving init-phase (at least one CMU_CLK[x] has been enabled) the sign of remainder r for each SYS_CLK cycle will be checked:

(3) If r>0 keep updating remainder and keep CMU_GCLK_EN='0':

r=r-OP1;

(4) If r<0 update remainder and set CMU_GCLK_EN='1':

r=r-OP2;

After at most (Z/N+1) subtractions (3) there will be a negative r and an active phase of the generated clock enable (for one cycle) will be triggered (4). The remainder r is a measure for the distance to a real Z/N clock and will be regarded for the next generated clock enable cycle phase. The new r value will be r=r+(Z-N). In the worst case the remainder r will sum up to an additional cycle in the generated clock enable period after Z-cycles. In the other cases equally distributed additional cycles will be inserted for the generated clock enable. If Z is an integer multiple of N no additional cycles will be included for the generated clock enable at all.

Note that for a better resource sharing all arithmetic has been reduced to subtractions and the initialization of the remainder r uses the complement of (Z-N).

25.8.3 Configurable Clock Generation Subunit (CFGU)

The CMU subunit CFGU provides up to eight configurable clock divider blocks that divide the common CMU_GCLK_EN signal into dedicated enable signals for the GTM subblocks.

The configuration of the eight different clock signals CMU_CLK[x] (x: 0…7) always depends on the configuration of the global clock enable signal CMU_GCLK_EN. Additionally, each clock source has its own configuration data, provided by the control register CMU_CLK_x_CTRL (x: 0…7).

According to the configuration of the Global Clock Divider, the configuration of the Clock Source x Divider is done by setting an appropriate value in the bit field CLK_CNT[x] of the register CMU_CLK_x_CTRL.

The frequency $f_x = 1/T_x$ of the corresponding clock enable signal CMU_CLK[x] can be determined by the unsigned representation of CLK_CNT[x] of the register CMU_CLK_x_CTRL in the following way:

TCMU_CLK[x]=(CLK_CNT[x]+1)*TCMU_GCLK_EN

The corresponding wave form is shown in **Figure 25-18**.

Each clock signal CMU_CLK[x] can be enabled individually by setting the appropriate bit field EN_CLK[x] in the register CMU_CLK_EN. Except for CMU_CLK6 and CMU_CLK7 individual enabling and disabling is active only if CLK6_SEL and CLK7_SEL is cleared.

Alternatively, clock source six and seven (CMU_CLK6 and CMU_CLK7) may provide the signal SUB_INC1 and SUB_INC2 coming from submodule DPLL as clock enable signal depending on the bit field CLK6_SEL of the register CMU_CLK_6_CTRL and on the bit field CLK7_SEL of the register CMU_CLK_7_CTRL.

To avoid unexpected behaviour of the hardware, the configuration of a register CMU_CLK_x_CTRL can only be changed, when the corresponding clock signal CMU_CLK[x] is disabled.

Further, any changes to the registers CMU_GCLK_NUM and CMU_GCLK_DEN can only be performed, when all clock enable signals CMU_CLK[x] and the EN_FXCLK bit inside the CMU_CLK_EN register are disabled.

The clock source signals CMU_CLK[x] (x:0…7) and CMU_FXCLK[y] are implemented in form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use the SYS_CLK signal.

The hardware guarantees that all clock signals CMU_CLK[x], which were enabled simultaneous, are synchronized to each other. Simultaneous enabling does mean that the bits EN_CLK[x] in the register CMU_CLK_EN are set by the same write access.

After EN_CLK[x] entries in CMU_CLK_EN have been disabled, internal states of these EN_CLK[x] paths will be reset to start with the same behaviour after enable.

25.8.4 Wave Form of Generated Clock Signal CMU_CLK[x]

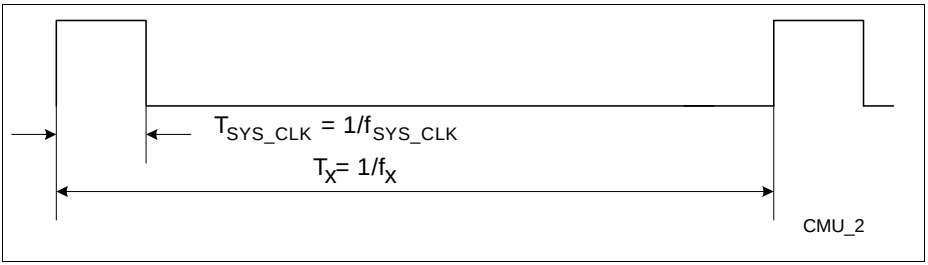

Figure 25-18 Example clock signal

25.8.5 Fixed Clock Generation (FXU)

The FXU subunit generates fixed clock enables out of the CMU_GCLK_EN or one of the eight CMU_CLKx enable signal depending on the CMU_CLK_5.FXCLK_SEL bit field of the CMU_FXCLK_CTRL register. These clock enables are used for the PWM generation inside the TOM submodules.

All clock enables CMU_FXCLK[y] can be enabled or disabled simultaneous by setting the appropriate bit field EN_FXCLK in the register CMU_CLK_EN.

The dividing factors are defined as 2^0, 2^4, 2^8, 2^{12}, and 2^{16}. The signals CMU_FXCLK[y] are implemented in form of enable signals for the corresponding registers (see also **Section 25.8.4**)

After EN_FXCLK entry in CMU_CLK_EN have been disabled, internal states of EN_FXCLK paths will be reset to start with the same behaviour after enable.

25.8.6 External Generation Unit (EGU)

The EGU subunit generate up to three separate clock output signals CMU_ECLK[z] (z: 0…2).

Each of these clock signals is derived from the corresponding External Clock Divider z subblock, which generates a clock signal derived from the GTM input clock SYS_CLK.

In contrast to the signals CMU_CLK[x] and CMU_FXCLK[y], which are treated as simple enable signals for the registers, the signals CMU_ECLK[z] have a duty cycle of about 50% that is used as a true clock signal for external peripheral components.

Each of the external clocks are enabled and disabled by setting the appropriate bit field EN_ECLK[z] in the register CMU_CLK_EN.

After EN_ECLK[z] entries in CMU_CLK_EN have been disabled, internal states of these EN_ECLK[z] paths will be reset to start with the same behaviour after enable.

The clock frequencies $f_{CMU\_ECLK[z]} = 1/T_{CMU\_ECLK[z]}$ of the external clocks are controlled with the registers CMU_ECLK_z_NUM and CMU_ECLK_z_DEN as follows:

$$T_{CMU\_ECLK[z]} = 2*(ECLK[z]\_NUM/ECLK[z]\_DEN)*T_{SYS\_CLK}$$

and is implemented according the following algorithm

(Z: CMU_ECLK_z_NUM(23:0); N: CMU_ECLK_z_DEN(23:0); Z,N >0; Z>=N; CMU_ECLK[z]='0'):

(1) Set remainder (r), operand1 (OP1) and operand2 (OP2) register during init-phase (with implicit conversion to signed):

r=Z, OP1=N, OP2=N-Z;

(2) After leaving init-phase (CMU_ECLK[z] has been enabled) the sign of remainder r for each SYS_CLK cycle will be checked:

(3) If r>0 keep updating remainder and keep CMU_ECLK[z]:

r=r-OP1;

(4) If r<0 update remainder and toggle CMU_ECLK[z]:

r=r-OP2;

After at most (Z/N+1) subtractions (3) there will be a negative r and an active phase of the generated clock enable (for one cycle) will be triggered (4). The remainder r is a measure for the distance to a real Z/N clock and will be regarded for the next generated clock toggle phase. The new r value will be r=r+(Z-N). In the worst case the remainder r will sum up to an additional cycle in the generated clock toggle period after Z-cycles. In the other cases equally distributed additional cycles will be inserted for the generated clock toggle. If Z is an integer multiple of N no additional cycles will be included for the generated clock toggle at all.

Note that for a better resource sharing all arithmetic has been reduced to subtractions and the initialization of the remainder r uses the complement of (Z-N).

The default value of the CMU_ECLK[z] output is low.

25.8.7 CMU Configuration Registers Overview

Following configuration registers are considered in CMU submodule:

Table 25-17 CMU Configuration Registers Overview

Register Name	Description	Details in Section
CMU_CLK_EN	CMU Clock enable register	Section 25.8.8.1
CMU_GCLK_NUM	CMU Global clock control numerator register	Section 25.8.8.2
CMU_GCLK_DEN	CMU Global clock control denominator register	Section 25.8.8.3
CMU_CLK_x_CTRL	CMU Control for clock source x register (x:0…5)	Section 25.8.8.4
CMU_CLK_6_CTRL	CMU Control for clock source 6 register	Section 25.8.8.5

Table 25-17 CMU Configuration Registers Overview (cont'd)

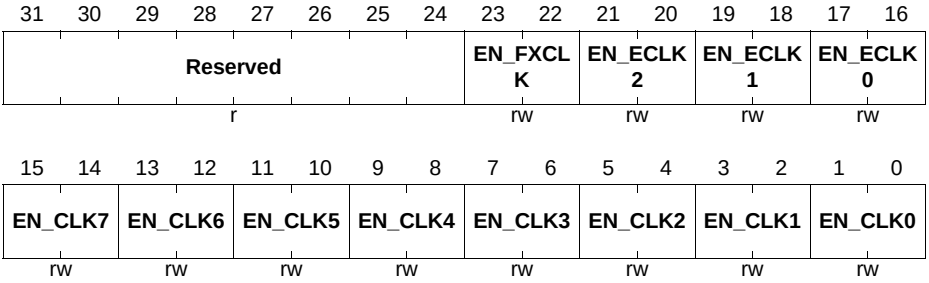
Register Name	Description	Details in Section
CMU_CLK_7_CTRL	CMU Control for clock source 7 register	Section 25.8.8.6
CMU_ECLK_z_NUM	CMU External clock z control numerator register (x:0…2)	Section 25.8.8.7
CMU_ECLK_z_DEN	CMU External clock z control denominator register (z:0…2)	Section 25.8.8.8
CMU_FXCLK_CTRL	Control FXCLK subunit input clock	Section 25.8.8.9

25.8.8 CMU Configuration Register Description

All of the following registers are 32-bit only accessible.

25.8.8.1 Register CMU_CLK_EN

GTM_CMU_CLK_EN
CMU Clock Enable Register **(00300_H)** **Reset Value: 00000000_H**

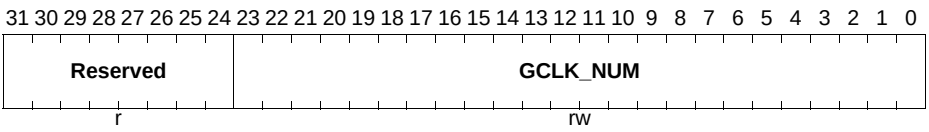


Field	Bits	Type	Description
EN_CLK0	[1:0]	rw	**Enable clock source 0** 00_B clock source is disabled (ignore write access) 01_B disable clock signal and reset internal states 10_B enable clock signal 11_B clock signal enabled (ignore write access) *Note: Any read access to an EN_CLKx, EN_ECLKz or EN_FXCLK bit field will always result in a value 00 or 11 indicating current state. A modification of the state is only performed with the values 01 and 10. Writing the values 00 and 11 is always ignored.* *Note: Any disabling to EN_CLKx will be reset internal counters for configurable clocks.*
EN_CLK1	[3:2]	rw	**Enable clock source 1** see bits [1:0]
EN_CLK2	[5:4]	rw	**Enable clock source 2** see bits [1:0]
EN_CLK3	[7:6]	rw	**Enable clock source 3** see bits [1:0]

Field	Bits	Type	Description
EN_CLK4	[9:8]	rw	**Enable clock source 4** see bits [1:0]
EN_CLK5	[11:10]	rw	**Enable clock source 5** see bits [1:0]
EN_CLK6	[13:12]	rw	**Enable clock source 6** see bits [1:0]
EN_CLK7	[15:14]	rw	**Enable clock source 7** see bits [1:0]
EN_ECLK0	[17:16]	rw	**Enable ECLK 0 generation subunit** see bits [1:0]
EN_ECLK1	[19:18]	rw	**Enable ECLK 1 generation subunit** see bits [1:0]
EN_ECLK2	[21:20]	rw	**Enable ECLK 2 generation subunit** see bits [1:0]
EN_FXCLK	[23:22]	rw	**Enable all CMU_FXCLK** see bits [1:0] *Note: An enable to EN_FXCLK from disable state will be reset internal fixed clock counters.*
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

25.8.8.2 Register CMU_GCLK_NUM

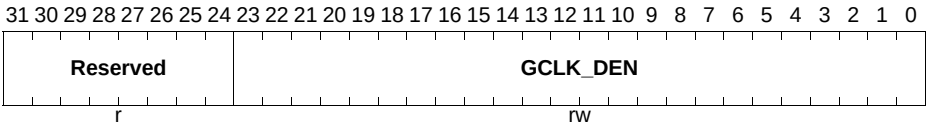
GTM_CMU_GCLK_NUM
CMU Global Clock Control Numerator Register
(00304_H) **Reset Value: 00000001_H**



Field	Bits	Type	Description
GCLK_NUM	[23:0]	rw	**Numerator for global clock divider** Defines numerator of the fractional divider. *Note: Value can only be modified when all clock enables EN_CLK[x] and the EN_FXCLK are disabled.* *Note: The CMU hardware alters the content of CMU_GCLK_NUM and CMU_GCLK_DEN automatically to 0x1, if CMU_GCLK_NUM is specified less than CMU_GCLK_DEN or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register CMU_GCLK_NUM followed by a single write to register CMU_GCLK_DEN.*
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

25.8.8.3 Register CMU_GCLK_DEN

GTM_CMU_GCLK_DEN
CMU Global Clock Control Denominator Register
(00308_H) **Reset Value: 00000001_H**

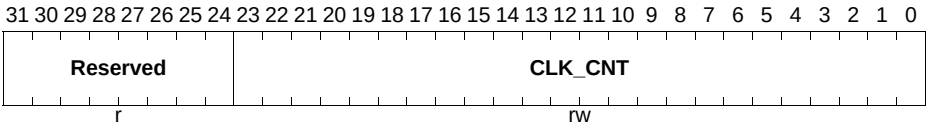


Field	Bits	Type	Description
GCLK_DEN	[23:0]	rw	**Denominator for global clock divider** Defines denominator of the fractional divider. *Note: Value can only be modified when all clock enables EN_CLK[x] and the EN_FXCLK are disabled.* *Note: The CMU hardware alters the content of CMU_GCLK_NUM and CMU_GCLK_DEN automatically to 0x1, if CMU_GCLK_NUM is specified less than CMU_GCLK_DEN or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register CMU_GCLK_NUM followed by a single write to register CMU_GCLK_DEN.*
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

25.8.8.4 Register CMU_CLK_x_CTRL (x:0…5)

GTM_CMU_CLK_x_CTRL (x=0-5)
CMU Control For Clock Source x Register

($0030C_H$+x*04_H) **Reset Value: 00000000_H**

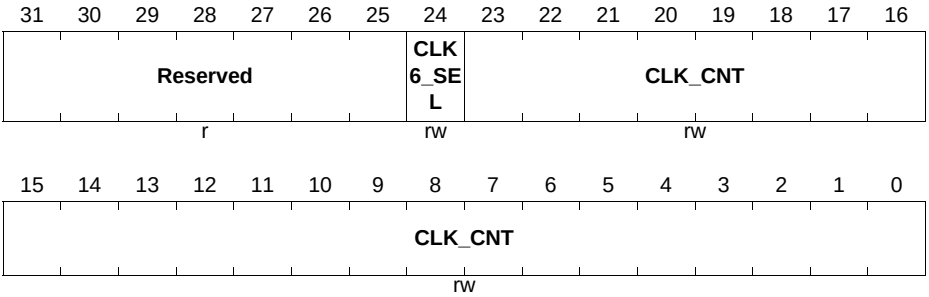


Field	Bits	Type	Description
CLK_CNT	[23:0]	rw	**Clock count Defines count value for the clock divider of clock source CMU_CLK[x] (x:0…5)** Note: Value can only be modified when clock enable EN_CLKx (x:0…5) is disabled.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

25.8.8.5 Register CMU_CLK_6_CTRL

GTM_CMU_CLK_6_CTRL
CMU Control For Clock Source 6 Register

(00324$_H$) **Reset Value: 00000000$_H$**

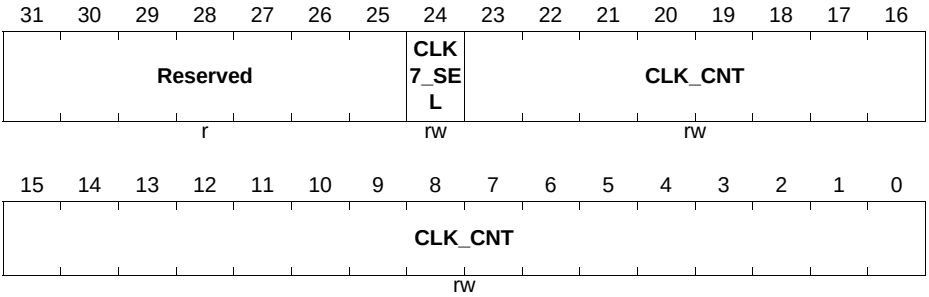


Field	Bits	Type	Description
CLK_CNT	[23:0]	rw	**Clock count. Define count value for the clock divider of clock source CMU_CLK6** Note: Value can only be modified when clock enable EN_CLK6 is disabled
CLK6_SEL	24	rw	**Clock source selection for CMU_CLK6** 0_B use Clock Source 6 Divider 1_B use signal SUB_INC2 of submodule DPLL Note: Value can only be modified when clock enable EN_CLK6 is disabled.
Reserved	[31:25]	r	**Reserved** Read as zero, should be written as zero

25.8.8.6 Register CMU_CLK_7_CTRL

GTM_CMU_CLK_7_CTRL
CMU Control For Clock Source 7 Register

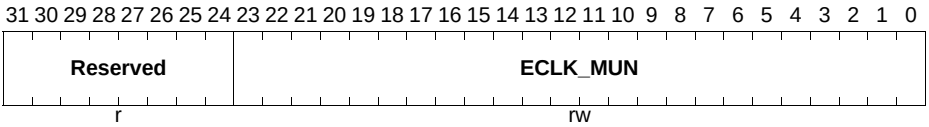
(00328_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
CLK_CNT	[23:0]	rw	**Clock count. Define count value for the clock divider of clock source CMU_CLK7** Note: Value can only be modified when clock enable EN_CLK7 is disabled
CLK7_SEL	24	rw	**Clock source selection for CMU_CLK7** 0_B use Clock Source 7 Divider 1_B use signal SUB_INC1 of submodule DPLL Note: Value can only be modified when clock enable EN_CLK7 is disabled.
Reserved	[31:25]	r	**Reserved** Read as zero, should be written as zero

25.8.8.7 Register CMU_ECLK_z_NUM (z:0…2)

GTM_CMU_ECLK_z_NUM (z=0-2)
CMU External Clock z Control Numerator Register
($0032C_H$+z*08_H) **Reset Value: 00000001_H**

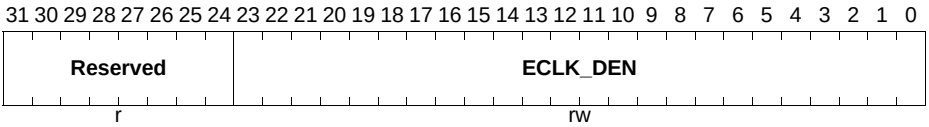


Field	Bits	Type	Description
ECLK_NUM	[23:0]	rw	**Numerator for external clock divider** Defines numerator of the fractional divider. *Note: Value can only be modified when clock enable EN_ECLK[z] is disabled.* *Note: The CMU hardware alters the content of CMU_ECLK_z_NUM and CMU_ECLK_z_DEN automatically to 0x1, if CMU_ECLK_z_NUM is specified less than CMU_ECLK_z_DEN or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register CMU_ECLK_z_NUM followed by a single write to register CMU_ECLK_z_DEN.*
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

25.8.8.8 Register CMU_ECLK_z_DEN (z:0…2)

GTM_CMU_ECLK_z_DEN (z=0-2)
CMU External Clock z Control Denominator Register

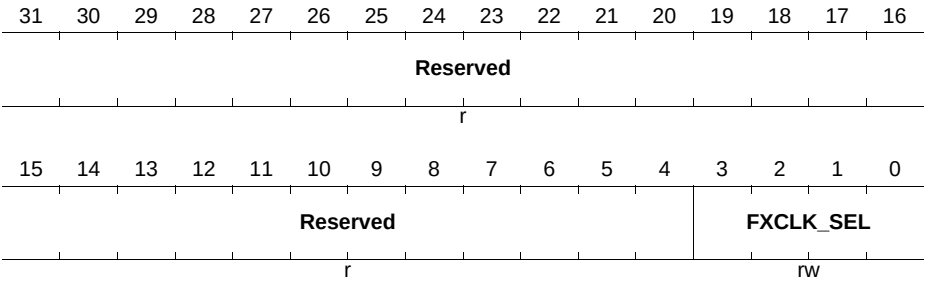
(00330_H + z*08_H) **Reset Value: 00000001_H**



Field	Bits	Type	Description
ECLK_DEN	[23:0]	rw	**Denominator for external clock divider** Defines denominator of the fractional divider. *Note: Value can only be modified when clock enable EN_ECLK[z] is disabled.* *Note: The CMU hardware alters the content of CMU_ECLK_z_NUM and CMU_ECLK_z_DEN automatically to 0x1, if CMU_ECLK_z_NUM is specified less than CMU_ECLK_z_DEN or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register CMU_ECLK_z_NUM followed by a single write to register CMU_ECLK_z_DEN.*
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

25.8.8.9 Register CMU_FXCLK_CTRL

GTM_CMU_FXCLK_CTRL
CMU FXCLK Control Register **(00344_H)** **Reset Value: 00000000_H**



Field	Bits	Type	Description
FXCLK_SEL	[3:0]	rw	**Input clock selection for EN_FXCLK line** 0000_BCMU_GCLK_EN selected 0001_BCMU_CLK0 selected 0010_BCMU_CLK1 selected 0011_BCMU_CLK2 selected 0100_BCMU_CLK3 selected 0101_BCMU_CLK4 selected 0110_BCMU_CLK5 selected 0111_BCMU_CLK6 selected 1000_BCMU_CLK7 selected *Note: This value can only be written, when the CMU_FXCLK generation is disabled. See bits 23…22 in register CMU_CLK_EN.* *Note: Other values for FXCLK_SEL are reserved and should not be used, but they behave like FXCLK_SEL = 0.*
Reserved	[31:4]	r	**Reserved bits** Read as zero, should be written as zero

25.9 Time Base Unit (TBU)

25.9.1 Overview

The Time Base Unit TBU provides common time bases for the GTM. The TBU submodule is organized in channels, where the number of channels is device dependent. There are at most three channels implemented inside the TBU. The TBU channel 0 time base register TBU_CH0_BASE is 27 bits and it is configurable whether the lower 24 bit or the upper 24 bit are provided to the GTM as signalTBU_TS0. The two TBU channels 1 and 2 have a time base register TBU_CHy_BASE (y: 1, 2) of 24 bit length. The time base register value TBU_TS[y] and the time base register update event TBU_UP[y] are provided to subsequent submodules of the GTM.

The TBU_UP[z] (z:1…2) signals are set to high for a single SYS_CLK period, whenever the corresponding signal TBU_TS[z] (z:1…2) or TBU_TS0 is getting updated. The signal TBU_UP0_L is set to high for a single SYS_CLK period if the signal TBU_TS0 and TBU_TS0 is getting updated and TBU_UP0_H is set to high for a single SYS_CLK period, whenever if the upper 24 bit of TBU_TS0 are updated.

The time base channels can run independently of each other and can be enabled and disabled synchronously by control bits in a global TBU channel enable register TBU_CHEN. **Section 25.9.1.1** shows a block diagram of the Time Base Unit.

25.9.1.1 TBU Block Diagram

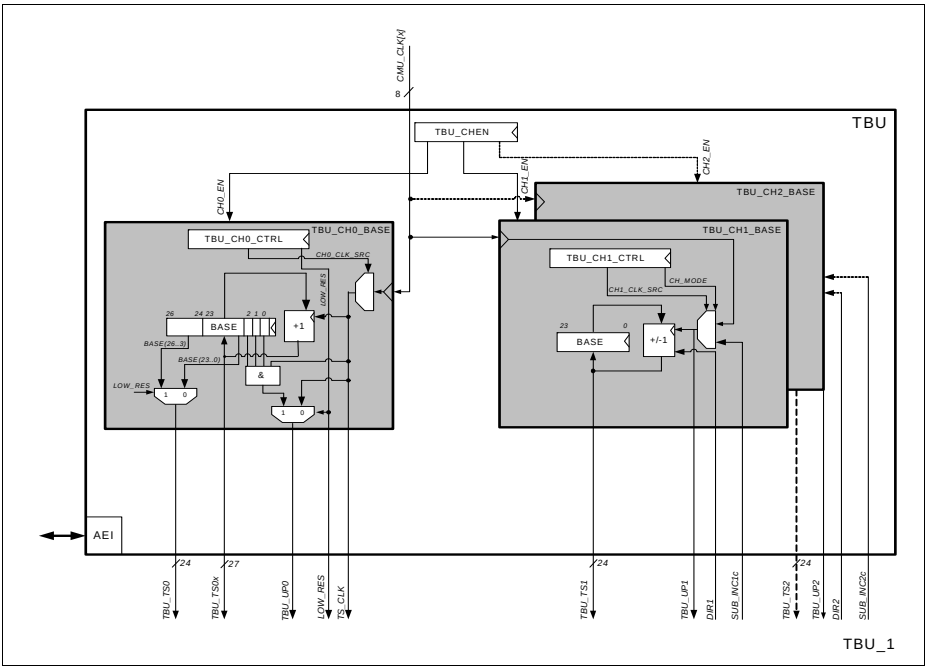


Figure 25-19 TBU Block Diagram

Dependent on the device a third TBU channel exists which offers the same functionality as the time base channel 1.

The configuration of the independent time base channels TBU_BASE_[z] is done via the AEI interface. Each TBU channel may select one of the eight CMU_CLK[x] (x: 0…7) signals coming from the CMU submodule.

For TBU channels 1 and 2 an additional clock signal SUB_INC[y]c (y: 1, 2) coming from the DPLL can be selected as input clock for the TBU_BASE_[y]. This clock in combination with the DIR[y] signals determines the counter direction of the TBU_BASE_[y].

The selected time stamp clock signal for the TBU_BASE_0 subunit is served via the TS_CLK signal line to the DPLL submodule. The TS_CLK signal equals the signal TBU_UP0.

25.9.2 TBU Time Base Channels

The time base values are generated within the TBU time base channels in two independent operation modes.

25.9.2.1 TBU Channel Modes

TBU channel 0 provides a 27 bit counter in a free running counter mode. Dependent on the bit field LOW_RES of register TBU_CH0_CTRL, the lower 24 bits (bit 0 to 23) or the upper 24 bits (bits 3 to 26) are provided to the GTM submodules.

TBU channel 1 and channel 2 can run in two modes; the free running counter mode and forward/backward counter mode, where the time base can run backwards dependent on the DIR[y] input signal values.

In both modes, the time base register TBU_CH[z]_BASE can be initialized with a start value just before enabling the corresponding TBU channel.

Moreover, the time base register TBU_CH[z]_BASE can always be read in order to determine the actual value of the counter.

Free Running Counter Mode

In TBU Free running counter mode, the time base register TBU_CHy_BASE is updated on every specified incoming clock event by the selected signal CMU_CLK[x] (dependent on TBU_CH[z]_CTRL register). In general the time base register TBU_CHy_BASE is increment on every CMU_CLK[x] clock tick.

Forward/Backward Counter Mode

As mentioned above TBU channels 1 and 2 can also be configured to run in Forward/Backward Counter Mode. In this mode the DIR[y] signal provided by the DPLL is taken into account.

The value of the time base register TBU_CHy_BASE is increment in case when the DIR[y] signal equals ‘0’ and decremented in case when the DIR[y] signal is ‘1’.

25.9.3 TBU Configuration Registers Overview

Following table shows a conclusion of configuration registers address offsets and initial values.

Table 25-18 TBU Configuration Registers Overview

Register Name	Description	Details in Section
TBU_CHEN	TBU global channel enable register	Section 25.9.4.1
TBU_CH0_CTRL	TBU channel 0 control register	Section 25.9.4.2

Table 25-18 TBU Configuration Registers Overview (cont'd)

Register Name	Description	Details in Section
TBU_CH0_BASE	TBU channel 0 base register	Section 25.9.4.3
TBU_CHy_CTRL	TBU channel y control register (y:1,2)	Section 25.9.4.4
TBU_CHy_BASE	TBU channel y base register (y:1,2)	Section 25.9.4.5

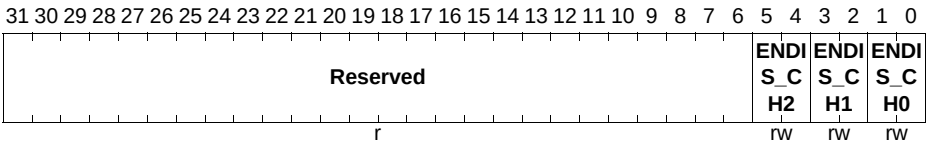
Note: In a typical application the Time Base Unit (TBU) considers channels 0 and 1 only. In this case register addresses 0x20…0x2C are reserved and shall be read as zero. Channel 2 can be additionally implemented on special high-end application requirements.

25.9.4 TBU Registers description

All of the following registers are 32-bit only accessible.

25.9.4.1 Register TBU_CHEN

GTM_TBU_CHEN
TBU Global Channel Enable Register(00100_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
ENDIS_CH0	[1:0]	rw	**TBU channel 0 enable/disable control** Write of following double bit values is possible: 00_B don't care, bits 1:0 will not be changed 01_B channel disabled: is read as 00 (see below) 10_B channel enabled: is read as 11 (see below) 11_B don't care, bits 1:0 will not be changed Note: Read of following double values means: 00_B channel disabled 11_B channel enabled
ENDIS_CH1	[3:2]	rw	**TBU channel 1 enable/disable control** See bits 1:0

Field	Bits	Type	Description
ENDIS_CH2	[5:4]	rw	**TBU channel 2 enable/disable control** See bits 1:0 Note: These bits are only applicable if channel is implemented for this device, otherwise read and write as zero
Reserved	[31:6]	r	**Reserved** Read as zero, should be written as zero

25.9.4.2 Register TBU_CH0_CTRL

GTM_TBU_CH0_CTRL
TBU Channel 0 Control Register (00104$_H$) **Reset Value: 00000000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
r															

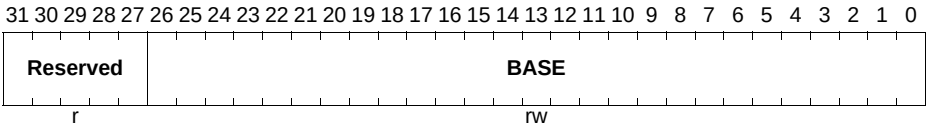
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												CH_CLK_SRC			LOW_RES
r												rw			rw

Field	Bits	Type	Description
LOW_RES	0	rw	**TBU_CH0_BASE register resolution** 0_B TBU channel uses lower counter bits (bit 0 to 23) 1_B TBU channel uses upper counter bits (bit 3 to 26) Note: The two resolutions for the TBU channel 0 can be used in the TIM channel 0 and the DPLL submodules. Note: This value can only be modified if channel 0 is disabled.

Field	Bits	Type	Description
CH_CLK_SRC	[3:1]	rw	**Clock source for channel x (x:0…2) time base counter** 000_B CMU_CLK0 selected 001_B CMU_CLK1 selected 010_B CMU_CLK2 selected 011_B CMU_CLK3 selected 100_B CMU_CLK4 selected 101_B CMU_CLK5 selected 110_B CMU_CLK6 selected 111_B CMU_CLK7 selected Note: This value can only be modified (written) if channel 0 was disabled
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

25.9.4.3 Register TBU_CH0_BASE

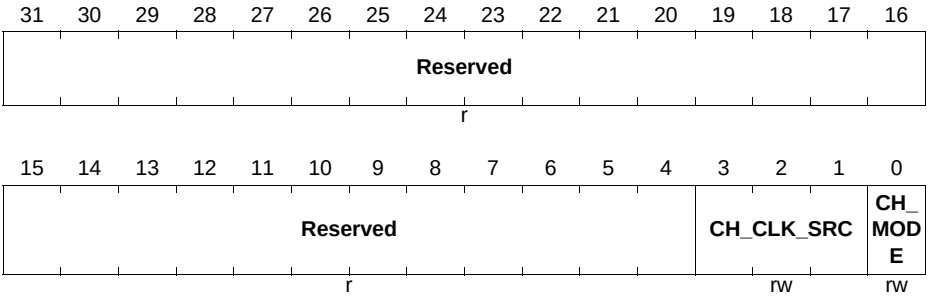
GTM_TBU_CH0_BASE
TBU Channel 0 Base Register (00108_H) Reset Value: 00000000_H



Field	Bits	Type	Description
BASE	[26:0]	rw	**Time base value for channel 0** Note: The value of BASE can only be written if the TBU channel 0 is disabled Note: If channel 0 is enabled, a read access to this register provides the current value of the underlying 27 bit counter.
Reserved	[31:27]	r	**Reserved** Read as zero, should be written as zero

25.9.4.4 Register TBU_CHy_CTRL (y:1, 2)

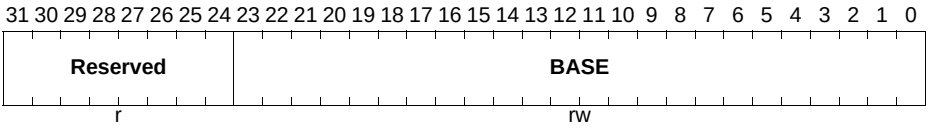
GTM_TBU_CHy_CTRL (y=1-2)
TBU Channel y Control Register (00104_H+y*08_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
CH_MODE	0	rw	**Channel mode** 0_B Free running counter mode 1_B Forward/backward counter mode Note: This value can only be modified if channel y (y:1,2) was disabled. In Free running counter mode the CMU clock source specified by CH_CLK_SRC is used for the counter. In Forward/Backward counter mode the SUB_INC[y]c clock signal in combination with the DIR[y] input signal is used to determine the counter direction and clock frequency.
CH_CLK_SRC	[3:1]	rw	**Clock source for channel x (x1…2) time base counter** 000_B CMU_CLK0 selected 001_B CMU_CLK1 selected 010_B CMU_CLK2 selected 011_B CMU_CLK3 selected 100_B CMU_CLK4 selected 101_B CMU_CLK5 selected 110_B CMU_CLK6 selected 111_B CMU_CLK7 selected Note: This value can only be modified if channel y was disabled
Reserved	[31:4]	r	**Reserved** Read as zero, should be written as zero

25.9.4.5 Register TBU_CHy_BASE (y:1,2)

GTM_TBU_CHy_BASE (y=1-2)
TBU Channel y Base Register (00108_H+y*08_H) Reset Value: 00000000_H



Field	Bits	Type	Description
BASE	[23:0]	rw	**Time base value for channel x (x 1, 2)** Note: The value of BASE can only be written if the corresponding TBU channel y is disabled Note: If the corresponding channel y is enabled, a read access to this register provides the current value of the underlying counter.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

25.10 Timer Input Module (TIM)

25.10.1 Overview

The Timer Input Module (TIM) is responsible for filtering and capturing input signals of the GTM. Several characteristics of the input signals can be measured inside the TIM channels. For advanced data processing the detected input characteristics of the TIM module can be routed through the ARU to subsequent processing units of the GTM.

Input characteristics mean either time stamp values of detected input rising or falling edges together with the new signal level or the number of edges received since channel enable together with the actual time stamp or PWM signal durations for a whole PWM period.

The architecture of TIM is shown in **Figure 25-20**.

25.10.1.1 TIM Block Diagram

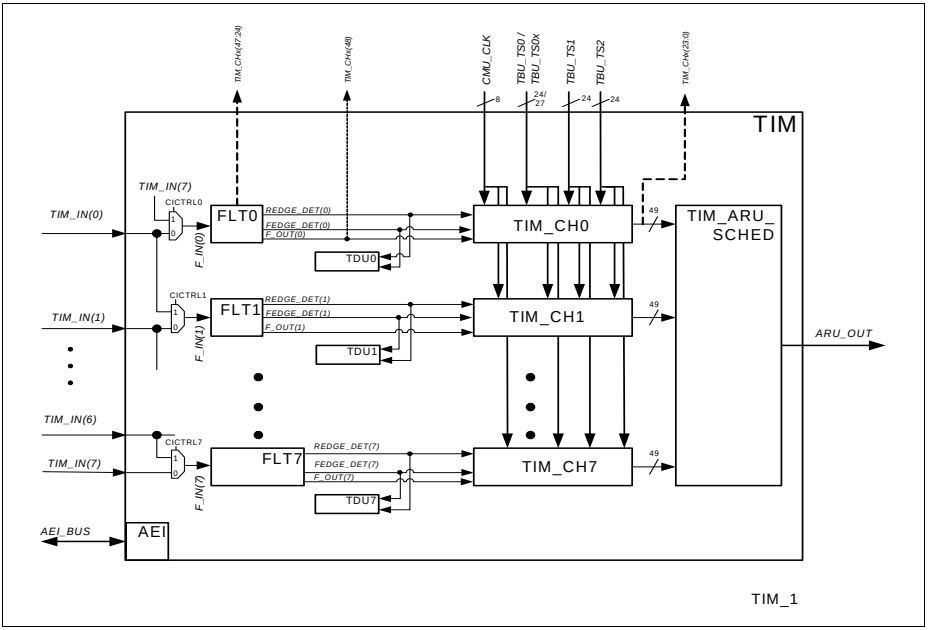


Figure 25-20 TIM Block Diagram

Each of the eight (8) dedicated input signals is filtered inside the FLTx subunit of the TIM Module. It should be noted that the incoming input signals are synchronized to the clock SYS_CLK, resulting in a delay of two SYS_CLK periods for the incoming signals.

The submodule TIM provides different filter mechanisms described in more detail in **Section 25.10.2**. After filtering, the signal is routed to the corresponding TIM channel.

The measurement values can be read by the CPU directly via the AEI-Bus or they can be routed through the ARU to other submodules of the GTM.

For timeout detection of an incoming signal (no subsequent edge detected during a specified duration) each individual channel has a Timeout Detection Unit (TDU).

For the GTM TIM0 submodule only, the dashed signal outputs TIM[i]_CH[x](23:0), TIM[i]_CH[x](47:24) and TIM[i]_CH[x](48) come from the TIM0 submodule channels zero (0) to five (5) and are connected to MAP submodule. There, they are used for further processing and for routing to the DPLL.

The two (three) time bases coming from the TBU are connected to the TIM channels to annotate time stamps to incoming signals. For TIM0 the extended 27 bit width time base TBU_TS0 is connected to the TIM channels, and the user has to select if the lower 24 bits (TBU_TS0(23…0)) or the higher 24 bits (TBU_TS0(26…3)) are stored inside the GPR0 and GPR1 registers.

25.10.1.2 Input source selection INPUTSRCx

It can be configured which source shall be used for processing in the FLT,TDU,TIM_CH units. It can be selected by the bit fields CICTRL and MODE_x, VAL_x in the register TIMi_CHx_IN_SRC which source is in use.

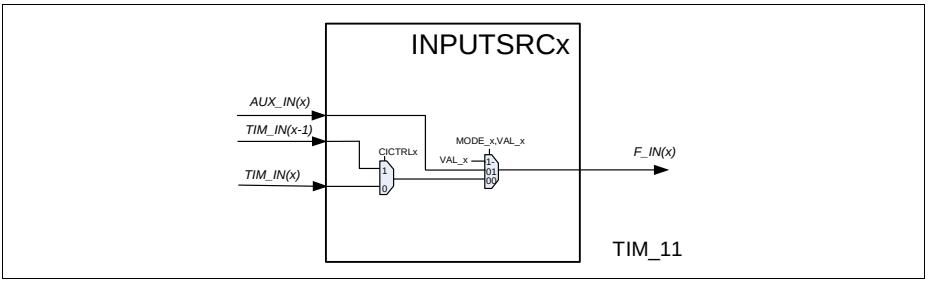

Figure 25-21 TIM Source Selection

In a certain MODE_x, VAL_x combination the input signal F_IN(x) can be driven by VAL_x(1) with 0 or 1 directly.

Due to the fact that all 8 channels are bundled in the register TIMi_CHx_IN_SRC a synchronous control of all 8 input channels is possible.

Two adjacent channels can be combined by setting the CICTRL bit field in the corresponding TIMi_CHx_CTRL register. This allows for a combination of complex measurements on one input signal with two TIM channels.

The additional input signal AUX_IN[x] can be selected as an input signal. The source of this signal is defined in the **Section 25.2.1.3**.

25.10.1.3 External capture source selection EXTCAPSRCx

Each channel can operate on an external capture signal EXT_CAPTURE. The source to use for this signal can be configured by the bit field EXT_CAP_SRCx in the register TIMi_CHx_ECTRL.

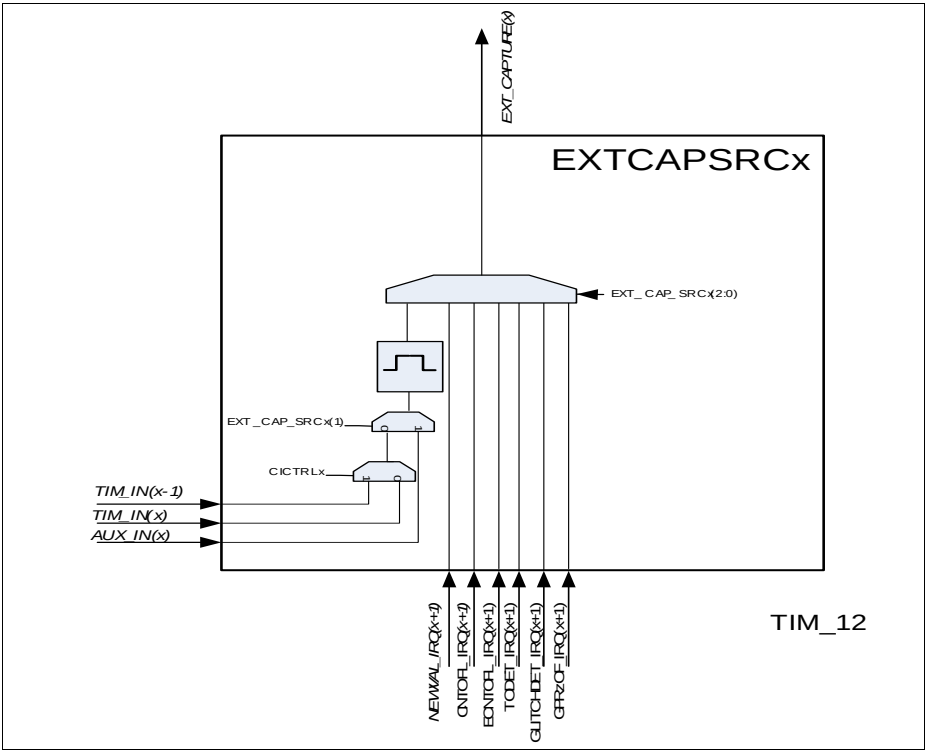

Figure 25-22 TIM external Capture Interrupt

The external capture functionality can be enabled for the TIM channel x with the bit EXT_CAP_EN in the register TIMi_CHx_CTRL, it will trigger on each rising edge. A pulse generation for each rising edge of the selected input signal TIM_IN[x] and AUX_IN[x] is applied.

The six TIM channel interrupt sources can be triggered by the operation in the certain TIM channel modes. Alternatively they can be issued by a soft trigger using the corresponding bits in the register TIMi_CHx+1_FORCINT.

25.10.2 TIM Filter Functionality (FLT)

25.10.2.1 Overview

The TIM submodule provides a configurable filter mechanism for each input signal. These filter mechanism is provided inside the FLT subunit.

FLT architecture is shown in **Figure 25-23**

The filter includes a clock synchronisation unit (CSU), an edge detection unit (EDU), and a filter counter associated to the filter unit (FLTU).

The CSU is synchronizing the incoming signal F_IN to the selected filter clock frequency, which is controlled with the bit field FLT_CNT_FRQ of register TIMi_CHx_CTRL.

The synchronized input signal F_IN_SYNC is used for further processing within the filter.

It should be noted that glitches with a duration less than the selected CMU clock period are lost.

The filter modes can be applied individually to the falling and rising edges of an input signal. The following filter modes are available:

- immediate edge propagation mode,
- individual de-glitch time mode (up/down counter), and
- individual de-glitch time mode (hold counter).

FLT Architecture

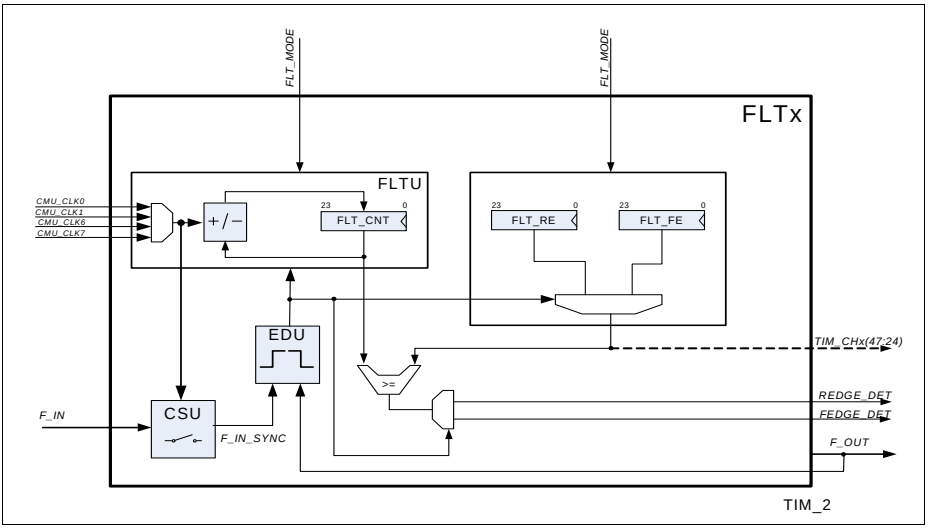

Figure 25-23 FLT Architecture

The filter parameters (deglitch and acceptance time) for the rising and falling edge can be configured inside the two filter parameter registers FLT_RE (rising edge) and FLT_FE (falling edge). The exact meaning of the parameter depends on the filter mode.

However the delay time T of both filter parameters FLT_xE can always be determined by:

T=(FLT_xE+1)*TFLT_CLK,

whereas TFLT_CLK is the clock period of the selected CMU clock signal in bit field FLT_CNT_FRQ of register TIMi_CHx_CTRL.

When a glitch is detected on an input signal a status flag GLITCHDET is set inside the TIMi_CHx_IRQ_NOTIFY register.

Table 25-19 gives an overview about the meanings for the registers FLT_RE and FLT_FE. In the individual deglitch time modes, the actual filter threshold for a detected regular edge is provided on the TIM[i]_CH[x](47:24) output line. In the case of immediate edge propagation mode, a value of zero is provided on the TIM[i]_CH[x](47:24) output line.

The TIM[i]_CH[x](47:24) output line is used by the MAP submodule for further processing (please see **Section 25.15**).

Filter Parameter summary for the different Filter Modes

Table 25-19 Filter Parameter summary for the different Filter Modes

Filter mode	Meaning of FLT_RE	Meaning of FLT_FE
Immediate edge propagation	Acceptance time for rising edge	Acceptance time for falling edge
Individual de-glitch time (up/down counter)	De-glitch time for rising edge	De-glitch time for falling edge
Individual de-glitch time (hold counter)	De-glitch time for rising edge	De-glitch time for falling edge

A counter FLT_CNT is used to measure the glitch and acceptance times.

The frequency of the FLT_CNT counter is configurable in bit field FLT_CNT_FRQ of register TIMi_CHx_CTRL.

The counter FLT_CNT can either be clock with the CMU_CLK0, CMU_CLK1, CMU_CLK6 or the CMU_CLK7 signal. These signals are coming from the CMU submodule.

The FLT_CNT, FLT_FE and FLT_RE registers are 24-bit width. For example, when the resolution of the CMU_CLK0 signal is 50ns this allows maximal de-glitch and acceptance times of about 838ms for the filter.

25.10.2.2 TIM Filter Modes

Immediate Edge Propagation Mode

In immediate edge propagation mode after detection of an edge the new signal level on F_IN_SYNC is propagated to F_OUT with a delay of one TFLT_CLK period and the new signal level remains unchanged until the configured acceptance time expires.

For each edge type the acceptance time can be specified separately in the FLT_RE and FLT_FE registers.

Each signal change on the input F_IN_SYNC during the duration of the acceptance time has no effect on the output signal level F_OUT of the filter but it sets the glitch GLITCHDET bit in the TIMi_CHx_IRQ_NOTIFY register.

After it expires an acceptance time the input signal F_IN_SYNC is observed and on signal level change the filter raises a new detected edge and the new signal level is propagated to F_OUT.

Independent of a signal level change the value of F_OUT is always set to F_IN_SYNC, when the acceptance time expires (see also **Figure 25-25**).

Figure 25-24 shows an example for the immediate edge propagation mode, in the case of rising edge detection. Both, the signal before filtering (F_IN) and after filtering (F_OUT) are shown. The acceptance time at1 is specified in the register FLT_RE.

Immediate Edge Propagation Mode in the case of a rising edge

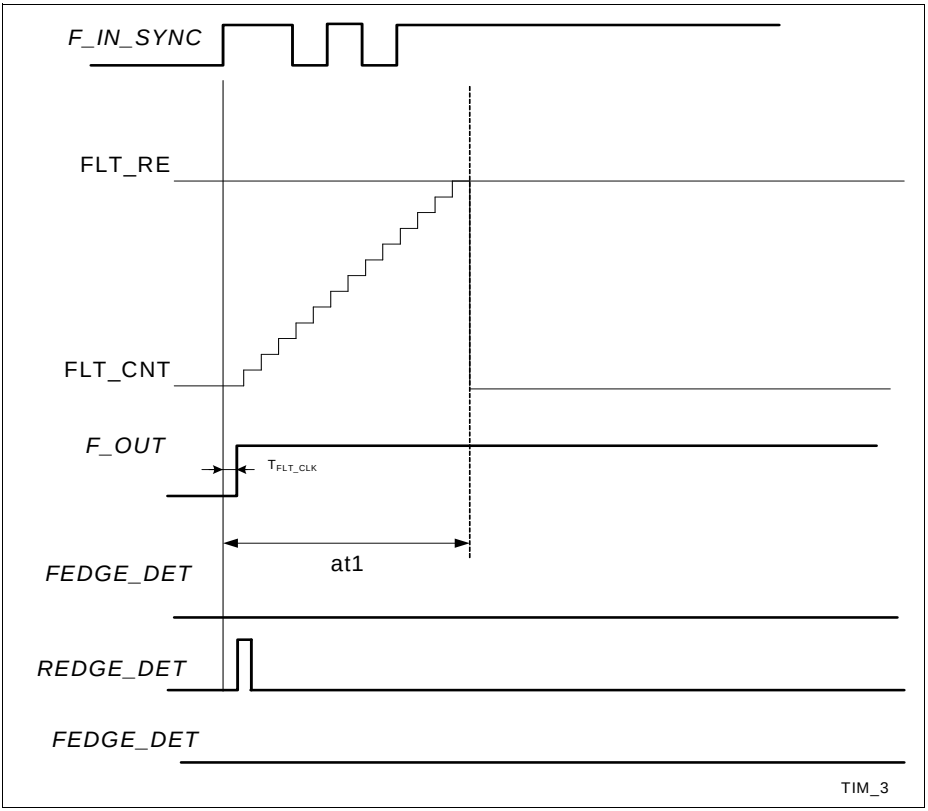

Figure 25-24 Immediate Edge Propagation Mode in the case of a rising edge

In immediate edge propagation mode the glitch measurement mechanism is not applied to the edge detection. Detected edges on F_IN_SYNC are transferred directly to F_OUT.

The counter FLT_CNT is increment until acceptance time threshold is reached.

Figure 25-25 shows a more complex example of the TIM filter, in which both, rising and falling edges are configured in immediate edge propagation mode.

Immediate Edge Propagation Mode in the case of a rising and falling edge

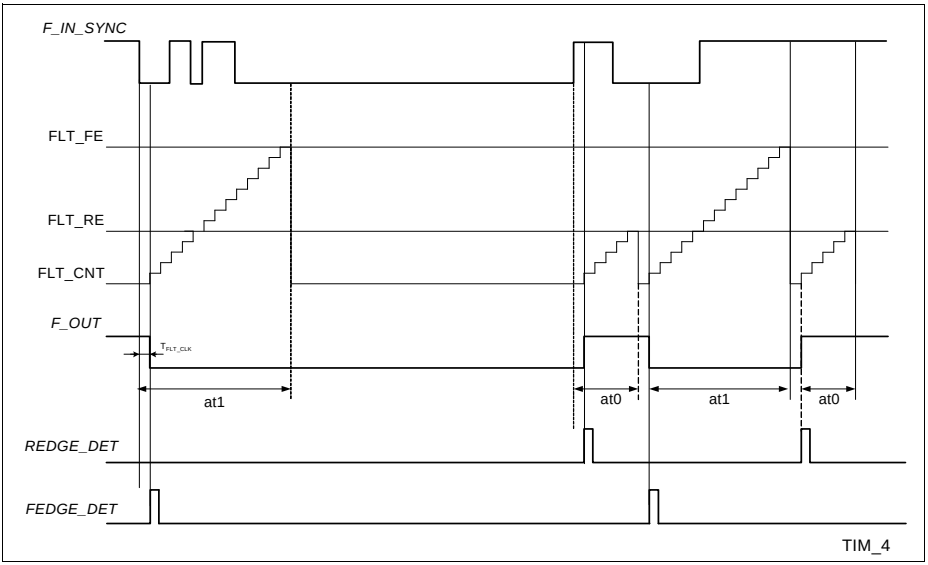

Figure 25-25 Immediate Edge Propagation Mode in the case of a rising and falling edge

If the FLT_CNT has reached the acceptance time for a specific signal edge and the signal F_IN_SYNC has already changed to the opposite level of F_OUT, the opposite signal level is set to F_OUT and the acceptance time measurement is started immediately. **Figure 25-25** shows this scenario at the detection of the first rising edge and the second falling edge.

Individual De-Glitch Time Mode (up/down counter)

In individual de-glitch time mode (up/down counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers FLT_RE and FLT_FE, respectively.

The filter counter register FLT_CNT is increment when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and decremented if F_IN_SYNC equals F_OUT.

If After FLT_CNT has reached a value of zero during decrease the counter is stopped immediately.

If a glitch is detected a glitch detection bit GLITCHDET is set in the TIMi_CHx_IRQ_NOTIFY register.

The detected edge signal together with the new signal level is propagated to F_OUT after the individual de-glitch threshold is reached. **Figure 25-26** shows the behaviour of the filter in individual de-glitch time (up/down counter) mode in the case of the rising edge detection.

Individual Deglitch Time Mode (up/down counter) in the case of a rising edge

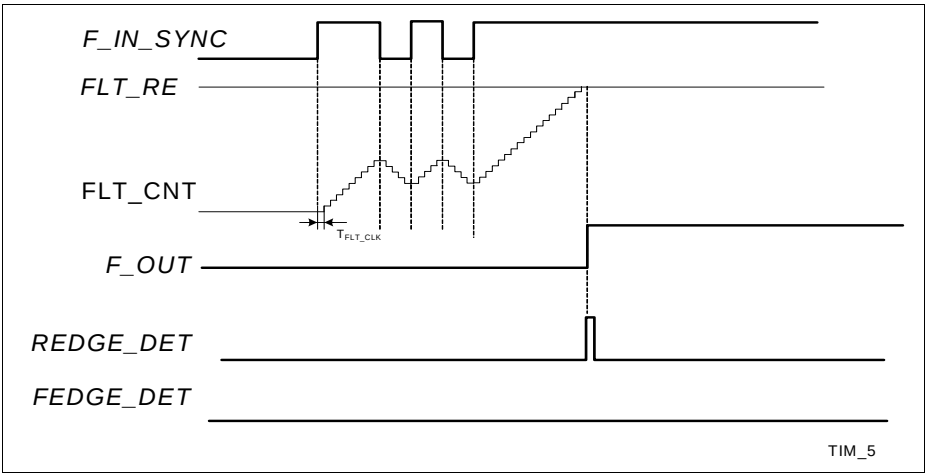

Figure 25-26 Individual Deglitch Time Mode (up/down counter) in the case of a rising edge

Individual De-Glitch Time Mode (hold counter)

In individual de-glitch time mode (hold counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers FLT_RE and FLT_FE, respectively.

The filter counter register FLT_CNT is increment when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and the counter value of FLT_CNT is hold if F_IN equals F_OUT.

If a glitch is detected the glitch detection bit GLITCHDET is set in the TIMi_CHx_IRQ_NOTIFY register.

The detected edge signal together with the new signal level is propagated to F_OUT after the individual de-glitch threshold is reached. **Figure 25-27** shows the behaviour of the filter in individual de-glitch time (hold counter) mode in the case of the rising edge detection.

Individual Deglitch Time Mode (hold counter) in the case of a rising edge

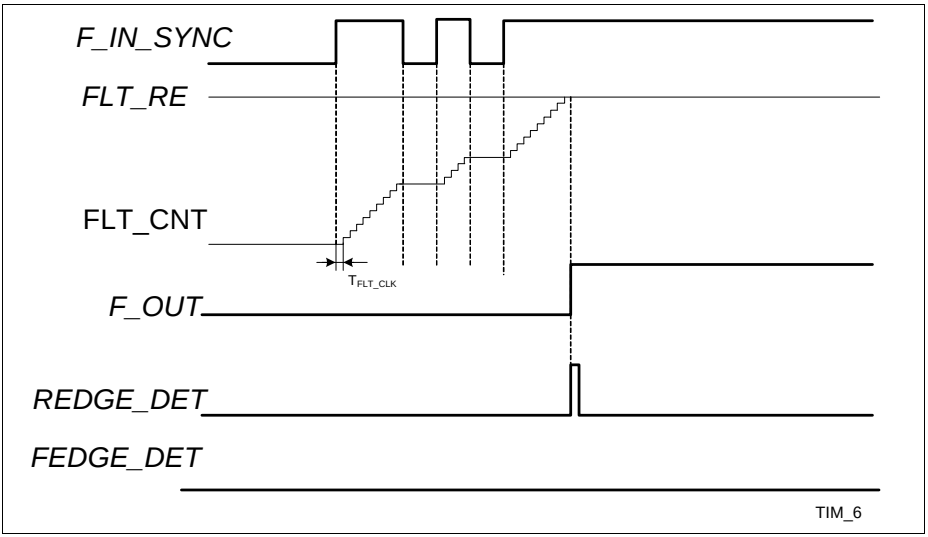

Figure 25-27 Individual Deglitch Time Mode (hold counter) in the case of a rising edge

Immediate Edge Propagation and Individual De-Glitch Mode

As already mentioned, the three different filter modes can be applied individually to each edge of the measured signal.

However, if one edge is configured with immediate edge propagation and the other edge with an individual deglitch mode (whether up/down counter or hold counter) a special consideration has to be applied.

Assume that the rising edge is configured for immediate edge propagation and the falling edge with individual deglitch mode (up/down counter) as shown in **Figure 25-28**.

If the falling edge of the incoming signal already occurs during the measuring of the acceptance time of the rising edge, the measurement of the deglitch time on the falling edge is started delayed, but immediately after the acceptance time measurement phase of the rising edge has finished.

Consequently, the deglitch counter can not measure the time TERROR, as shown in **Figure 25-28**.

Mixed mode measurement

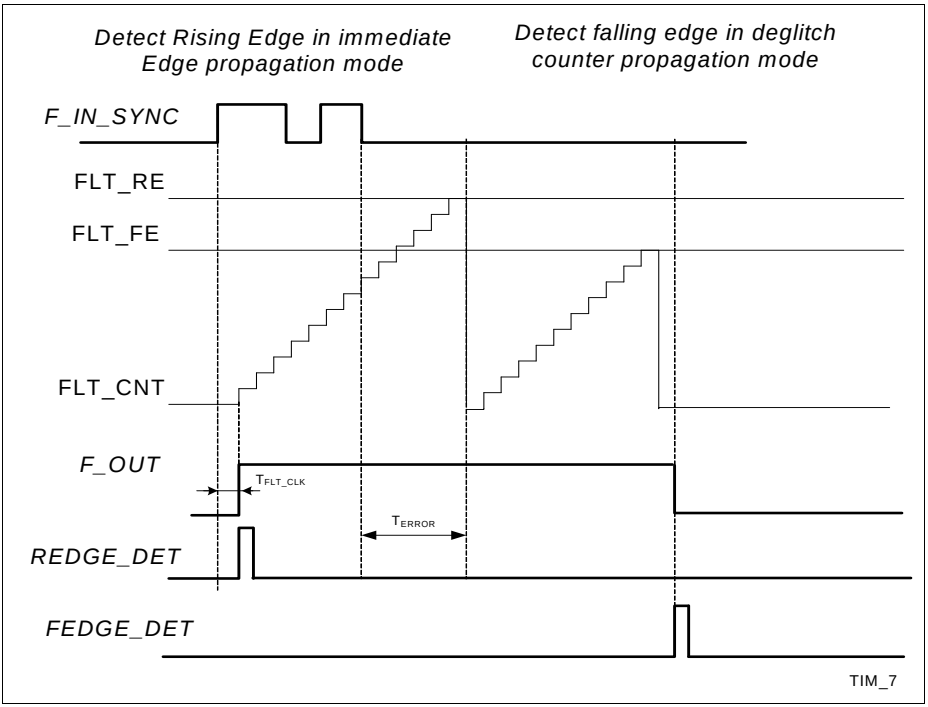

Figure 25-28 Mixed mode measurement

25.10.2.3 TIM Filter reconfiguration

If FLT_EN=1 a change of FLT_RE or FLT_FE will take place immediately. If FLT_EN=1 a change of FLT_MODE_RE or FLT_FE will be used with the next occurring corresponding edge. If mode is changed while the filter unit is processing a certain mode, it will end this edge filtering in the mode as started.

If FLT_EN=1 a change of FLT_DTR_RE or FLT_CTR_FE will take place immediately.

25.10.3 Timeout Detection Unit (TDU)

The Timeout Detection Unit (TDU) is responsible for timeout detection of the TIM input signals.

Each channel of the TIM submodule has its own Timeout Detection Unit (TDU) where a timeout event can be set up on the filtered input signal of the corresponding channel.

The TDU architecture is shown in **Figure 25-29**.

25.10.3.1 Architecture of the TDU Subunit

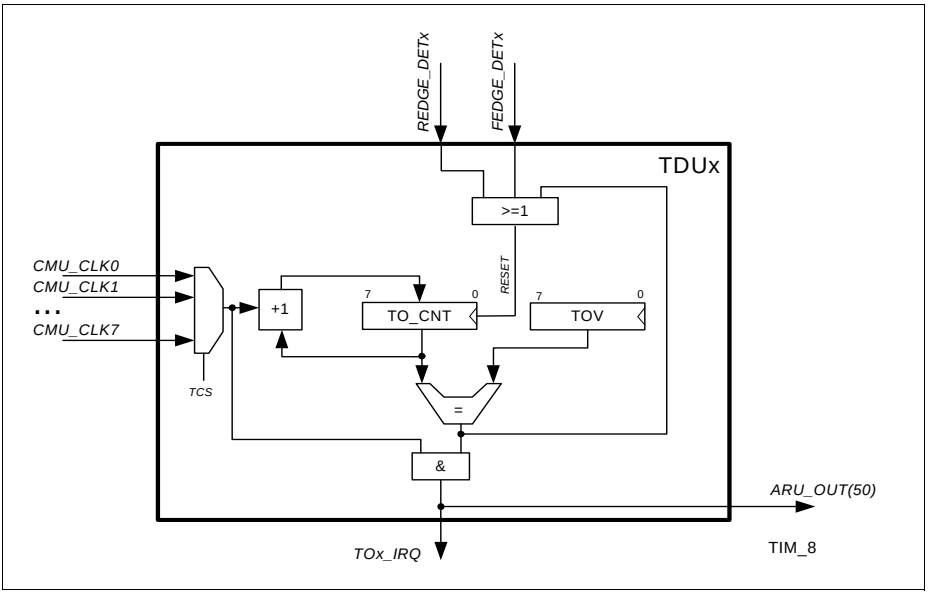

Figure 25-29 Architecture of the TDU Subunit

It is possible to detect timeouts with the resolution of the specified CMU_CLKx input signal selected with the bit field TCS of the register TIMi_CHx_TDU. The individual timeout values have to be specified in number of ticks of the selected input clock signal and have to be specified in the field TOV of timeout value register TIMi_CHx_TDUV of the TIM channel x (x:0…7).

The exact time out value TTDU can be calculated with:

$$T_{TDU}=(TOV+1)*T_{CMU\_GCLKx},$$

whereas T_{CMU_GCLKx} is the clock period of the selected CMU clock signal.

Timeout detection can be enabled or disabled individually inside the TIMi_CHx_CTRL register by setting/resetting the TO_CTRL bit.

Timeout detection can be enabled to be sensitive to falling, rising or both edges of the input signal by writing the corresponding values to the bit field TOCTRL.

The counter TO_CNT is reset by each detected input edge coming either from the filtered input signal or when the timeout value TOV is reached by the counter TO_CNT.

After such a reset or by enabling the channel inside the TIMi_CHx_CTRL register the counter TO_CNT starts counting again with the specified clock input signal.

Otherwise, timeout measurements starts immediately after the TO_CTRL bit inside the TIMi_CHx_CTRL register is written (enabled).

The TDU generates an interrupt signal TIM_TODETx_IRQ whenever a timeout is detected for an individual input signal, and the TODET bit is set inside the TIMi_CHx_IRQ_NOTIFY register.

In addition, when the ARU access is enabled with the ARU_EN bit inside the TIMi_CHx_CTRL register, the actual values stored inside the registers TIM[i]_CHx_GPR0 and TIM[i]_CHx_GPR1 are sent together with the last stored signal level to the ARU if a timeout event occurs.

To signal that a timeout occurred, the ARU_OUT(50) bit (ACB(2)) is set. The bit ACB(0) will be updated with the timeout event to the signal level on which the timeout was detected.

Thus, a destination could determine if a timeout occurred at the TIM input by evaluating ACB bit 2.

Since the TIM channel still monitors its input pin although the timeout happened, a valid edge could occur at the input pin while the timeout information is still valid at the ARU. In that case, the new edge associated data is stored inside the registers TIM[i]_CHx_GPR0 and TIM[i]_CHx_GPR1, the GPR overflow detected bit is set together in the ACB field (ACB(1)) with the timeout bit (ACB(2)) and the values are marked as valid to the ARU.

The ACB bit 2 is cleared, when a successful ARU write access by the TIM channel took place.

The ACB bit 1 is cleared, when a successful ARU write access by the TIM channel took place.

When a valid edge initiates an ARU write access which has not ended while a new timeout occurs the GPR overflow detected bit (ACB(1)) is set. The bit ACB(0) will be updated to the level on which the timeout occurred.

When a timeout occurred and initiates an ARU write access which has not ended while a new timeout occurs the GPR overflow detected bit (ACB(1)) is not set.

The following table clarifies the meaning of the ACB Bits for valid data provided by a TIM channel:

Table 25-20 TIM ARU Control Bits

ACB4/3	ACB2	ACB1	ACB0	Description
dc	0	0	SL	Valid edge detected
dc	0	1	SL	Input edge overwritten by subsequent edge

Table 25-20 TIM ARU Control Bits (cont'd)

ACB4/3	ACB2	ACB1	ACB0	Description
dc	1	0	SL	Timeout detected without valid edge
dc	1	1	SL	Timeout detected with subsequent valid edge detected

25.10.4 TIM Channel Architecture

25.10.4.1 Overview

Each TIM channel consist of an input edge counter ECNT, a Signal Measurement Unit (SMU) with a counter CNT, a counter shadow register CNTS for SMU counter and two general purpose registers GPR0 and GPR1 for value storage.

The value TOV of the timeout register TIMi_CHx_TDU is provided to TDU subunit of each individual channel for timeout measurement. The architecture of the TIM channel is depicted in **Figure 25-30**.

TIM Channel Architecture

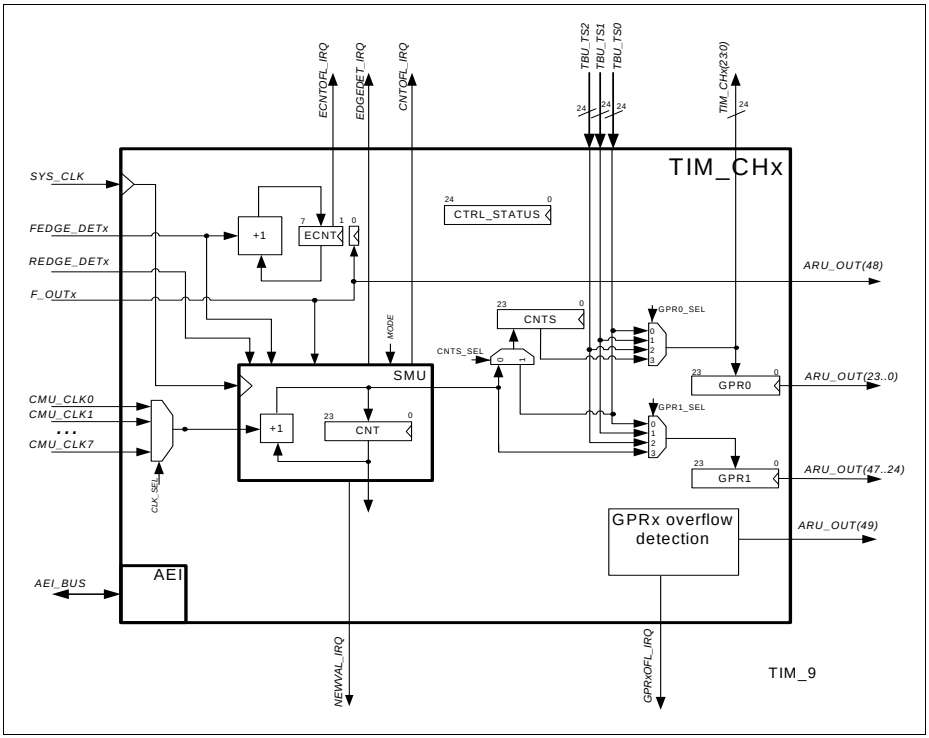

Figure 25-30 TIM Channel Architecture

Each TIM channel receives both input trigger signals REDGE_DETx and FEDGE_DETx, generated by the corresponding filter module in order to signalize a detected echo of the input signal F_INx. The signal F_OUTx shows the filtered signal of the channel's input signal F_INx.

The edge counter ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT. (However, the actual counter implementation counts only falling edges on ECNT[n:1] bits. It generates ECNT by composing the ECNT[n:1] bits with F_OUTx as bit 0).

Thus, the whole counter value is always odd, when a positive edge was received and always even, when a negative edge was received.

The current ECNT[7:0] register content is made visible on the bits 31 down to 24 of the registers GPR0, GPR1 and CNTS. This allows the software to detect inconsistent read accesses to registers GPR0, GPR1, and CNTS. However, the update strategy of these

registers depends on the selected TIM modes, and thus the consistency check has to be adapted carefully.

It can be chosen with the bit field FR_ECNT_OFL when an ECNT overflow is signaled on ECNTOFL. An ECNT overflow can be signaled on 8 bit or full range resolution.

While reading the register TIMi_CHx_ECNT the bit ECNT[0] shows the input signal value F_OUTx independent of the state (enabled / disabled) of the channel. If a channel gets disabled (OSM mode or resetting TIM_EN) the content of TIMi_CHx_ECNT will be frozen until a read of the register takes place. this read will reset the ECNT counter. Continuing reads will show the input signal in bit ECNT[0] again.

When new data is written into GPR0 and GPR1 the NEWVAL bit is set in TIMi_CHx_IRQ_NOTIFY register and depending on corresponding enable bit value the NEWVALx_IRQ interrupt is raised.

Each TIM input channel has an ARU connection for providing data via the ARU to the other GTM submodules. The data provided to the ARU depends on the TIM channel mode and its corresponding adjustments (e.g. multiplexer configuration).

The bit ARU_EN of register TIMi_CHx_CTRL decides, whether the measurement results of registers GPR0 and GPR1 are consumed by another submodule via ARU (ARU_EN = 1) or the CPU via AEI (ARU_EN = 0).

To guarantee a consistent delivery of data from the GPR0 and GPR1 registers to the ARU or the CPU each TIM channel has to ensure that the data is consumed before it is overwritten with new values.

If new data was produced by the TIM channel (bit NEWVAL is set inside TIMi_CHx_IRQ_NOTIFY register) while the old data is not consumed by the ARU (ARU_EN = 1) or CPU (ARU_EN = 0), the TIM channel sets the GPROFL bit inside the status register TIMi_CHx_IRQ_NOTIFY and it overwrites the data inside the GPR registers GPR0 and GPR1. In addition when ARU_EN=1 the bit ACB(1) is set to 1 to indicate the overflow in the ARU data.

If the CPU is selected as consumer for the registers GPR0 and GPR1 (ARU_EN = 0), the acknowledge for reading out data is performed by a read access to the register GPR0. Thus, register GPR1 should be read always before GPR0.

If the ARU is selected as consumer for the registers GPR0 and GPR1 (ARU_EN = 1), the acknowledge for reading out data is performed by the ARU itself. However, the registers GPR0 and GPR1 could be read by CPU without giving an acknowledge.

25.10.4.2 TIM Channel Modes

The TIM provides six different measurement modes that can be configured with the bit field TIM_MODE of register TIMi_CHx_CTRL. The measurement modes are described in the following subsections. Besides these different basic measurement modes, there exist distinct configuration bits in the register TIMi_CHx_CTRL for a more detailed controlling of each mode. The meanings of these bits are as follows:

- DSL: control the signal level for the measurement modes (e.g. if a measurement is started with rising edge or falling edge, or if high level pulses or low level pulses are measured.
- EGPR0_SEL, GPR0_SEL and EGPR1_SEL, GPR1_SEL: control the actual content of the registers GPR0 and GPR1 after a measurement has finished.
- CNTS_SEL: control the content of the registers CNTS. The actual time for updating the CNTS register is mode dependent.
- OSM: activate measurement in one-shot mode or continuous mode. In one-shot mode only one measurement cycle is performed and after that the channel is disabled.
- NEWVAL: The NEWVAL IRQ interrupt is triggered at the end of a measurement cycle, signalling that the registers GPR0 and GPR1 are updated.
- ARU_EN: enables sending of the registers GPR0 and GPR1 together with the actual signal level (in bit 48) and the overflow signal GPROFL (in bit 49), and the timeout status information (bit 50) to the ARU.
- EXT_CAP_EN: forces an update of the registers GPR0 and GPR1 and CNTS (TIM channel mode dependant) only on each rising edge of the EXT_CAPTURE signal and triggers a NEWVAL IRQ interrupt. If this mode is disabled the NEWVAL IRQ interrupt is triggered at the end of each measurement cycle.

For each channel the source of the EXT_CAPTURE signal can be configured with the bit fields EXT_CAP_SRC in the register TIMi_CHx_ECTRL.

TIM PWM Measurement Mode (TPWM)

In TIM PWM Measurement Mode the TIM channel measures duty cycle and period of an incoming PWM signal. The DSL bit defines the polarity of the PWM signal to be measured.

When measurement of pulse high time and period is requested (PWM with a high level duty cycle, DSL=1), the channel starts measuring after the first rising edge is detected by the filter.

Measurement is done with the CNT register counting with the configured clock coming from CMU_CLKx until a falling edge is detected.

Then the counter value is stored inside the shadow register CNTS (if CNTS_SEL = 0) and the counter CNT counts continuously until the next rising edge is reached.

On this following rising edge the content of the CNTS register is transferred to GPR0 and the content of CNT register is transferred to GPR1, assuming settings for the selectors GPR0_SEL=11 and GPR1_SEL=11. By this, GPR0 contains the duty cycle length and GPR1 contains the period. It should be noted, that the bits 1 to 7 of the ECNT may be used to check data consistency of the registers GPR0 and GPR1.

In addition the CNT register is cleared NEWVAL status bit inside of TIMi_CHx_IRQ_NOTIFY status register and depending on corresponding interrupt enable condition TIM_NEWVALx_IRQ interrupt is raised.

The CNTS register update is not performed until measurement is started (first edge defined by DSL is detected). Afterwards each edge leaving the level defined by DSL is performing a CNTS register update.

If a PWM with a low level duty cycle should be measured (DSL = 0), the channel waits for a falling edge until measurement is started. On this edge the low level duty cycle time is stored first in CNTS and then finally in GPR0 and the period is stored in GPR1.

When a PWM period was successfully measured, the data in registers GPr0 and GPR1 is marked as valid for reading by the ARU when the ARU_EN bit is set inside TIMi_CHx_CTRL register, the NEWVAL bit is set inside the TIMi_CHx_IRQ_NOTIFY register, and a new measurement is started.

If the preceding PWM values were not consumed by a reader attached to the ARU (ARU_EN bit enabled) or by the CPU the TIM channel set GPROFL status bit in TIMi_CHx_IRQ_NOTIFY and depending on corresponding interrupt enable bit value raises a GPROFL_IRQ and overwrites the old values in GPR0 and GPR1. A new measurement is started afterwards.

If the register CNT produces an overflow during the measurement, the bit CNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_CNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

External capture TIM PWM Measurement Mode (TPWM)

If external capture is enabled, the pwm measurement is done continuously. The actual measurement values are captured to GPRx if an external capture event occurs.

Operation is done depending on cmu clock, ISL, DSL bit and the input signal value defined in the next table:

Table 25-21 TIM PWM Measurement Mode

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
0	1	0	-	0	CNT++
1	1	0	-	0	no
rising edge	-	0	0	0	capture CNT value in CNTS
falling edge	-	0	0	0	CNT = 0
rising edge	-	0	1	0	no
falling edge	-	0	1	0	capture CNT value in CNTS; CNT = 0

Table 25-21 TIM PWM Measurement Mode (cont'd)

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
1	1	0	-	1	CNT++
0	1	0	-	1	no
falling edge	-	0	0	1	capture CNT value in CNTS
rising edge	-	0	0	1	CNT = 0
falling edge	-	0	1	1	no
rising edge	-	0	1	1	capture CNT value in CNTS; CNT = 0
-	-	rising edge	-	-	do GPRx capture; issue NEWVAL_IRQ
-	0	0	-	-	no

The CNTS register update is not performed until measurement is started (first edge defined by DSL is detected). Afterwards the update of the CNTS register is defined by ISL, DSL combinations in the table above.

TIM Pulse Integration Mode (TPIM)

In TIM Pulse Integration Mode each TIM channel is able to measure a sum of pulse high or low times on an input signal, depending on the selected signal level bit DSL of register TIMi_CHx_CTRL register.

The pulse times are measured by incrementing the TIM channel counter CNT whenever the pulse has the specified signal level DSL. The counter is stopped whenever the input signal has the opposite signal level.

The counter CNT counts with the CMU_CLKx clock specified by the CLK_SEL bit field of the TIMi_CHx_CTRL register.

The CNT register is reset at the time the channel is activated (enabling via AEI write access) and it accumulates pulses while the channel is staying enabled.

Whenever the counter is stopped, the registers CNTS, GPR0 and GPR1 are updated according to settings of its corresponding input multiplexers, using the bits GPR0_SEL, EGPR0_SEL, EGPR1_SEL, GPR1_SEL, and CNTS_SEL. It should be noted, that the bits 1 to 7 of the ECNT may be used to check data consistency of the registers GPR0 and GPR1.

When the ARU_EN bit is set inside the TIMi_CHx_CTRL register the measurement results of the registers GPR0 and GPR1 can be send to subsequent submodules attached to the ARU.

External capture TIM Pulse Integration Mode (TPIM)

If external capture is enabled, the pulse integration is done until next external capture event occurs.

Operation is done depending on CMU clock, DSL bit and the input signal value defined in the next table:

Table 25-22 TIM integration Mode

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
0	1	0	-	0	CNT++
1	1	0	-	0	no
1	1	0	-	1	CNT++
0	1	0	-	1	no
-	-	rising edge	-	-	do GPRx capture; issue NEWVAL_IRQ
-	0	0	-	-	no

TIM Input Event Mode (TIEM)

In TIM Input Event Mode the TIM channel is able to count edges.

It is configurable if rising, falling or both edges should be counted. This can be done with the bit fields DSL and ISL in TIMi_CHx_CTRL register.

In addition, a TIM[i]_NEWVAL[x]_IRQ interrupt is raised when the configured edge was received and this interrupt was enabled.

The counter register CNT is used to count the number of edges, and the bit fields EGPR0_SEL, EGPR1_SEL, GPR0_SEL, GPR1_SEL, and CNTS_SEL can be used to configure the desired update values for the registers GPR0, GPR1 and CNTS. These register are updated whenever the edge counter CNT is increment due to the arrival of a desired edge.

If the preceding data was not consumed by a reader attached to the ARU or by the CPU the TIM channel sets GPROFL status bit and raises a GPROFL[x]_IRQ if it was enabled in TIMi_CHx_IRQ_EN register and overwrites the old values in GPR0 and GPR1 with the new ones.

If the register CNT produces an overflow during the measurement, the bit CNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_CNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

The TIM Input Event Mode does not depend on the bit field CLK_SEL of register TIMi_CHx_CTRL.

External capture TIM Input Event Mode (TIEM)

If external capture is enabled, capturing is done depending on ISL, DSL bit and the input signal value defined in the next table:

Table 25-23 TIM Input Event Mode

Input signal F_OUTx	External capture	ISL	DSL	Action description
-	rising edge	1	-	do capture; issue NEWVAL_IRQ; CNT++
-	0	-	-	no
1	rising edge	0	1	do capture; issue NEWVAL_IRQ; CNT++
0	-	0	1	no
0	rising edge	0	0	do capture; issue NEWVAL_IRQ; CNT++
1	-	0	0	no

TIM Input Prescaler Mode (TIPM)

In the TIM Input Prescaler Mode the number of edges which should be detected before a TIM[i]_NEWVAL[x]_IRQ is raised is programmable. In this mode it must be specified in the CNTS register after how many edges the interrupt has to be raised.

A value of 0 in CNTS means that after one edge an interrupt is raised, and a value of 1 means that after two edges an interrupt is raised, and so on.

The edges to be counted can be selected by the bit fields DSL and ISL of register TIMi_CHx_CTRL.

With each triggered interrupt, the registers GPR0 and GPR1 are updated according to bits EGPR0_SEL, EGPR1_SEL, GPR0_SEL and GPR1_SEL.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

The TIM Input Prescaler Mode does not depend on the bit field CLK_SEL of register TIMi_CHx_CTRL.

External capture TIM Input Prescaler Mode (TIPM)

If external capture is enabled, the external capture events are counted instead of the input signal edges.

Operation is done depending on DSL, ISL bit and the input signal value defined in the next table:

Table 25-24 TIM Input Event Mode

Input signal F_OUTx	External capture	ISL	DSL	Action description
-	rising edge	1	-	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
-	0	1	-	no
1	rising edge	0	1	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	-	0	1	no
0	rising edge	0	0	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
1	-	0	0	no

TIM Bit Compression Mode (TBCM)

The TIM Bit Compression Mode can be used to combine all filtered input signals of a TIM submodule to a parallel 8 bit data word, which can be routed to the ARU.

Since this mode uses all eight input signals with its input filters, it is only available within TIM channel 0 of each TIM submodule. **Figure 25-31** gives an overview of the TIM bit compression mode.

TIM Bit Compression Mode

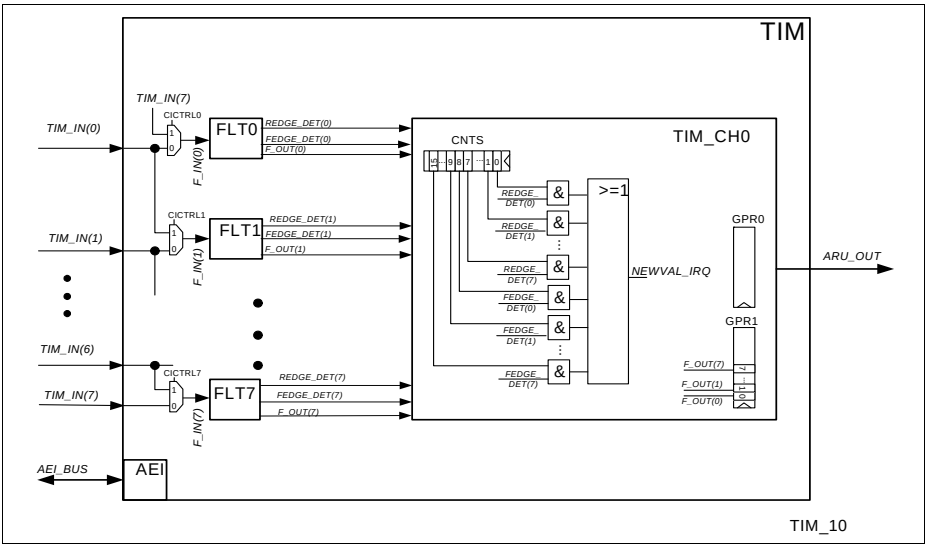

Figure 25-31 TIM Bit Compression Mode

The register CNTS of TIM channel 0 is used to configure the event that releases the NEWVAL_IRQ and samples the input signals F_IN(0) to F_IN(7) in ascending order as a parallel data word in GPR1.

The bits 0 to 7 of the CNTS register are used to select the REDGE_DET signals of the TIM filters 0 to 7 as a sampling event, and the bits 8 to 15 are used to select the FEDGE_DET signals of the TIM filters 0 to 7, respectively. If multiple events are selected, the events are OR-combined (see also **Figure 25-31**).

EGPR0_SEL, GRP0_SEL selects the timestamp value, which is routed through the ARU. GRP1_SEL is not applicable in TBCM mode.

If the bit ARU_EN of register TIMi_CH0_CTRL is set, the sampled data of register GPR1 is routed together with a time stamp of register GPR0 to the ARU, whenever the NEWVAL_IRQ is released.

In TIM Bit compression mode, the register ECNT increments on with each NEWVAL_IRQ, which means that the value of ECNT may depend on all eight input signals. Consequently, the LSB of ECNT does not reflect the actual level of the input signal TIM_IN0.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

The TIM Bit Compression Mode does not depend on the bit field CLK_SEL of register TIMi_CHx_CTRL.

External capture Bit Compression Mode (TBCM)

If external capture is enabled, capturing is done depending on DSL, ISL bit and the input signal value defined in the next table:

Table 25-25 TIM Input Event Mode

Input signal F_OUTx	External capture	ISL	DSL	Action description
-	rising edge	1	-	do capture; issue NEWVAL_IRQ; CNT++
-	0	1	-	no
1	rising edge	0	1	do capture; issue NEWVAL_IRQ; CNT++
0	-	0	1	no
0	rising edge	0	0	do capture; issue NEWVAL_IRQ; CNT++
1	-	0	0	no

TIM Gated Periodic Sampling Mode (TGPS)

In the TIM Gated Periodic Sampling Mode the number of CMU clock cycles which should elapse before capturing and rising TIMi_NEWVALx_IRQ is programmable. In this mode it must be specified in the CNTS register after how many CMU clock cycles the interrupt has to be raised.

A value of 0 in TIMi_CHx_CNTS means that after one CLK_SEL edge a trigger/interrupt is raised, and a value of 1 means that after two edges a trigger/interrupt is raised, and so on.

In the TIMi_CHx_CNT register the elapsed cycles were incremented and compared against TIMi_CHx_CNTS. If TIMi_CHx_CNT is greater or equal to TIMi_CHx_CNTS a trigger will be raised. This allows by writing a value to TIMi_CHx_CNTS that the actual period time can be changed on the fly.

Operation is done depending on CMU clock, DSL, ISL bit and the input signal value defined in the next table:

Table 25-26 TIM Gated Periodic Sampling Mode

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
-	1	0	1	-	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	0	0	0	1	no
1	1	0	0	1	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	0	-	0	1	no
0	1	0	0	0	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
1	0	0	0	0	no
-	0	0	-	-	no

In this mode the TIMi_CHx_GPR1 operates as a shadow register for TIMi_CHx_CNTS. This would allow that the period for the next sampling period could be specified. The update of TIMi_CHx_CNTS will only take place once on a trigger if the TIMi_CHx_GPR1 was written by the CPU. This means that the capture value from the previous trigger can be read by the CPU from TIMi_CHx_GPR1 and afterwards the new sampling period (the one after the actual sampling period) could be written.

With each triggered interrupt, the registers GPR0 and GPR1 are updated according to bits GPR0_SEL, GPR1_SEL, EGPR0_SEL and EGPR1_SEL.

When selecting ECNT as a source for the capture registers, GPRx will show the edge count and the input signal value at point of capture. Selecting GPR0_SEL = 11_B and EGPR0_SEL = 0_B for TIM channel 0 all 8 TIM input signals will captured to GPR[7:0].

In the TGPS Mode the bit field CLK_SEL of register TIMi_CHx_CTRL will define the selected CMU clock which will be used.

The behaviour of the ECNT counter is configurable by ECNT_RESET. If set to 1 on each interrupt (period expired) the ECNT will be reset. Otherwise it operates in wrap around mode.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFLx_IRQ is raised depending on corresponding interrupt enable condition.

External capture Bit Gated Periodic Sampling Mode (TGPS)

If external capture is enabled, the external capture events will capture the GPRx, reset the counter CNT and issue a NEWVAL_IRQ.

Operation is done depending on CMU clock, DSL, ISL bit and the input signal value defined in the next table:

Table 25-27 TIM Gated Periodic Sampling Mode

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
-	1	0	1	-	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	0	0	0	1	no
1	1	0	0	1	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	0	-	0	1	no
0	1	0	0	0	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
1	0	0	0	0	no
-	0	0	-	-	no
-	-	rising edge	-	-	do capture; issue NEWVAL_IRQ; CNT = 0

25.10.5 MAP Submodule Interface

The GTM provides one dedicated TIM submodule TIM0 where channels zero (0) to five (5) are connected to the MAP submodule described in **Section 25.15**. There, the TIM0 submodule channels provide the input signal level together with the actual filter value and the annotated time stamp for the edge together in a 49 bit wide signal to the MAP

submodule. This 49 bit wide data signal is marked as valid with a separate valid signal tim0_map_dval[x] (x:0…5).

Table 25-28 TIM0 to MAP Interface

tim0_map_data[x](48)	signal level bit from tim0_ch[x]
tim0_map_data[x](47:24)	actual filter value TIM0_CHx_FLT_RE/TIM0_CHx_FLT_FE if corresponding channel x bit field FLT_MODE_RE/FLT_MODE_FE is 1 else 0 is assigned.
tim0_map_data[x](23:0)	time stamp value selected by TBU0_SEL, GRP0_SEL, EGPR0_SEL, CNTS_SEL if channel x if bit field TIM_EN=1
tim0_map_dval[x]	mark tim0_map_data[x] valid for one clock cycle

Note: With TIM_EN=1 the MAP interface starts operation, it is not dependent on the setting of the bit fields TIM_MODE, ISL, and DSL.

Note: While the MAP interface is in the use the following guidelines have to be fulfilled, otherwise inconsistent filter values can be transferred.
Change TIM0_CHx_FLT_RE only between occurance of rising and falling edge.
Change TIM0_CHx_FLT_FE only between occurance of falling and rising edge.

25.10.6 TIM Interrupt Signals

TIM provides 6 interrupt lines per channel. These interrupts are shown below:

Table 25-29 TIM Interrupt Signals

Signal	Description
TIM[i]_NEWVAL[x]_IRQ	New measurement value detected by SMU of channel x (x:0…7)
TIM[i]_ECNTOFL[x]_IRQ	ECNT counter overflow of channel x (x:0…7)
TIM[i]_CNTOFL[x]_IRQ	SMU CNT counter overflow of channel x (x:0…7)
TIM[i]_GPROF[x]_IRQ	GPR0 and GPR1 data overflow, old data was not read out before new data has arrived at input pin (x:0…7)
TIM[i]_TODET[x]_IRQ	Time out reached for input signal of channel x (x:0…7)
TIM[i]_GLITCHDET_IRQ	A glitch was detected by the TIM filter of channel (x: 0…7).

25.10.7 TIM Configuration Registers Overview

TIM contains following configuration registers:

Table 25-30 TIM Configuration Registers Overview

Register Name	Description	Detail in Section
TIMi_CHx_CTRL	TIM channel x control register (x:0…7)	Section 25.10.8.1 Section 25.10.8.2
TIMi_CHx_ECTRL	TIM channel x (x:0…7) extended control	Section 25.10.8.20
TIMi_CHx_FLT_RE	TIM channel x filter parameter 0 register (x:0…7)	Section 25.10.8.3
TIMi_CHx_FLT_FE	TIM channel x filter parameter 1 register (x:0…7)	Section 25.10.8.4
TIMi_CHx_TDUV	TIM channel x TDU control register (x:0…7)	Section 25.10.8.17
TIMi_CHx_TDUC	TIM channel x TDU counter register (x:0…7)	Section 25.10.8.18
TIMi_CHx_GPR0	TIM channel x general purpose 0 register (x:0…7)	Section 25.10.8.6
TIMi_CHx_GPR1	TIM channel x general purpose 1 register (x:0…7)	Section 25.10.8.7
TIMi_CHx_CNT	TIM channel x SMU counter register (x:0…7)	Section 25.10.8.8
TIMi_CHx_ECNT	TIM channel x (x:0…7) SMU edge counter	Section 25.10.8.19
TIMi_CHx_CNTS	TIM channel x SMU shadow counter register (x:0…7)	Section 25.10.8.9
TIMi_CHx_IRQ_NOTIFY	TIM channel x interrupt notification register (x:0…7)	Section 25.10.8.10
TIMi_CHx_IRQ_EN	TIM channel x interrupt enable register (x:0…7)	Section 25.10.8.11
TIMi_CHx_EIRQ_EN	TIM channel x (x:0…7) error interrupt enable	Section 25.10.8.16
TIMi_CHx_IRQ_FORCINT	TIM channel x software interrupt force register (x:0…7)	Section 25.10.8.12
TIMi_CHx_IRQ_MODE	TIM IRQ mode configuration register (x=0…7)	Section 25.10.8.13

Table 25-30 TIM Configuration Registers Overview (cont'd)

Register Name	Description	Detail in Section
TIMi_RST	TIM global software reset register	Section 25.10.8.14
TIMi_IN_SRC	TIM AUX IN source selection	Section 25.10.8.15

25.10.8 TIM Configuration Registers Description

All of the following registers are 32-bit only accessible.

25.10.8.1 Register TIMi_CHx_CTRL (x:0…7) (i: 13)

GTM_TIM1_CHx_CTRL (x=0-7)
TIM1_Channelx_CTRL Register
(01824_H+x*80_H) **Reset Value: 00000000_H**

GTM_TIM2_CHx_CTRL (x=0-7)
TIM2_Channelx_CTRL Register
(02024_H+x*80_H) **Reset Value: 00000000_H**

GTM_TIM3_CHx_CTRL (x=0-7)
TIM3_Channelx_CTRL Register
(02824_H+x*80_H) **Reset Value: 00000000_H**

ECNT_RESET	ISL	DSL	CNTS_SEL	GPR1_SEL		GPR0_SEL		Reserved	CICTRL	ARU_EN	OSM	TIM_MODE			TIM_EN
rw	rw	rw	rw	rw		rw		r	rw	rw	rw	rw			rwh

Field	Bits	Type	Description
TIM_EN	0	rwh	**TIM channel x (x:0…7) enable** 0_B Channel disabled 1_B Channel enabled Note: Enabling of the channel resets the registers ECNT, TIMi_CHx_CNT, TIMi_CHx_GPR0, and TIMi_CHx_GPR1 to their reset values. Note: After finishing the action in one-shot mode the TIM_EN bit is cleared automatically. Otherwise, the bit must be cleared manually.

Field	Bits	Type	Description
TIM_MODE	[3:1]	rw	**TIM channel x (x:0…7) mode** 000_B PWM Measurement Mode (TPWM) 001_B Pulse Integration Mode (TPIM) 010_B Input Event Mode (TIEM) 011_B Input Prescaler Mode (TIPM) 100_B Bit Compression Mode (TBCM) 101_B Gated Periodic Sampling Mode (TGPS) Note: The Bit Compression Mode is only available in TIM channel 0. If this mode is selected in any other channels, the TIM_MODE = 000 (TPWM mode) is used instead. However, the register TIM_MODE is read with value 100. Note: If an undefined value is written to the TIM_MODE register, the hardware switches automatically to TIM_MODE = 000 (TPWM mode). Note: The TIM_MODE register should not be changed while the TIM channel is enabled. Note: If TIM channel is enabled and operating in TPWM or TPIM mode after the first valid edge defined by DSL has occurred, a reconfiguration of DSL, ISL, and TIM_MODE will not change the channel behavior. Reading these bit fields after reconfiguration will show the newly configured settings but the initial channel behavior will not change. Only a disabling of the TIM_EN=1 will change the channel operation mode.
OSM	4	rw	**One-shot mode** 0_B Continuous operation mode 1_B One-shot mode Note: After finishing the action in one-shot mode the TIM_EN bit is cleared automatically.
ARU_EN	5	rw	**GPR0 and GPR1 register values routed to ARU** 0_B Registers content not routed 1_B Registers content routed
CICTRL	6	rw	**Channel Input Control** 0_B use signal TIM_IN(x) as input for channel x 1_B use signal TIM_IN(x-1) as input for channel x (or TIM_IN(7) if x is 0)
Reserved	7	r	**Reserved** Read as zero, should be written as zero

Field	Bits	Type	Description
GPR0_SEL	[9:8]	rw	**Selection for GPR0 register** If EGPR0_SEL =0: 00_B use TBU_TS0 as input 01_B use TBU_TS1 as input 10_B use TBU_TS2 as input 11_B use CNTS as input; if TGPS mode in channel = 0 is selected use TIM Filter F_OUT as input If EGPR0_SEL =1: 00_B use ECNT as input 01_B reserved 10_B reserved 11_B reserved *Note: If a reserved value is written to the EGPR0_SEL, GPR0_SEL bit fields, the hardware will use TBU_TS0 input.*
GPR1_SEL	[11:10]	rw	**Selection for GPR1 register** If EGPR0_SEL =0: 00_B use TBU_TS0 as input 01_B use TBU_TS1 as input 10_B use TBU_TS2 as input 11_B use CNT as input If EGPR0_SEL =1: 00_B use ECNT as input 01_B reserved 10_B reserved 11_B reserved *Note: In TBCM mode EGPR1_SEL, GPR1_SEL are ignored TIM Filter F_OUT is used as input.* *Note: If a reserved value is written to the EGPR1_SEL, GPR1_SEL bit fields, the hardware will use TBU_TS0 input.*
CNTS_SEL	12	rw	**Selection for CNTS register** 0_B use CNT register as input 1_B use TBU_TS0 as input Note: The functionality of the CNTS_SEL is disabled in the modes TIPM and TBCM.

Field	Bits	Type	Description
DSL	13	rw	**Signal level control** 0_B Measurement starts with falling edge (low level measurement) 1_B Measurement starts with rising edge (high level measurement)
ISL	14	rw	**Ignore signal level** 0_B use DSL bit for selecting active signal level 1_B ignore DSL and treat both edges as active edge Note: This bit is only applicable in Input Event mode (TIEM)
ECNT_RESET	15	rw	**Enables resetting the ECNT counter in periodic sampling mode** 0_B ECNT counter operating in wrap around mode 1_B ECNT counter is reset with periodic sampling
FLT_EN	16	rw	**Filter enable for channel x (x:0…7)** 0_B Filter disabled and internal states are reset 1_B Filter enabled Note: If the filter is disabled all filter related units (including CSU) are bypassed, which means that the signal F_IN is directly routed to signal F_OUT.
FLT_CNT_FRQ	[18:17]	rw	**Filter counter frequency select** 00_B FLT_CNT counts with CMU_CLK0 01_B FLT_CNT counts with CMU_CLK1 10_B FLT_CNT counts with CMU_CLK6 11_B FLT_CNT counts with CMU_CLK7
EXT_CAP_EN	19	rw	**Enables external capture mode** The selected TIM mode is only sensitive to external capture pulses the input event changes are ignored 0_B External capture disabled 1_B External capture enabled
FLT_MODE_RE	20	rw	**Filter mode for rising edge** 0_B Immediate edge propagation mode 1_B individual de-glitch mode
FLT_CTR_RE	21	rw	**Filter counter mode for rising edge** 0_B Up/Down Counter 1_B Hold Counter Note: This bit is only applicable in Individual Deglitch Time Mode

Field	Bits	Type	Description
FLT_MODE_FE	22	rw	**Filter mode for falling edge** 0_B Immediate edge propagation mode 1_B individual de-glitch mode
FLT_CTR_FE	23	rw	**Filter counter mode for falling edge** 0_B Up/Down Counter 1_B Hold Counter Note: This bit is only applicable in Individual Deglitch Time Mode
CLK_SEL	[26:24]	rw	**CMU clock source select for channel** 000_B CMU_CLK0 selected 001_B CMU_CLK1 selected 010_B CMU_CLK2 selected 011_B CMU_CLK3 selected 100_B CMU_CLK4 selected 101_B CMU_CLK5 selected 110_B CMU_CLK6 selected 111_B CMU_CLK7 selected
FR_ECNT_OFL	27	rw	**Extended Edge counter overflow behaviour** 0_B Overflow will be signalled on ECNT bit width = 8 1_B Overflow will be signalled on EECNT bit width (full range)
EGPR0_SEL	28	rw	**Extension of GPR0_SEL bit field** Details described in GPR0_SEL bit field.
EGPR1_SEL	29	rw	**Extension of GPR1_SEL bit field** Details described in GPR1_SEL bit field.
TOCTRL	[31:30]	rw	**Timeout control** 00_B Timeout feature disabled 01_B Timeout feature enabled for rising edge only 10_B Timeout feature enabled for falling edge only 11_B Timeout feature enabled for both edges

25.10.8.2 Register TIM0_CHx_CTRL (x:0…7)

GTM_TIM0_CHx_CTRL (x=0-7)
TIM Channel x Control Register (01024_H+x*80_H) **Reset Value: 00000000_H**

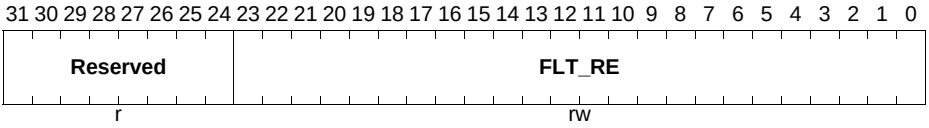
25.10.8.3 Register TIMi_CHx_FLT_RE (i:0…3)(x:0…7)

GTM_TIM0_CHx_FLT_RE (x=0-7)
GTM_TIM0 Channel x Filter Parameter 0 Register
($0101C_H$+x*80_H) **Reset Value: 00000000_H**

GTM_TIM1_CHx_FLT_RE (x=0-7)
GTM_TIM1 Channel x Filter Parameter 0 Register
($0181C_H$+x*80_H) **Reset Value: 00000000_H**

GTM_TIM2_CHx_FLT_RE (x=0-7)
GTM_TIM2 Channel x Filter Parameter 0 Register
($0201C_H$+x*80_H) **Reset Value: 00000000_H**

GTM_TIM3_CHx_FLT_RE (x=0-7)
GTM_TIM3 Channel x Filter Parameter 0 Register
($0281C_H$+x*80_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
FLT_RE	[23:0]	rw	**Filter parameter for rising edge** Note: This register has different meanings in the various filter modes. Immediate edge propagation mode = acceptance time for rising edge Individual deglitch time mode = deglitch time for rising edge
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

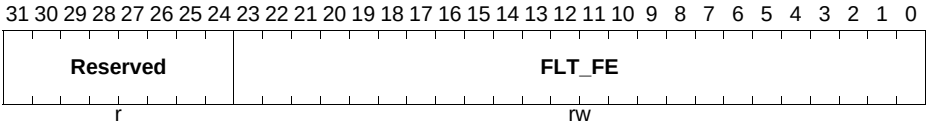
25.10.8.4 Register TIMi_CHx_FLT_FE (i:0…3)(x:0…7)

GTM_TIM0_CHx_FLT_FE (x=0-7)
TIM0 Channel x Filter Parameter 1 Register
(01020_H+x*80_H) **Reset Value: 00000000_H**

GTM_TIM1_CHx_FLT_FE (x=0-7)
TIM1 Channel x Filter Parameter 1 Register
(01820_H+x*80_H) **Reset Value: 00000000_H**

GTM_TIM2_CHx_FLT_FE (x=0-7)
TIM2 Channel x Filter Parameter 1 Register
(02020_H+x*80_H) **Reset Value: 00000000_H**

GTM_TIM3_CHx_FLT_FE (x=0-7)
TIM3 Channel x Filter Parameter 1 Register
(02820_H+x*80_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
FLT_FE	[23:0]	rw	**Filter parameter for falling edge** Note: This register has different meanings in the various filter modes. Immediate edge propagation mode = acceptance time for falling edge Individual deglitch time mode = deglitch time for falling edge
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

25.10.8.5 Register TIMi_CHx_TDU (i:0...3)(x:0...7)

Functionality is replaced by register TIMi_CHx_TDUV, TIMi_CHx_TDUC and bit field TOCTRL in Register TIMi_CHx_CTRL

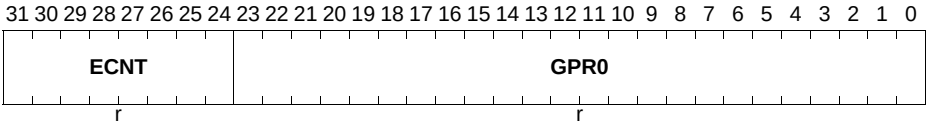
25.10.8.6 Register TIMi_CHx_GPR0 (i:0…3)(x:0…7)

GTM_TIM0_CHx_GPR0 (x=0-7)
TIM0 Channel x General Purpose 0 Register
(01000_H+x*80_H) **Reset Value: $0X000000_H$**

GTM_TIM1_CHx_GPR0 (x=0-7)
TIM1 Channel x General Purpose 0 Register
(01800_H+x*80_H) **Reset Value: $0X000000_H$**

GTM_TIM2_CHx_GPR0 (x=0-7)
TIM2 Channel x General Purpose 0 Register
(02000_H+x*80_H) **Reset Value: $0X000000_H$**

GTM_TIM3_CHx_GPR0 (x=0-7)
TIM3 Channel x General Purpose 0 Register
(02800_H+x*80_H) **Reset Value: $0X000000_H$**



Field	Bits	Type	Description
GPR0	[23:0]	r	**Input signal characteristic parameter 0** Note: The content of this register has different meaning for the TIM channels modes. The content directly depends on the bit fields EGPR0_SEL, GPR0_SEL of register TIMi_CHx_CTRL.
ECNT	[31:24]	r	**Edge counter** Note: The ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT. Note: The ECNT register is reset to its initial value when the channel is enabled. Please note, that bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.

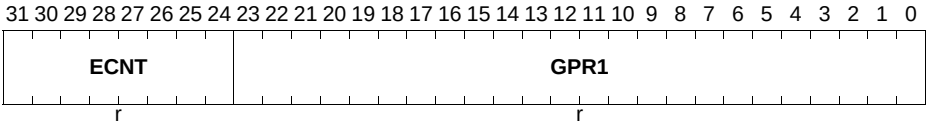
25.10.8.7 Register TIMi_CHx_GPR1 (i:0…3)(x:0…7)

GTM_TIM0_CHx_GPR1 (x=0-7)
TIM0 Channel x General Purpose 1 Register
(01004_H+x*80_H) **Reset Value: 0X000000$_H$**

GTM_TIM1_CHx_GPR1 (x=0-7)
TIM1 Channel x General Purpose 1 Register
(01804_H+x*80_H) **Reset Value: 0X000000$_H$**

GTM_TIM2_CHx_GPR1 (x=0-7)
TIM2 Channel x General Purpose 1 Register
(02004_H+x*80_H) **Reset Value: 0X000000$_H$**

GTM_TIM3_CHx_GPR1 (x=0-7)
TIM3 Channel x General Purpose 1 Register
(02804_H+x*80_H) **Reset Value: 0X000000$_H$**



Field	Bits	Type	Description
GPR1	[23:0]	r	**Input signal characteristic parameter 1** Note: The content of this register has different meaning for the TIM channels modes. The content directly depends on the bit fields EGPR1_SEL, GPR1_SEL of register TIMi_CHx_CTRL. Note: In TBCM mode if EGPR1_SEL=1, GPR1_SEL=01 then TIM_INP_VAL is used as input in all other cases TIM filter F_OUT is used as input and bits GPR1(23:8)=0. Note: The content of this register can only be written in TIM channel mode TGPS.

Field	Bits	Type	Description
ECNT	[31:24]	r	**Edge counter** Note: The ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT. Note: The ECNT register is reset to its initial value when the channel is enabled. Please note, that bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.

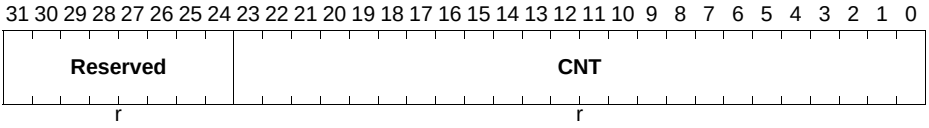
25.10.8.8 Register TIMi_CHx_CNT (i:0…3)(x:0…7)

GTM_TIM0_CHx_CNT (x=0-7)
TIM0 Channel x SMU Counter Register
(01008_H+x*80_H) **Reset Value: 00000000_H**

GTM_TIM1_CHx_CNT (x=0-7)
TIM1 Channel x SMU Counter Register
(01808_H+x*80_H) **Reset Value: 00000000_H**

GTM_TIM2_CHx_CNT (x=0-7)
TIM2 Channel x SMU Counter Register
(02008_H+x*80_H) **Reset Value: 00000000_H**

GTM_TIM3_CHx_CNT (x=0-7)
TIM3 Channel x SMU Counter Register
(02808_H+x*80_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
CNT	[23:0]	r	**Actual SMU counter value** Note: The meaning of this value depends on the configured mode: TPWM = actual duration of PWM signal. TPIM = actual duration of all pulses (sum of pulses). TIEM = actual number of received edges. TIPM = actual number of received edges.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

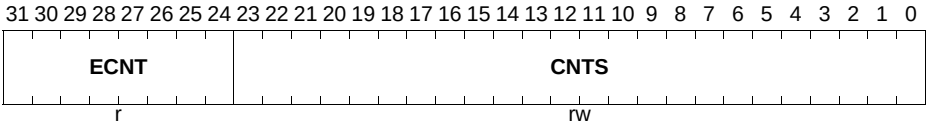
25.10.8.9 Register TIMi_CHx_CNTS (i:0…3)(x:0…7)

GTM_TIM0_CHx_CNTS (x=0-7)
TIM0 Channel x SMU Shadow Counter Register
(01010_H+x*80_H) **Reset Value: $0X000000_H$**

GTM_TIM1_CHx_CNTS (x=0-7)
TIM1Channel x SMU Shadow Counter Register
(01810_H+x*80_H) **Reset Value: $0X000000_H$**

GTM_TIM2_CHx_CNTS (x=0-7)
TIM2 Channel x SMU Shadow Counter Register
(02010_H+x*80_H) **Reset Value: $0X000000_H$**

GTM_TIM3_CHx_CNTS (x=0-7)
TIM3 Channel x SMU Shadow Counter Register
(02810_H+x*80_H) **Reset Value: $0X000000_H$**



Field	Bits	Type	Description
CNTS	[23:0]	rw	**Counter shadow register** Note: The content of this register has different meaning for the TIM channels modes. The content depends directly on the bit field CNTS_SEL of register TIMi_CHx_CTRL. Note: The register TIMi_CHx_CNTS is only writable in TIPM, TBCM, and TGPS mode.
ECNT	[31:24]	r	**Edge counter** Note: The ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT. Note: The ECNT register is reset to its initial value when the channel is enabled. Please note, that bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.

25.10.8.10Register TIMi_CHx_IRQ_NOTIFY (i:0…3)(x:0…7)

GTM_TIM0_CHx_IRQ_NOTIFY (x=0-7)
TIM0 Channel x Interrupt Notification Register
($0102C_H$+x*80_H) **Reset Value: 00000000_H**

GTM_TIM1_CHx_IRQ_NOTIFY (x=0-7)
TIM1 Channel x Interrupt Notification Register
($0182C_H$+x*80_H) **Reset Value: 00000000_H**

GTM_TIM2_CHx_IRQ_NOTIFY (x=0-7)
TIM2 Channel x Interrupt Notification Register
($0202C_H$+x*80_H) **Reset Value: 00000000_H**

GTM_TIM3_CHx_IRQ_NOTIFY (x=0-7)
TIM3 Channel x Interrupt Notification Register
($0282C_H$+x*80_H) **Reset Value: 00000000_H**

25.11 Timer Output Module (TOM)

25.11.1 Overview

The Timer Output Module (TOM) offers 16 independent channels to generate simple PWM signals at each output pin TOM[i]_CH[x]_OUT (i=0…2; x=0…15).

Additionally, at TOM output TOM[i]_CH15_OUT a pulse count modulated signal can be generated.

The architecture of the TOM submodule is depicted in **Figure 25-32**.

Some useful indices are defined as:

y=0,1

z=0…7

25.11.1.1 TOM Block diagram

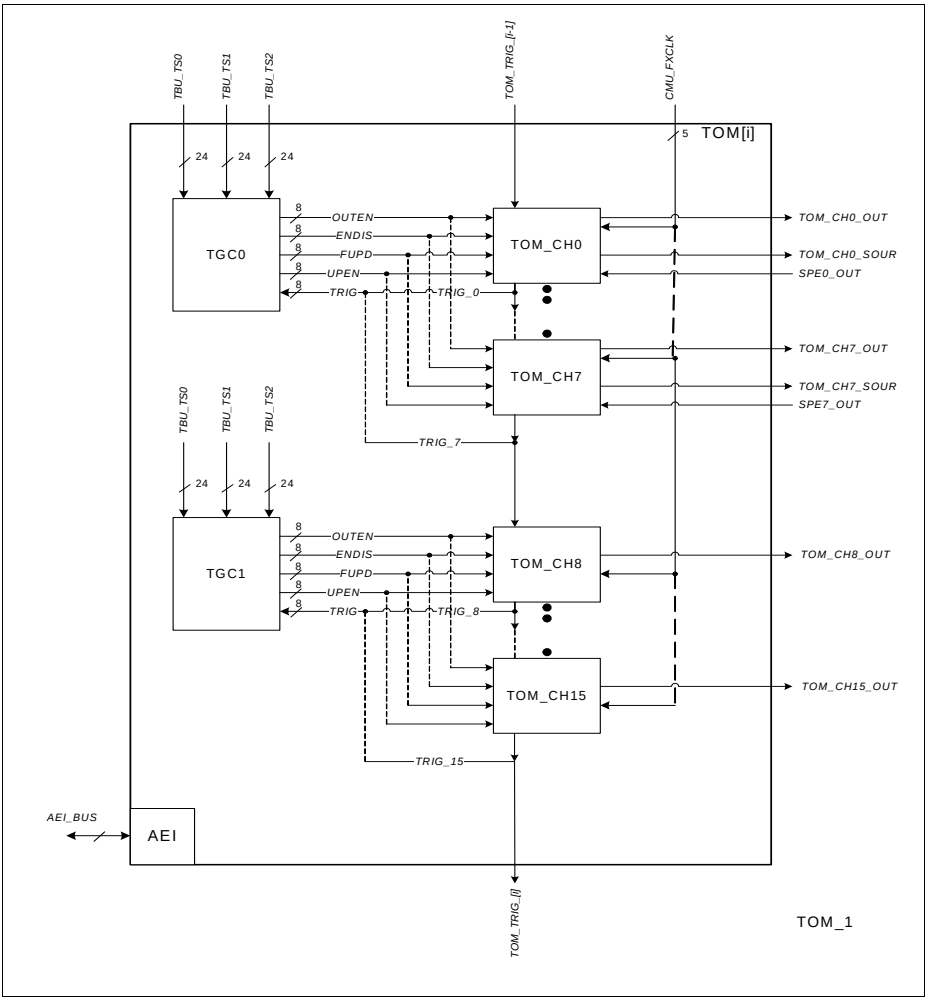

Figure 25-32 TOM Block diagram

The two submodules TGC0 and TGC1 are global channel control units that control the enabling/disabling of the channels and their outputs as well as the update of their period and duty cycle register.

The module TOM receives two (three) timestamp values TBU_TS0, TBU_TS1 (and TBU_TS2) in order to realize synchronized output behaviour on behalf of a common time base.

The 5 dedicated clock line inputs CMU_FXCLK are providing divided clocks that can be selected to clock the output pins.

25.11.2 TOM Global Channel Control (TGC0, TGC1)

25.11.2.1 Overview

There exist two global channel control units (TGC0 and TGC1) to drive a number of individual TOM channels synchronously by external or internal events.

Each TGC[y] can drive up to eight TOM channels where TGC0 controls TOM channels 0 to 7 and TGC1 controls TOM channels 8 to 15.

The TOM submodule supports four different kinds of signalling mechanisms:

- Global enable/disable mechanism for each TOM channel with control register TOMi_TGCy_ENDIS_CTRL and status register TOMi_TGCy_ENDIS_STAT
- Global output enable mechanism for each TOM channel with control register TOMi_TGCy_OUTEN_CTRL and status register TOMi_TGCy_OUTEN_STAT
- Global force update mechanism for each TOM channel with control register TOMi_TGCy_FUPD_CTRL
- Update enable of the register CM0, CM1 and CLK_SRC_STAT for each TOM channel with the control bit field UPEN_CTRL[z] of TOMi_TGCy_GLB_CTRL

25.11.2.2 TGC Subunit

Each of the first three individual mechanisms (enable/disable of the channel, output enable and force update) can be driven by three different trigger sources.

The three trigger sources are:

- the host CPU (bit HOST_TRIG of register TOMi_TGCy_GLB_CTRL)
- the TBU time stamp (signal TBU_TS0., TBU_TS1, TBU_TS2)
- the internal trigger signal TRIG (bunch of trigger signals TRIG_[x])

Note: The trigger signal is only active for one configured CMU clock period.

As a consequence, if the configured CMU clock period of the channel generating the trigger TRIG_[X] is smaller than the CMU clock period of triggered channel, the triggered channel may not recognize the trigger signal TRIG_[X].

Thus, it is recommended to configure all channels connected via the trigger TRIG_[x] to the same CMU clock period.

The first way is to trigger the control mechanism by a direct register write access via host CPU (bit HOST_TRIG of register TOMi_TGCy_GLB_CTRL).

The second way is provided by a compare match trigger on behalf of a specified time base coming from the module TBU (selected by bits TBU_SEL) and the time stamp compare value defined in the bit field ACT_TB of register TOMi_TGCy_ACT_TB.

Note, a signed compare of ACT_TB and selected TBU_TS[x] with x=0,1,2 is performed.

The third possibility is the input TRIG (bunch of trigger signals TRIG_[x]) coming from the TOM channels 0 to 7 / 8 to 15.

The corresponding trigger signal TRIG_[x] coming from channel [x] can be masked by the register TOMi_TGCy_INT_TRIG.

To enable or disable each individual TOM channel, the registers TOMi_TGCy_ENDIS_CTRL and/or TOMi_TGCy_ENDIS_STAT have to be used.

The register TOMi_TGCy_ENDIS_STAT controls directly the signal ENDIS. A write access to this register is possible.

The register TOMi_TGCy_ENDIS_CTRL is a shadow register that overwrites the value of register TOMi_TGCy_ENDIS_STAT if one of the three trigger conditions matches.

TOM Global channel control mechanism

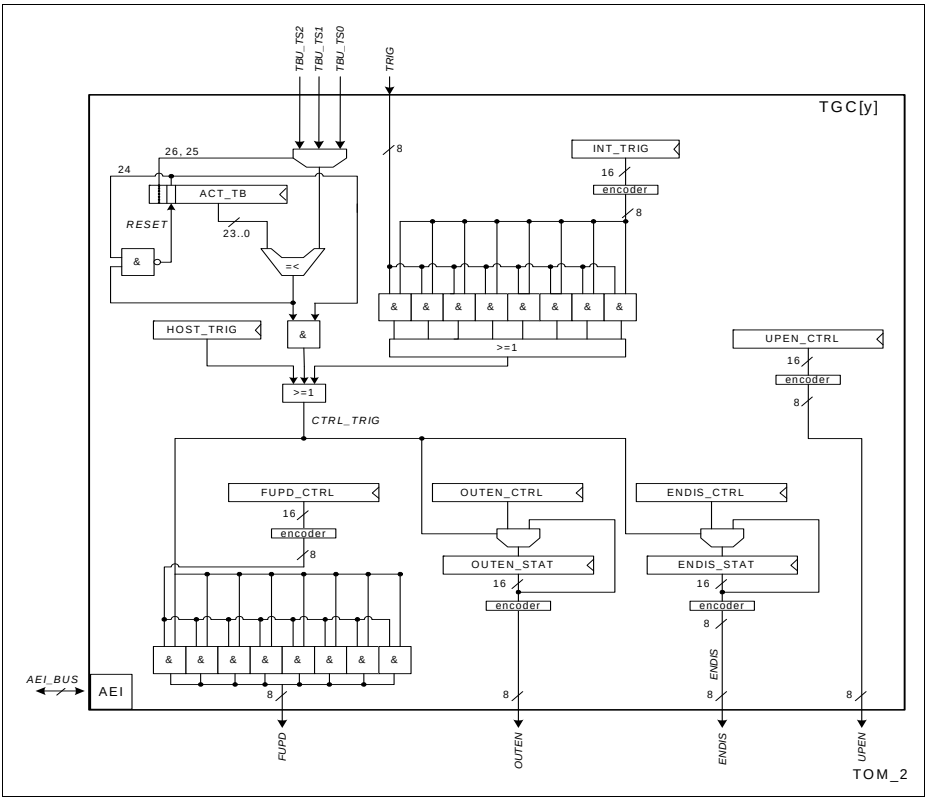

Figure 25-33 TOM Global channel control mechanism

The output of the individual TOM channels can be controlled using the register TOMi_TGCy_OUTEN_CTRL and TOMi_TGCy_OUTEN_STAT.

The register TOMi_TGCy_OUTEN_STAT controls directly the signal OUTEN. A write access to this register is possible.

The register TOMi_TGCy_OUTEN_CTRL is a shadow register that overwrites the value of register TOMi_TGCy_OUTEN_STAT if one of the three trigger conditions matches.

If a TOM channel is disabled by the register TOMi_TGCy_OUTEN_STAT, the actual value of the channel output at TOM_CH[x]_OUT is defined by the signal level bit (SL) defined in the channel control register TOMi_CHx_CTRL.

If the output is enabled, the output at TOM_CH[x]_OUT depends on value of FlipFlop SOUR.

The register TOMi_TGCy_FUPD_CTRL defines which of the TOM channels receive a FORCE_UPDATE event if the trigger signal CTRL_TRIG is raised.

The register bits UPEN_CTRL[z] defines for which TOM channel the update of the working register CM0, CM1 and CLK_SRC by the corresponding shadow register SR0, SR1 and CLK_SRC_SR is enabled. If update is enabled, the register CM0, CM1 and CLK_SRC will be updated on reset of counter register CN0 (see **Figure 25-34** and **Figure 25-35**).

25.11.3 TOM Channel (TOM_CH[x])

Each individual TOM channel comprises a Counter Compare Unit 0 (CCU0), a Counter Compare Unit 1 (CCU1) and the Signal Output Generation Unit (SOU). The architecture is depicted in **Figure 25-34** for channels 0 to 7 and in **Figure 25-35** for channels 8 to 15.

25.11.3.1 TOM Channel 0…7 architecture

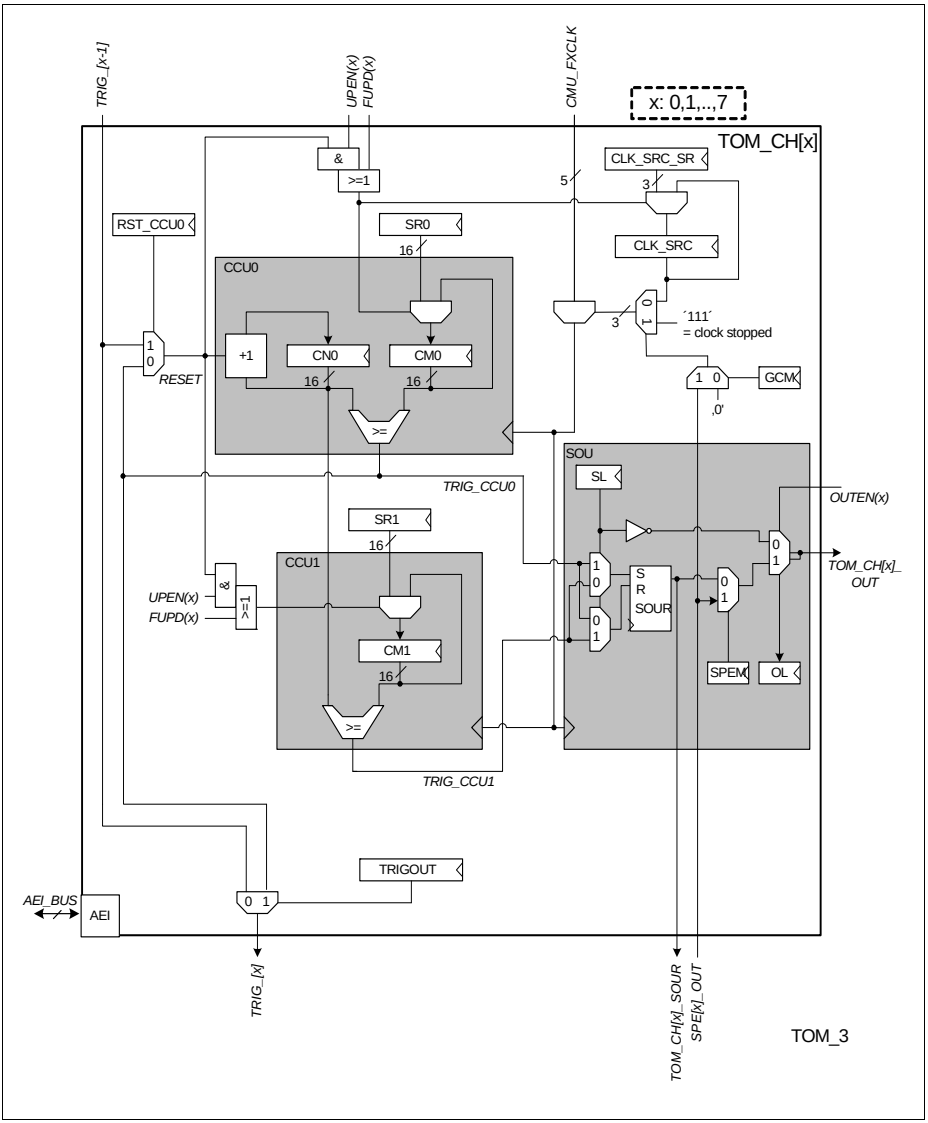

Figure 25-34 TOM Channel 0…7 architecture

25.11.3.2 TOM Channel 8…14 architecture

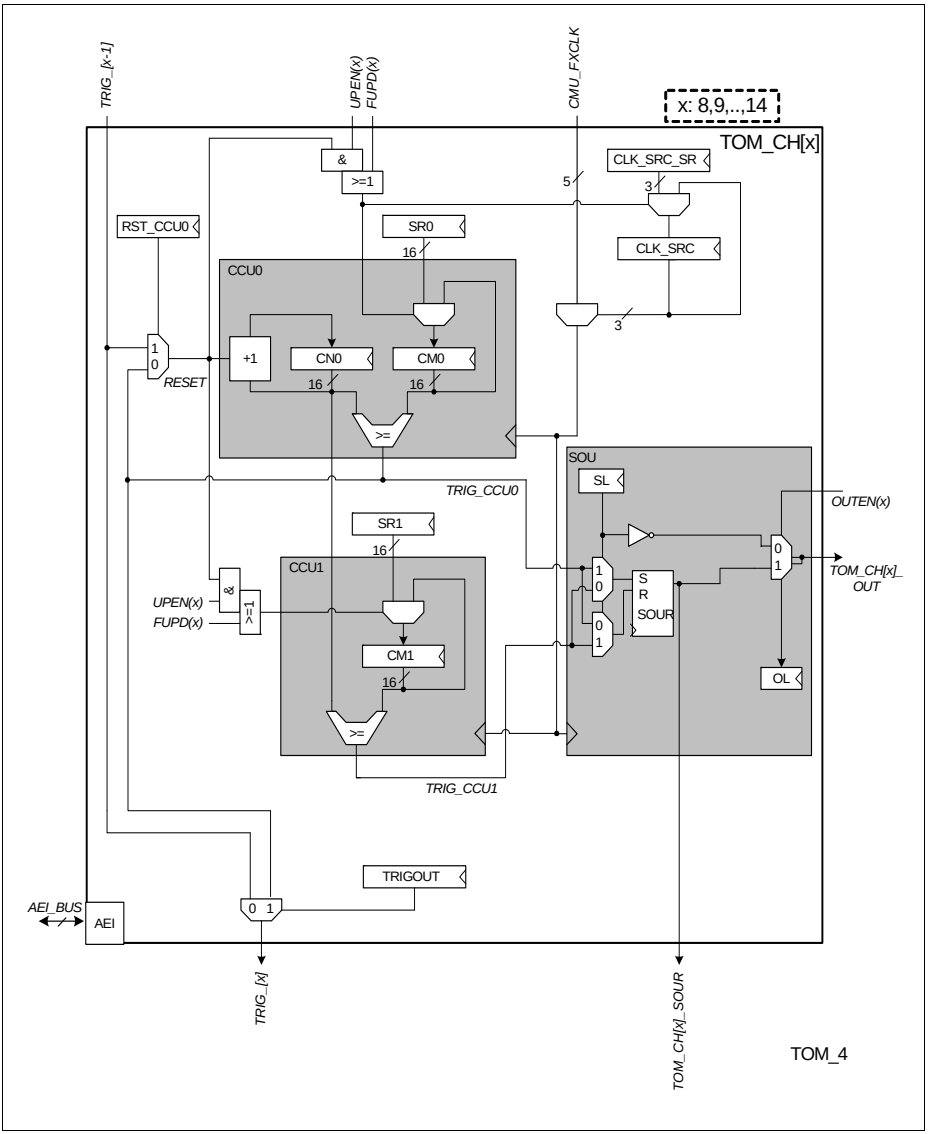

Figure 25-35 TOM Channel 8…14 architecture

25.11.3.3 TOM Channel 15 architecture for PCM generation

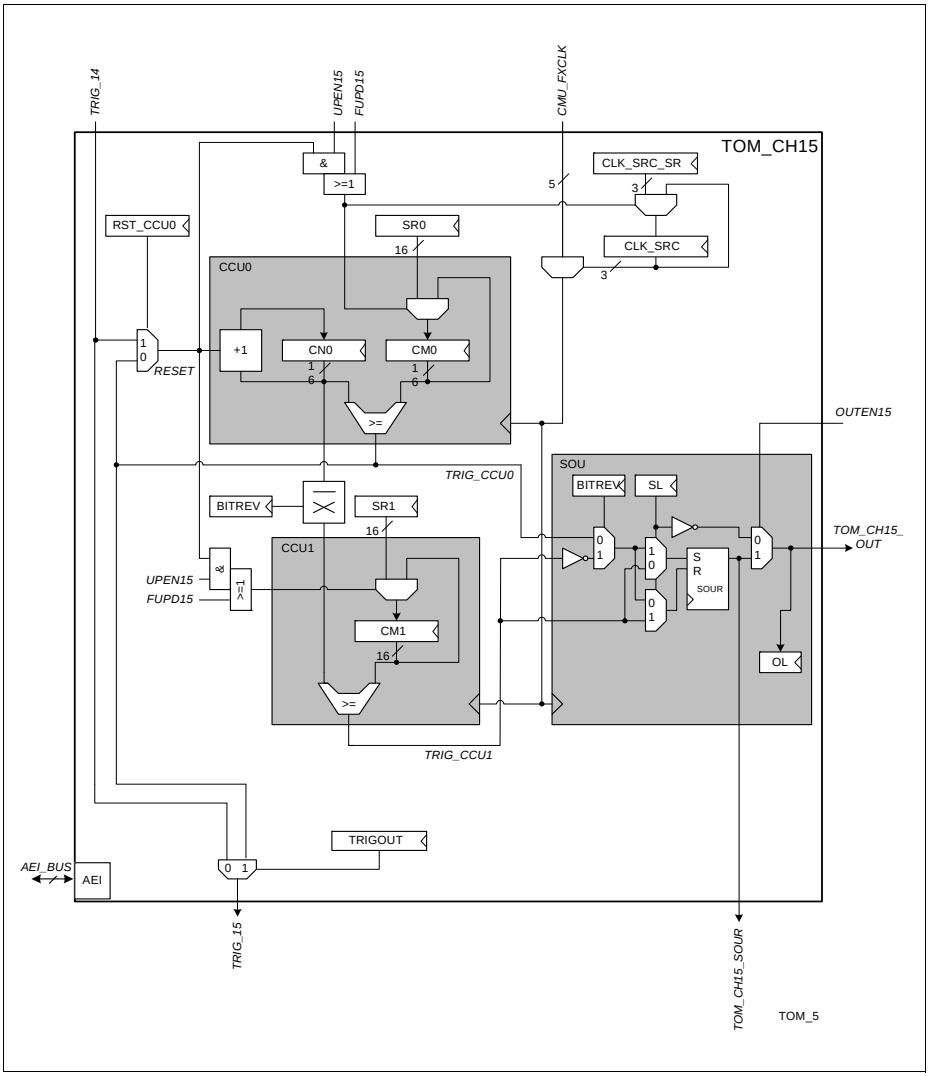

Figure 25-36 TOM Channel 15 architecture for PCM generation

The CCU0 contains a counter CN0 which is clocked with one of the selected input frequencies (CMU_FXCLK) provided from outside of the submodule.

Depending on configuration bits RST_CCU0 of register TOMi_CHx_CTRL the counter can be reset either when the counter value is equal to the compare value CM0 or when signalled by the TOM[i] trigger signal TRIG_[x-1] of the preceding channel [x-1] (which can also be the last channel of preceding instance TOM[i-1]).

When the counter register CN0 is greater or equal than the register CM0, the subunit CCU0 triggers the SOU subunit and the succeeding TOM submodule channel (signal TRIG_CCU0).

In the subunit CCU1 the counter register CN0 is compared with the value of register CM1. If CN0 is greater or equal than CM1 the subunit CCU1 triggers the SOU subunit (signal TRIG_CCU1).

If counter register CN0 of channel x is reset by its own CCU0 unit (i.e. the compare match of CN0>=CM0 configured by RST CCU0=0, following statements are vaild:

- if CM0=0 or CM0=1, 0% duty cycle (=$\overline{SL}$) is generated independent of CM1. The counter CN0 is not counting.
- the configuration of CM1=0 represents 0% duty cycle (=$\overline{SL}$) at the output
- the configuration of CM1>=CM0 represents 100% duty cycle (=SL)

If counter register CN0 of x channel is reset by the trigger signal coming from another channel or the assuigned TIM module (configured by RST CCU0=1), following statements are valid:

- CM0 defines the edge to SL value, CM1 defines the edge to $\overline{SL}$ value
- if CM0=CM1, the output is 100% SL (CM0 has higher priority)
- if CM0=0, the output stays at its last value (CN0 stops counting)

The hardware ensures that for both 0% and 100% duty cycle no glitch occurs at the output of the TOM channel.

The SOU subunit is responsible for output signal generation. On a trigger TRIG_CCU0 from subunit CCU0 or TRIG_CCU1 from subunit CCU1 a SR-FlipFlop of subunit SOU is either set or reset. If it is set or reset depends on the configuration bit SL of the control register TOMi_CHx_CTRL. The initial signal output level for the channel is the erse value of the bit SL.

Figure 25-39 clarifies the PWM output behaviour with respect to the SL bit definition.

The output level on the TOM channel output pin TOM[i]_CH[x]_OUT is captured in bit OL of register TOMi_CHx_STAT.

25.11.3.4 Duty cycle, period and selected counter clock frequency update mechanisms

The two action registers CM0 and CM1 can be reloaded with the content of the shadow registers SR0 and SR1. The register CLK_SRC that determines the clock frequency of

the counter register CN0 can be reloaded with its shadow register CLK_SRC_SR (bit field in register TOMi_CHx_CTRL)

The update of the register CM0, CM1 and CLK_SRC with the content of its shadow register is done when the reset of the counter register CN0 is requested (via signal RESET). This reset of CN0 is done if the comparison of CN0 greater or equal than CM0 is true or when the reset is triggered by another TOM channel [x-1] via the signal TRIG_[x-1].

For TOM0 channel 0 TRIG_[-1] is '0' hard coded.

With the update of the register CLK_SRC at the end of a period a new counter CN0 clock frequency can easily be adjusted.

An update of duty cycle, period and counter CN0 clock frequency becoming effective synchronously with start of a new period can easily be reached by performing following steps:

1. disable the update of the action register with the content of the corresponding shadow register by setting the channel specific configuration bit UPEN_CTRL[z] of register TOMi_TGCy_GLB_CTRL to '0'.

2. write new desired values to SR0, SR1, CLK_SRC_SR

3. enable update of the action register by setting the channel specific configuration bit UPEN_CTRL[z] of register TOMi_TGCy_GLB_CTRL to '1'.

synchronous update of duty cycle only

A synchronous update of only the duty cycle can be done by simply writing the desired new value to register SR1 without preceding disable of the update mechanism (as described in the section above). The new duty cycle is then applied in the period following the period where the update of register SR1 was done.

synchronous update of duty cycle

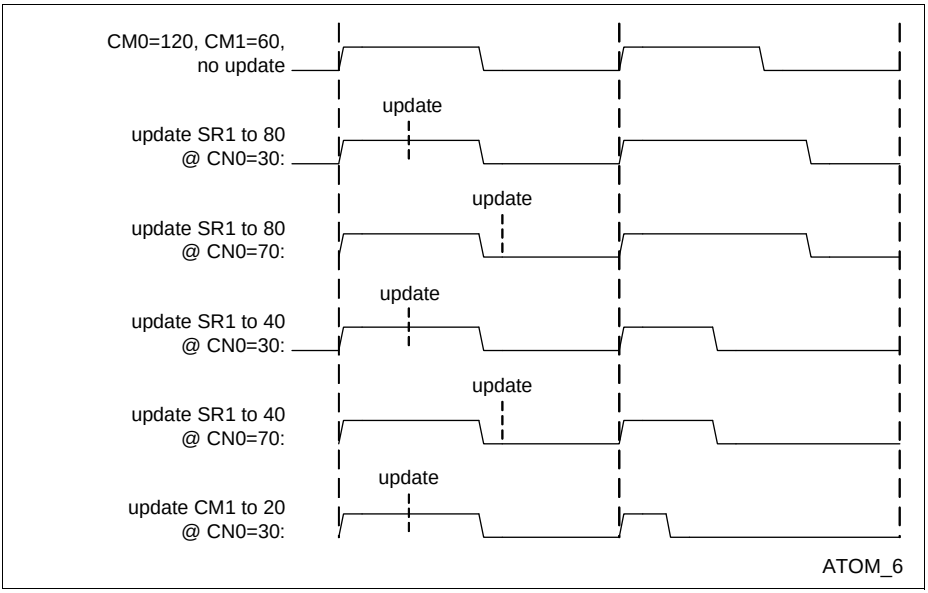

Figure 25-37 synchronous update of duty cycle

asynchronous update of duty cycle only

If the update of the duty cycle should be performed independent of the start of a new period (asynchronous), the desired new value can be written directly to register CM1. In this case it is recommended to additionally either disable the synchronous update mechanism as a whole (i.e. clearing bits UPEN_CTRL[z] of corresponding channel [x] in register TOMi_TGXy_GLB_CTRL) or updating SR1 with the same value as CM1 before writing to CM1.

Depending on the point of time of the update of CM1 in relation to the actual value of CN0 and CM1, the new duty cycle is applied in the current period or the following period (see **Figure 25-38**). In any case the creation of glitches are avoided. The new duty cycle may jitter from update to update by a maximum of one period (given by CM0). However, the period remains unchanged.

asynchronous update of duty cycle

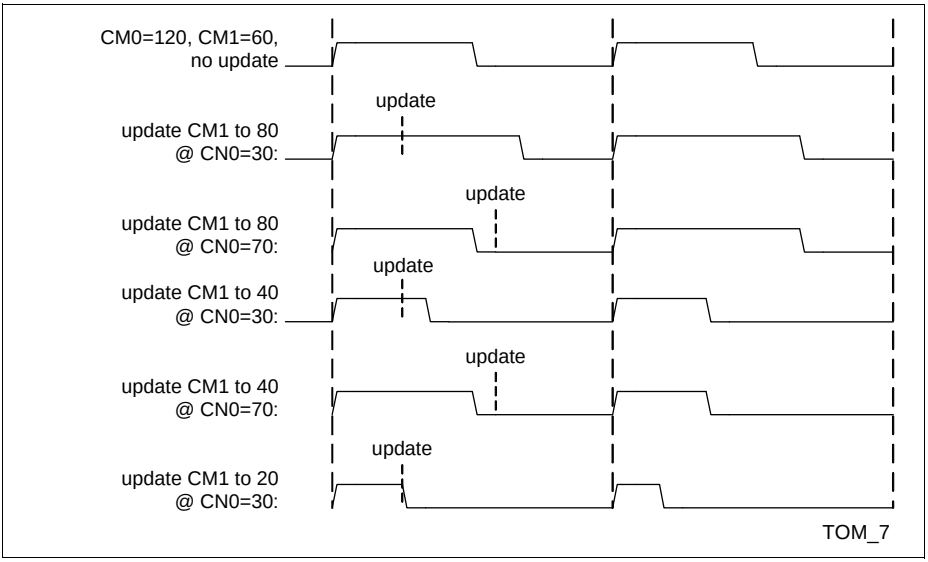

Figure 25-38 asynchronous update of duty cycle

25.11.3.5 TOM continuous mode

In continuous mode the TOM channel starts incrementing the counter register CN0 once it is enabled by setting the corresponding bits in register TOMi_TGCy_ENDIS_STAT (refer to **Section 25.11.2.2** for details of enabling a TOM channel).

The signal level of the generated output signal can be configured with the configuration bit SL of the channel configuration register TOMi_CHx_CTRL.

If the counter CN0 is reset from CM0 back to zero, the first edge of a period is generated at TOM[i]_CH[x]_OUT.

The second edge of the period is generated if CN0 has reached CM1.

Every time the counter CN0 has reached the value of CM0 it is reset back to zero and proceeds with incrementing.

PWM Output with respect to configuration bit SL in continuos mode

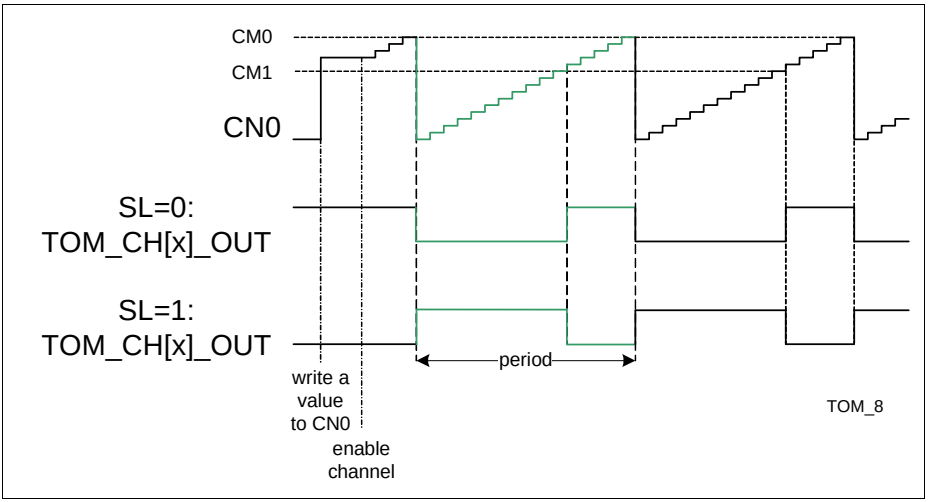

Figure 25-39 PWM Output with respect to configuration bit SL in continuos mode

25.11.3.6 TOM One shot mode

In One-shot mode, the TOM channel generates one pulse with a signal level specified by the configuration bit SL in the channel [x] configuration register TOMi_CHx_CTRL.

First the channel has to be enabled by setting the corresponding TOMi_TGCy_ENDIS_STAT value and the one-shot mode has to be enabled by setting bit OSM in register TOMi_CHx_CTRL.

In one-shot mode the counter CN0 will not be increment once the channel is enabled.

A write access to the register CN0 triggers the start of pulse generation (i.e. the increment of the counter register CN0).

If SPE mode of TOM[i] channel 2 is enabled (set bit SPEM of register TOMi_CH2_CTRL), also the trigger signal SPE[i]_NIPD can trigger the reset of register CN0 to zero and a start of the pulse generation.

The new value of CN0 determines the start delay of the first edge. The delay time of the first edge is given by (CM0-CN0) multiplied with period defined by current value of CLK_SRC.

If the counter CN0 is reset from CM0 back to zero, the first edge at TOM[i]_CH[x]_OUT is generated.

To avoid an update of CMx register with content of SRx register at this point in time, the automatic update should be disabled by setting UPEN_CTRLx = 00 (in register TOMi_CHx_CTRL).

The second edge is generated if CN0 is greater or equal than CM1 (i.e. CN0 was increment until it has reached CM1 or CN0 is greater than CM1 after an update of CM1).

If the counter CN0 has reached the value of CM0 a second time, the counter stops.

PWM Output with respect to configuration bit SL in one-shot mode: trigger by writing to CN0

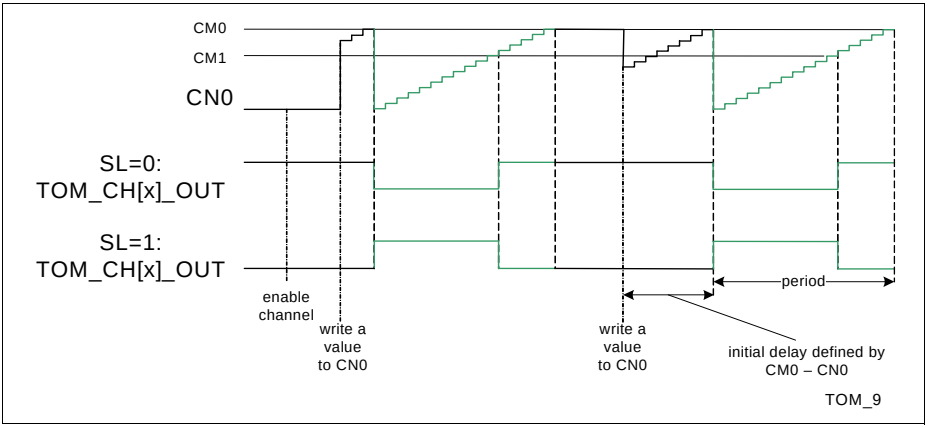

Figure 25-40 PWM Output with respect to configuration bit SL in one-shot mode: trigger by writing to CN0

Further output of single periods can be started by a write access to register CN0.

If CN0 is already incrementing (i.e. started by writing to CN0 a value CN0start < CM0), the affect of a second write access to CN0 depends on the phase of CN0:
phase 1: update of CN0 before CN0 reaches first time CM0
phase 2: update of CN0 after CN0 has reached first time CM0 but less than CM1
phase 3: update of CN0 after CN0 has reached first time CM0 and CN0 is greater than or equal CM1

In phase 1: writing to counter CN0 a value CN0new < CM0 leads to shift of first edge (generated if CN0 reaches CM0 first time) by the time CM0-CN0new.

In phase 2: writing to incrementing counter CN0 a value CN0new < CM1 while CN0old is below CM1 leads to a lengthening of the pulse. The counter CN0 stops if it reaches CM0.

In phase 3: writing to incrementing counter CN0 a value CN0new while CN0old is already greater than or equal CM1 leads to an immediate restart of a single pulse generation inclusive the initial delay defined by CM0 - CN0new.

25.11.3.7 Pulse count modulation

At the output TOM[i]_CH15_OUT a pulse count modulated signal can be generated instead of the simple PWM output signal.

Figure 25-36 outlines the circuit for Pulse Count Modulation.

The PCM mode is enabled by setting bit BITREV to 1.

With the configuration bit BITREV=1 a bit-reversing of the counter output CN0 is configured. In this case the bits LSB and MSB are swapped, the bits LSB+1 and MSB-1 are swapped, the bits LSB+2 and MSB-2 are swapped and so on.

The effect of bit-reversing of the CN0 register value is shown in the following **Figure 25-41**.

Bit reversing of counter

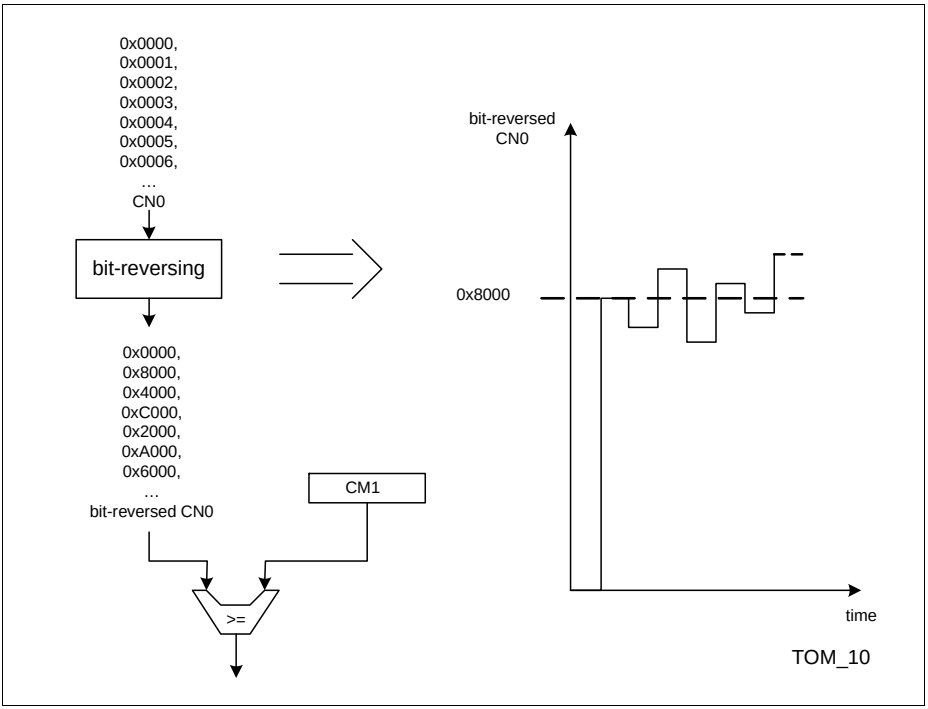

Figure 25-41 Bit reversing of counter

In the PCM mode the counter register CN0 is increment by every clock tick depending on configured CMU clock (CMU_FXCLK).

The output of counter register CN0 is first bit-reversed and than compared with the configured register value CM1.

If the bit-reversed value of register CN0 is greater than CM1, the SR-FlipFlop of submodule SOU is set (depending on configuration register SL) otherwise the SR-FlipFlop is reset. This generates at the output TOM[i]_CH15_OUT a pulse count modulated signal.

In PCM mode the CM0 register - in which the period id defined - normally has to be set to its maximum value 0xFFFF.

Note: In this mode the interrupt CCU1TC (see register ATOMi_CHx_IRQ_NOTIFY) is set every time if bitreserve values of CN0 is greater than or equal CM1 which may

be multiple times during one period. Therefore, from application point of view it is not useful to enable this interrupt.

25.11.4 TOM BLDC Support

The TOM submodule offers in combination with the SPE submodule a BLDC support. To drive a BLDC engine TOM channels 0 to 7 can be used.

The BLDC support can be configured by setting the SPEM bit inside the TOMi_CH[z]_CTRL register. When this bit is set the TOM channel output is controlled through the SPE_OUT(z) signal coming from the SPE submodule (see **Figure 25-34**). Please refer to **Section 25.17** for a detailed description of the SPE submodule.

The TOM[i]_CH2 can be used together with the SPE module to trigger a delayed update of the SPE_OUT_CTRL register after new input pattern detected by SPE (signalled by SPE[i]_NIPD). This feature is configured on TOM[i]_CH2 by setting SPEM=1 and OSM=1. For details please refer to section of SPE submodule description.

25.11.5 TOM Gated Counter Mode

Each TOM - SPE module combination provides also the feature of a gated counter mode. This is reached by using the FSOI input of a TIM module to gate the clock of a CCU0 submodule.

To configure this mode, registers of module SPE should be set as following:

- the SPE should be enabled (bit SPE_EN = 1),
- all three TIM inputs should be disabled (SIE0 = SIE1 = SIE2 = 0),
- SPEi_OUT_CTRL should be set to 00005555h (set SPE_OUT() to '0'),
- mode FSOM should be enabled (FSOM=1),
- set in bit field FSOL bit c if channel c of module TOM is chosen for gated counter mode

Additionally in module TOM

- the SPE mode should be disabled (SPEM=0) and
- the gated counter mode should be enabled (GCM=1)

As a result of this configuration, the counter CN0 in submodule CCU0 of TOM channel c counts as long as input FSOI is '0'.

25.11.6 TOM Interrupt signals

The following table describes TOM interrupt signals:

Table 25-31 TOM Interrupt signals

Signal	Description
TOM_CCU0TCx_IRQ	CCU0 Trigger condition interrupt for channel x
TOM_CCU1TCx_IRQ	CCU1 Trigger condition interrupt for channel x

25.11.7 TOM Configuration Register overview

The following table gives an overview of the TOM configuration registers.

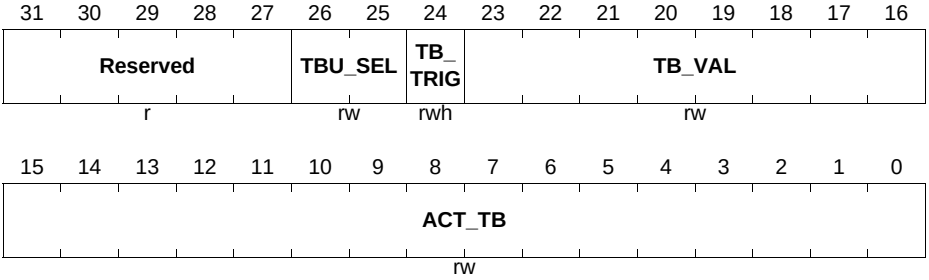
GTM_ATOMi_AGC_ACT_TB (i=0-4)
TOMi TGC0 Action Time Base Register
($0D04C_H$+i*800_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
ACT_TB	[23:0]	rw	**Time base value** specifies the signed compare value with selected signal TBU_TCx (x=0…2). If selected TBU_TSx value is in the interval [ACT_TB-$007FFFFF_H$,ACT_TB] the event is in the past and the trigger is generated immediately. Otherwise the event is in the future and the trigger is generated if selected TBU_TSx is equal to ACT_TB.
TB_TRIG	24	rwh	**Set trigger request** 0_B no trigger request 1_B set trigger request Note: This flag is reset automatically if the selected time base unit (TBU_TS0 or TBU_TS1 or TBU_TS2 if present) has reached the value ACT_TB and the update of the register were triggered.

Field	Bits	Type	Description
TBU_SEL	[26:25]	rw	**Selection of time base used for comparison** 00_B TBU_TS0 selected 01_B TBU_TS1 selected 10_B TBU_TS2 selected 11_B Reserved; same as 00_B Note: The bit combination “10” is only applicable if the TBU of the device contains three time base channels. Otherwise, this bit combination is also reserved. Please refer to GTM Architecture block diagram on page 3 to determine the number of channels for TBU of this device.
Reserved	[31:27]	r	**Reserved** Read as zero, should be written as zero

25.12 ARU-connected Timer Output Module (ATOM)

25.12.1 Overview

The ARU-connected Timer Output Module (ATOM) is able to generate complex output signals without CPU interaction due to its connectivity to the ARU. Typically, output signal characteristics are provided over the ARU connection through submodules connected to ARU like e.g. the MCS, DPLL or PSM. Each ATOM submodule contains eight output channels which can operate independently from each other in several configurable operation modes. A block diagram of the ATOM submodule is depicted in **Figure 25-42**.

25.12.1.1 ATOM Block diagram

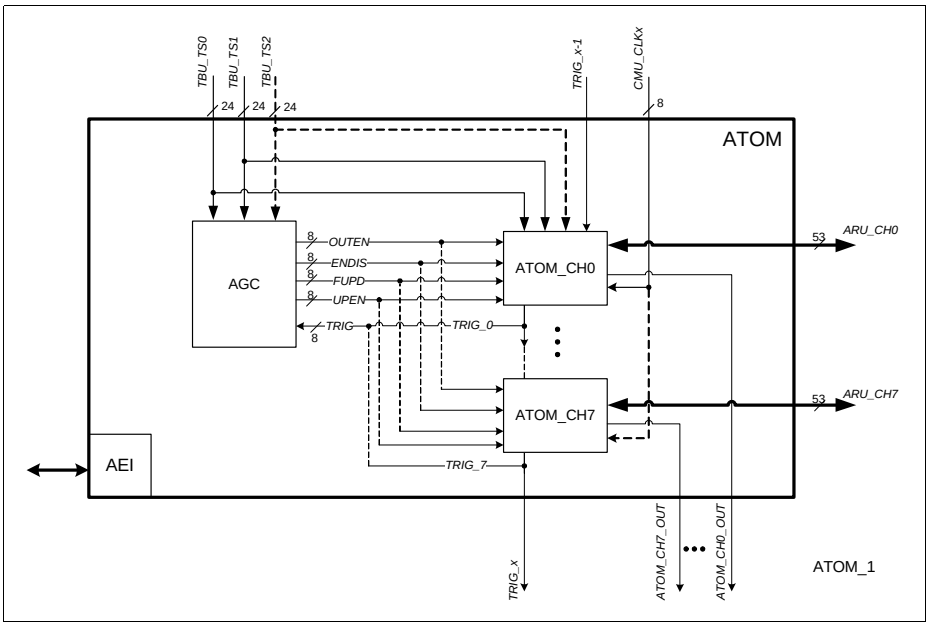

Figure 25-42 ATOM Block diagram

The architecture of the ATOM submodule is similar to the TOM submodule, but there are some differences. First, the ATOM integrates only eight output channels. Hence, there exists one ATOM Global Control subunit (AGC) for the ATOM channels. The ATOM is

connected to the ARU and can set up individual read requests from the ARU and write requests to the ARU. Furthermore, the ATOM channels are able to generate signals on behalf of time stamps and the ATOM channels are able to generate a serial output signal on behalf of an internal shift register.

Each ATOM channel provides four modes of operation:

- ATOM Signal Output Mode Immediate (SOMI)
- ATOM Signal Output Mode Compare (SOMC)
- ATOM Signal Output Mode PWM (SOMP)
- ATOM Signal Output Mode Serial (SOMS)

These modes are described in more detail in **Section 25.12.3**.

The ATOM channels' operation registers (e.g. counter, compare registers) are 24 bit wide. Moreover, the input clocks for the ATOM channels come from the configurable CMU_CLKx signals of the CMU submodule. This gives the freedom to select a programmable input clock for the ATOM channel counters. The ATOM channel is able to generate a serial bit stream, which is shifted out at the ATOM[i]_CH[x]_OUT output. When configured in this serial shift mode (SOMS) the selected CMU clock defines the shift frequency.

Each ATOM channel provides a so called operation and shadow register set. With this architecture it is possible to work with the operation register set, while the shadow register set can be reloaded with new parameters over CPU and/or ARU.

When update via ARU is selected, it is possible to configure if both shadow registers are updated via ARU or only one of the shadow registers is updated for SOMP mode.

On the other hand, the shadow registers can be used to provide data to the ARU when one or both of the compare units inside an ATOM channel match. This feature is only applicable in SOMC mode.

In TOM channels it is possible to reload the content of the operation registers with the content of the corresponding shadow registers and change the clock input signal for the counter register simultaneously. This simultaneous change of the input clock frequency together with reloading the operation registers is also implemented in the ATOM channels.

In addition to the feature that the CPU can select another CMU_CLKx during operation (i.e. updating the shadow register bit field CLK_SRC_SR of the ATOMi_CHx_CTRL register), the selection can also be changed via the ARU. Then, for the clock source update, the ACBI register bits of the ATOMi_CHx_STAT register are used as a shadow register for the new clock source.

In general, the behaviour of the compare units CCU0 and CCU1 and the output signal behaviour is controlled with the ACB bit field inside the ATOMi_CHx_CTRL register when the ARU connection is disabled and the behaviour is controlled via ARU through the ACBI bit field of the ATOMi_CHx_STAT register, when the ARU is enabled.

Since the ATOM is connected to the ARU, the shadow registers of an ATOM channel can be reloaded via the ARU connection or via CPU over its AEI interface. When loaded via the ARU interface, the shadow registers act as a buffer between the ARU and the channel operation registers. Thus, a new parameter set for a PWM can be reloaded via ARU into the shadow registers, while the operation registers work on the actual parameter set.

25.12.1.2 ATOM Global control (AGC)

Synchronous start and stop of more then one output channel is possible with the AGC subunit. This subunit has the same functionality as the TGC subunit of the TOM submodule. For a description of the AGC subunit functionality, please refer therefore to **Section 25.11.2**.

25.12.1.3 ATOM Channel mode overview

Each ATOM channel offers the following different operation modes.

In ATOM Signal Output Mode Immediate (SOMI), the ATOM channels generate an output signal immediately after receiving an ARU word according to the two signal level output bits of the ARU word received through the ACBI bit field. Due to the fact, that the ARU destination channels are served in a round robin order, the output signal can jitter in this mode with a jitter of the ARU round trip time.

In ATOM Signal Output Mode Compare (SOMC), the ATOM channel generates an output signal on behalf of time stamps that are located in the ATOM operation registers. These time stamps are compared with the time stamps, the TBU generates. The ATOM is able to receive new time stamps either by CPU or via the ARU. The new time stamps are directly loaded into the channels operation register. The shadow registers are used as capture registers for the two time base values, when a compare match of the channels operation registers occurs.

In ATOM Signal Output Mode PWM (SOMP), the ATOM channel is able to generate simple and complex PWM output signals like the TOM submodule by comparing its operation registers with a submodule internal counter. In difference to the TOM, the ATOM shadow registers can be reloaded by the CPU and by the ARU in the background, while the channel operates on the operation registers.

In ATOM Signal Output Mode Serial (SOMS), the ATOM channel generates a serial output bit stream on behalf of a shift register. The number of bits shifted and the shift direction is configurable. The shift frequency is determined by one of the CMU_CLKx clock signals. Please refer to **Section 25.12.3.4** for further details.

25.12.2 ATOM Channel architecture

Each ATOM channel is able to generate output signals according to four operation modes. The architecture of the ATOM channels is similar to the architecture of the TOM channels. The general architecture of an ATOM channel is depicted in **Figure 25-43**.

25.12.2.1 ATOM Channel architecture

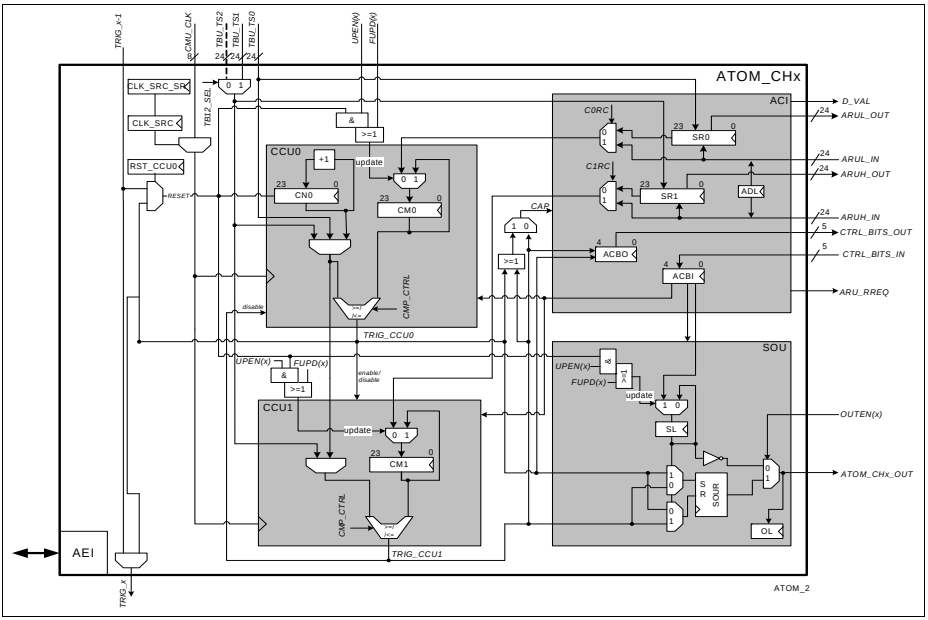

Figure 25-43 ATOM Channel architecture

For all ATOM channels the bit width is 24 of the operation register CN0, CM0 and CM1 and the shadow register SR0 and SR1. The comparators inside CCU0 and CCU1 provide a selectable signed greater/equal or less/equal comparison to compare against the GTM time bases TBU_TS0 and TBU_TS1. If there is a third time base TBU_TS2 implemented inside the GTM, this time base can also be selected inside the ATOM channel with the TB12_SEL bit inside the ATOMi_CHx_CTRL register for comparison. Please refer to TBU **Section 25.9** for further details. For an overview of the implemented TBU submodule version please refer to **Section 25.2.1.1**. The CCU0 and CCU1 units have different tasks for the different ATOM channel modes.

The signed compare is used to detect time base overflows and to guarantee, that a compare match event can be set up for the future even when the time base will first

overflow and then reach the compare value. Please note, that for a correct behaviour of this signed compare, the new compare value must not be specified larger/smaller than half of the range of the total time base value (0x7FFFFF).

In SOMC mode, the two compare units CCUx can be used in combination to each other. When used in combination, the trigger lines TRIG_CCU0 and TRIG_CCU1 can be used to enable/disable the other compare unit on a match event. Please refer to **Section 25.12.3.2** for further details.

The Signal Output Unit (SOU) generates the output signal for each ATOM channel. This output signal level depends on the ATOM channel mode and on the SL bit of the ATOMi_CHx_CTRL register in combination with the two control bits. These two control bits ACB(1) and ACB(0) can either be received via CPU in the ACB register field of the ATOMi_CHx_CTRL register or via ARU in the ACBI bit field of the ATOMi_CHx_STAT register.

The SL bit in the ATOMi_CHx_CTRL register defines in all modes the operational behaviour of the ATOM channel.

When the channel and its output is disabled, the output signal level of the channel is the inverse of the SL bit.

In SOMI and SOMC mode the output signal level depends on the SL, ACB0 and ACB1 bits. In SOMP mode the output signal level depends on the two trigger signals TRIG_CCU0 and TRIG_CCU1 since theses two triggers define the PWM timing characteristics and the SL bit defines the level of the duty cycle. In SOMS mode the output signal level is defined by the bit pattern that has to be shifted out by the ATOM channel. The bit pattern is located inside the CM1 register.

The ARU Communication Interface (ACI) subunit is responsible for requesting data routed through ARU to the ATOM channel in SOMI, SOMP and SOMS modes, and additionally for providing data to the ARU in SOMC mode.

In SOMC mode the ACI shadow registers have a different behaviour and are used as output buffer registers for data send to ARU.

25.12.2.2 ARU Communication Interface

The ATOM channels have an ARU Communication Interface (ACI) subunit. This subunit is responsible for data exchange from and to the ARU. This is done with the two implemented registers SR0, SR1, and the ACBI and ACBO bit fields that are part of the ATOMi_CHx_STAT register. The ACI architecture is shown in **Figure 25-44**.

If the ARU_EN bit is set inside the ATOMi_CHx_CTRL register, the ATOM channel is enabled by setting the enable bits inside the ATOMi_AGC_ENDIS_STAT register and the CPU hasn't written data not equal to zero into the CM0, CM1, SR0, SR1 register, the ATOM channel will first request data from the ARU before the signal generation starts in SOMP, SOMS and SOMC mode.

Note: if in SOMP mode there is data inside the CM0 or SR0 register not equal to '0' the channel counter CN0 will start counting immediately, regardless whether the channel has received ARU data yet.

Note: if in SOMS mode there is data inside the CM0 or SR0 register not equal to '0' the channel will start shifting immediately, regardless whether the channel has received ARU data yet.

ACI Architecture overview

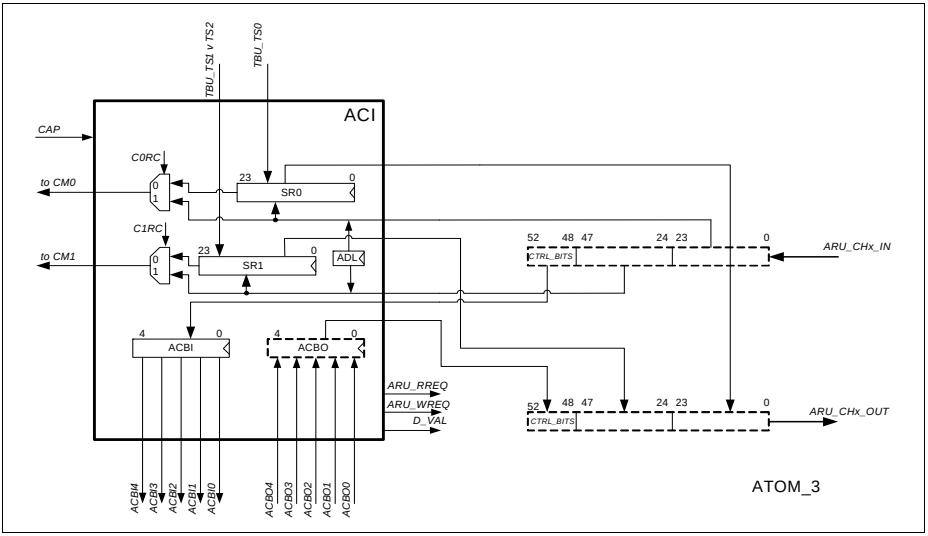

Figure 25-44 ACI Architecture overview

Incoming ARU data (53 bit width signal ARU_CHx_IN) is split into three parts by the ACI and communicated to the ATOM channel registers. In SOMI, SOMP and SOMS modes incoming ARU data ARU_CHx_IN is split in a way that the lower 24 bits of the ARU data (23 down to 0) are stored in the SR0 register, the upper bits (47 down to 24) are stored in the SR1 register and the bits 52 down to 48 (CTRL_BITS) are stored in the ACBI bit field of the register ATOMi_CHx_STAT.

The ATOM channel has to ensure, that in a case when the channel operation registers CM0 and CM1 are updated with the SR0 and SR1 register content and an ARU transfer to these shadow registers happens in parallel that either the old data in both shadow registers is transferred into the operation registers or both new values from the ARU are transferred.

In SOMC mode incoming ARU data ARU_CHx_IN is written directly to the ATOM channel operation register in the way that the lower 24 bits (23 down to 0) are written to CM0, and the bits 47 down to 24 are written to register CM1. The bits 52 down to 48 are stored in the ACBI bit field of the ATOMi_CHx_STAT register and control the behaviour of the compare units and the output signal of the ATOM channel.

In SOMC mode the SR0 and SR1 registers serve as capture registers for the time stamps coming from TBU whenever a compare match event is signalled by the CCU0 and/or CCU1 subunits via the CAP signal line. These two time stamps are then provided together with actual ATOM channel status information located in the ACBO bit field to the ARU at the dedicated ARU write address of the ATOM channel when the ARU is enabled.

The encoding of the ARU control bits in the different ATOM operation modes is described in more detail in the following sections.

25.12.3 ATOM Channel modes

As described above, each ATOM channel can operate independently from each other in one of four dedicated output modes:

- ATOM Signal Output Mode Immediate (SOMI)
- ATOM Signal Output Mode Compare (SOMC)
- ATOM Signal Output Mode PWM (SOMP)
- ATOM Signal Output Mode Serial (SOMS)

The Signal Output Mode PWM (SOMP) is principally the same like the output mode for the TOM submodule except the bit erse mode which is not included in the ATOM. In addition, it is possible to reload the shadow registers over the ARU without the need of a CPU interaction. The three other modes provide additional functionality for signal output control. All operation modes are described in more detail in the following sections.

25.12.3.1 ATOM Signal Output Mode Immediate (SOMI)

In ATOM Signal Output Mode Immediate (SOMI), the ATOM channel generates output signals on the ATOM[i]_CH[x]_OUT output port immediate after update of the bit ACBI(0) of register ATOMi_CHx_STAT or ACB(0) bit of register ATOMi_CHx_CTRL.

If ARU access is enabled by setting bit ARU_EN in register ATOMi_CHx_CTRL, the update of the output ATOM[i]_CH[x]_OUT depends on the bit ACBI(0) of register ATOMi_CHx_STAT received at the ACI subunit and the bit SL bit of register ATOMi_CHx_CTRL. The remaining 48 ARU bits (47 down to 0) have no meaning in this mode.

If ARU access is disabled, the update of the output ATOM[i]_CH[x]_OUT depends on the bit ACB(0) and the bit SL of register ATOMi_CHx_CTRL.

The initial ATOM channel port pin ATOM[i]_CH[x]_OUT signal level has to be specified by the SL bit field (

=0 defined in this mode, see **Figure 25-43**) of the ATOMi_CHx_CTRL register when OUTEN_CTRL register bit field OUTEN_CTRLx is disabled (see **Chapter 25.11.8.9**) for details.

In SOMI mode the output behaviour depends on the SL bit of register ATOMi_CHx_CTRL and the bit ACBI(0) of the ATOMi_CHx_STAT register or the bit ACB0 of register ATOMi_CHx_CTRL:

Table 25-33 Signal Output Mode Immediate Status information

SL	ACBI(0)/ ACB(0)	Output behaviour
0	0	Set output to inverse of SL (1)
0	1	Set output to SL (0)
1	0	Set output to inverse of SL (0)
1	1	Set output to SL (1)

The signal level bit ACBI(0) is transferred to the SOU subunit of the ATOM and made visible at the output port according to the table above immediately after the data was received by the ACI. This can introduce a jitter on the output signal since the ARU channels are served in a time multiplexed fashion.

25.12.3.2 ATOM Signal Output Mode Compare (SOMC)

Overview

In ATOM Signal Output Mode Compare (SOMC) the output action is performed in dependence of the comparison between input values located in CM0 and/or CM1 registers and the two (three) time base values TBU_TS0 or TBU_TS1 (or TBU_TS2) provided by the TBU. For a description of the time base generation please refer to the TBU specification in **Section 25.9**. It is configurable, which of the two (three) time bases is to be compared with one or both values in CM0 and CM1.

The behaviour of the two compare units CCU0 and CCU1 is controlled either with the bits 4 down to 2 of ACB bit field inside the ATOMi_CHx_CTRL register, when the ARU connection is disabled or with the ACBI bit field of the ATOMi_CHx_STAT register, when the ARU is enabled. In that case the ACB bit field is updated via the ARU control bits 52 down to 48.

The CCUx trigger signals TRIG_CCU0 and TRIG_CCU1 always create edges, dependent on the predefined signal level in SL bit in combination with two control bits that can be specified by either ARU or CPU within the aforementioned ATOMi_CHx_CTRL or ATOMi_CHx_STAT registers.

In SOMC mode the channel is always disabled after the specified compare match event occurred. The shadow registers are used to store two time stamp values at the match time. The channel can be enabled again by first reading the shadow registers, either by CPU or ARU and by providing new data for CMx registers through CPU or ARU. For a detailed description please refer to **SOMC Mode under CPU control** and **SOMC Mode under ARU control**.

If three time bases exist for the GTM-IP there must be a preselection between TBU_TS1 and TBU_TS2 for the ATOM channel. This can be done with TB12_SEL bit in the ATOMi_CHx_CTRL register.

The comparison in CCU0/1 with time base TBU_TS1 or TBU_TS2 can be done on a greater/equal or less/equal compare according to the CMP_CTRL bit. This control bit has no effect to a compare unit CCU0 or CCU1 that compares against TBU_TS0. In this case always a greater/equal compare is done. The bit CMP_CTRL is part of the ATOMi_CHx_CTRL register.

When configured in SOMC mode, the channel port pin has to be initialized to an initial signal level. This initial level after enabling the ATOM channel is determined by the SL bit in the ATOMi_CHx_CTRL register. If the output is disabled, the signal level is set to the inverse level of the SL bit.

If the channel is disabled, the register SOUR is set to the SL bit in the ATOMi_CHx_CTRL register.

On a compare match event the shadow register SR0 and SR1 are used to capture the TBU time stamp values. SR0 always holds TBU_TS0 and SR1 either holds TBU_TS1 or TBU_TS2 dependent on the TB12_SEL bit in the ATOMi_CHx_CTRL register.

Please note, that when the channel is disabled and the compare registers are written, the compare registers CMx are loaded with the written value and the channel starts with the comparison on behalf of this values, when the channel is enabled.

SOMC Mode under CPU control

As already mentioned above the ATOM channel can be controlled either by CPU or by ARU. When the channel should be controlled by CPU, the ARU_EN bit inside the ATOMi_CHx_CTRL register has to be reset.

The output of the ATOM channel is set on a compare match event depending on the ACB10 bit field in combination with the SL bit both located in the ATOMi_CHx_CTRL register. The output behaviour according to the ACB10 bit field in the control register is shown in the following table:

Table 25-34 SOMC Output behaviour

SL	ACB10(5)	ACB10(4)	Output behaviour
0	0	0	No signal level change at output (exception in **Figure 25-45** mode ACB42=001)
0	0	1	Set output signal level to 1
0	1	0	Set output signal level to 0
0	1	1	Toggle output signal level (exception in **Figure 25-45** mode ACB42=001)
1	0	0	No signal level change at output (exception in **Figure 25-45** mode ACB42=001)
1	0	1	Set output signal level to 0
1	1	0	Set output signal level to 1
1	1	1	Toggle output signal level (exception in **Figure 25-45** mode ACB42=001)

The capture/compare strategy of the two CCUx units can be controlled with the ACB42 bit field inside the ATOMi_CHx_CTRL register. The meaning of these bits is shown in the following table:

Table 25-35 Bit definitions for Capture / Compare operation

ACB42(8)	ACB42(7)	ACB42(6)	CCUx control
0	0	0	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACB10(5) and ACB10(4). Details see **Figure 25-45**
0	0	1	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACB10(5) and ACB10(4). Details see **Figure 25-45**
0	1	0	Compare in CCU0 only, use time base TBU_TS0. Output signal level is defined by combination of SL, ACB10(5) and ACB10(4) bits.
0	1	1	Compare in CCU1 only, use time base TBU_TS1 or TBU_TS2. Output signal level is defined by combination of SL, ACB10(5) and ACB10(4) bits.
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS0. Output signal level when CCU0 matches is defined by combination of SL, ACB10(5) and ACB10(4). On the CCU1 match the output level is toggled.
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU0 matches is defined by combination of SL, ACB10(5) and ACB10(4). On the CCU1 match the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using TBU_TS0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU1 matches is defined by combination of SL, ACB10(5) and ACB10(4).
1	1	1	Not used when ARU disabled.

The behaviour of the ACBI/ACB42 bit combinations '000' and '001' is described in more detail in **Figure 25-45**.

ATOM_tab

Figure 25-45 ATOM CCUx Serve first definition

If the ATOM channel is enabled, the CM0 and/or CM1 registers and the ACB42 bit field of the ATOMi_CHx_CTRL register can be updated by the CPU as long as the first match event occurs in case of a serve last compare strategy or as long as the overall match event in case of the other compare strategies.

After a compare match event that causes an update of the shadow registers SR0/SR1 and before reading the SR0 and/or SR1 register via ARU, the update of the registers CM0 and/or CM1 is possible but has no effect.

To set up a new compare action, first the SR0 and/or SR1 register containing captured values have to be read and then new compare values have to be written into the register CM0 and/or CM1.

Which CMx register has to be updated depends on the compare strategy defined in the ACB42 bit field of the channel control register. Since the channel immediately starts with the comparison after the CMx register was/were written, the compare strategy has to be updated before the CMx registers are written.

For the serve last compare strategies, if the register CM0 and CM1 are updated, it can happen that one or both compare values are already located in the past. In any way the ATOM channel will first wait until both compare values are written, before it starts the time base comparisons to avoid a deadlock.

The CPU can check at any time if at least one of the ATOM channels' capture compare registers contains valid data and waits for a compare event to happen. This is signalled by the DV bit inside the ATOMi_CHx_STAT register.

Note: For serve last compare strategies, if DV bit is currently not set, writing to CM0 or CM1 sets immediately the DV bit although the compare is only started if both values are written.

In SOMC mode and CCUx control mode 'serve last' exist an exception for update of register CM0/CM1. If in this mode the CCU0 compare match event occurred, the update of register CM0/CM1 via CPU is blocked until the CCU1 compare match event.

In the serve last mode (ACB42="100" or ACB42="101") it is possible to generate very small spikes on the output pin by loading CM0 and CM1 with two time stamp values for TBU_TS0, TBU_TS1 or TBU_TS2 close together. The output pin will then be set or reset dependent on the SL bit and the specified ACB10(5) and ACB10(4) bits in the ACB10 bit field of the ATOMi_CHx_CTRL register on the first match event and the output will toggle on the second compare event in the CCU1 compare unit.

It is important to note, that the bigger (smaller) time stamp has to be loaded into the CM1 register, since the CCU0 will enable the CCU1 once it has reached its comparison time stamp. The order of the comparison time stamps depends on the defined greater/equal or less/equal comparison of the CCUx units.

In addition to storing the captured time stamps in the shadow registers, the ATOM channel provides the result of the compare match event in the ACBO(4) and ACBO(3)

bits of the ATOMi_CHx_STAT register. The meaning of the bits is shown in the following table:

Table 25-36 ACBO3 / 4 Bit encoding

ACBO(4)	ACBO(3)	Indication
0	1	CCU0 compare match occurred
1	0	CCU1 compare match occurred

Please note, that in case of the 'serve last' compare strategy, when the SLA-bit in the ATOMi_CHx_CTRL register is not set, the ACBO(4) bit is always set and the ACBO(3) bit is always reset after the compare match event occurred.

The ACBO bit field is reset, when the DV bit is set.

Depending on the capture compare unit where the time base matched the interrupt CCU0TCx_IRQ or CCU1TCx_IRQ is raised.

The behaviour of an ATOM channel in SOMC mode under CPU control is visualized in **Figure 25-46**.

SOMC state diagram for channel under CPU control

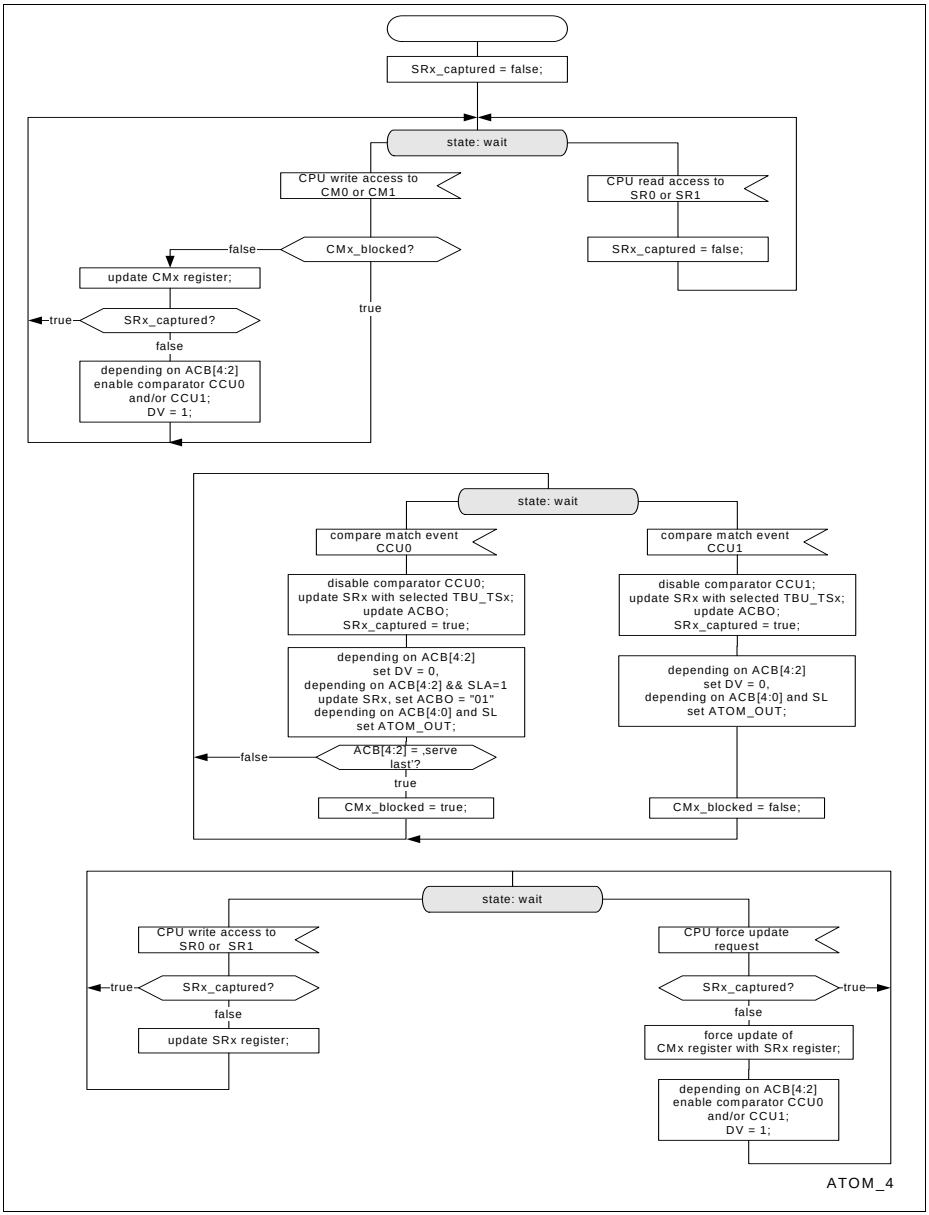

Figure 25-46 SOMC state diagram

SOMC Mode under ARU control

When the channel should be controlled by ARU, the ARU_EN bit inside the ATOMi_CHx_CTRL register has to be set.

In case, the ATOM channel is under ARU control the content for the compare registers CM0 and CM1 as well as the update of the compare strategy can be loaded via the 53 bit ARU word.

The ARU word 23 to 0 is loaded into the CM0 register while the ARU word 47 to 24 is loaded into the CM1 register. The five ARU control bits 52 to 48 are loaded into the ACBI bit field of the ATOMi_CHx_STAT register and control the channel compare strategy as well as the output behaviour in case of compare match events.

For the five ARU control bits 52 to 48 the bits 49 and 48 are loaded into the ACBI bits 1 and 0. The output behaviour also depends on the setting of the SL bit inside of the ATOMi_CHx_CTRL register and is shown in the following table:

Table 25-37 SL Bit encoding

SL	ACBI(1)	ACBI(0)	Output behaviour
0	0	0	No signal level change at output (exception in **Figure 25-45** mode ACB42=001)
0	0	1	Set output signal level to 1
0	1	0	Set output signal level to 0
0	1	1	Toggle output signal level (exception in **Figure 25-45** mode ACB42=001)
1	0	0	No signal level change at output (exception in **Figure 25-45** mode ACB42=001)
1	0	1	Set output signal level to 0
1	1	0	Set output signal level to 1
1	1	1	Toggle output signal level (exception in **Figure 25-45** mode ACB42=001)

For the five ARU control bits 52 to 48 the bits 52 to 50 are loaded into the ACBI bits 4 to 2. With these three bits the capture/compare units CCUx can be controlled as shown in the following table:

Table 25-38 CCU control via ACBI[4:2] control bits

ACBI(4)	ACBI(3)	ACBI(2)	CCUx control
0	0	0	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACBI(1) and ACBI(0). Details see **Figure 25-45**
0	0	1	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACBI(1) and ACBI(0). Details see **Figure 25-45**
0	1	0	Compare in CCU0 only, use time base TBU_TS0. Output signal level is defined by combination of SL, ACBI(1) and ACBI(0) bits.
0	1	1	Compare in CCU1 only, use time base TBU_TS1 or TBU_TS2. Output signal level is defined by combination of SL, ACBI(1) and ACBI(0) bits.
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS0. Output signal level when CCU0 matches is defined by combination of SL, ACBI(1) and ACBI(0). On the CCU1 match the output level is toggled.
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU0 matches is defined by combination of SL, ACBI(1) and ACBI(0). On the CCU1 match the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using TBU_TS0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU1 matches is defined by combination of SL, ACBI(1) and ACBI(0).
1	1	1	Change ARU read address to ATOM_RDADDR1 DV flag is not set. Neither ACBI(1) nor ACBI(0) is evaluated.

It is important to note that the bit combination "111" for the ACBI(4), ACBI(3) and ACBI(2) bits forces the channel to request new compare values from another destination read address defined in the ATOM_RDADDR1 bit field of the ATOMi_CHx_RDADDR register. After data was successfully received and the compare event occurred the ATOM channel switches back to ATOM_RDADDR0 to receive the next data from there.

After the specified compare match event, the captured time stamps are stored in SR0 and SR1 and the compare result is stored in the ACBO bit field of the ATOMi_CHx_STAT register. The meaning of the ACBO(4) and ACBO(3) bits of the ATOMi_CHx_STAT is shown in the following table:

Table 25-39 ACBO[4:3] bid encoding

ACBO(4)	ACBO(3)	Return value to ARU
0	1	CCU0 compare match occurred
1	0	CCU1 compare match occurred

Please note, that in case of the 'serve last' compare strategy, when the SLA-bit in the ATOMi_CHx_CTRL register is not set, the ACBO(4) bit is always set and the ACBO(3) bit is always reset after the compare match event occurred.

The ACBO bit field is reset, when the DV bit is set.

Depending on the capture compare unit where the time base matched the interrupt CCU0TCx_IRQ or CCU1TCx_IRQ is raised.

When CCU0 and CCU1 is used for comparison it is possible to generate very small spikes on the output pin by loading CM0 and CM1 with two time stamp values for TBU_TS0, TBU_TS1 or TBU_TS2 close together. The output pin will then be set or reset dependent on the SL bit and the specified ACBI(0) and ACBI(1) bits in the ACBI bit field of the ATOMi_CHx_STAT register on the first match event and the output will toggle on the second match event.

It is important to note, that the bigger (smaller) time stamp has to be loaded into the CM1 register, since the CCU0 will enable the CCU1 once it has reached its comparison time stamp. The order of the comparison time stamps depends on the defined greater/equal or less/equal comparison of the CCUx units.

For compare strategy ‘serve last’ the CCU0 and CCU1 compare match mwy occur sequently. During different phases of compare match the CPU access rights to registers CM0 and CM1 and the WR REQ are depected in the following figure.

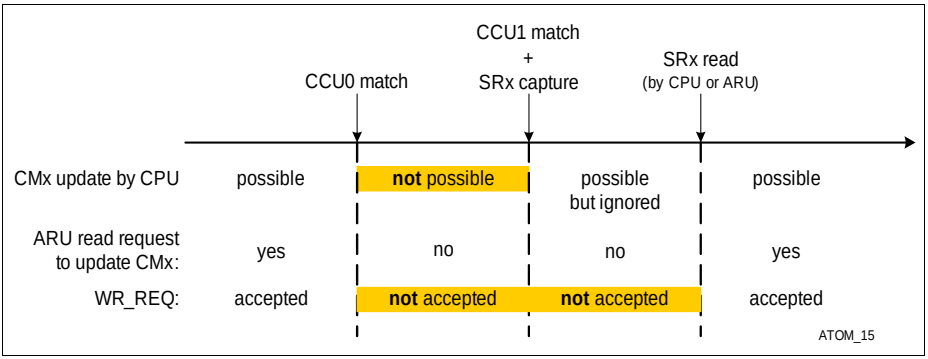

Figure 25-47 CPU access rights in case of compare strategy 'serve last'

ARU Non-Blocking mode

When the compare registers are updated via ARU the update behaviour of the channel is configurable with the ABM bit inside the ATOMi_CHx_CTRL register. When the ABM bit is reset, the ATOM channel is in ARU non-blocking mode.

In this ARU non-blocking mode, data received via ARU is continuously transferred to the registers CM0 and CM1 and the bit field ACBI of register ATOMi_CHx_STAT as long as no specified compare match event occurs.

After a compare match event that causes an update of the shadow register SR0/SR1 and before reading the SR0/SR1 register via CPU or ARU, the update of the registers CM0/ CM1 via CPU or ARU is possible but has no effect.

To set up a new compare action, first the SR0/SR1 registers containing captured values have to be read and then new compare values have to be written into the register CM0/CM1. This can be done either by ARU or by CPU.

When the CPU does the register accesses, only one of the shadow registers has to be read. Dependent on the compare strategy, the CPU has to write one or both of the compare registers.

In SOMC mode and CCUx control mode 'serve last' exist an exception for update of register CM0/CM1. If in this mode the CCU0 compare match event occurred, the update of register CM0/CM1 via CPU or ARU is blocked until the CCU1 compare match event occurs.

The CPU can check at any time if the ATOM channel has received valid data from the ARU and waits for a compare event to happen. This is signalled by the DV bit inside the ATOMi_CHx_STAT register.

The behaviour of an ATOM channel in SOMC mode, when ARU is enabled and ARU blocking mode is disabled is shown in **Figure 25-48**.

SOMC State diagram for SOMC mode, ARU enabled, ABM disabled

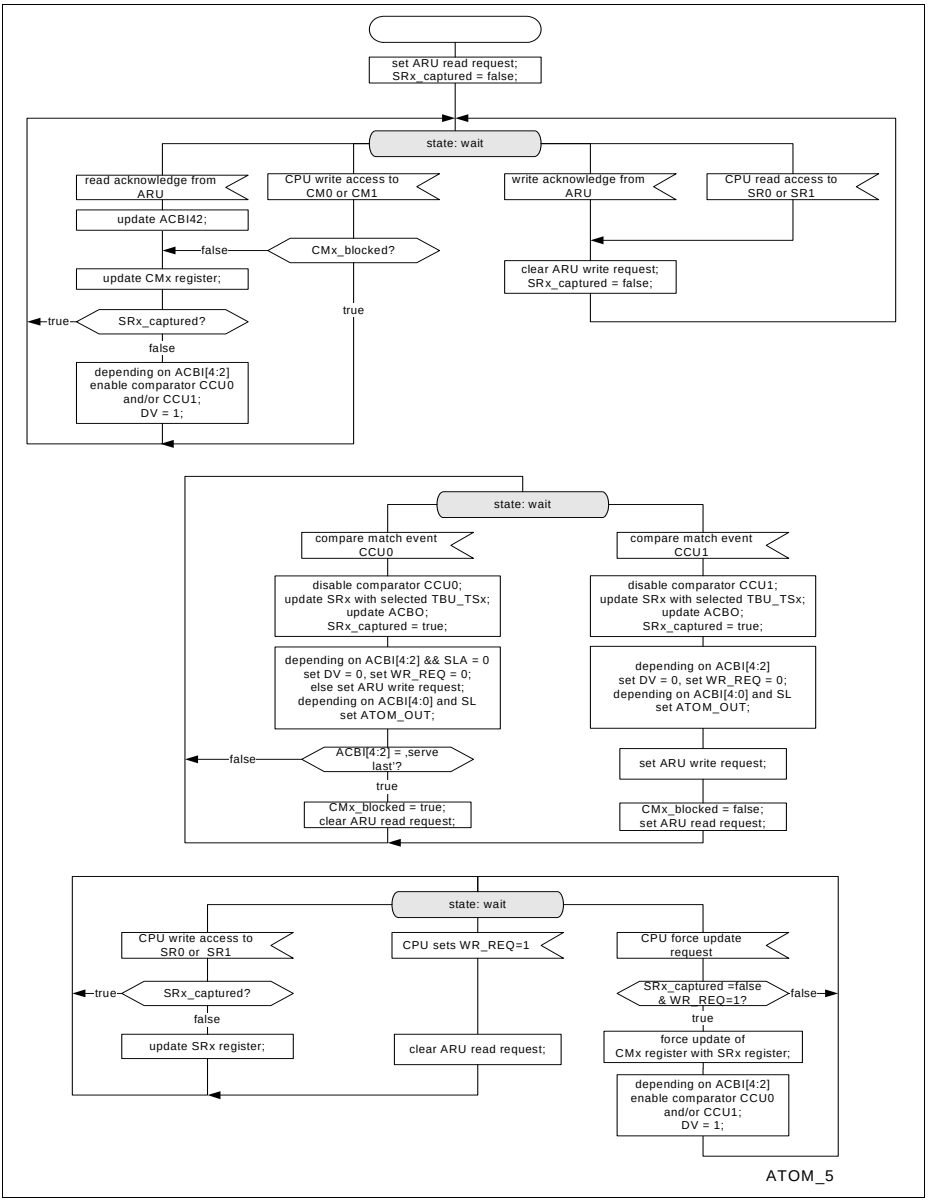

Figure 25-48 SOMC State diagram for SOMC mode, ARU enabled, ABM disabled

ARU Blocking mode

When the compare registers are updated by ARU, the ATOM channel can be configured to receive ARU data in a blocking manner. This can be configured by setting the ABM bit in the ATOMi_CHx_CTRL register.

If the ABM and ARU_EN bits are set, the (one) two compare values for CM0 and/or CM1 can be provided by ARU or CPU. If the compare registers CM0 and/or CM1 are/is updated, the ATOM channel waits for the compare match event to happen. No further data is requested from the ARU.

When the specified compare match event happens, the shadow registers SR0 and SR1 are updated together with the ACBO bits in the ATOMi_CHx_STAT register. The data in the shadow registers is marked as valid for the ARU and the DV bit is reset inside the ATOMi_CHx_CTRL register.

If the register SR0 and SR1 holding the captured TBU time stamp values are read by either the ARU or the CPU, the next write access to or update of the register CM0 or CM1 via ARU or the CPU enables the new compare match check again.

At least one of the registers SR0 or SR1 has to be read, before new data is requested from ARU.

The CPU can check at any time if the ATOM channel has received valid data from the ARU and waits for a compare event to happen. This is signalled by a set DV bit inside the ATOMi_CHx_STAT register.

The behaviour of an ATOM channel in SOMC mode, when ARU is enabled and ARU blocking mode is enabled is shown in **Figure 25-49**.

SOMC State diagram for SOMC mode, ARU enabled and ABM enabled

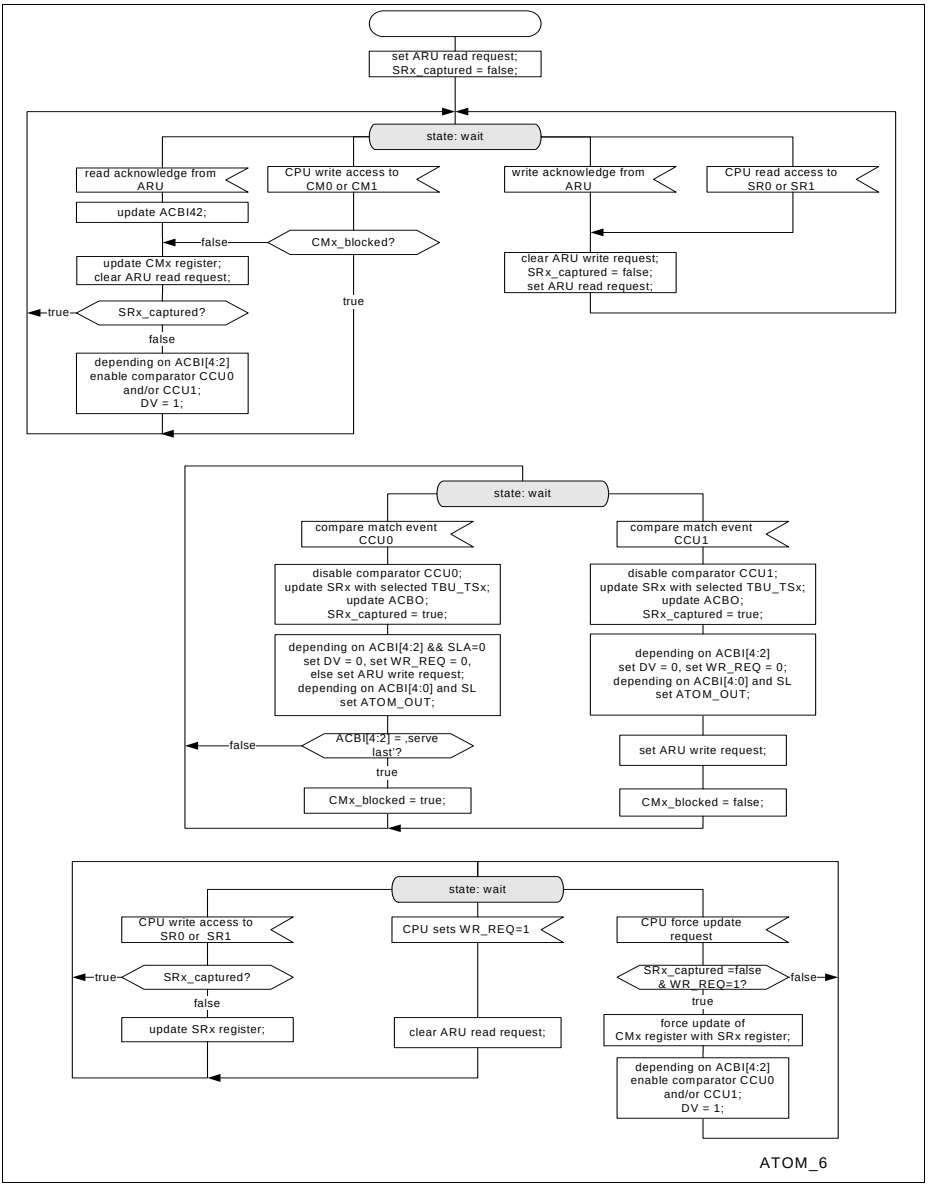

Figure 25-49 SOMC State diagram for SOMC mode, ARU enabled and ABM enabled

ATOM SOMC Late update mechanism

Although, the ATOM channel may be controlled by data received via the ARU, the CPU is able to request at any time a late update of the compare register. This can be initiated by setting the WR_REQ bit inside the ATOMi_CHx_CTRL register. By doing this, the ATOM will request no further data from ARU (if ARU access was enabled). The channel will in any case continue to compare against the values stored inside the compare registers (if bit DV was set). The CPU can now update the new compare values until the compare event happens by writing to the shadow registers, and force the ATOM channel to update the compare registers by writing to the force update register bits in the AGC register.

If the WR_REQ bit is set and a compare match event happens, any further access to the shadow registers SR0, SR1 is blocked and the force update of this channel is blocked. In addition, the WRF bit is set in the ATOMi_CHx_STAT register. Thus, the CPU can determine that the late update failed by reading the WRF bit.

If a compare match event already happened, the WR_REQ bit could not be set until the channel is unlocked for a new compare match event by reading the shadow registers. In addition, the WRF bit is set if the CPU tries to write the WR_REQ bit in that case.

If between a correct WR_REQ bit set, a correct shadow register write, and before the force update is requested by the AGC a match event occurs on the old compare values, the WRF bit will be set.

The WRF bit will be set in any case if the CPU tries to write to a blocked shadow register.

The WR_REQ bit and the DV bit will be reset on a compare match event.

A blocked force update mechanism will be enabled again after a read access to the register SR0 or SR1 by either the ARU or the CPU.

The ATOM SOMC late update mechanism from CPU is shown in **Figure 25-50**.

SOMC State diagram for late update requests by CPU

Field	Bits	Type	Description
SLA	25	rw	**Serve last ARU communication strategy** 0_B Capture SRx time stamps after CCU0 match event not provided to ARU 1_B Capture SRx time stamps after CCU0 match event provided to ARU Note: Please note, that setting of this bit has only effect, when ACBI(4:2) is configured for serve last compare strategy ("100", "101", or "110"). Note: When this bit is not set, the captured time stamps in the shadow registers SRx are only provided after the CCU1 match occurred. The ACBO(4:3) bits always return "10" in that case. Note: By setting this bit, the ATOM channel also provides the captured time stamps after the CCU0 match event to the ARU. The ACBO(4:3) bits are set to “01” in that case. After the CCU1 match event, the time stamps are captured again in the SRx registers and provided to the ARU. The ACBO(4:3) bits are set to “10”. When the data in the shadow registers after the CCU0 match was not consumed by an ARU destination and the CCU1 match occurs, the data in the shadow registers is overwritten by the new captured time stamps. The ATOM channel does not request new data from the ARU when the CCU0 match values are read from an ARU destination.
NotUsed	26	rw	**Not used in this mode**
ABM	27	rw	**ARU blocking mode** 0_B ARU blocking mode disabled: ATOM reads continuously from ARU and updates CM0, CM1 independent of pending compare match event 1_B ARU blocking mode enabled: after updating CM0,CM1 via ARU, no new data is read from ARU until compare match event occurred and SR0 and/or SR1 are read.
Reserved	[31:28]	r	**Reserved** Read as zero, should be written as zero.

25.12.3.3 ATOM Signal Output Mode PWM (SOMP)

In ATOM Signal Output Mode PWM (SOMP) the ATOM submodule channel is able to generate complex PWM signals with different duty cycles and periods. Duty cycles and periods can be changed synchronously and asynchronously. Synchronous change of the duty cycle and/or period means that the duty cycle or period duration changes after the end of the preceding period. An asynchronous change of period and/or duty cycle means that the duration changes during the actual running PWM period.

The signal level of the pulse generated inside the period can be configured inside the channel control register (SL bit of ATOMi_CHx_CTRL register). The initial signal output level for the channel is the erse pulse level defined by the SL bit. **Figure 25-51** clarifies this behaviour.

In SOMP mode, depending on configuration bits RST_CCU0 of register ATOMi_CHx_CRTL the counter register CN0 can be reset either when the counter value is equal to the compare value CM0 or when signaled by the ATOMi trigger signal TRIG [x-1] of the preceding channel.

In this case, if UPEN_CTRLx=1, also the working register CM0, CM1 and CLK_SRC are updated.

PWM Output behaviour with respect to the SL bit in the ATOMi_CHx_CTRL register

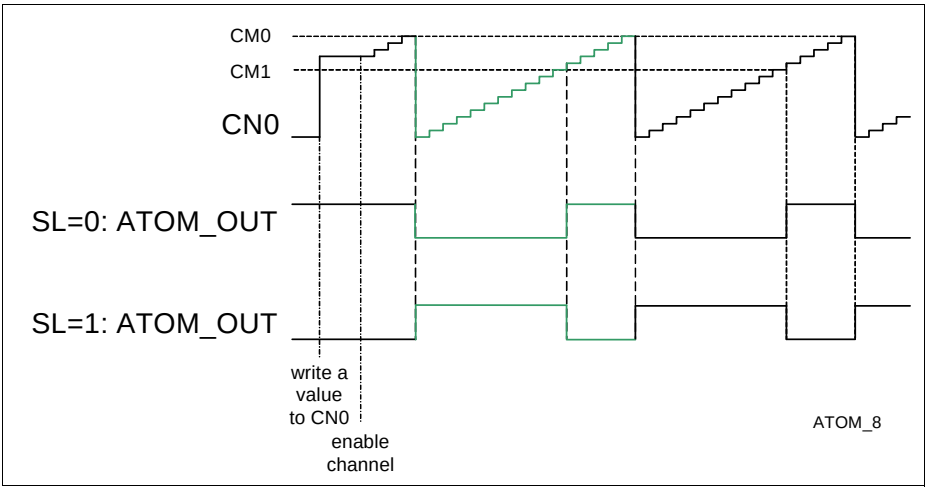

Figure 25-51 PWM Output behaviour with respect to the SL bit in the ATOMi_CHx_CTRL register

On an asynchronous update, it is guaranteed, that no spike occurs at the output port of the channel due to a too late update of the operation registers. The behaviour of the output signal due to the different possibilities of an asynchronous update during a PWM period is shown in **Figure 25-52**.

PWM Output behaviour in case of an asynchronous update of the duty cycle

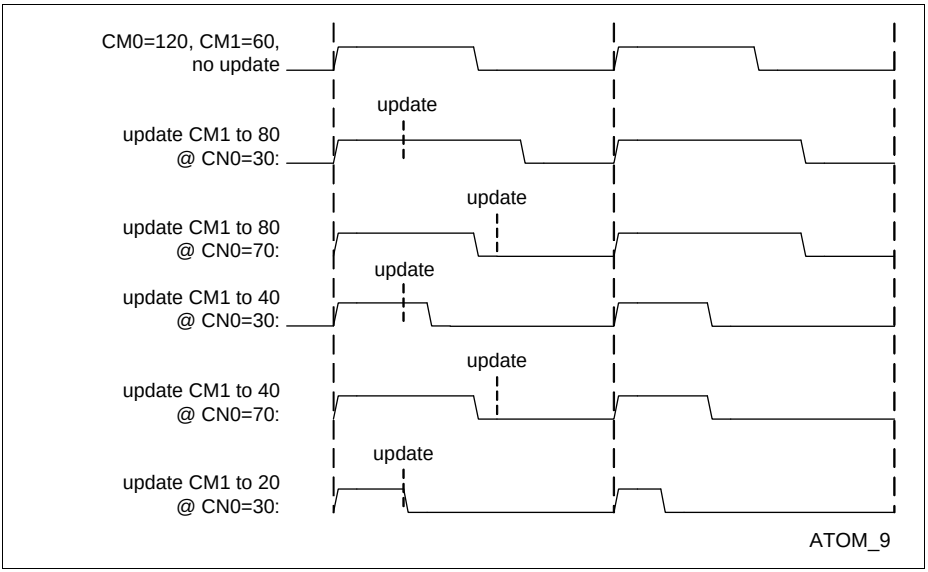

Figure 25-52 PWM Output behaviour in case of an asynchronous update of the duty cycle

The duration of the pulse high or low time and period is measured with the counter in subunit CCU0. The trigger of the counter is one of the eight CMU clock signals configurable in the channel control register ATOMi_CHx_CTRL. The register CM0 holds the duration of the period and the register CM1 holds the duration of the duty cycle in clock ticks of the selected CMU clock.

If counter register CN0 of channel x is reset by its own CCU0 unit (i.e. the compare match of CN0>=CM0 configured by RST CCU0=0, following statements are valid:

- if CM0=0 or CM0=1, 0% duty cycle (=$\overline{SL}$) is generated independent of CM1. The counter CN0 is not counting.
- the configuration of CM1=0 represents 0% duty cycle (=$\overline{SL}$) at the output
- the configuration of CM1>=CM0 represents 100% duty cycle (=SL)

If counter register CN0 of x channel is reset by the trigger signal coming from another channel or the assigned TIM module (configured by RST CCU0=1), following statements are valid:

- CM0 defines the edge to SL value, CM1 defines the edge to $\overline{SL}$ value
- if CM0=CM1, the output is 100% SL (CM0 has higher priority)

- if CM0=0, the output stays at its last value (CN0 stops counting)

In case the counter value CN0 reaches the compare value in register CM0 or the channel receives an external update trigger via the FUPD(x) signal, a synchronous update is performed. A synchronous update means that the registers CM0 and CM1 are updated with the content of the shadow registers SR0 and SR1 and the CLK_SRC register is updated with the value of the CLK_SRC_SR register.

The clock source for the counter can be changed synchronously at the end of a period. If ARU access is disabled, this is done by using the bit field CLK_SRC_SR of register ATOMi_CHx_CTRL as shadow registers for the next CMU clock source.

If ARU access is enabled, the bits ACBI(4), ACBI(3) and ACBI(2) received via ARU and stored in register ATOM_i_CHx_STAT are used as shadow register for the update of the CMU clock source register CLK_SRC.

For the synchronous update mechanism the generation of a complex PWM output waveform is possible without CPU interaction by reloading the shadow registers SR0, SR1 and the ACBI bit field over the ACI subunit from the ARU, while the ATOM channel operates on the CM0 and CM1 registers.

This internal update mechanism is established, when the old PWM period ends. The shadow registers are loaded into the operation registers, the counter register is reset, the new clock source according to the CLK_SRC_SR or ACBI(4), ACBI(3) and ACBI(2) bits is selected and the new PWM generation starts.

In parallel, the ATOM channel issues a read request to the ARU to reload the shadow registers with new values while the ATOM channel operates on the operation registers. To guarantee the reloading, the PWM period must not be smaller than the worst case ARU round trip time and source for the PWM characteristic must provide the new data within this time. Otherwise, the old PWM values are used from the shadow registers.

When updated over the ARU the user has to ensure that the new period duration is located in the lower (bits 23 to 0) and the duty cycle duration is located in the upper (bits 47 to 24) ARU data word and the new clock source is specified in the ARU control bits 52 to 50.

This pipelined data stream character is shown in **Figure 25-53**.

ARU Data input stream pipeline structure for SOMP mode

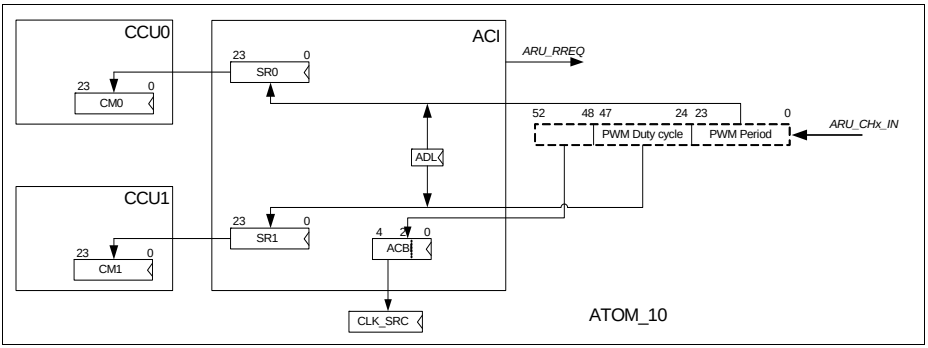

Figure 25-53 ARU Data input stream pipeline structure for SOMP mode

When an ARU transfer is in progress which means the ARU_RREQ is served by the ARU, the ACI locks the update mechanism of CM0, CM1 and CLK_SRC until the read request has finished. The CCU0 and CCU1 operate on the old values when the update mechanism is locked.

The shadow registers SR0 and SR1 can also be updated over the AEI bus interface. When updated via the AEI bus the CM0 and CM1 update mechanism has to be locked via the AGC_GLB_CTRL register with the UPENx signal in the AGC subunit. To select the new clock source in this case, the CPU has to write to the CLK_SRC_SR bit field of the ATOMi_CHx_CTRL register.

For an asynchronous update of the duty cycle and/or period the new values must be written directly into the compare registers CM0 and/or CM1 while the counter CN0 continues counting. This update can be done only via the AEI bus interface immediately by the CPU or by the FUPD(x) trigger signal triggered from the AGC global trigger logic. Values received through the ARU interface are never loaded asynchronously into the operation registers CM0 and CM1. Therefore, the ATOM channel can generate a PWM signal on the output port pin ATOM[i]_CH[x]_OUT on behalf of the content of the CM0 and CM1 registers, while it receives new PWM values via the ARU interface ACI in its shadow registers.

On a compare match of CN0 and CM0 or CM1 the output signal level of ATOM[i]_CH[x]_OUT is toggled according to the signal level output bit SL in the ATOMi_CHx_CTRL register.

Thus, the duty cycle output level can be changed during runtime by writing the new duty cycle level into the SL bit of the channel configuration register. The new signal level becomes active for the next trigger CCU_TRIGx (since bit SL is written).

Since the ATOM[i]_CH[x]_OUT signal level is defined as the erse duty cycle output level when the ATOM channel is enabled, a PWM period can be shifted earlier by writing an initial offset value to CN0 register. By doing this, the ATOM channel first counts until CN0 reaches CM0 and then it toggles the output signal at ATOM[i]_CH[x]_OUT.

SOMP One-shot mode

The ATOM channel can operate in One-shot mode when the OSM bit is set in the channel control register. One-shot mode means that a single pulse with the pulse level defined in bit SL is generated on the output line.

First the channel has to be enabled by setting the corresponding ENDIS_STAT value.

In One-shot mode the counter CN0 will not be increment once the channel is enabled.

A write access to the register CN0 triggers the start of pulse generation (i.e. the increment of the counter register CN0).

If the counter CN0 is reset from CM0 back to zero, the first edge at ATOM[i]_CH[x]_OUT is generated.

To avoid an update of CMx register with content of SRx register at this point in time, the automatic update should be disabled by setting UPEN_CTRLx = 00 (in register ATOMi_CHx_CTRL).

The second edge is generated if CN0 is greater or equal than CM1 (i.e. CN0 was increment until it has reached CM1 or CN0 is greater than CM1 after an update of CM1).

If the counter CN0 has reached the value of CM0 a second time, the counter stops.

The new value of CN0 determines the start delay of the first edge. The delay time of the first edge is given by (CM0-CN0) multiplied with period defined by current value of CLK_SRC.

Figure 25-54 clarifies the pulse generation in SOMP One-shot mode.

PWM Output with respect to configuration bit SL in One-shot mode: trigger by writing to CN0

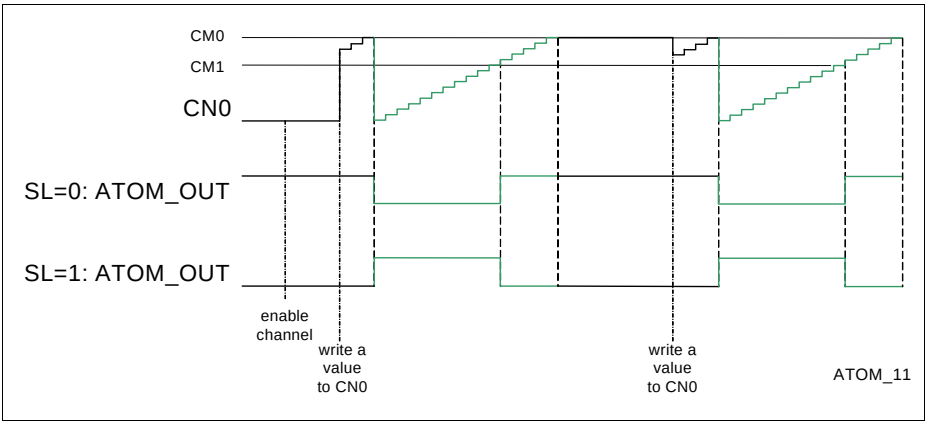

Figure 25-54 PWM Output with respect to configuration bit SL in One-shot mode:

trigger by writing to CN0

Further output of single pulses can be started by a write access to register CN0.

If CN0 is already incrementing (i.e. started by writing to CN0 a value CN0start < CM0), the affect of a second write access to CN0 depends on the phase of CN0:
phase 1: update of CN0 before CN0 reaches first time CM0
phase 2: update of CN0 after CN0 has reached first time CM0 but less than CM1
phase 3: update of CN0 after CN0 has reached first time CM0 and CN0 is greater than or equal CM1

In phase 1: writing to counter CN0 a value CN0new < CM0 leads to shift of first edge (generated if CN0 reaches CM0 first time) by the time CM0-CN0new.

In phase 2: writing to incrementing counter CN0 a value CN0new < CM1 while CM0old is below CM1 leads to a lengthening of the pulse. The counter CN0 stops if it reaches CM0.

In phase 3: writing to incrementing counter CN0 a value CN0new while CNold is already greater than or equal CM1 leads to an immediate restart of a single pulse generation inclusive the initial defined by CM0 - CN0new.

25.12.3.4 ATOM Signal Output Mode Serial (SOMS)

In ATOM Signal Output Mode Serial (SOMS) the ATOM channel acts as a serial output shift register where the content of the CM1 register in the CCU1 unit is shifted out whenever the unit is triggered by the selected CMU_CLK input clock signal. The shift direction is configurable with the ACB(0) bit inside the ATOMi_CHx_CTRL register when ARU is disabled and the ACBI(0) bit inside the ATOMi_CHx_STAT register when ARU is enabled.

The data inside the CM1 register has to be aligned according to the selected shift direction in the ACB(0)/ACBI(0) bit. This means that when a right shift is selected, that

the data word has to be aligned to bit 0 of the CM1 register and when a left shift is selected, that the data has to be aligned to bit 23 of the CM1 register.

SOMS Mode output generation

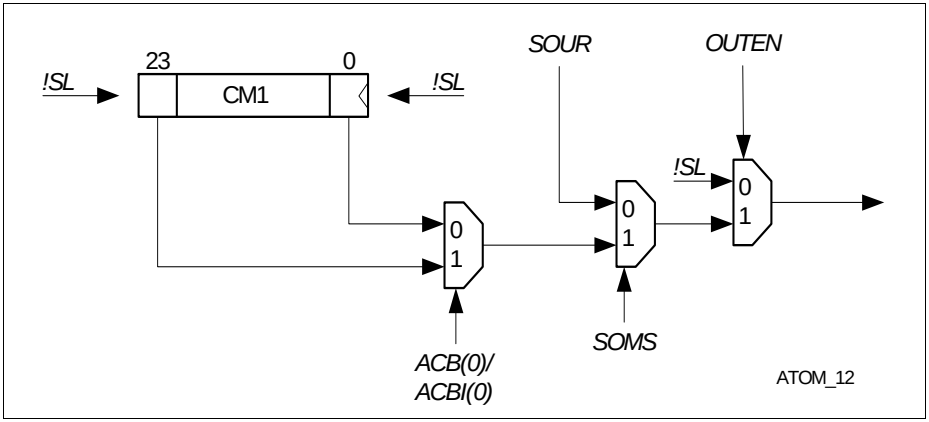

Figure 25-55 SOMS Mode output generation

Figure 12.3.4.1 shows the output generation in case of SOMS mode is selected.

In SOMS mode CCU0 runs in counter/compare mode and counts the number of bits shifted out so far. The total number of bits that should be shifted is defined as CM0. The total number of bits that are visible at ATOM_OUT is CM0+1.

When the output is disabled the ATOM_OUT is set to the inverse SL bit definition.

When the content of the CM1 register is shifted out, the inverse signal level is shifted into the CM1 register.

When the output is enabled while UPEN_CTRL[x] is disabled, the ATOM_OUT signal level is defined by CM1 bit 0 or 23, dependent on the shift direction defined by ACB(0) or ACBI(0) register setting. Figure 12.3.4.2 should clarify the ATOM channel startup behaviour in this case for right shift. For left shift the CM1 bit 0 in 12.3.4.2 has to be replaced by CM1 bit 23.

SOMS Output signal level at startup, UPEN_CTRL[x] disabled

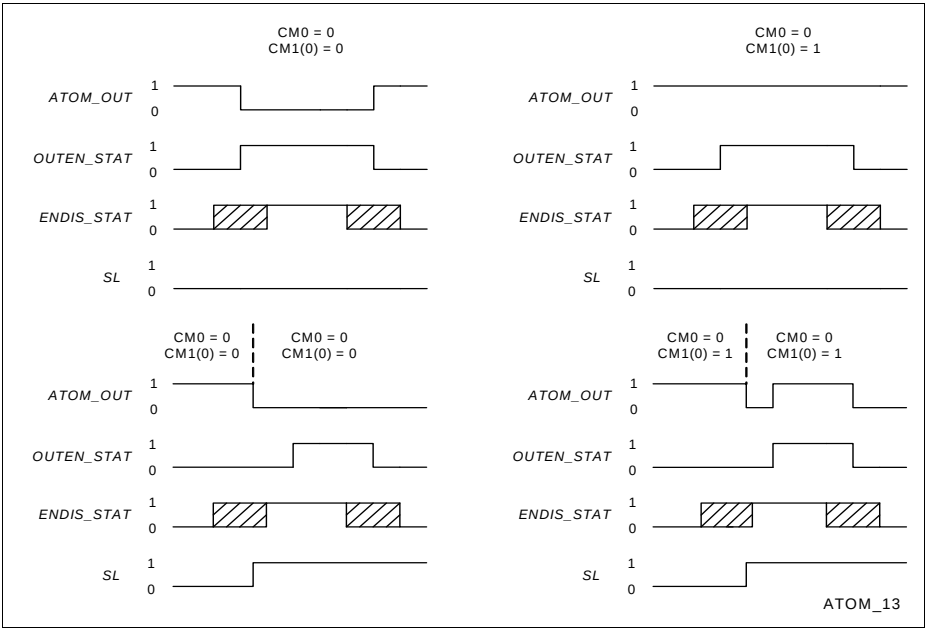

Figure 25-56 SOMS Output signal level at startup, UPEN_CTRL[x] disabled

If UPEN_CTRL[x] is set and the channel is enabled, the output level is defined by bit 0 or 23 of CM1 register dependent on the shift direction. Figure 12.3.4.3 shows the output behaviour in that case.

SOMS Output signal level at startup, UPEN_CTRL[x] enabled

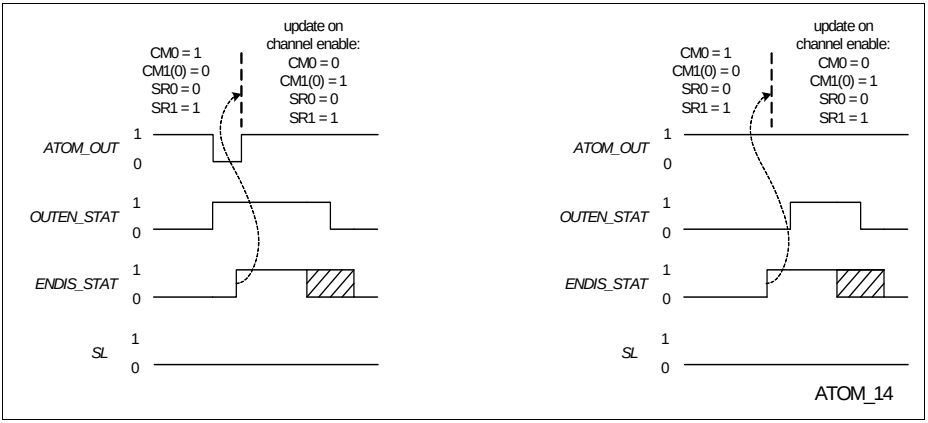

Figure 25-57 SOMS Output signal level at startup, UPEN_CTRL[x] enabled

When the serial data to be shifted is provided via ARU the number of bits that should be shifted has to be defined in the lower 24 bits of the ARU word (23 to 0) and the data that is to be shifted has to be defined in the ARU bits 47 to 24 aligned according to the shift direction. This shift direction has to be defined in the ARU word bit 48 (SL0 bit).

If bit UPEN_CTRL[x] of a channel x is set, after update of CM0/CM1 register with the content of the SR0/SR1 register, a new ARU read request is set up.

If bit UPEN_CTRL[x] of a channel x is not set, no (further) ARU read request is set up (because the SR0/SR1 register are never used for update) and the ATOM may stop shifting after CN0 has reached CM0. Note, that in this case also no automatic restart of shifting is possible.

If a channel is enabled with the settings SOMS mode and ARU_EN = 1, the first received values from ARU are stored in register SR0 and SR1. If CN0 and CM0 are 0 (i.e. CN0 is not counting) and the update of channel x is enabled (UPEN_CTRL[x]=1), an immediate update of the register CM0 and CM1 is also done. This update of CM0 and CM1 triggers the start of shifting.

It is recommended to configure the ATOM channel in One-shot mode when the ARU_EN bit is not set, since the ATOM channel would reload new values from the shadow registers when CN0 reaches CM0.

SOMS mode with ARU_EN = 1 and OSM = 0, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is set and bit OSM is not set, the channel is running in the SOMS continuous mode. Then, if the content of the CM0 register equals the counter CN0, the CM0 and CM1 registers are reloaded with the SR0 and SR1 content and new values are requested from the ARU. If the update of the shadow registers does not happen before

CN0 reaches CM0 the old values of SR0 and SR1 are used to reload the operation registers.

In contrast to controlling the channel via AEI, the shift direction defined by ARU word bit 48 has only effect after the update of CMx operation registers from the SRx registers.

SOMS mode with ARU_EN = 1 and OSM = 1, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is set and bit OSM is set, the channel is running in the SOMS one-shot mode. Then, if the content of the CM0 register equals the counter CN0 and if new values are available in SR0 and SR1 (bit DV set), the CM0 and CM1 registers are reloaded with the SR0 and SR1 content and new values are requested from the ARU. If no new values are available in SR0 and SR1, the register CM0 and CM1 will not be updated, the counter CN0 stops and the ATOM channel continues to request new data from ARU. A later reception of new ARU data in SR0 and SR1 will immediately force the update of the register CM0 and CM1 and restart the counter CN0.

SOMS mode with ARU_EN = 0 and OSM = 0, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is not set and bit OSM is not set, the ATOM channel updates its CM0/CM1 register with the content of the SR0/SR1 register and restarts shifting immediately. The first bit of new CM1 register value will be applied at the output without any gap to the last bit of the previous CM1 register value.

SOMS mode with ARU_EN = 0 and OSM = 1, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is not set and bit OSM is set, the ATOM channel stops shifting when CN0 reaches CM0 and no update of CM0 and CM1 is performed.

Then, the shifting of the channel can be restarted again by writing a zero (0) to the CN0 register again. Please note, that the CN0 register should be written with a zero since the CN0 register counts the number of bits shifted out by the ATOM channel.

The writing of a zero to CN0 causes also an immediate update of CM0/CM1 register with the content of SR0/SR1 register.

Interrupts in SOMS mode

In ATOM Signal Output Mode Serial only the interrupt CCU0TC (ATOM[i]_CH[x]_IRQ_NOTIFY) in case of CN0 >= CM0 is generated. The interrupt CCU1TC has no meaning and is not generated.

Note: An enable or disable of the channel x has no effect on ATOM_OUT[x].

Field	Bits	Type	Description
CLK_SRC	[14:12]	rw	**Shift frequency select for channel** 000_B CMU_CLK0 selected 001_B CMU_CLK1 selected 010_B CMU_CLK2 selected 011_B CMU_CLK3 selected 100_B CMU_CLK4 selected 101_B CMU_CLK5 selected 110_B CMU_CLK6 selected 111_B CMU_CLK7 selected Note: This register is a shadow register for the CMU_CLKx select. Thus, if the channel should operate on another CMU_CLK then CMU_CKL0 at the beginning, the different CMU_CLK has to be specified inside this register and the CMU_CLK has to be configured with a FORCE_UPDATE in that case before the channel operation would start.
Reserved	15	r	**Reserved** Read as zero, should be written as zero.
NotUsed	16	rw	**Not used in this mode**
Reserved	[19:17]	r	**Reserved** Read as zero, should be written as zero.
NotUsed	20	rw	**Not used in this mode**
NotUsed	[23:21]	r	**Not used in this mode**
NotUsed	24	rw	**Not used in this mode**
Reserved	25	r	**Reserved** Read as zero, should be written as zero.
OSM	26	rw	**One-shot mode** 0_B Continuous shifting is enabled 1_B Channel stops, after number of bits defined in CM0 is shifted out
NotUsed	27	rw	**Not used in this mode**
Reserved	[31:28]	r	**Reserved** Read as zero, should be written as zero.

25.12.4 ATOM Interrupt signals

The following table describes ATOM interrupt signals:

Table 25-40 ATOM interrupt signals

Signal	Description
CCU0TCx_IRQ	CCU0 Trigger condition interrupt for channel x
CCU1TCx_IRQ	CCU1 Trigger condition interrupt for channel x

25.12.5 ATOM Register overview

The following table shows a conclusion of ATOM register address offset and initial values.

Table 25-41 ATOM Register overview

Register name	Description	Details in Section
ATOMi_AGC_GLB_CTRL	AGC Global control register	Section 25.12.6.1
ATOMi_AGC_ENDIS_CTRL	AGC Enable/disable control register	Section 25.11.8.2
ATOMi_AGC_ENDIS_STAT	AGC Enable/disable status register (represents status of ATOM channels)	Section 25.11.8.3
ATOMi_AGC_ACT_TB	AGC Action time base register	Section 25.11.8.4
ATOMi_AGC_OUTEN_CTRL	AGC Output enable control register	Section 25.11.8.5
ATOMi_AGC_OUTEN_STAT	AGC Output enable status register	Section 25.11.8.6
ATOMi_AGC_FUPD_CTRL	AGC Force update control register	Section 25.11.8.7
ATOMi_AGC_INT_TRIG	AGC Internal trigger control register	Section 25.11.8.8
ATOMi_CHx_CTRL	ATOM Channel x control register (x=0…7)	Section 25.12.6.2
ATOMi_CHx_STAT	ATOM Channel x status register (x=0…7)	Section 25.12.6.3
ATOMi_CHx_RDADDR	ATOM Channel x ARU read address register (x=0…7)	Section 25.12.6.4

Table 25-41 ATOM Register overview (cont'd)

Register name	Description	Details in Section
ATOMi_CHx_CN0	ATOM Channel x CCU0 counter register (x=0…7)	Section 25.12.6.5
ATOMi_CHx_CM0	ATOM Channel x CCU0 compare register (x=0…7)	Section 25.12.6.6
ATOMi_CHx_SR0	ATOM Channel x CCU0 compare shadow register (x=0…7)	Section 25.12.6.7
ATOMi_CHx_CM1	ATOM Channel x CCU1 compare register (x=0…7)	Section 25.12.6.8
ATOMi_CHx_SR1	ATOM Channel x CCU1 compare shadow register (x=0…7)	Section 25.12.6.9
ATOMi_CHx_IRQ_NOTIFY	ATOM channel x interrupt notification register (x=0…7)	Section 25.12.6.10
ATOMi_CHx_IRQ_EN	ATOM channel x interrupt enable register (x=0…7)	Section 25.12.6.11
ATOMi_CHx_IRQ_FORCINT	ATOM channel x software interrupt generation register (x=0…7)	Section 25.12.6.12
ATOMi_CHx_IRQ_MODE	IRQ mode configuration register (x=0…7)	Section 25.12.6.13

25.12.6 ATOM Register description

All of the following registers are 32-bit only accessible.

25.12.6.1 Register ATOMi_AGC_GLB_CTRL

GTM_ATOMi_AGC_GLB_CTRL (i=0-4)
ATOMi AGC Global control register($0D040_H$+i*800_H) **Reset Value: 00000000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	w	w	w	w	w	r							w

Field	Bits	Type	Description
HOST_TRIG	0	w	**Trigger request signal (see AGC) to update the register ENDIS_STAT and OUTEN_STAT** 0_B no trigger request 1_B set trigger request Read as 0. *Note:* This flag is cleared automatically after triggering the update
Reserved	[7:1]	r	**Reserved** Read as zero, should be written as zero
RST_CH0	8	w	**Software reset of channel 0** 0_B No action 1_B Reset channel Read as 0. *Note:* This bit is cleared automatically after write by CPU. The channel registers are set to their reset values and channel operation is stopped immediately. The S-r FlipFlop SOUR is reset to '1'.

Field	Bits	Type	Description
RST_CH1	9	w	**Software reset of channel 1** See bit 8
RST_CH2	10	w	**Software reset of channel 2** See bit 8
RST_CH3	11	w	**Software reset of channel 3** See bit 8
RST_CH4	12	w	**Software reset of channel 4** See bit 8
RST_CH5	13	w	**Software reset of channel 5** See bit 8
RST_CH6	14	w	**Software reset of channel 6** See bit 8
RST_CH7	15	w	**Software reset of channel 7** See bit 8
UPEN_CTRL0	[17:16]	rw	**ATOM channel 0 enable update of register CM0, CM1 and CLK_SRC from SR0, SR1 and CLK_SRC_SR** Write of following double bit values is possible: 00_B don't care, bits 1:0 will not be change 01_B update disabled: is read as 00 (see below) 10_B update enabled: is read as 11 (see below) 11_B don't care, bits 1:0 will not be changed Read of following double values means: 00_B channel disabled 11_B channel enabled
UPEN_CTRL1	[19:18]	rw	**ATOM channel 1 enable update of register CM0, CM1 and CLK_SRC** See bits 17:16
UPEN_CTRL2	[21:20]	rw	**ATOM channel 2 enable update of register CM0, CM1 and CLK_SRC** See bits 17:16
UPEN_CTRL3	[23:22]	rw	**ATOM channel 3 enable update of register CM0, CM1 and CLK_SRC** See bits 17:16
UPEN_CTRL4	[25:24]	rw	**ATOM channel 4 enable update of register CM0, CM1 and CLK_SRC** See bits 17:16

Field	Bits	Type	Description
UPEN_CTRL5	[27:26]	rw	**ATOM channel 5 enable update of register CM0, CM1 and CLK_SRC** See bits 17:16
UPEN_CTRL6	[29:28]	rw	**ATOM channel 6 enable update of register CM0, CM1 and CLK_SRC** See bits 17:16
UPEN_CTRL7	[31:30]	rw	**ATOM channel 7 enable update of register CM0, CM1 and CLK_SRC** See bits 17:16

25.12.6.2 Register ATOMi_CHx_CTRL (x: 0…7)

GTM_ATOM0_CHx_CTRL (x=0-7)
ATOM0 Channel x Control Register
($0D004_H$+x*0080_H) **Reset Value: 00000800_H**

GTM_ATOM1_CHx_CTRL (x=0-7)
ATOM1 Channel x Control Register
($0D804_H$+x*0080_H) **Reset Value: 00000800_H**

GTM_ATOM2_CHx_CTRL (x=0-7)
ATOM2 Channel x Control Register
($0E004_H$+x*0080_H) **Reset Value: 00000800_H**

GTM_ATOM3_CHx_CTRL (x=0-7)
ATOM3 Channel x Control Register
($0E804_H$+x*0080_H) **Reset Value: 00000800_H**

GTM_ATOM4_CHx_CTRL (x=0-7)
ATOM4 Channel x Control Register
($0F004_H$+x*0080_H) **Reset Value: 00000800_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved				ABM	OSM	SLA	TRIGOUT	Reserved			RST_CCU0	Reserved			WR_REQ
r				rw	rw	rw	rw	r			rw	r			rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	CLK_SRCCLK_SRC_SR			SL	Reserved	CMP_CTRL	ACB					ARU_EN	TB12_SEL	MODE	
r	rw			rw	r	rw	rw					rw	rw	rw	

Field	Bits	Type	Description
MODE	[1:0]	rw	**ATOM channel mode select** 00_B ATOM Signal Output Mode Immediate (SOMI) 01_B ATOM Signal Output Mode Compare (SOMC) 10_B ATOM Signal Output Mode PWM (SOMP) 11_B ATOM Signal Output Mode Serial (SOMS)
TB12_SEL	2	rw	**Select time base value TBU_TS1 or TBU_TS2.** 0_B TBU_TS1 selected for comparison 1_B TBU_TS2 selected for comparison Note: this bit is only applicable in SOMC mode.
ARU_EN	3	rw	**ARU Input stream enable** 0_B ARU Input stream disabled 1_B ARU Input stream enabled
ACB	[8:4]	rw	**ATOM Mode control bits** Note: These bits have different meaning in the different ATOM channel modes. Please refer to the mode description sections. Note: These bits are only applicable when ARU_EN = '0'.
CMP_CTRL	9	rw	**CCUx compare strategy select** 0_B Greater/equal compare against TBU time base values (TBU_TSx >= CMx) 1_B Less/equal compare against TBU time base values (TBU_TSx <= CMx) Note: this bit is only applicable in SOMC mode.
Reserved	10	r	**Reserved** Read as zero, should be written as zero

Field	Bits	Type	Description
SL	11	rw	**Initial signal level** 0_B Low signal level 1_B High signal level Note: If the output is disabled, the output ATOM_OUT[x] is set to inverse SL independent of ATOM channel mode. Note: In SOMP, SOMI, and SOMS mode, if the channel is disabled, the intrernal register SOUR inside ATOM sub unit SOU is set to inverse value of SL. By enabling the channel the register SOUR is not changed. Thus, if the output is enabled afterwards, the output ATOM_OUT[x] is the inverse value of SL. Note: In SOMC mode, if the channel is disabled, the internal register SOUR inside ATOM sub unit SOU is set to value of SL. By enabling the channel the register SOUR in not changed. Thus, if the output is enabled and the channel is disabled, the output ATOM_OUT[x] is the value of SL. Note: In SOMS mode, this bit is only applicable when the channel and its outputs are disabled.

Field	Bits	Type	Description
CLK_SRC CLK_SRC _SR	[14:12]	rw	**actual CMU clock source (SOMS)/ shadow register for CMU clock source (SOMP)** 000_B CMU_CLK0 selected 001_B CMU_CLK1 selected 010_B CMU_CLK2 selected 011_B CMU_CLK3 selected 100_B CMU_CLK4 selected 101_B CMU_CLK5 selected 110_B CMU_CLK6 selected 111_B CMU_CLK7 selected Note: This register is a shadow register for the CMU_CLKx select. Thus, if the CMU_CLK source for PWM generation should be changed during operation, the old CMU_CLK has to operate until the update of the ATOM channels internal CLK_SRC register by the CLK_SRC_SR content is done either by an end of a period or a FORCE_UPDATE. Note: After (channel) reset the selected CLK_SRC value is the SYS_CLK (input of Global Clock Divider). To use in SOMP mode one of the CMU_CLKx, it is required to perform a forced update of CLK_SRC with the value of CLK_SRC_SR value before/with enabling the channel.
Reserved	15	r	**Reserved** Read as zero, should be written as zero
WR_REQ	16	rw	**CPU Write request bit for late compare register update**
Reserved	[19:17]	r	**Reserved** Read as zero, should be written as zero
RST_CCU 0	20	rw	**Reset source of CCU0** 0_B Reset counter register CN0 to 0 on matching comparison with CM0 1_B Reset counter register CN0 to 0 on trigger TRIG_[x-1] *Note: If RST_CCU0=1 and UPEN_CTRLx=1 are set , TRIG_[x-1] triggers also the update of work register (CM0, CM1, and CLK_SRC).*
Reserved	[23:21]	r	**Reserved** Read as zero, should be written as zero

Field	Bits	Type	Description
TRIGOUT	24	rw	**Trigger output selection (output signal TRIG_CHx) of module ATOM_CHx.** 0_B TRIG_[x[is TRIG_[x-1] 1_B TRIG_[x] is TRIG_CCU0 Note: this bit is only applicable in SOMC and SOMP mode.
SLA	25	rw	**Serve last ARU communication strategy** 0_B Capture SRx time stamps after CCU0 match event not provided to ARU 1_B Capture SRx time stamps after CCU0 match event provided to ARU Note: This bit is only applicable in SOMC mode. Note: Please note, that setting of this bit has only effect, when ACBI(4:2) is configured for serve last compare strategy (“100”, “101”, or “110”). Note: When this bit is not set, the captured time stamps in the shadow registers SRx are only provided after the CCU1 match occurred. The ACBO(4:3) bits always return "10" in that case. Note: By setting this bit, the ATOM channel also provides the captured time stamps after the CCU0 match event to the ARU. The ACBO(4:3) bits are set to “01” in that case. After the CCU1 match event, the time stamps are captured again in the SRx registers and provided to the ARU. The ACBO(4:3) bits are set to “10”. When the data in the shadow registers after the CCU0 match was not consumed by an ARU destination and the CCU1 match occurs, the data in the shadow registers is overwritten by the new captured time stamps. The ATOM channel does not request new data from the ARU when the CCU0 match values are read from an ARU destination.
OSM	26	rw	**One-shot mode** 0_B Continuous PWM generation after channel enable 1_B A single pulse is generated Note: this bit is only applicable in SOMP and SOMS modes.

Field	Bits	Type	Description
ABM	27	rw	**ARU blocking mode** 0_B ARU blocking mode disabled: ATOM reads continuously from ARU and updates CM0, CM1 independent of pending compare match event 1_B ARU blocking mode enabled: after updating CM0,CM1 via ARU, no new data is read from ARU until compare match event is occurred. Note: this bit is only applicable in SOMC mode.
Reserved	[31:28]	r	**Reserved** Read as zero, should be written as zero

25.12.6.3 Register ATOMi_CHx_STAT (x: 0…7)

GTM_ATOM0_CHx_STAT (x=0-7)
ATOM0 Channel x Status Register
($0D01C_H$+x*0080_H) **Reset Value: 00000000_H**

25.13 Multi Channel Sequencer (MCS)

25.13.1 Overview

The Multi Channel Sequencer (MCS) submodule is a generic data processing module that is connected to the ARU.

One of its major applications is to calculate complex output sequences that may depend on the time base values of the TBU and are processed in combination with the ATOM submodule.

Other applications can use the MCS submodule to perform extended data processing of input data resulting from the TIM submodule that are provided to the CPU (e.g. using the PSM submodule).

Moreover, some applications may process data provided by the CPU within the MCS submodule, and the calculated results are sent to the outputs using the ATOM submodules.

25.13.1.1 Architecture

Figure 25-58 gives an overview of the MCS architecture.

MCS architecture

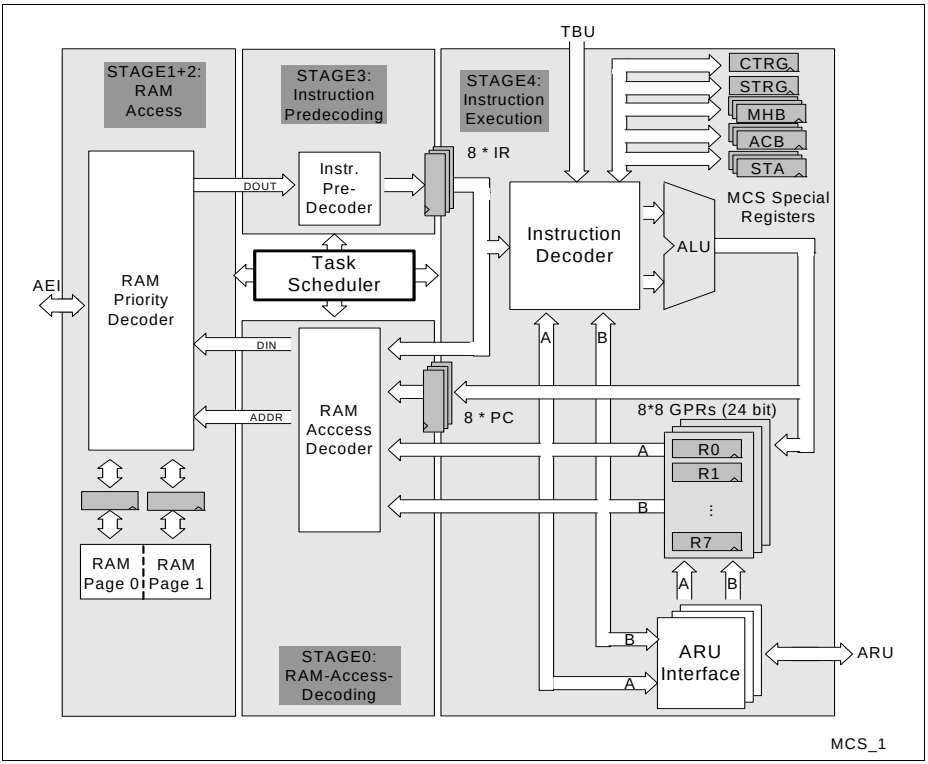

Figure 25-58 MCS architecture

The MCS submodule mainly embeds a single data path with five pipeline stages, consisting of a simple 24-bit Arithmetic Logic Unit (ALU), several decoders, and a connection to two RAM pages located outside of the MCS submodule.

The data path of the MCS is shared by eight so called MCS-channels, whereas each MCS-channel executes a dedicated micro-program that is stored inside the RAM pages connected to the MCS submodule. The execution of the different MCS-channels is controlled by a central task scheduler.

Both RAM pages may contain arbitrary sized code and data sections that are accessible by all MCS-channels and the CPU via AEI.

The MCS submodule supports a memory layout of up to 2^{12} memory locations each 32 bit wide leading to a maximum address range from 0 to 2^{14}-4.

This address space of the MCS is divided into two seamless memory pages.

Memory page 0 begins from address 0 and ranges to address MP0-[i] and memory page 1 ranges from MP0 to MP1-[i].

The parameters MP0 and MP1 are defined externally by the memory configuration submodule MCFG of **Section 25.14**.

If an ECC Error occurs while an MCS-channel reads data from a memory page, the corresponding MCS-channel is disabled and the ERR bit in register STA is raised.

After a resetting the MCS submodule, the content of both memory pages is initialized with zeros.

An MCS-channel can also be considered as an individual task of a processor that is scheduled at a specific point in time.

A more detailed description of the scheduling can be found in **Section 25.13.1.2**.

Moreover, each MCS-channel has a dedicated ARU interface for communication with other ARU connected modules, an Instruction Register (IR), a Program Counter Register (PC), a Status Register (STA), an ARU Control Bit Register (ACB), a Memory High Byte Register (MHB) and a Register Bank with eight 24 bit general purpose registers (R0, R1, …R7).

All the registers, mentioned above, are only visible within its dedicated MCS-channel and thus the MCS-channels cannot exchange data using registers.

The only exception is the common 16 bit wide trigger register that can be accessed by all MCS channels in order to trigger other MCS-channels located in the same submodule. STRG is used to set a bits and CTRG is used to clear bits in the trigger register.

To enable triggering of MCS-channels by CPU, it can set bits in the common trigger register by writing to MCS[i]_STRG and clear bits by writing to MCSi_CTRG.

Whenever data has to be exchanged between different MCS-channels, the connected RAM pages, which are accessible by all MCS-channels, must be used.

However, since the data registers are writable by the CPU, an MCS channel may also exchange data with the CPU using its data registers.

The main actions of the different pipeline stages are as follows:

Pipeline stage 0 performs a setup of address, input data, and control signals for the next RAM access of a specific MCS-channel.

The actual RAM access of a specific MCS-channel is executed in pipeline stage 1 and 2, assuming an external connection of a synchronous RAM with a latency of one clock cycle.

The RAM priority decoder arbitrates RAM accesses that are requested by the CPU via AEI and by the active MCS-channel.

If both, CPU and an MCS-channel request a memory access to the same memory page the MCS-channel is prioritized.

Pipeline stage 3 performs pre-decoding of instruction and data resulting from the RAM.

Finally, in pipeline stage 4 the current instruction is executed.

Since the internal registers of the MCS can be updated by different sources (MCS write access, AEI write access and ARU read access) a write conflict occurs if more than one source wants to write to the same register. In this cascade the result of the register is unpredictable.

However, the software should setup its application in a way that such conflicts do not occur.

One exception is the common trigger register which may be written by multiple sources (different MCS channels and AEI) in order to enable fast triggering of different MCS channels. Typically, the software should setup its application in a manner that different sources should not write the same bits in the trigger register.

25.13.1.2 Scheduling

The MCS submodule provides two different scheduling schemes: round-robin schedule and accelerated schedule.

The scheduling scheme can be selected by the SCHED bit in the global MCSi_CTRL register.

The round-robin order scheduling assigns all MCS-channels an equal amount of time slices.

In addition, the scheduler also assigns one time slice to the CPU, in order to guarantee at least one memory access by the CPU within each round-trip cycle.

Figure 25-59 shows the round-robin scheduling with 8 MCS-channels (C_0 to C_7) that are scheduled together with a single CPU access.

Scheduling

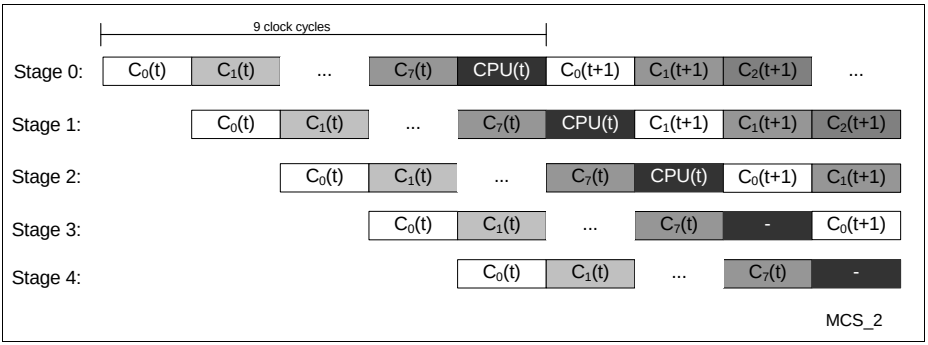

Figure 25-59 Scheduling

The figure also shows which MCS-channel is activated in specific pipeline stage at a specific point in time.

The execution time of an MCS-channel in a specific pipeline stage is always one clock cycle.

The index t marks all instruction parts of the corresponding MCS-channels belonging to the same round-trip cycle.

Consequently, a single cycle instruction of an MCS-channel requires an effective execution time of 9 clock cycles, ignoring the five clock cycles of pipeline latency.

To improve memory bandwidth between CPU and MCS memory, the time slices of any suspended MCS-channel is also granted to the CPU.

An MCS-channel can be suspended due to the following reasons:

- An MCS-channel is executing a blocking read or write request to an ARU connected submodule (instruction ARD, AWR, ARDI, AWRI).
- An MCS-channel waits on a register match event (instruction WURM), in order to wait on a time base value or a trigger event from another MCS channel.
- An MCS-channel is disabled.

The round-robin scheduling leads to a deterministic round trip time for the whole submodule, however it may waste clock cycles by scheduling MCS-channels that are not able to run at a specific point in time assuming that there is no high CPU bandwidth required.

The second scheduling mode, the accelerated scheduling mode, improves the computational performance of the MCS in the following way:

Initially, the accelerated scheduling mode behaves similar to round-robin scheduling mode.

Whenever the scheduler detects an MCS-channel that is suspended, due to its suspended state (or it is already scheduled in stage 0, 1, 2, or 3), the scheduler is

selecting the next non-suspended MCS-channel that would follow if round-robin scheduling is continued.

Considering the timing of **Figure 25-59** in conjunction with the accelerated scheduling scheme, a single cycle instruction of an MCS-channel requires an effective execution time between 5 and 9 clock cycles, depending on the number of suspended MCS-channels.

In summary, the round-robin scheduling mode grants time slices of suspended MCS-channels to the CPU and the accelerated scheduling mode grants time slices of suspended MCS-channels to non-suspended MCS-channels.

25.13.2 Instruction Set

This section describes the entire instruction set of the MCS submodule.

After the introduction of the different instruction formats in **Section 25.13.2.1**, the individual instructions are described in **Section** to **Section 25.13.2.7**.

In general, each instruction is 32 bit wide but the duration of each instruction varies between several instruction cycles. An instruction cycle is defined as the time in SYS_CLK clock cycles that rest between two consecutive instructions of a channel.

As already described in **Section 25.13.1.2**, the number of required clock cycles for a single instruction cycle can vary in the range of 5 to 9 clock cycles, depending on the number suspended MCS-channels, when the accelerated scheduling scheme is selected inside the MCSi_CTRL register.

In the round robin scheduling scheme, each single cycle instruction takes exactly 9 clock cycles.

Before the instruction formats and the actual instructions are described, some commonly used terms, abbreviations and expressions are introduced:

OREG: The operation register set OREG = {R0, R1, R2,…, R7, STA, ACB, CTRG, STRG, TBU_TS0, TBU_TS1, TBU_TS2, MHB} includes all MCS accessible internal registers, as well as the global time bases TBU_TS0, TBU_TS1, and TBU_TS2 that are provided by the submodule TBU.

AREG: The ARU register set AREG = {R0, R1, R2,…, R7, ZERO} includes the all registers that can be written by incoming ARU transfers (ARD, ARDI instructions). These registers include all eight general purpose registers. The dummy register ZERO may be used to discard an incoming 24 bit ARU word.

LIT4: The set LIT4 = {0,1, …, 15} is an unsigned 4 bit literal.

LIT16: The set LIT16 = {0,1, …, 2^{16} -1} is an unsigned 16 bit literal.

LIT24: The set LIT24 = {0,1, …, 2^{24} -1} is an unsigned 24 bit literal.

BIT SELECTION: The expression VAR[i] represents the i-th bit of a variable VAR.

BIT RANGE SELECTION: The expression VAR[m:n] represents the bit slice of variable VAR that is ranging from bit n to bit m.

MEMORY ADRESSING: The expression MEM(X) represents the 32 bit value at address X of the memory.

Address X ranges between 0 and 2^{14}-4, whereas X must be an integral multiple of 4.

The expression MEM(X)[m:n] represents the bit slice ranging from bit n to m of the 32 bit word at memory location X.

ARU ADRESSING: In the case of ARU reading, the expression ARU(X) represents the 53 bit ARU word of ARU channel at address X.

The read address X ranges between 0 and 2^{9}-1.

In the case of ARU writing, the expression ARU(X) represents a 53 bit ARU word that is written to an ARU channel indexed by the index X.

The index X selects a single ARU write channel from the pool of the MCS submodule's allocated ARU write channels.

An MCS submodule has 24 ARU write channels, indexed by values 0 to 23.

The expression ARU(X)[m:n] represents the bit slice ranging from bit n to m of the 53 bit ARU word.

25.13.2.1 Instruction Format

The first instruction format, called literal instruction format, embeds a primary 4 bit opcode OPC0, a 24 bit literal value C ∈ LIT24, and a 4 bit value A, which may be an element of set OREG or AREG, depending on the actual instruction.

Figure 25-60 shows the bit alignment of the literal instruction format.

Literal Instruction format

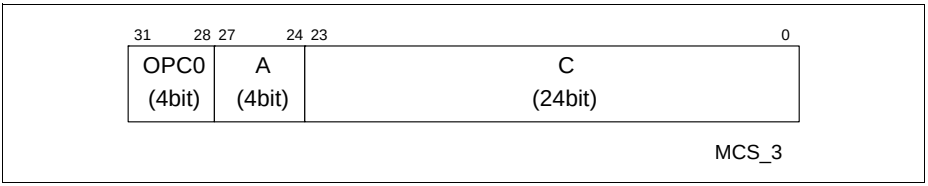

Figure 25-60 Literal Instruction format

The literal instruction format is primarily used for instructions that are accessing a 24 bit literal and a single 24 bit register as operands.

In the following subsections the binary codes of a 24 bit literal instruction is defined as "xxxxaaaaccccccccccccccccccccccc", whereas the digits 'x' encode the field OPC0, the digits 'a' encode the operand field A, and the digits 'c' encode the 24 bit literal field C.

If an instruction ignores several bits of field, the bits are defined as '-' in its code.

The second instruction format, called double operand instruction format, embeds a 4 bit primary opcode OPC0, a 4 bit secondary opcode OPC1, a 16 bit literal C ∈ LIT16 and two 4 bit values A and B, which may be an element of set OREG, AREG, or LIT4 depending on the actual instruction.

Figure 25-61 shows the bit alignment of the double operand instruction format.

Double Operand Instruction format

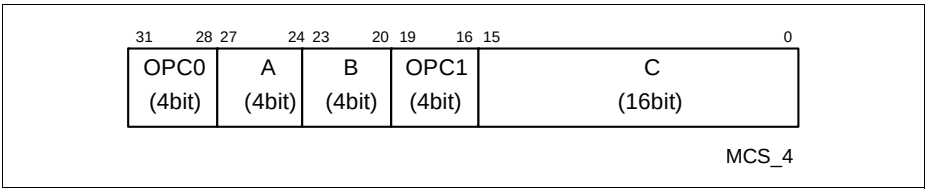

Figure 25-61 Double Operand Instruction format

The double operand instruction format is primarily used for instructions that are accessing two operands stored in the 24 bit registers.

In the following subsections the binary codes of a 16 bit literal instruction is defined as "xxxxaaaabbbbyyyyccccccccccccccc", whereas the digits 'x' encode the bit field OPC0, 'y' the digits of field OPC2, the digits 'a' encode the operand field A, the digits 'b' the operand field B, and the digits 'c' encode the 16 bit literal field C.

If an instruction ignores several bits of field, the bits are defined as '-' in its code.

25.13.2.2 Data Transfer Instructions

MOVL Instruction

Syntax: MOVL A, C

Operation: A ← C

Status: Z

Duration: 1 instruction cycle

Code: 0001aaaaccccccccccccccccccccccc

Description: Transfer literal value C (C ∈ LIT24) to register A (A ∈ OREG).

The zero bit Z of status register STA is set, if the transferred value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

MOV Instruction

Syntax: MOV A, B

Operation: A ← B

Status: Z

Duration: 1 instruction cycle

Code: 1010aaaabbbb0000----------

Description: Transfer value B (B ∈ OREG) to register A (A ∈ OREG).

The zero bit Z of status register STA is set, if the transferred value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

MRD Instruction

Syntax: MRD A, C

Operation: A ← MEM(C[13:0])[23:0];

MHB ← MEM(C[13:0])[31:24]

Status: Z

Duration: 2 instruction cycles

Code: 1010aaaa----0001--cccccccccccccc

Description: Transfer the lower 24 bits of memory content at address C (C ∈ LIT16) to register A (A ∈ OREG). The upper 8 bits of the memory content at address C are transferred to MHB register.

The zero bit Z of status register STA is set, if the lower 24 bits of the transferred value are zero, otherwise the zero bit is cleared.

If the MHB register is selected as destination register A (A ? OREG), the bits 0 to 7 of the referred memory location are transferred to MHB.

The program counter PC is increment by the value 4.

MWR Instruction

Syntax: MWR A, C

Operation: MEM(C[13:0])[23:0] ← A;

MEM(C[13:0])[31:24] ← MHB

Status: -

Duration: 2 instruction cycles

Code: 1010aaaa----0010--cccccccccccccc

Description: Transfer 24 bit value of register A (A ∈ OREG) together with the MHB register to the memory location at address C (C ∈ LIT16).

The 24 bit value of register A is stored in the lower significant bits (bit 0 to 23) of the memory location and the MHB register is stored in bits 24 to 31.

The program counter PC is increment by the value 4.

MWR24 Instruction

Syntax: MWR24 A, C

Operation: MEM(C[13:0])[23:0] ← A

Status: -

Duration: 3 instruction cycles

Code: 1010aaaa----0111--cccccccccccccc

Description: Transfer 24 bit value of register A (A ∈ OREG) to memory at address C (C (C ∈ LIT16).

The 24 bit value of register A is stored in the lower significant bits (bit 0 to 23) of the memory location and the bits 24 to 31 are left unchanged.

The program counter PC is increment by the value 4.

It should be noted that this operation is not an atomic instruction.

MRDI Instruction

Syntax: MRDI A, B

Operation: A ← MEM(B[13:0])[23:0]

MHB ← MEM(B[13:0])[31:24]

Status: Z

Duration: 2 instruction cycles

Code: 1010aaaabbbb0011----------

Description: Transfer the lower 24 bits of a memory location to register A (A ∈ OREG) using indirect addressing. The upper 8 bits of the memory location are transferred to MHB register.

The memory location where to read from is defined by the bits 0 to 15 of register B (B ∈ OREG).

The 24 bit value is received from the lower significant bits (bit 0 to 23) of the memory location.

The zero bit Z of status register STA is set, if the lower 24 bit of the transferred value is zero, otherwise the zero bit is cleared.

If the MHB register is selected as destination register A (A ? OREG), the bits 0 to 7 of the referred memory location are transferred to MHB.

The program counter PC is increment by the value 4.

MWRI Instruction

Syntax: MWRI A, B

Operation: MEM(B[13:0])[23:0] ← A;

MEM(B[13:0])[31:24] v MHB

Status: -

Duration: 2 instruction cycles

Code: 1010aaaabbbb0100----------

Description: Transfer 24 bit value of register A (A ∈ OREG) together with the MHB register to the memory using indirect addressing.

The memory location where to write to is defined by the bits 0 to 15 of register B (B ∈ OREG).

The 24 bit value is stored in the lower significant bits (bit 0 to 23) of the memory location and the MHB register is stored in bits 24 to 31.

The program counter PC is increment by the value 4.

MWRI24 Instruction

Syntax: MWRI24 A, B

Operation: MEM(B[13:0])[23:0] ← A;

Status: -

Duration: 3 instruction cycles

Code: 1010aaaabbbb1000----------

Description: Transfer 24 bit value of A (A ∈ OREG) to memory using indirect addressing.

The memory location where to write to is defined by the bits 0 to 15 of register B (B ∈ OREG).

The 24 bit value is stored in the lower significant bits (bit 0 to 23) of the memory location and the bits 24 to 31 are left unchanged.

The program counter PC is increment by the value 4.

It should be noted that this operation is not an atomic instruction.

POP Instruction

Syntax: POP A

Operation: A ← MEM(R7[13:0])[23:0];

MHB ← MEM(R7[13:0])[31:24];

R7 ← R7 - 4;

SP_CNT ← SP_CNT - 1

Status: Z, EN

Duration: 2 instruction cycles

Code: 1010aaaa----0101----------

Description: Transfer the lower significant bits (bit 0 to 23) from the top of stack to register A (A ∈ OREG), followed by decrementing the stack pointer register R7 with the value 4. The upper 8 bits (bit 24 to 31) from the top of the stack are transferred to register MHB.

If the MHB register is selected as destination register A (A ? OREG), the bits 0 to 7 from the top of the stack are transferred to MHB.

The memory location for the top of the stack is identified by the bits 0 to 15 of the stack pointer register R7.

The zero bit Z of status register STA is set, if the lower 24 bit of the transferred value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

The SP_CNT bit field inside the MCSi_CHx_CTRL register is decremented.

If an underflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.

If an underflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCSi_CTRL is set, the current MCS-channel is disabled by clearing the EN bit of STA.

PUSH Instruction

Syntax: PUSH A

Operation: R7 ← R7 + 4;

SP_CNT ← SP_CNT + 1;

MEM(R7[13:0])[23:0] ← A;

MEM(R7[13:0])[31:24] ← MHB

Status: EN

Duration: 2 instruction cycles

Code: 1010aaaa----0110----------

Description: Increment the stack pointer register R7 with the value 4, followed by transferring a 24 bit value of operand A (A ∈ OREG) together with a MHB register to the

new top of the stack. The 24 bit value of A is stored in the bits 0 to 23 and content of the MHB register is stored in the bit 24 to 31 of the memory location.

The memory location for the top of the stack is addressed by the bits 0 to 15 of the stack pointer register.

The program counter PC is increment by the value 4.

The SP_CNT bit field inside the MCSi_CHx_CTRL register is increment.

If an overflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.

If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCSi_CTRL is set, the current MCS-channel is disabled by clearing the EN bit of STA.

If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCSi_CTRL is set, the memory write operation for the A and MHB is discard.

25.13.2.3 ARU Instructions

ARD Instruction

Syntax: ARD A, B, C

Operation: A ← ARU(C[8:0])[23:0];

B ← ARU(C[8:0])[47:24];

ACB[4:0] ← ARU(C[8:0])[52:48]

Status: CAT

Duration: suspends current MCS-channel

Code: 1011aaaabbbb0000-------ccccccccc

Description: Perform a blocking read access to the ARU and transfer both 24 bit values received at the ARU port to the registers A and B (A ∈ AREG, B ∈ AREG), whereas A holds the lower 24 bit ARU word and B holds the upper 24 bit ARU word.

If A and B refer to the same register, only the upper 24 bit ARU word is stored and the lower 24 bit ARU word is discard.

If any transferred 24 bit value from the ARU should not stored in a register, the dummy register ZERO ∈ AREG can be selected in A or B to discard the corresponding ARU data. Actually, all address values of A and B that exceed the range 0 to 7 discard the corresponding ARU data.

The received ARU control bits are stored in the register ACB.

The lower significant bits of the literal C (C ∈ LIT16) define the ARU address where to read from.

At the beginning of the instruction execution the CAT bit in the register STA is always cleared. After the execution of the instruction the CAT bit is updated in order to show if the instruction finished successfully (CAT = 0) or it was cancelled by the CPU (CAT = 1).

The program counter PC is increment by the value 4.

ARDI Instruction

Syntax: ARDI A, B

Operation: A ← ARU(R6[8:0])[23:0];

B ← ARU(R6[8:0])[47:24];

ACB[4:0] ← ARU(R6[8:0])[52:48]

Status: CAT

Duration: suspends current MCS-channel

Code: 1011aaaabbbb0100----------

Description: Perform a blocking read access to the ARU and transfer both 24 bit values received at the ARU port to the registers A and B (A ∈ AREG, B ∈ AREG), whereas A holds the lower 24 bit ARU word and B holds the upper 24 bit ARU word.

If A and B refer to the same register, only the upper 24 bit ARU word is stored and the lower 24 bit ARU word is discard.

If any transferred 24 bit value from the ARU should not stored in a register, the dummy register ZERO ∈ AREG can be selected in A or B to discard the corresponding ARU data. Actually, all address values of A and B that exceed the range 0 to 7 discard the corresponding ARU data.

The received ARU control bits are stored in the register ACB.

The read address is obtained from the bits 0 to 8 of the channels register R6.

At the beginning of the instruction execution the CAT bit in the register STA is always cleared. After the execution of the instruction the CAT bit is updated in order to show if the instruction finished successfully (CAT = 0) or it was cancelled by the CPU (CAT = 1).

The program counter PC is increment by the value 4.

AWR Instruction

Syntax: AWR A, B, C

Operation: ARU(C[4:0])[23:0] ← A;

ARU(C[4:0])[47:24] ← B;

ARU(C[4:0])[52:48] ← ACB[4:0];

Status: CAT

Duration: suspends current MCS-channel

Code: 1011aaaabbbb0001----------ccccc

Description: Perform a blocking write access to the ARU and transfer two 24 bit values to the ARU port using the registers A and B (A ∈ OREG, B ∈ OREG), whereas A holds the lower 24 bit ARU word and B holds the upper 24 bit ARU word.

The ARU control bits to be sent are taken from the register ACB.

The lower significant bits (bit 0 to bit 4) of the literal C (C ∈ LIT16) define an index into the pool of ARU write address that is used for writing data.

Each MCS submodule has a pool of several write addresses that can be shared between all MCS-channels arbitrarily.

At the beginning of the instruction execution the CAT bit in the register STA is always cleared. After the execution of the instruction the CAT bit is updated in order to show if the instruction finished successfully (CAT = 0) or it was cancelled by the CPU (CAT = 1).

The program counter PC is increment by the value 4.

AWRI Instruction

Syntax: AWRI A, B

Operation: ARU(R6[4:0])[23:0] ← A;

ARU(R6[4:0])[47:24] ← B;

ARU(R6[4:0])[52:48] ← ACB[4:0];

Status: CAT

Duration: suspends current MCS-channel

Code: 1011aaaabbbb0101----------

Description: Perform a blocking write access to the ARU and transfer two 24 bit values to the ARU port using the registers A and B (A ∈ OREG, B ∈ OREG), whereas A holds the lower 24 bit ARU word and B holds the upper 24 bit ARU word.

The ARU control bits to be sent are taken from the register ACB.

The bits 0 to 4 of the register R6 define an index into the pool of ARU write address that is used for writing data.

Each MCS submodule has a pool of several write addresses that can be shared between all MCS-channels arbitrarily.

At the beginning of the instruction execution the CAT bit in the register STA is always cleared. After the execution of the instruction the CAT bit is updated in order to show if the instruction finished successfully (CAT = 0) or it was cancelled by the CPU (CAT = 1).

The program counter PC is increment by the value 4.

NARD Instruction

Syntax: NARD A, B, C

Operation: A ? ARU(C[8:0])[23:0];

B ? ARU(C[8:0])[47:24];

ACB[4:0] ? ARU(C[8:0])[52:48]

Status: SAT

Duration: suspends current MCS-channel for a maximum of one ARU round trip cycle

Code: 1011aaaabbbb0010-------ccccccccc

Description: Perform a non-blocking read access to the ARU trying to transfer both 24 bit values received at the ARU port to the registers A and B (A ? AREG, B ? AREG), whereas A holds the lower 24 bit ARU word, B holds the upper 24 bit ARU word, and the ACB register holds the received ARU control bits.

The lower significant bits of the literal C (C ? LIT16) define the ARU address where to read from.

If the transfer finished successfully, the bit SAT of the register STA is set and the transferred values are stored in the registers A, B, and ACB.

If the transfer failed due to missing data at requested source, the bit SAT of the register STA is cleared and registers A, B, and ACB are not changed.

If A and B refer to the same register, only the upper 24 bit ARU word is stored and the lower 24 bit ARU word is discard.

If any transferred 24 bit value from the ARU should not stored in a register, the dummy register ZERO ? AREG can be selected in A or B to discard the corresponding ARU data. Actually, all address values of A and B that exceed the range 0 to 7 discard the corresponding ARU data.

The program counter PC is incremented by the value 4.

NARDI Instruction

Syntax: NARDI A, B

Operation: A ? ARU(R6[8:0])[23:0];

B ? ARU(R6[8:0])[47:24];

ACB[4:0] ? ARU(R6[8:0])[52:48]

Status: SAT

Duration: suspends current MCS-channel for a maximum of one ARU round trip cycle

Code: 1011aaaabbbb0011----------

Description: Perform a non-blocking read access to the ARU trying to transfer both 24 bit values received at the ARU port to the registers A and B (A ? AREG, B ? AREG),

whereas A holds the lower 24 bit ARU word, B holds the upper 24 bit ARU word, and the ACB register holds the received ARU control bits.

The read address is obtained from the bits 0 to 8 of the channels register R6.

If the transfer finished successfully, the bit SAT of the register STA is set and the transferred values are stored in the registers A, B, and ACB.

If the transfer failed due to missing data at requested source, the bit SAT of the register STA is cleared and registers A, B, and ACB are not changed.

If A and B refer to the same register, only the upper 24 bit ARU word is stored and the lower 24 bit ARU word is discard.

If any transferred 24 bit value from the ARU should not stored in a register, the dummy register ZERO ? AREG can be selected in A or B to discard the corresponding ARU data. Actually, all address values of A and B that exceed the range 0 to 7 discard the corresponding ARU data.

The program counter PC is incremented by the value 4.

25.13.2.4 Arithmetic Logic Instructions

ADDL Instruction

Syntax: ADDL A, C

Operation: A ← A + C

Status: Z, CY, N, V

Duration: 1 instruction cycle

Code: 0010aaaaccccccccccccccccccccccc

Description: Perform addition operation of a register A (A ∈ OREG) with a 24 bit literal value C (C ∈ LIT24) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if an unsigned overflow occurred during addition, otherwise the bit is cleared. An unsigned overflow has occurred, when the result of the operation cannot be represented in the interval [0; 2^{24}-1], assuming that both operands A and C are unsigned values within the interval [0; 2^{24}-1].

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during addition, otherwise the bit is cleared. A signed overflow/underflow has occurred, when the result of the operation cannot be represented in the interval [-2^{23}; 2^{23}-1], assuming that both operands A and C are signed values within the interval [-2^{23}; 2^{23}-1].

The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is increment by the value 4.

ADD Instruction

Syntax: ADD A, B

Operation: A ← A + B

Status: Z, CY, N, V

Duration: 1 instruction cycle

Code: 1100aaaabbbb0000----------

Description: Perform addition operation of a register A (A ∈ OREG) with an operand B (B ∈ OREG) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if an unsigned overflow occurred during addition, otherwise the bit is cleared. An unsigned overflow has occurred, when the result of the operation cannot be represented in the interval [0; 2^{24}-1], assuming that both operands A and B are unsigned values within the interval [0; 2^{24}-1].

The overflow bit V of status register STA is set, if a signed overflow occurred during addition, otherwise the bit is cleared. A signed overflow/underflow has occurred, when the result of the operation cannot be represented in the interval [-2^{23}; 2^{23}-1], assuming that both operands A and B are signed values within the interval [-2^{23}; 2^{23}-1].

The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is increment by the value 4.

SUBL Instruction

Syntax: SUBL A, C

Operation: A ← A - C

Status: Z, CY, N, V

Duration: 1 instruction cycle

Code: 0011aaaaccccccccccccccccccccccc

Description: Perform subtraction operation of a register A (A ∈ OREG) with a 24 bit literal value C (C ∈ LIT24) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if an unsigned underflow occurred during subtraction, otherwise the bit is cleared. An unsigned underflow has occurred, when the result of the operation cannot be represented in the interval [0; 2^{24}-1], assuming that both operands A and C are unsigned values within the interval [0; 2^{24}-1].

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred, when the result of the operation cannot be represented in the interval [-2^{23}; 2^{23}-1], assuming that both operands A and C are signed values within the interval [-2^{23}; 2^{23}-1].

The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is increment by the value 4.

SUB Instruction

Syntax: SUB A, B

Operation: A ← A - B

Status: Z, CY, N, V

Duration: 1 instruction cycle

Code: 1100aaaabbbb0001----------

Description: Perform subtraction operation of a register A (A ∈ OREG) with an operand B (B ∈ OREG) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if an unsigned underflow occurred during subtraction, otherwise the bit is cleared. An unsigned underflow has occurred, when the result of the operation cannot be represented in the interval [0; 2^{24}-1], assuming that both operands A and B are unsigned values within the interval [0; 2^{24}-1].

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred, when the result of the operation cannot be represented in the interval [-2^{23}; 2^{23}-1], assuming that both operands A and B are signed values within the interval [-2^{23}; 2^{23}-1].

The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is increment by the value 4.

NEG Instruction

Syntax: NEG A, B

Operation: A ← - B

Status: Z, N, V

Duration: 1 instruction cycle

Code: 1100aaaabbbb0010----------

Description: Perform negation operation (2's Complement) with an operand B (B ∈ OREG) and store the result in a register A (A ∈ OREG).

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred, when the result of the operation cannot be represented in the interval [-2^{23}; 2^{23}-

1], assuming that both operands A and B are signed values within the interval [-2^{23}; 2^{23}-1].

The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is increment by the value 4.

ANDL Instruction

Syntax: ANDL A, C

Operation: A ← A AND C

Status: Z

Duration: 1 instruction cycle

Code: 0100aaaaccccccccccccccccccccccc

Description: Perform bitwise AND conjunction of a register A (A ∈ OREG) with a 24 bit literal value C (C ∈ LIT24) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

AND Instruction

Syntax: AND A, B

Operation: A ← A AND B

Status: Z

Duration: 1 instruction cycle

Code: 1100aaaabbbb0011----------

Description: Perform bitwise AND conjunction of a register A (A ∈ OREG) with an operand B (B ∈ OREG) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

ORL Instruction

Syntax: ORL A, C

Operation: A ← A OR C

Status: Z

Duration: 1 instruction cycle

Code: 0101aaaaccccccccccccccccccccccc

Description: Perform bitwise OR conjunction of a register A (A ∈ OREG) with a 24 bit literal value C (C ∈ LIT24) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

OR Instruction

Syntax: OR A, B

Operation: A ← A OR B

Status: Z

Duration: 1 instruction cycle

Code: 1100aaaabbbb0100----------

Description: Perform bitwise OR conjunction of a register A (A ∈ OREG) with an operand B (B ∈ OREG) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

XORL Instruction

Syntax: XORL A, C

Operation: A ← A XOR C

Status: Z

Duration: 1 instruction cycle

Code: 0110aaaaccccccccccccccccccccccc

Description: Perform bitwise XOR conjunction of a register A (A ∈ OREG) with a 24 bit literal value C (C ∈ LIT24) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

XOR Instruction

Syntax: XOR A, B

Operation: A ← A XOR B

Status: Z

Duration: 1 instruction cycle

Code: 1100aaaabbbb0101----------

Description: Perform bitwise XOR conjunction of a register A (A ∈ OREG) with an operand B (B ∈ OREG) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

SHR Instruction

Syntax: SHR A, C

Operation: A ← A >> C

Status: Z, CY

Duration: 1 instruction cycle

Code: 1100aaaa----0110----------ccccc

Description: Perform right shift operation C (C ∈ LIT16) times of register A (A ∈ OREG), whereas C must be in the range [0; 24]. The most significant bits that are shifted into A are cleared.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is updated to the last LSB that is shifted out of the register.

The program counter PC is increment by the value 4._

SHL Instruction

Syntax: SHL A, C

Operation: A ← A << C

Status: Z, CY

Duration: 1 instruction cycle

Code: 1100aaaa----0111----------ccccc

Description: Perform left shift operation C (C ∈ LIT16) times of register A (A ∈ OREG), whereas C must be in the range [0; 24]. The lower significant bits that are shifted into A are cleared.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is updated to the last MSB that is shifted out of the register.

The program counter PC is increment by the value 4.

25.13.2.5 Test Instructions

ATUL Instruction

Syntax: ATUL A, C

Operation: A - C

Status: Z, CY

Duration: 1 instruction cycle

Code: 0111aaaaccccccccccccccccccccccc

Description: Arithmetic Test with an unsigned operand A (A ∈ OREG) and an unsigned 24 bit literal value C (C ∈ LIT24).

The carry bit CY of status register STA is set if unsigned operand A is less than unsigned literal C.

Otherwise, the carry bit CY of status register STA is cleared if unsigned operand A is greater than or equal to unsigned literal C.

The zero bit Z of status register STA is set, if A equals to C.

Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to C.

The program counter PC is increment by the value 4.

ATU Instruction

Syntax: ATU A, B

Operation: A - B

Status: Z, CY

Duration: 1 instruction cycle

Code: 1101aaaabbbb0000----------

Description: Arithmetic Test with an unsigned operand A (A ∈ OREG) and an unsigned operand B (B ∈ OREG).

The carry bit CY of status register STA is set if unsigned operand A is less than unsigned operand B.

Otherwise, the carry bit CY of status register STA is cleared if unsigned operand A is greater than or equal to unsigned operand B.

The zero bit Z of status register STA is set, if A equals to B.

Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to B.

The program counter PC is increment by the value 4.

ATSL Instruction

Syntax: ATSL A, C

Operation: A - C

Status: Z, CY

Duration: 1 instruction cycle

Code: 1000aaaaccccccccccccccccccccccc

Description: Arithmetic Test with a signed operand A (A ∈ OREG) and a signed 24 bit literal value C (C ∈ LIT24).

The carry bit CY of status register STA is set if signed operand A is less than signed literal C.

Otherwise, the carry bit CY of status register STA is cleared if signed operand A is greater than or equal to signed literal C.

The zero bit Z of status register STA is set, if A equals to C.

Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to C.

The program counter PC is increment by the value 4.

ATS Instruction

Syntax: ATS A, B

Operation: A - B

Status: Z, CY

Duration: 1 instruction cycle

Code: 1101aaaabbbb0001----------

: Arithmetic Test with a signed operand A (A ∈ OREG) and a signed operand B (B ∈ OREG).

The carry bit CY of status register STA is set if signed operand A is less than signed operand B.

Otherwise, the carry bit CY of status register STA is cleared if signed operand A is greater than or equal to signed operand B.

The zero bit Z of status register STA is set, if A equals to B.

Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to B.

The program counter PC is increment by the value 4.

BTL Instruction

Syntax: BTL A, C

Operation: A AND C

Status: Z

Duration: 1 instruction cycle

Code: 1001aaaaccccccccccccccccccccc

Description: Bit test of an operand A (A ∈ OREG) with a 24 bit literal bit mask C (C ∈ LIT24).

The bit test is performed by applying a bitwise logical AND operation with operand A and the bit mask C without storing the result.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

BT Instruction

Syntax: BT A, B

Operation: A AND B

Status: Z

Duration: 1 instruction cycle

Code: 1101aaaabbbb0010----------

Description: Bit test of an operand A (A ∈ OREG) with an operand B (B ∈ OREG), whereas usually one of the operands is a register holding a bit mask.

The bit test is performed by applying a bitwise logical AND operation with register A and register B without storing the result.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

25.13.2.6 Control Flow Instructions

JMP Instruction

Syntax: JMP C

Operation: PC ← C[13:0]

Status: -

Duration: 1 instruction cycle

Code: 1110--------0000--cccccccccccccc

Description: Execute unconditional jump to the memory location C (C ∈ LIT16).

The program counter PC is loaded with literal C.

JBS Instruction

Syntax: JBS A, B, C[13:0]

Operation: PC ← C if A[B] is set

Status: -

Duration: 1 instruction cycle

Code: 1110aaaabbbb0001--cccccccccccccc

Description: Execute conditional jump to the memory location C (C ∈ LIT16).

The program counter PC is loaded with literal C, if the bit at position B (B ∈ LIT4) of operand A (A ∈ OREG) is set.

Otherwise, if the bit is cleared, the program counter PC is increment by the value 4.

JBC Instruction

Syntax: JBC A, B, C[13:0]

Operation: PC ← C if A[B] is cleared

Status: -

Duration: 1 instruction cycle

Code: 1110aaaabbbb0010--cccccccccccccc

Description: Execute conditional jump to the memory location C (C ∈ LIT16).

The program counter PC is loaded with literal C, if the bit at position B (B ∈ LIT4) of operand A (A ∈ OREG) is cleared.

Otherwise, if the bit is set, the program counter PC is increment by the value 4.

CALL Instruction

Syntax: CALL C

Operation: R7 ← R7 + 4;

MEM(R7[15:0])[15:0] ← PC + 4;

PC ← C[13:0];

SP_CNT ← SP_CNT + 1

Status: EN

Duration: 2 instruction cycles

Code: 1110--------0011--cccccccccccccc

Description: Call subprogram at memory location C (C ∈ LIT16).

The stack pointer register R7 is increment by the value 4.

The memory location for the top of the stack is identified by the bits 0 to 15 of the stack pointer register.

After the stack pointer is increment, the increment value of the PC is transferred to the top of the stack.

The program counter PC is loaded with literal C.

The SP_CNT bit field inside the MCSi_CHx_CTRL register is increment.

If an overflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.

If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCSi_CTRL is set, the channel current MCS-channel is disabled by clearing the EN bit of STA.

If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCSi_CTRL is set, the memory write operation of the increment PC is discarding.

RET Instruction

Syntax: RET

Operation: PC ← MEM(R7[15:0])[15:0];

R7 ← R7 - 4;

SP_CNT ← SP_CNT - 1

Status: EN

Duration: 2 instruction cycles

Code: 1110--------0100----------

Description: Return from subprogram.

The program counter PC is loaded with current value on the top of the stack.

Finally, the stack pointer register R7 is decremented by the value 4.

The memory location for the top of the stack is identified by the bits 0 to 15 of the stack pointer register.

The SP_CNT bit field inside the MCSi_CHx_CTRL register is decremented.

If an underflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.

If an underflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCSi_CTRL is set, the channel current MCS-channel is disabled by clearing the EN bit of STA.

25.13.2.7 Other Instructions

WURM Instruction

Syntax: WURM A B C

Operation: Wait until register match

Status: CWT

Duration: suspends current MCS-channel

Code: 1111aaaabbbb0000ccccccccccccccc

Description: Suspend current MCS-channel until the following register match condition occurs:

A = (B AND MASK)

whereas A ∈ OREG, B ∈ OREG, AND is a bitwise AND operation with bitmask MASK. The bits 16 to 23 of MASK are set to true and the bits 0 to 15 are copied from the instructions literal C ∈ LIT16.

If the match condition is true at the beginning of the instruction execution, the instruction does not suspend the channel and the program counter PC is increment by the value 4.

This instruction can be used to wait for one or more trigger events generated by other MCS-channels or the CPU. In this case register B is the trigger register STRG, A is a general purpose register holding the bits with the trigger condition to wait for and C is the bitmask that enables trigger bits of interest.

The trigger bits can be set by other MCS channels with a write access (e.g. using a MOVL instruction) to the STRG register or the CPU with a write access to the MCSi_STRG register.

The trigger bits are not cleared automatically by hardware after resuming an MCS-channel, but they have to be cleared explicitly with a write access to the register CTRG by the MCS-channel or with a write access to the register MCSi_CTRG by the CPU.

Please note that more than one channel can wait for the same trigger bit to continue.

The instruction can also be used to wait on a specific time/angle event provided by the TBU. In this case register B is the interesting TBU register TBU_TS0, TBU_TS1, or TBU_TS2, register A is a general purpose register holding the value to wait for and bitmask C should be set to 0xFFFF.

At the beginning of the instruction execution the CWT bit in the register STA is always cleared. After the execution of the instruction the CWT bit is updated in order to show if the instruction finished successfully (CWT = 0) or it was cancelled by the CPU (CWT = 1).

If the CWT bit is set simultaneously with the occurrence of the register match condition, the register match condition is prioritized resulting in a cleared CWT bit.

The program counter PC is increment by the value 4, when the trigger bit is set and the channel continues its operation.

NOP Instruction

Syntax: NOP

Operation: -

Status: -

Duration: 1 instruction cycle

Code: 0000----------

Description: No operation is performed.

The program counter PC is increment by the value 4.

25.13.3 MCS Internal Registers

This section describes MCS internal registers which are partly only accessible by the corresponding MCS-channel itself and partly global to all channels. Please see **Table 25-42** for clarification.

These registers can be directly accessed with the entire MCS instruction set, e.g. using the ORL instruction to set a specific bit.

25.13.3.1 MCS Internal Registers Overview

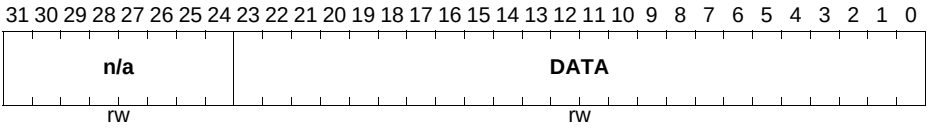
The table describes the MCS internal registers. Only parts of this register set can be accessed by the CPU:

Table 25-42 MCS Internal Registers Overview

Register Name	Description	Details in Section
Rx	General purpose register x (x: 0…7), MCS Task internal register	**Section 25.13.3.2**
STA	Status register, MCS Task internal register	**Section 25.13.3.3**
ACB	ARU Control Bit register, MCS Task internal register	**Section 25.13.3.4**
CTRG	Clear Trigger Bits register, MCS Global register from task view	**Section 25.13.3.5**
STRG	Set Trigger Bits register, MCS Global register from task view	**Section 25.13.3.6**
TBU_TS0	TBU Timestamp TS0 register, MCS Global register from task view	**Section 25.13.3.7**
TBU_TS1	TBU Timestamp TS1 register, MCS Global register from task view	**Section 25.13.3.8**
TBU_TS2	TBU Timestamp TS2 register, MCS Global register from task view	**Section 25.13.3.9**
MHB	Memory High Byte register, MCS Task internal register	**Section 25.13.3.10**

25.13.3.2 General purpose register Rx (x:0…7)

Rx (x=0-7)
General Purpose Register x **(0 + x_H)** **Reset Value: 000000_H**

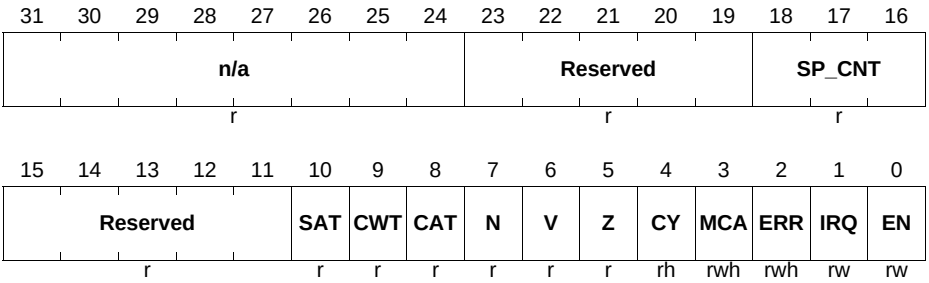


Field	Bits	Type	Description
DATA	[23:0]	rw	**Data field of general purpose register** Note: Register R7 is also used as stack pointer register, if stack operations are used in the MCS micro program. Note: Register R6 used also as index/address register for indirect ARU addressing instructions.
n/a	[31:24]	rw	**Not applicable**

25.13.3.3 Register STA

Note: If both, the CPU and the MCS-channel are writing to the same register at the clock cycle, the value of the CPU is written to the register and the value of the MCS-channel is discarding.

STA
Status Register **(8_H)** **Reset Value: $000000XX_H$**



Field	Bits	Type	Description
EN	0	rw	**Enable current MCS-channel** 0_B Disable current MCS-channel. 1_B Enable current MCS-channel.
IRQ	1	rw	**Trigger IRQ** 0_B No triggered IRQ signal. 1_B Trigger IRQ signal. Note: An MCS-channel trigger an IRQ by writing value 1 to bit IRQ. Writing a value 0 to this bit does not cancel the IRQ, and thus has no effect. Note: An MCS-channel can read the IRQ bit in order to determine the current state of the IRQ handling. The MCS-channel reads a value 1 if an IRQ was released but not cleared by CPU. If an MCS-channel reads a value 0 no IRQ was released or it has been cleared by CPU. Note: The IRQ bit can only be cleared by CPU, by writing a 1 to the corresponding MCSi_CHx_NOTIFY register (see **Section 25.13.4.6**).

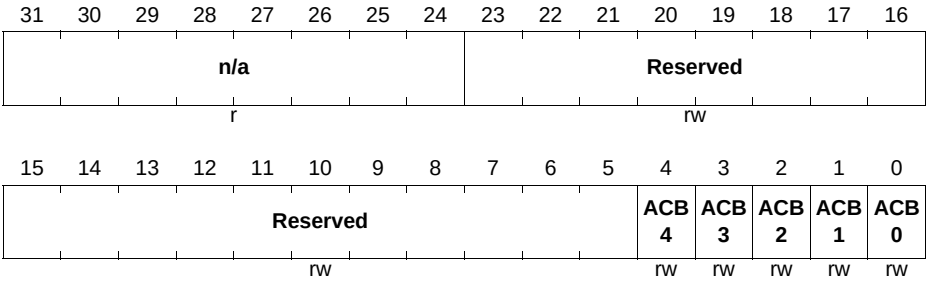
Field	Bits	Type	Description
ERR	2	rwh	**Set Error Signal** 0_B No Error occurred 1_B Error occurred Note: The ERR signal of an MCS-channel reflects Error status that may be caused by one of the following conditions: • MCS-channel program sets the ERR signal by writing to this bit • ?ECC RAM Error occurred while accessing the connected RAM pages (also disables MCS-channel by clearing bit EN) • Decoding an instruction with an invalid opcode (also disables MCS-channel by clearing bit EN) Note: If the GTM includes a MON submodule, the ERR signal is always captured by this module. Note: An MCS-channel releases an error signal by writing value 1 to bit ERR. Writing a value 0 to this bit does not cancel the error signal, and thus has no effect. Note: An MCS-channel can read the ERR bit in order to determine the current state of the error signal. The MCS-channel reads a value 1 if an ERR occurred previously, but not cleared by CPU. If an MCS-channel reads a value 0 no error was set or it has been cleared by CPU. Note: The ERR bit can only be cleared by CPU, by writing a 1 to the MCSi_ERR register (see **Register MCSi_ERR**).
MCA	3	rwh	**MON Activity signalling for MCS channel** 0_B No activity signalled to submodule MON. 1_B Activity signalled to submodule MON. Note: When this bit is set the corresponding channel in the MON submodule register MON_ACTIVITY is set (see **Section 25.20.8.2**. This bit is automatically cleared after writing it by the MCS channel program.
CY	4	rh	**Carry bit** The carry bit is updated by several arithmetic and logic instructions. In arithmetic operations, the carry bit indicates an unsigned under/overflow.
Z	5	r	**Zero bit** The zero bit is updated by several arithmetic, logic and data transfer instructions to indicate a result of zero.

Field	Bits	Type	Description
V	6	r	**Overflow bit** The overflow bit is updated by arithmetic instructions in order to indicate a signed under/overflow.
N	7	r	**Negative bit** The negative bit is updated by arithmetic instructions in order to indicate a negative result.
CAT	8	r	**Cancel ARU transfer bit** 0_B Last ARU transfer was not cancelled. 1_B CPU cancelled last ARU transfer. *Note: This bit is updated after each ARU transfer and it should be evaluated immediately after the ARU instruction. Otherwise, the CPU could set the bit leading to a bad status information in the MCS program.*
CWT	9	r	**Cancel WURM instruction bit** 0_B Last WURM instruction was not cancelled. 1_B CPU cancelled last WURM instruction of channel. *Note: This bit is updated after each WURM instruction and it should be evaluated immediately after the WURM instruction. Otherwise, the CPU could set the bit leading to a bad status information in the MCS program.*
SAT	10	r	**Successful ARU transfer bit** 0_B Non-blocking ARU transfer failed due to missing data 1_B Non-blocking ARU transfer finished successfully
Reserved	[15:11]	r	**Reserved** Read as zero, should be written as zero
SP_CNT	[18:16]	r	**Stack pointer counter value** Actual stack depth of channel. The bit field is increment on behalf of a CALL or PUSH instruction and decremented on behalf of a RET or POP instruction. The MCS channel STK_ERR_IRQ is raised, when an overflow or underflow is detected on this bit field.
Reserved	[23:19]	r	**Reserved** Read as zero, should be written as zero
n/a	[31:24]	r	**Not applicable**

Note: Writing to bits of the register STA with instructions that do implicitly a read-modify-write operation (e.g. “ANDL STA, 0xFFFFFE” or “OR STA, R0”) is dangerous, since writing back the possibly modified content of the read access (which reflects status information) may cause undesirable results. A secure way for writing of bits of the register STA is to use instructions that do not read the content of STA (e.g. “MOVL STA, 0x0” or “MOV STA, R1”).

25.13.3.4 Register ACB

ACB
ARU Control Bit Register **(9_H)** **Reset Value: $01FE00XX_H$**



Field	Bits	Type	Description
ACB0	0	rw	**ARU Control bit 0** Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 48 of the ARU word.
ACB1	1	rw	**ARU Control bit 1** Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 49 of the ARU word.
ACB2	2	rw	**ARU Control bit 2** Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 50 of the ARU word.
ACB3	3	rw	**ARU Control bit 3** Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 51 of the ARU word.
ACB4	4	rw	**ARU Control bit 4** Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 52 of the ARU word.
Reserved	[23:5]	rw	**Reserved** Read as zero, should be written as zero
n/a	[31:24]	r	**Not applicable**

25.13.3.5 Register CTRG

CTRG
Clear Trigger Bits Register **(A_H)** **Reset Value: 00000000_H**

Trigger bits can be used for signalizing specific events to MCS-channels or the CPU. An MCS-channel suspended with a WURM instruction can be resumed by setting the appropriate trigger bit.
Reserved	[23:16]	rw	**Reserved** Read as zero, should be written as zero
n/a	[31:24]	r	**Not applicable**

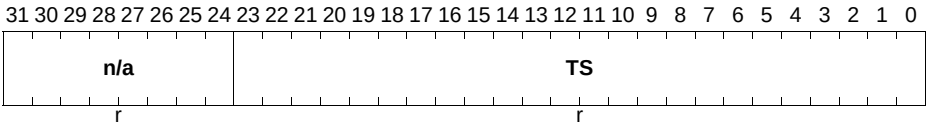
25.13.3.7 Register TBU_TS0

TBU_TS0
TBU Timestamp TS0 Register **(C_H)** **Reset Value: $XXXXXXXX_H$**

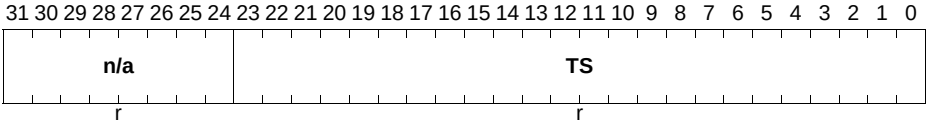


Field	Bits	Type	Description
TS	[23:0]	r	**Current TBU time stamp 0**

Field	Bits	Type	Description
n/a	[31:24]	r	**Not applicable** Note: Any write access to a time base register discards the written data. A write access to a time base register may be used to destroy an unused 24-bit data word of an ARU read transfer.

25.13.3.8 Register TBU_TS1

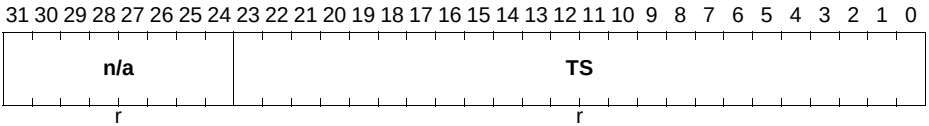
TBU_TS1
TBU Timestamp TS1 Register **(D_H)** **Reset Value: $XXXXXXXX_H$**



Field	Bits	Type	Description
TS	[23:0]	r	**Current TBU time stamp 1**
n/a	[31:24]	r	**Not applicable** Note: Any write access to a time base register discards the written data. A write access to a time base register may be used to destroy an unused 24-bit data word of an ARU read transfer.

25.13.3.9 Register TBU_TS2

TBU_TS2
TBU Timestamp TS2 Register **(E_H)** **Reset Value: $XXXXXXXX_H$**

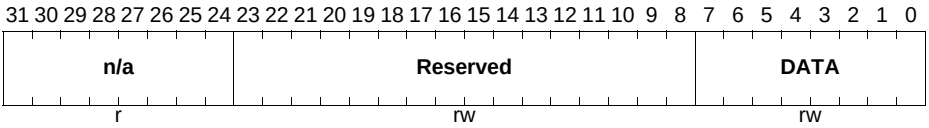


Field	Bits	Type	Description
TS	[23:0]	r	**Current TBU time stamp 2**

Field	Bits	Type	Description
n/a	[31:24]	r	**Not applicable** Note: Any write access to a time base register discards the written data. A write access to a time base register may be used to destroy an unused 24-bit data word of an ARU read transfer.

25.13.3.10Register MHB

MHB
Memory High Byte Register (F_H) Reset Value: $XX000000_H$



Field	Bits	Type	Description
DATA	[7:0]	rw	**High Byte of a memory transfer**
Reserved	[23:8]	rw	**Reserved** Read as zero, should be written as zero
n/a	[31:24]	r	**Not applicable**

25.13.4 MCS Configuration Registers

This section describes the configuration registers of the MCS submodule.

These registers can only be accessed by the CPU using AEI, but not within the MCS-channel using MCS instructions.

25.13.4.1 MCS Configuration Registers Overview

The table describes the MCS registers that are visible and accessible by the CPU:

Table 25-43 MCS Configuration Registers Overview

Register Name	Description	Details in Section
MCSi_CHx_CTRL	MCS Channel control register (x: 0…7)	**Section 25.13.4.2**
MCSi_CHx_PC	MCS Channel Program counter register (x: 0…7)	**Section 25.13.4.3**
MCSi_CHx_Ry	MCS Channel GPRz registers (x: 0…7; y: 0…7)	**Section 25.13.4.4**
MCSi_CHx_ACB	MCS Channel ACB register (x: 0…7)	**Section 25.13.4.5**
MCSi_CHx_IRQ_NOTIFY	MCS Channel x interrupt notification register (x: 0…7)	**Section 25.13.4.6**

Table 25-43 MCS Configuration Registers Overview (cont'd)

Register Name	Description	Details in Section
MCSi_CHx_IRQ_EN	MCS Channel x interrupt enable register (x: 0…7)	Section 25.13.4.7
MCSi_CHx_IRQ_FORCINT	MCS Channel x software interrupt generation register (x: 0…7)	Section 25.13.4.8
MCSi_CHx_IRQ_MODE	IRQ mode configuration register (x=0…7)	Section 25.13.4.9
MCSi_CHx_EIRQ_EN	MSC Channel x error interrupt enable register (x=0…7)	Section 25.13.4.10
MCSi_CTRL	MCS Control register	Section 25.13.4.11
MCSi_CTRG	MCS Clear trigger control register	Section 25.13.4.12
MCSi_STRG	MCS Set trigger control register	Section 25.13.4.13
MCSi_RST	MCS Channel reset register	Section 25.13.4.14
MCSi_ERR	MCS Error register	Section 25.13.4.15

25.13.4.2 Register MCSi_CHx_CTRL (x:07)

All of the following registers are 32-bit only accessible.

GTM_MCS0_CHx_CTRL (x=0-7)
MCS0 Channel Control Register (30020_H+x*80_H) **Reset Value: 00000000_H**
GTM_MCS1_CHx_CTRL (x=0-7)
MCS1 Channel Control Register (31020_H+x*80_H) **Reset Value: 00000000_H**
GTM_MCS2_CHx_CTRL (x=0-7)
MCS2 Channel Control Register (32020_H+x*80_H) **Reset Value: 00000000_H**
GTM_MCS3_CHx_CTRL (x=0-7)
MCS3 Channel Control Register (33020_H+x*80_H) **Reset Value: 00000000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved													SP_CNT		
r													r		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						CWT	CAT	N	V	Z	CY	Reserved	ERR	IRQ	EN
r						r	r	r	r	r	r	r	r	r	rw

Field	Bits	Type	Description
EN	0	rw	**Enable MCS-channel** 0_B Disable current MCS-channel. 1_B Enable current MCS-channel. Note: Enabling or disabling of an MCS-channel is synchronized to the ending of an instruction and thus it may take several clock cycles, e.g. active memory transfers or pending WURM transfers have to be finished before disabling the MCS-channel. The internal state of a channel can be obtained by reading the bit EN. Note: In order to disable an MCS channel reliably the EN bit should be cleared following by setting the CAT and CWT bit in order to cancel any pending WURM or ARU instructions. Note: The EN bit is write protected during RAM reset phase.

Field	Bits	Type	Description
IRQ	1	r	**Interrupt state** 0_B No interrupt pending in MCS-channel x. 1_B Interrupt is pending in MCS-channel x. Note: This bit is read only and it mirrors the internal IRQ state.
ERR	2	r	**Error state** 0_B No error signal pending in MCS-channel x. 1_B Error signal is pending in MCS-channel x. Note: This bit is read only and it mirrors the internal error state.
Reserved	3	r	**Reserved** Read as zero, should be written as zero
CY	4	r	**Carry bit state** Note: This bit is read only and it mirrors the internal carry flag CY.
Z	5	r	**Zero bit state** Note: This bit is read only and it mirrors the internal zero flag Z.
V	6	r	**Overflow bit state** Note: This bit is read only and it mirrors the internal carry flag V.
N	7	r	**Negative bit state** Note: This bit is read only and it mirrors the internal zero flag N.
CAT	8	r	**Cancel ARU transfer state** Note: This bit is read only and it mirrors the internal cancel ARU transfer status flag CAT.
CWT	9	r	**Cancel WURM instruction state** Note: This bit is read only and it mirrors the internal cancel WURM instruction status flag CWT.
Reserved	[15:10]	r	**Reserved** Read as zero, should be written as zero
SP_CNT	[18:16]	r	**Stack pointer counter value** Actual stack depth of channel. The bit field is increment on behalf of a CALL or PUSH instruction and decremented on behalf of a RET or POP instruction. The MCS channel STK_ERR_IRQ is raised, when an overflow or underflow is detected on this bit field.

Field	Bits	Type	Description
Reserved	[31:19]	r	**Reserved** Read as zero, should be written as zero

25.13.4.3 Register MCSi_CHx_PC (x:0…7)

All of the following registers are 32-bit only accessible.

GTM_MCSi_CH0_PC (i=0-3)
MCSi Channel 0 Program Counter Register
(30040_H+i*1000_H) **Reset Value: 00000000_H**

GTM_MCSi_CH1_PC (i=0-3)
MCSi Channel 1 Program Counter Register
($300C0_H$+i*1000_H) **Reset Value: 00000004_H**

GTM_MCSi_CH2_PC (i=0-3)
MCSi Channel 2 Program Counter Register
(30140_H+i*1000_H) **Reset Value: 00000008_H**

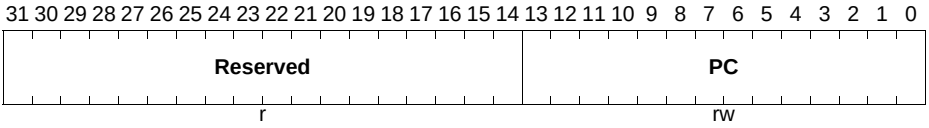
GTM_MCSi_CH3_PC (i=0-3)
MCSi Channel 3 Program Counter Register
($301C0_H$+i*1000_H) **Reset Value: $0000000C_H$**

GTM_MCSi_CH4_PC (i=0-3)
MCSi Channel 4 Program Counter Register
(30240_H+i*1000_H) **Reset Value: 00000010_H**

GTM_MCSi_CH5_PC (i=0-3)
MCSi Channel 5 Program Counter Register
($302C0_H$+i*1000_H) **Reset Value: 00000014_H**

GTM_MCSi_CH6_PC (i=0-3)
MCSi Channel 6 Program Counter Register
(30340_H+i*1000_H) **Reset Value: 00000018_H**

GTM_MCSi_CH7_PC (i=0-3)
MCSi Channel 7 Program Counter Register
($303C0_H$+i*1000_H) **Reset Value: $0000001C_H$**



Field	Bits	Type	Description
PC	[13:0]	rw	**Current Program Counter** Note: The program counter is only writable if the corresponding MCS-channel is disabled. The bits 0 and 1 are always written as zeros.
Reserved	[31:14]	r	**Reserved** Read as zero, should be written as zero

25.13.4.4 Register MCSi_CHx_Ry (x:0…7, y:0…7)

All of the following registers are 32-bit only accessible.

GTM_MCS0_CH0_Ry (y=0-7)
MCS0 Channel 0 Program Counter Register y
(30000_H+y*04_H) **Reset Value: 00000000_H**

GTM_MCS1_CH0_Ry (y=0-7)
MCS1 Channel 0 Program Counter Register y
(31000_H+y*04_H) **Reset Value: 00000000_H**

GTM_MCS2_CH0_Ry (y=0-7)
MCS2 Channel 0 Program Counter Register y
(32000_H+y*04_H) **Reset Value: 00000000_H**

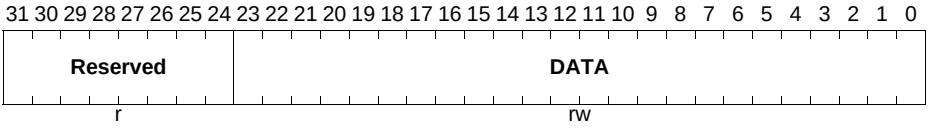
GTM_MCS3_CH0_Ry (y=0-7)
MCS3 Channel 0 Program Counter Register y
(33000_H+y*04_H) **Reset Value: 00000000_H**

GTM_MCS0_CH1_Ry (y=0-7)
MCS0 Channel 1 Program Counter Register y
(30080_H+y*04_H) **Reset Value: 00000000_H**

GTM_MCS1_CH1_Ry (y=0-7)
MCS1 Channel 1 Program Counter Register y
(31080_H+y*04_H) **Reset Value: 00000000_H**

GTM_MCS2_CH1_Ry (y=0-7)
MCS2 Channel 1 Program Counter Register y
(32080_H+y*04_H) **Reset Value: 00000000_H**

GTM_MCS3_CH1_Ry (y=0-7)
MCS3 Channel 1 Program Counter Register y
(33080_H+y*04_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
DATA	[23:0]	rw	**Data of MCS general purpose register ry**
Reserved	[31:24]	r	**Read as zero, should be written as zero** Note: This register is the same as described in **Section 25.13.2**.

GTM_MCS0_CH2_Ry (y=0-7)
MCS0 Channel 2 Program Counter Register y
(30100_H+y*04_H) **Reset Value: 00000000_H**

GTM_MCS1_CH2_Ry (y=0-7)
MCS1 Channel 2 Program Counter Register y
(31100_H+y*04_H) **Reset Value: 00000000_H**

GTM_MCS2_CH2_Ry (y=0-7)
MCS2 Channel 2 Program Counter Register y

25.13.4.5 Register MCSi_CHx_ACB (x:0…7)

All of the following registers are 32-bit only accessible.

GTM_MCS0_CHx_ACB (x=0-7)
MCS0 Channel ACB Register **(30024_H+x*80_H)** **Reset Value: 00000000_H**
GTM_MCS1_CHx_ACB (x=0-7)
MCS1 Channel ACB Register **(31024_H+x*80_H)** **Reset Value: 00000000_H**
GTM_MCS2_CHx_ACB (x=0-7)
MCS2 Channel ACB Register **(32024_H+x*80_H)** **Reset Value: 00000000_H**
GTM_MCS3_CHx_ACB (x=0-7)
MCS3 Channel ACB Register **(33024_H+x*80_H)** **Reset Value: 00000000_H**

Field	Bits	Type	Description
ACB0	0	r	**ARU Control bit 0** Note: This bit is read only and it mirrors the internal state.
ACB1	1	r	**ARU Control bit 1** Note: This bit is read only and it mirrors the internal state.
ACB2	2	r	**ARU Control bit 2** Note: This bit is read only and it mirrors the internal state.
ACB3	3	r	**ARU Control bit 3** Note: This bit is read only and it mirrors the internal state.
ACB4	4	r	**ARU Control bit 4** Note: This bit is read only and it mirrors the internal state.

Field	Bits	Type	Description
Reserved	[31:5]	r	**Reserved** Read as zero, should be written as zero

25.13.4.6 Register MCSi_CHx_IRQ_NOTIFY (x:0…7)

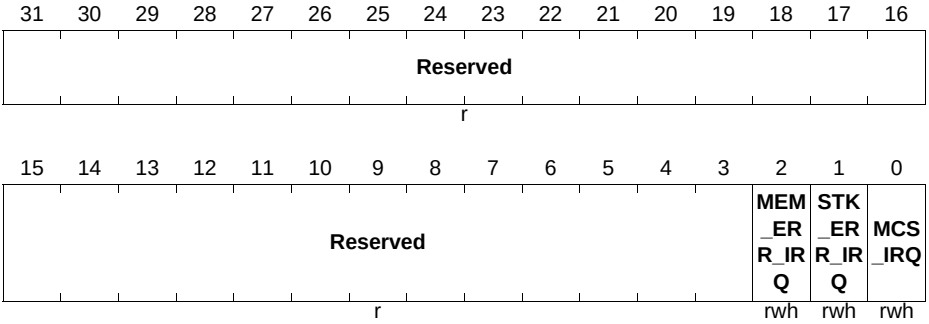
All of the following registers are 32-bit only accessible.

GTM_MCS0_CHx_IRQ_NOTIFY (x=0-7)
MCS0 Channel x interrupt notification register
(30044_H+x*80_H) **Reset Value: 00000000_H**

GTM_MCS1_CHx_IRQ_NOTIFY (x=0-7)
MCS1 Channel x interrupt notification register
(31044_H+x*80_H) **Reset Value: 00000000_H**

GTM_MCS2_CHx_IRQ_NOTIFY (x=0-7)
MCS2 Channel x interrupt notification register
(32044_H+x*80_H) **Reset Value: 00000000_H**

GTM_MCS3_CHx_IRQ_NOTIFY (x=0-7)
MCS3 Channel x interrupt notification register
(33044_H+x*80_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
MCS_IRQ	0	rwh	**Interrupt request by MCS-channel x** 0_B No IRQ released 1_B IRQ released by MCS-channel Note: This bit will be cleared on a CPU write access with a value '1'. A read access leaves the bit unchanged. Note: By writing a '1' to this register, the IRQ flag in the MCS channel status register STA is cleared.
STK_ERR_IRQ	1	rwh	**Stack counter overflow/underflow of channel x** 0_B No IRQ released 1_B A stack counter overflow or underflow occurred Note: This bit will be cleared on a CPU write access with a value '1'. A read access leaves the bit unchanged.

Field	Bits	Type	Description
MEM_ERR_IRQ	2	rwh	**Memory access out of range in channel x** 0_B No IRQ released 1_B MCS-channel request a memory location out of range 0 to MP1-4. Note: This bit will be cleared on a CPU write access with a value '1'. A read access leaves the bit unchanged. Note: In the case of a memory overflow, any read or write access to the RAM is always blocked. The read data is unpredictable. Note: It should be noted that in case of a memory overflow, the MSC channel will continue. Thus it is recommended that the CPU immediately stops the MSC channel.
Reserved	[31:3]	r	**Reserved** Read as zero, should be written as zero

25.13.4.7 Register MCSi_CHx_IRQ_EN (x:0…7)

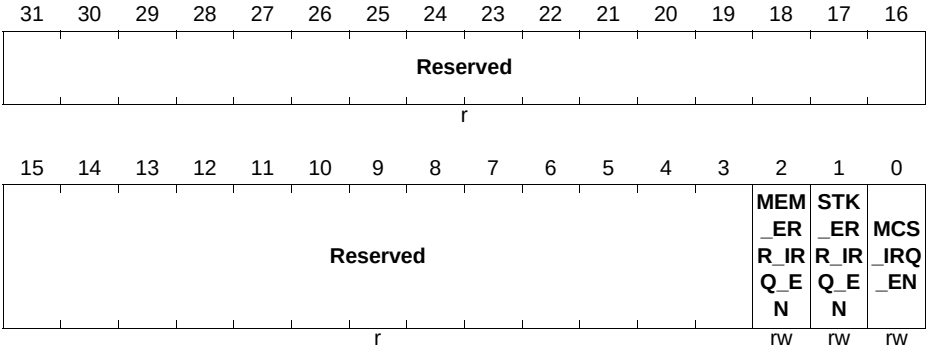
All of the following registers are 32-bit only accessible.

GTM_MCS0_CHx_IRQ_EN (x=0-7)
MCS0 Channel x Interrupt Enable Register
(30048_H+x*80_H) **Reset Value: 00000000_H**

GTM_MCS1_CHx_IRQ_EN (x=0-7)
MCS1 Channel x Interrupt Enable Register
(31048_H+x*80_H) **Reset Value: 00000000_H**

GTM_MCS2_CHx_IRQ_EN (x=0-7)
MCS2 Channel x Interrupt Enable Register
(32048_H+x*80_H) **Reset Value: 00000000_H**

GTM_MCS3_CHx_IRQ_EN (x=0-7)
MCS3 Channel x Interrupt Enable Register
(33048_H+x*80_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
MCS_IRQ_EN	0	rw	**MCS channel x MCS_IRQ interrupt enable** 0_B Disable interrupt, interrupt is not visible outside GTM 1_B Enable interrupt, interrupt is visible outside GTM
STK_ERR_IRQ_EN	1	rw	**MCS channel x STK_ERR_IRQ interrupt enable** 0_B Disable interrupt, interrupt is not visible outside GTM 1_B Enable interrupt, interrupt is visible outside GTM
MEM_ERR_IRQ_EN	2	rw	**MCS channel x MEM_ERR_IRQ interrupt enable** 0_B Disable interrupt, interrupt is not visible outside GTM 1_B Enable interrupt, interrupt is visible outside GTM

Field	Bits	Type	Description
Reserved	[31:3]	r	**Reserved** Read as zero, should be written as zero

25.13.4.8 Register MCSi_CHx_IRQ_FORCINT (x:0…7)

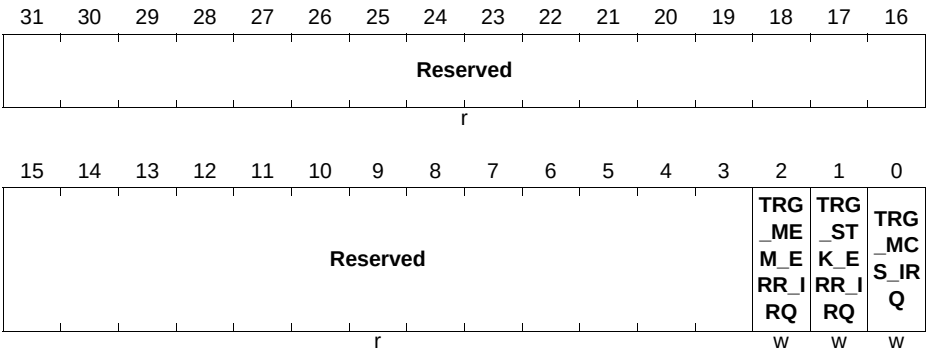
All of the following registers are 32-bit only accessible.

GTM_MCS0_CHx_IRQ_FORCINT (x=0-7)
MCS0 Channel x Software Interrupt Generation Register
($3004C_H$+x*80_H) **Reset Value: 00000000_H**

GTM_MCS1_CHx_IRQ_FORCINT (x=0-7)
MCS1 Channel x Software Interrupt Generation Register
($3104C_H$+x*80_H) **Reset Value: 00000000_H**

GTM_MCS2_CHx_IRQ_FORCINT (x=0-7)
MCS2 Channel x Software Interrupt Generation Register
($3204C_H$+x*80_H) **Reset Value: 00000000_H**

GTM_MCS3_CHx_IRQ_FORCINT (x=0-7)
MCS3 Channel x Software Interrupt Generation Register
($3304C_H$+x*80_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
TRG_MCS_IRQ	0	w	**Trigger IRQ bit in MCS_CH_x_IRQ_NOTIFY register by software** 0_B No interrupt triggering 1_B Assert corresponding field in MCSi_CHx_IRQ_NOTIFY register Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
TRG_STK_ERR_IRQ	1	w	**Trigger IRQ bit in MCS_CH_x_IRQ_NOTIFY register by software** 0_B No interrupt triggering 1_B Assert corresponding field in MCSi_CHx_IRQ_NOTIFY register Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
TRG_MEM_ERR_IRQ	2	w	**Trigger IRQ bit in MCS_CH_x_IRQ_NOTIFY register by software** 0_B No interrupt triggering 1_B Assert corresponding field in MCSi_CHx_IRQ_NOTIFY register Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
Reserved	[31:3]	r	**Reserved** Read as zero, should be written as zero

25.13.4.9 Register MCSi_CHx_IRQ_MODE (x:0…7)

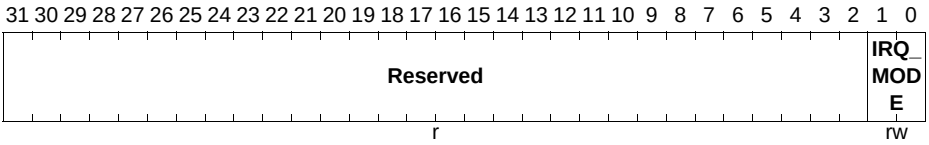
All of the following registers are 32-bit only accessible.

GTM_MCS0_CHx_IRQ_MODE (x=0-7)
MCS0 IRQ Mode Configuration Register
(30050_H+x*80_H) **Reset Value: 00000000_H**

GTM_MCS1_CHx_IRQ_MODE (x=0-7)
MCS1 IRQ Mode Configuration Register
(31050_H+x*80_H) **Reset Value: 00000000_H**

GTM_MCS2_CHx_IRQ_MODE (x=0-7)
MCS2 IRQ Mode Configuration Register
(32050_H+x*80_H) **Reset Value: 00000000_H**

GTM_MCS3_CHx_IRQ_MODE (x=0-7)
MCS3 IRQ Mode Configuration Register
(33050_H+x*80_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
IRQ_MODE	[1:0]	rw	**IRQ mode selection** 00_B Level mode 01_B Pulse mode 10_B Pulse-Notify mode 11_B Single-Pulse mode Note: The interrupt modes are described in **Section 25.2.5**.
Reserved	[31:2]	r	**Reserved** Read as zero, should be written as zero

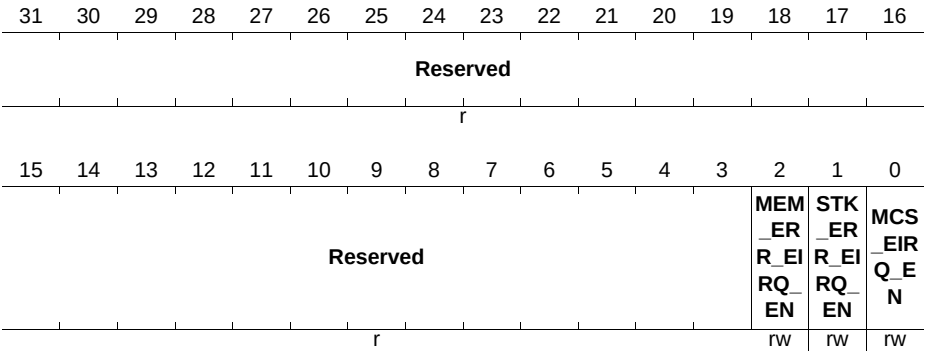
25.13.4.10Register MCSi_CHx_EIRQ_EN (x:0…7)

GTM_MCS0_CHx_EIRQ_EN (x=0-7)
MCS0_Channel x Error Interrupt Enable Register
(30054_H+x*80_H) **Reset Value: 00000000_H**

GTM_MCS1_CHx_EIRQ_EN (x=0-7)
MCS1_Channel x Error Interrupt Enable Register
(31054_H+x*80_H) **Reset Value: 00000000_H**

GTM_MCS2_CHx_EIRQ_EN (x=0-7)
MCS2_Channel x Error Interrupt Enable Register
(32054_H+x*80_H) **Reset Value: 00000000_H**

GTM_MCS3_CHx_EIRQ_EN (x=0-7)
MCS3_Channel x Error Interrupt Enable Register
(33054_H+x*80_H) **Reset Value: 00000000_H**

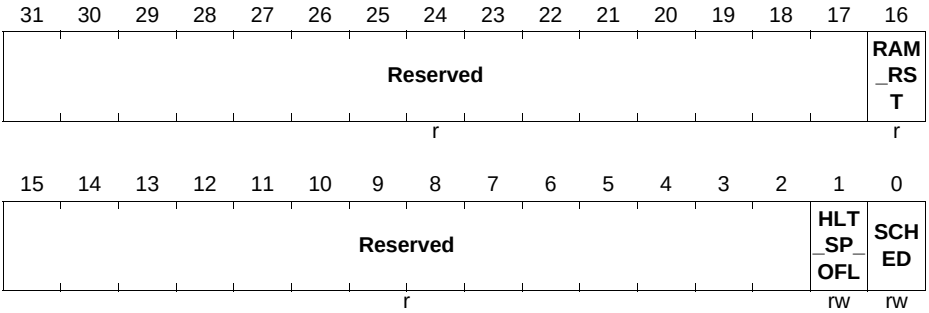


Field	Bits	Type	Description
MCS_EIRQ_EN	0	rw	**MCS channel x MCS_EIRQ error interrupt enable** 0_B Disable error interrupt 1_B Enable error interrupt
STK_ERR_EIRQ_EN	1	rw	**MCS channel x STK_ERR_IRQ error interrupt enable** 0_B Disable error interrupt 1_B Enable error interrupt
MEM_ERR_EIRQ_EN	2	rw	**MCS channel x MEM_ERR_EIRQ error interrupt enable** 0_B Disable error interrupt 1_B Enable error interrupt
Reserved	[31:3]	r	**Reserved** Read as zero, should be written as zero

25.13.4.11Register MCSi_CTRL

All of the following registers are 32-bit only accessible.

GTM_MCSi_CTRL (i=0-3)
MCSi Control Register **(30074_H+i*1000_H)** **Reset Value: 00010000_H**



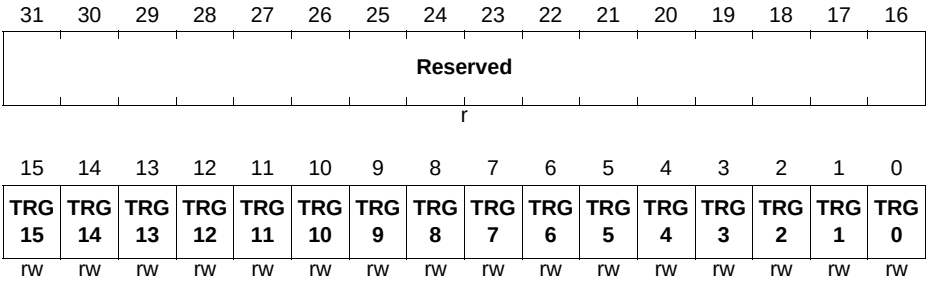
Field	Bits	Type	Description
SCHED	0	rw	**MCS submodule scheduling scheme** 0_B Accelerated scheduling scheme. 1_B Round-Robin scheduling scheme.
HLT_SP_OFL	1	rw	**Halt on stack pointer overflow** 0_B No halt on MCS-channel stack pointer counter over/underflow. 1_B MCS-channel is disabled if a stack pointer counter over/underflow occurs.
Reserved	[15:2]	r	**Reserved** Read as zero, should be written as zero
RAM_RST	16	r	**RAM reset bit** 0_B READ: no RAM reset is active / WRITE: do nothing. 1_B READ: MCS currently resets RAM content / WRITE: trigger RAM reset. Note: The RAM reset initializes the memory content with zeros. RAM access and enabling of MCS channels is disabled during active RAM reset. Note: This bit is only writable if the bit RF_PROT in register GTM_CTRL is cleared and all MCS-channels are disabled.

Field	Bits	Type	Description
Reserved	[31:17]	r	**Reserved** Read as zero, should be written as zero

25.13.4.12Register MCSi_CTRG

All of the following registers are 32-bit only accessible.

GTM_MCSi_CTRG (i=0-3)
MCSi Clear Trigger Control Register(30028_H+i*1000_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
TRG0	0	rw	**Trigger bit 0** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit
TRG1	1	rw	**Trigger bit 1** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit
TRG2	2	rw	**Trigger bit 2** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit
TRG3	3	rw	**Trigger bit 3** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit
TRG4	4	rw	**Trigger bit 4** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit
TRG5	5	rw	**Trigger bit 5** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit
TRG6	6	rw	**Trigger bit 6** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit

Field	Bits	Type	Description
TRG7	7	rw	**Trigger bit 7** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit
TRG8	8	rw	**Trigger bit 8** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit
TRG9	9	rw	**Trigger bit 9** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit
TRG10	10	rw	**Trigger bit 10** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit
TRG11	11	rw	**Trigger bit 11** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit
TRG12	12	rw	**Trigger bit 12** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit
TRG13	13	rw	**Trigger bit 13** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit
TRG14	14	rw	**Trigger bit 14** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit

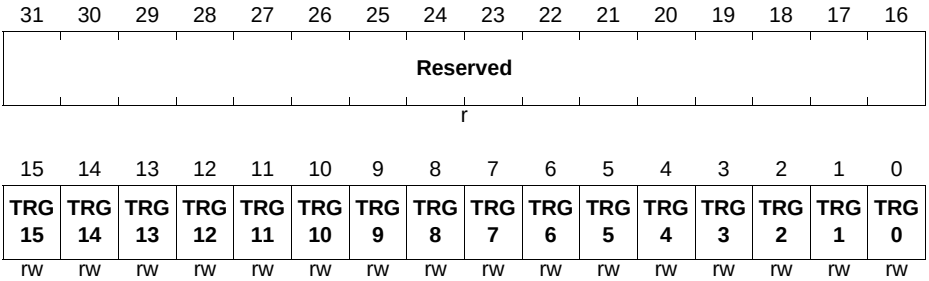
Field	Bits	Type	Description
TRG15	15	rw	**Trigger bit 15** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit Note: The trigger bits TRGx (x = 0…15) are accessible by all MCS channels as well as the CPU. Setting a trigger bit can be performed with the STRG register, in the case of an MCS-channel or the MCSi_STRG register in the case of the CPU. Clearing a trigger bit can be performed with the CTRG register, in the case of an MCS-channel or the MCSi_CTRG register in the case of the CPU. Trigger bits can be used for signalizing specific events to MCS-channels or the CPU. An MCS-channel suspended with a WURM instruction can be resumed by setting the appropriate trigger bit.
Reserved	[31:16]	r	**Reserved** Read as zero, should be written as zero

Note: A write access to MCSi_CTRG may take up to 9 clock cycles, since the write access is scheduled to the next CPU time slot determined by the MCS scheduler.

25.13.4.13Register MCSi_STRG

All of the following registers are 32-bit only accessible.

GTM_MCSi_STRG (i=0-3)
MCSi Set Trigger Control Register($3002C_H$+i*1000_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
TRG0	0	rw	**Trigger bit 0** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG1	1	rw	**Trigger bit 1** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG2	2	rw	**Trigger bit 2** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG3	3	rw	**Trigger bit 3** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG4	4	rw	**Trigger bit 4** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG5	5	rw	**Trigger bit 5** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG6	6	rw	**Trigger bit 6** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG7	7	rw	**Trigger bit 7** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG8	8	rw	**trigger bit 8** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG9	9	rw	**Trigger bit 9** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG10	10	rw	**Trigger bit 10** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG11	11	rw	**Trigger bit 11** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit

Field	Bits	Type	Description
TRG12	12	rw	**Trigger bit 12** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG13	13	rw	**Trigger bit 13** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG14	14	rw	**Trigger bit 14** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit
TRG15	15	rw	**Trigger bit 15** 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: set trigger bit Note: The trigger bits TRGx (x = 0…15) are accessible by all MCS channels as well as the CPU. Setting a trigger bit can be performed with the STRG register, in the case of an MCS-channel or the MCSi_STRG register in the case of the CPU. Clearing a trigger bit can be performed with the CTRG register, in the case of an MCS-channel or the MCSi_CTRG register in the case of the CPU. Trigger bits can be used for signalizing specific events to MCS-channels or the CPU. An MCS-channel suspended with a WURM instruction can be resumed by setting the appropriate trigger bit.
Reserved	[31:16]	r	**Reserved** Read as zero, should be written as zero

Note: A write access to MCSi_STRG may take up to 9 clock cycles, since the write access is scheduled to the next CPU time slot determined by the MCS scheduler.

25.13.4.14Register MCSi_RST

All of the following registers are 32-bit only accessible.

GTM_MCSi_RST (i=0-3)
MCSi Channel Reset Register (30078_H+i*1000_H) **Reset Value: 00000000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								CWT7	CWT6	CWT5	CWT4	CWT3	CWT2	CWT1	CWT0
r								rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
RST0	0	w	**Software reset of channel 0** 0_B No action 1_B Reset channel
RST1	1	w	**Software reset of channel 1** 0_B No action 1_B Reset channel
RST2	2	w	**Software reset of channel 2** 0_B No action 1_B Reset channel
RST3	3	w	**Software reset of channel 3** 0_B No action 1_B Reset channel
RST4	4	w	**Software reset of channel 4** 0_B No action 1_B Reset channel
RST5	5	w	**Software reset of channel 5** 0_B No action 1_B Reset channel
RST6	6	w	**Software reset of channel 6** 0_B No action 1_B Reset channel

Field	Bits	Type	Description
RST7	7	w	**Software reset of channel 7** 0_B No action 1_B Reset channel Note: The RSTx (x = 0 …7) bits is cleared automatically after write access of CPU. All channel related registers are set to their reset values and channel operation is stopped immediately. The reset action RSTx has a higher priority than setting the bits CWTx or CATx (x = 0 7). Note: Channel related registers are all registers MCSi_CHx_*, all MCS internal registers accessible by the corresponding channel, with exception of the common trigger register (accessed by CTRG/STRG).
CAT0	8	rwh	**Cancel ARU transfer for channel 0** 0_B Do nothing. 1_B Cancel any pending ARU read or write transfer.
CAT1	9	rwh	**Cancel ARU transfer for channel 1** 0_B Do nothing. 1_B Cancel any pending ARU read or write transfer.
CAT2	10	rwh	**Cancel ARU transfer for channel 2** 0_B Do nothing. 1_B Cancel any pending ARU read or write transfer.
CAT3	11	rwh	**Cancel ARU transfer for channel 3** 0_B Do nothing. 1_B Cancel any pending ARU read or write transfer.
CAT4	12	rwh	**Cancel ARU transfer for channel 4** 0_B Do nothing. 1_B Cancel any pending ARU read or write transfer.
CAT5	13	rwh	**Cancel ARU transfer for channel 5** 0_B Do nothing. 1_B Cancel any pending ARU read or write transfer.
CAT6	14	rwh	**Cancel ARU transfer for channel 6** 0_B Do nothing. 1_B Cancel any pending ARU read or write transfer.

Field	Bits	Type	Description
CAT7	15	rwh	**Cancel ARU transfer for channel 7** 0_B Do nothing. 1_B Cancel any pending ARU read or write transfer. This bit is cleared if no read or write is performed actually or with the next read or write after the currently performed read or write is cancelled. *Note: The CATx (x = 0 …7) bit inside the STA register of the corresponding MCS-channel is set and any pending ARU read or write request is cancelled. The MCS-channel resumes with the instruction after the ARU transfer instruction.* *Note: Note: The CATx (x = 0 …7) bit is cleared by the corresponding MCS channel, when the channel reaches an ARU read or write instruction.*
CWT0	16	rwh	**Cancel WURM instruction for channel 0** 0_B Do nothing. 1_B Cancel any pending WURM instruction.
CWT1	17	rwh	**Cancel WURM instruction for channel 1** 0_B Do nothing. 1_B Cancel any pending WURM instruction.
CWT2	18	rwh	**Cancel WURM instruction for channel 2** 0_B Do nothing. 1_B Cancel any pending WURM instruction.
CWT3	19	rwh	**Cancel WURM instruction for channel 3** 0_B Do nothing. 1_B Cancel any pending WURM instruction.
CWT4	20	rwh	**Cancel WURM instruction for channel 4** 0_B Do nothing. 1_B Cancel any pending WURM instruction.
CWT5	21	rwh	**Cancel WURM instruction for channel 5** 0_B Do nothing. 1_B Cancel any pending WURM instruction.
CWT6	22	rwh	**Cancel WURM instruction for channel 6** 0_B Do nothing. 1_B Cancel any pending WURM instruction.

Field	Bits	Type	Description
CWT7	23	rwh	**Cancel WURM instruction for channel 7** 0_B Do nothing. 1_B Cancel any pending WURM instruction. This bit is cleared if no WURM is performed actually or with the next WURM after the currently performed WURM is cancelled. *Note:* The CWTx (x = 0 …7) bit inside the STA register of the corresponding MCS-channel is set and any pending WURM instruction is cancelled. The MCS-channel resumes with the instruction after the WURM instruction. *Note: Note: The CWTx (x = 0 7) bit is cleared by the corresponding MCS channel, when the channel reaches a WURM instruction.*

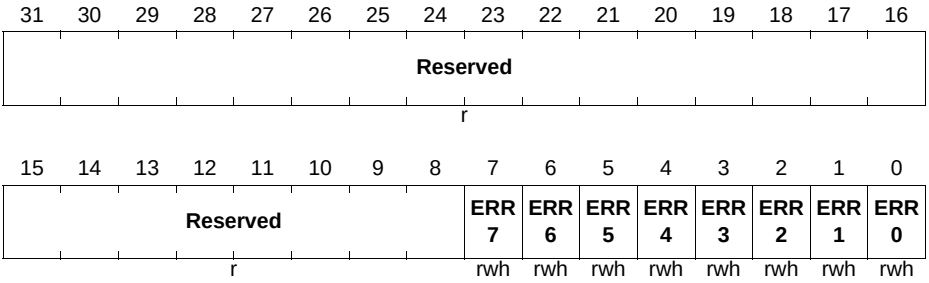
25.13.4.15Register MCSi_ERR

All of the following registers are 32-bit only accessible.

GTM_MCSi_ERR (i=0-3)
MCSi Error Register **($3007C_H+i*1000_H$)** **Reset Value: 00000000_H**



Field	Bits	Type	Description
ERR0	0	rwh	**Error State of MCS-channel 0** 0_B No error signal. 1_B Error signal is pending.
ERR1	1	rwh	**Error State of MCS-channel 1** 0_B No error signal. 1_B Error signal is pending.
ERR2	2	rwh	**Error State of MCS-channel 2** 0_B No error signal. 1_B Error signal is pending._
ERR3	3	rwh	**Error State of MCS-channel3** 0_B No error signal. 1_B Error signal is pending.
ERR4	4	rwh	**Error State of MCS-channel 4** 0_B No error signal. 1_B Error signal is pending.
ERR5	5	rwh	**Error State of MCS-channel 5** 0_B No error signal. 1_B Error signal is pending.
ERR6	6	rwh	**Error State of MCS-channel 6** 0_B No error signal. 1_B Error signal is pending.

Field	Bits	Type	Description
ERR7	7	rwh	**Error State of MCS-channel 7** 0_B No error signal. 1_B Error signal is pending. Note: The CPU can read the ERRx (x = 07) bits in order to determine the current error state of the corresponding MCS-channel x. The error state is also evaluated by the module MON, if this module is available. Note: Writing a value 1 to this bit resets the corresponding error state and resets the channel internal ERR bit in the STA and channel CTRL registers.

25.14 Memory Configuration (MCFG)

25.14.1 Overview

The Memory Configuration submodule (MCFG) is an infrastructure module that organizes physical memory blocks and maps them to the instances of Multi Channel Sequencer (MCS) submodules.

The default configuration maps a memory of size 1K*32 bit = 4KB to MCS memory page 0 and a memory of size 0.5K*32 bit = 2 KB to MCS memory page 1.

In order to support different memory size for different MCS instances, the MCFG module provides two additional layout configurations for reorganization of memory pages between neighboring MCS modules. **Figure 25-63** shows all layout configurations.

The layout configurations SWAP is swapping the 2KB memory page of the current MCS instance with the 4KB memory page of the successive MCS instance. Thus the memory of the current MCS module is increased by 2KB but the memory of the successor is decreased by 2KB.

The layout configurations BORROW is borrowing the 4KB memory page of the successive MCS instance for the current instance. Thus the memory of the current MCS module is increased by 4KB but the memory of the successor is decreased by 4KB.

It should be noted that the successor of the last MCS instance MCS[i] is the first MCS instance MCS0.

The actual size of the memory pages for an MCS instance depends on the layout configuration for the current instance MCS[i] and the layout configuration of the preceding memory instance MCS[i-1].

Figure 25-62 summarizes the layout parameters MP0 and MP1 for MCS instance MCS[i].

The addressing of memory page 0 ranges from 0 to MP0-[i] and the addressing of memory page 1 ranges from MP0 to MP1-[i].

Besides these software related layout configurations, the MCFG submodule has an additional input port MCS_RAM1_EN_ADDR_MSB which is routed to the top level of the GTM.

The above mentioned behaviour of the MCFG submodule is applied if this port is connected to a constant logic level of zero (0).

If a constant logic level of one (1) is applied to this port, the MCFG submodule assumes that a memory of size 1K*32 bit = 4KB is also mapped to MCS memory page 1.

In this case the memory layout configurations of the MCFG submodule change as shown in **Figure 25-64** and the memory layout parameters are modified according to **Figure 25-65**.

25.15 TIM0 Input Mapping Module (MAP)

25.15.1 Overview

The MAP submodule generates the two input signals TRIGGER and STATE for the submodule DPLL by evaluating the output signals of the channel 0 up to channel 5 of submodule TIM0. By using the TIM as input submodule, the filtering of the input signals can be done inside the TIM channels themselves. The MAP submodule architecture is depicted in **Figure 25-66**.

25.15.1.1 MAP Submodule architecture

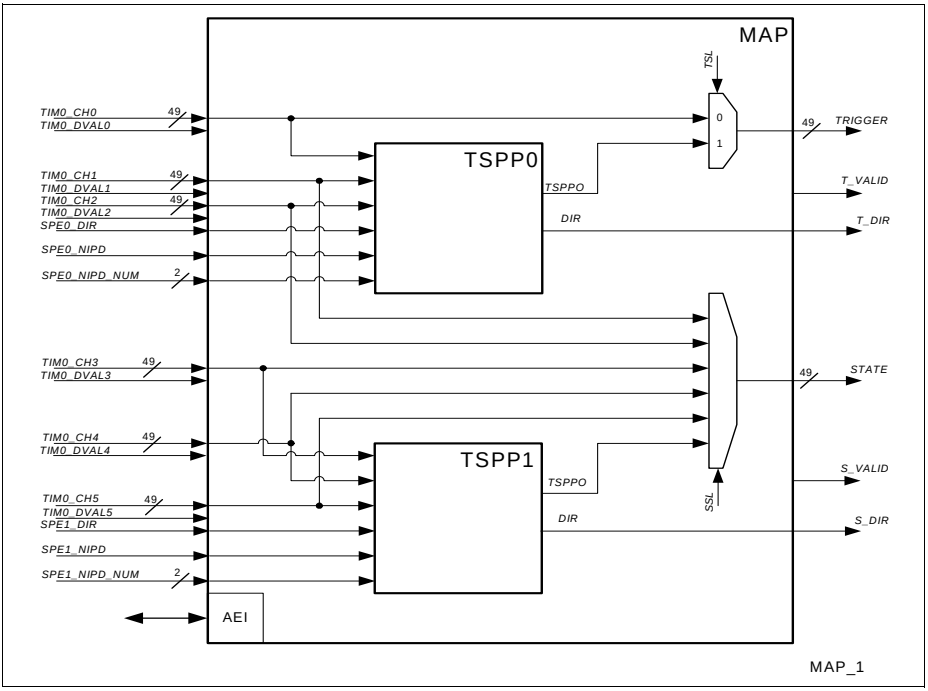

Figure 25-66 MAP Submodule architecture

Generally, the MAP submodule can route the channel signals coming from TIM0 in three ways. First, it is possible to route the whole 49 bits of data coming from channel 0 of

module TIM0 (TIM0_CH0) to the TRIGGER signal which is then provided to the DPLL together with the T_VALID signal.

Second, the MAP module can route one of the five signals coming from the module TIM0 (i.e. the signals coming from channel 1 up to channel 5) to the output signal STATE which is then provided to the module DPLL together with the S_VALID signal.

Third, the TRIGGER, T_VALID, STATE and S_VALID signals can be generated out of the TIM Signal Preprocessing (TSPP) subunits. This is done in combination with the Sensor Pattern Evaluation (SPE) submodule described in **Section 25.17**.

There, the signal TRIGGER is generated in subunit TSPP0 out of the TIM0 signals coming from channel 0 up to 2.

The signal STATE is generated in subunit TSPP1 out of the TIM signals coming from channel 3 up to channel 5.

This is only be done, when the TSSPx subunits are enabled and when the SPEx_NIPD signal is raised by the SPE submodule. The SPEx_NIPD_NUM signal encodes, which of the 3 TIMx_CHy input signals has been changed. The SPEx_DIR signal is routed through the TSPPx subunit and implements the T_DIR or S_DIR signal.

A third method to provide a direction signal to DPLL is to use TIM0 channel 6 input (TIM0_IN6) and to route it instead of the DIR signal coming from TSSOP0 to the MAP output T_DIR (set TSEL=0)

25.15.2 TIM Signal Preprocessing (TSPP)

The TSPP combines the three 49 bit input streams coming from the TIM0 submodule and generates one combined 49 bit output stream TSPPO. The input stream combination is done in the unit Bit Stream Combination (BSC). The architecture of the TSPP is shown in **Figure 25-67**.

25.15.2.1 TIM Signal Preprocessing (TSPP) subunit architecture

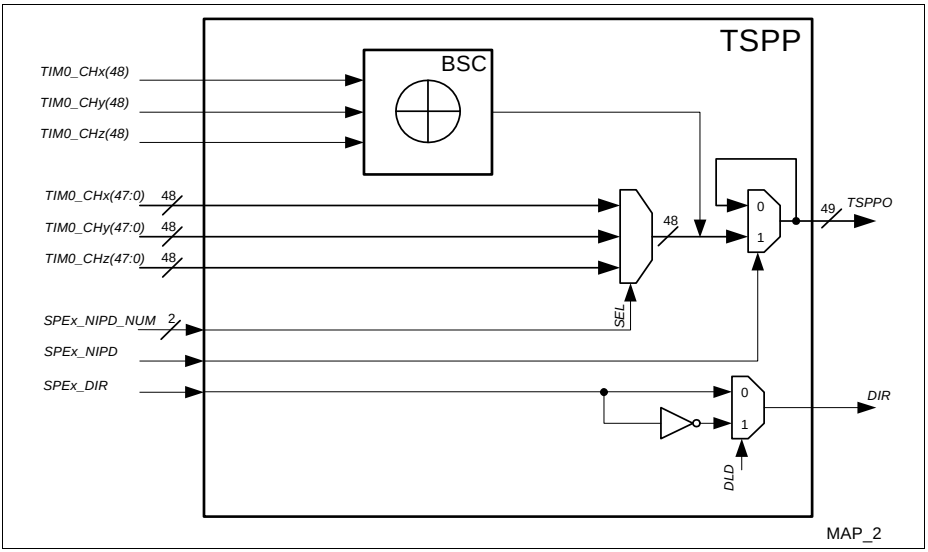

Figure 25-67 TIM Signal Preprocessing (TSPP) subunit architecture

25.15.2.2 Bit Stream Combination

The BSC subunit is used to xor-combine the three most significant bits TIM0_CHx(48), TIM0_CHy(48) and TIM0_CHz(48) of the TIM0 inputs. The xor-combined signal is merged with the remaining 48 bits of one of the three input signals TIM0_CHx(47…0), TIM0_CHy(47…0) or TIM0_CHz(47…0) the TSPPO signal. The selection is done with the SPEx_NIPD_NUM input signal coming from the SPE submodule. The action, when the 49 bits are transferred to the TSPPO and the T_VALID or S_VALID signal is raised is determined by the SPEx_NIPD signal coming from the SPE submodule. The TSPPO output signal generation is shown in the example in **Chapter 25.17.3**.

TSPP Signal generation for signal TSPPO

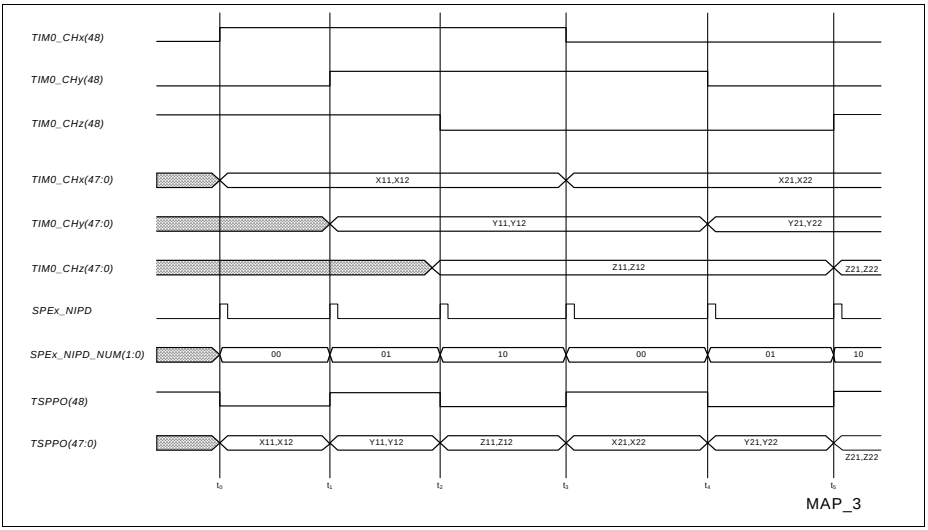

Figure 25-68 TSPP Signal generation for signal TSPPO

The SPEx_NIPD_NUM input signal determines, which data is routed to the TSPPO signal. At the first edge of TIM0_CHx(48) the new data X11 and X12 are routed to TSPPO(47:0). The values X11 and X12 are the two 24 bit values coming from the TIM input channel TIM0_CHx. The next edge is at time t1 on signal TIM0_CHy(48). Therefore, at time t1 the TSPPO(48) signal level changes and the TSPPO(47:0) is set to Y11 and Y12 and so forth.

25.16 Digital PLL Module (DPLL)

25.16.1 Overview

The digital PLL (DPLL) submodule is used for frequency multiplication. The purpose of this module is to get a higher precision of position or value information also in the case of applications with rapidly changed input frequencies. There are two input signals TRIGGER and STATE for which periodic events are processed. The time period between two valid events is called an increment. Each increment is divided into a given number of subincrements by pulses called SUB_INC. The resolution of the generated pulses is restricted by the period of the CMU_CLK0 clock or the TS_CLK respectively (see description of the modules TBU, CMU). The input signals TRIGGER and STATE can have the meaning of position information of linear or angle motions, mass flow values, temperature, pressure or level of liquids.

By means of the DPLL the load of the CPU can be reduced essentially by relieving it from repeated or periodic standard tasks.

The DPLL has to perform the following tasks:

- prediction of the duration of the current increment in **Section 25.16.8**
- synchronization of the actual position (under CPU control, see **Synchronization description**)
- possibility of seamless switch to emergency mode and back under CPU control, see configuration register DPLL_CTRL_0 at **Section 25.16.11**
- prediction of position and time related events in **Section 25.16.7**

25.16.2 Requirements and demarcation

The two input signals TRIGGER and STATE can be sensor signals from the same device or from two independent devices. When they come from the same device the TRIGGER input is typically a more frequent signal and STATE is a less frequent signal. In such a case the STATE signal can support an emergency mode, when no TRIGGER signal is available. There are also applications supported when STATE and TRIGGER are independent signals from different devices. Both input signals are combined with a validation signal T_VALID or S_VALID respectively, which shows the appearance of new data and must result in a data fetch and a start of the correspondent state machine to perform the calculations (see explanation below).

When STATE is a redundant signal of the same device only the TRIGGER input is used to generate the SUB_INC1 pulses in normal mode. There is a configuration possible, called emergency mode, for which the SUB_INC1 pulses are generated using the STATE input signal.

The decision to switch in the emergency mode and back is made outside the DPLL. The CPU must switch the configuration bit RMO (reference mode) in the DPLL_CTRL_0

register (see **Section 25.16.11**). Because a switch in emergency mode can appear suddenly, the information of the last increment durations of the STATE input up to FULL_SCALE should be stored always as a precaution.

The filtering as well as the combination or choice of the input signals is made in the TIM submodule (see **Section 25.10**) by use of a configurable filter algorithm for each slope and signal as well as in the MAP module (see **Section 25.15**) the right TRIGGER or STATE signal is selected by a multiplexer or in the SPE module (see **Section 25.18**) different signals are combined to a TRIGGER or STATE signal by using an antivalence operation.

The filter delay value of the signal is transmitted from the TIM module in the FT part of the corresponding signal, because the delay conditions of the signals can change during application.

The filter delays depend also on the filter algorithms used. Only the effective filter delay can be considered in the DPLL.

In order to provide the timing conditions to the DPLL the input trigger signals should have a time stamp (and optional in addition a filter value and a signal level value, as stated above) with an appropriate resolution. The resolution of the time stamps can be either the same resolution as the input time base TBU_TS0 (see **Section 25.16.4.1**) or 8 times higher, selected by configuration bits in the DPLL_CTRL_1 register (see **Section 25.16.11.2**). The time base TBU_TS0 is used to predict events in the future, called actions.

At the SUB_INCx outputs a predefined number of pulses between each active slope of the TRIGGER/STATE signal is generated, when the correspondent pulse generator is enabled by the enable bits SGEx=1 in the DPLL_CTRL_1 register (see **Section 25.16.11.2**).

Dependent on configuration different strategies can be used to correct a wrong pulse number.

The FULL_SCALE range is divided into a fix number of nominal increments. Nominal increments do have the same size. The number of nominal increments in HALF_SCALE is specified in the DPLL_CTRL_0 register (see **Section 25.16.11**).

For synchronization purposes some TRIGGER/STATE input signals can be suppressed in dependency on the current position. Therefore an increment as duration between two valid input events can be either a nominal increment or it can consist of more then one nominal increment.

While a true nominal increment starts with a valid event a virtual increment (of always nominal size) is an increment which starts with a missing event. Each increment which represents a gap (e.g. for synchronization purposes) consists of exactly one true nominal increment and at least one virtual increment, each of them having the same nominal duration (see figure below).

25.16.3 Input signal courses

Typical input signal courses are shown in the figure below.

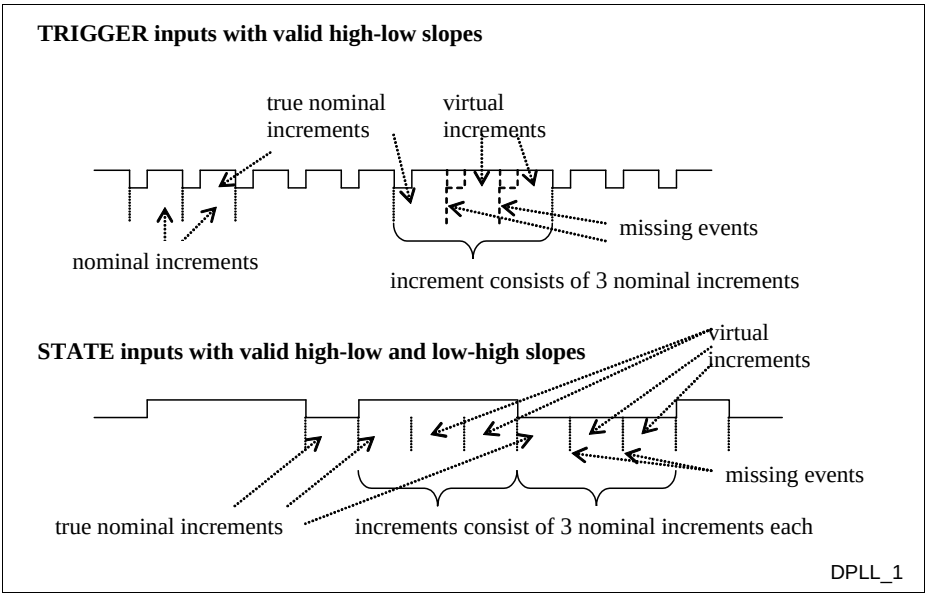

Figure 25-69 Input signal courses

25.16.4 Block and interface description

The block description of the DPLL is shown in the following figure.

25.16.4.1 DPLL Block diagram

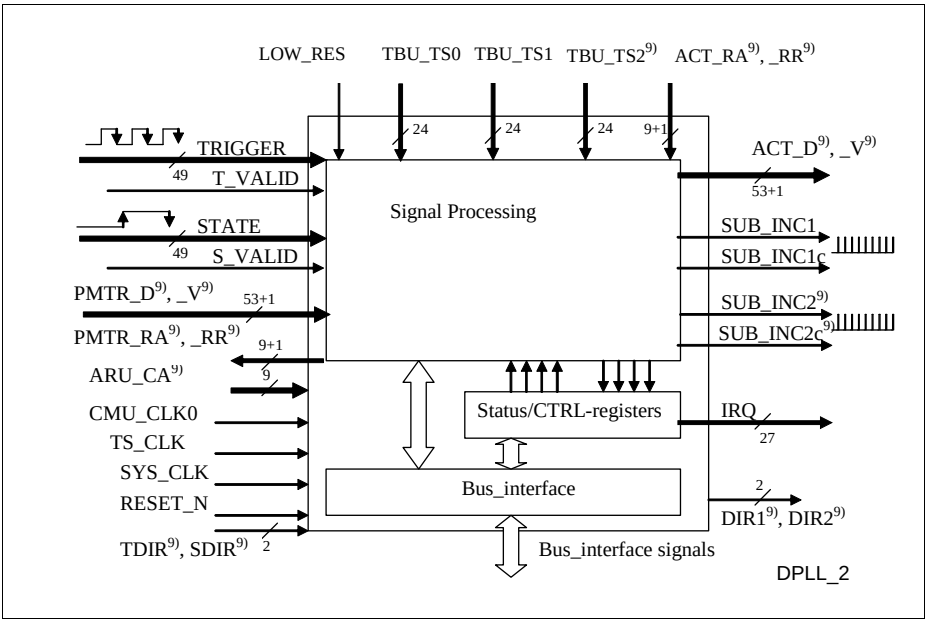

Figure 25-70 DPLL Block diagram

Table 25-46 summarizes the interface signals of the DPLL shown by the block diagram above.

25.16.4.2 Interface description of DPLL

Table 25-46 Interface description of DPLL

Name	Width	I/O	Description	Comment
TRIGGER	49	I	Normal Signal for triggering DPLL by positions/values Bit(48)= TRIGGER_S Bits(47:24)= TRIGGER_FT Bits(23:0)= TRIGGER_TS	one bit signal value (SV), 24 bits filter delay value info and 24 bits time stamp, filtered in different modes.
T_VALID	1	I	The values of TRIGGER are valid	Announces the arrival of a new TRIGGER value
STATE	49	I	Assistance signal for synchronisation STATE(48)= STATE_S STATE(47:24)= STATE_FT STATE(23:0)= STATE_TS	Replacement of signal TRIGGER for emergency situations, or signal from an independent device; bits like above, corresponding
S_VALID	1	I	The values of STATE are valid	Announces the arrival of a new STATE value
PMTR_D	53	I	Position minus time request data, delivered by ARU on request for up to 24 requests PMTR_RR; SV_i=PMTR_D(52:48): ACB bits, directly written to the correspondent DPLL_ACB_j registers PSAi=PMTR_D(47:24): position value for action DLAi=PMTR_D(23:0) time delay value for action	Data values for calculation of actual ACTIONs; the values are requested by AENi=11[1)] and CAIP=02[2)]; a served request is shown by PMTR_V which signals that valid PMTR data arrived and they are written immediately after that to the corresponding RAM regions and registers; The DLAi values must have the same resolution as the TBU_TS0 input.

Table 25-46 Interface description of DPLL (cont'd)

Name	Width	I/O	Description	Comment
PMTR_V	1	I	signals a valid PMTR_D value, that means data is delivered on request	when valid: PMTR_D overwrites data in the PSAi and DLAi registers, also when the corresponding ACT_Ni[3] bit =1;
ARU_CA	9	I	Channel address; for valid PMTR addresses: demand data by setting PMTR_RR=1 when enabled by AENi=11[1] and CAIP=02[2];	counter value of ARU selects PMTR_RA and PMTR_RR when a valid address
PMTR_RA	9	O	read address of PMTR access	reflects ID_PMTR_i according to the selected channel address
PMTR_RR	1	O	read request of PMTR access; suppressed for CAIPi=1 (see DPLL_STATUS register)	reflects the value of the corresponding AENi[1] bit while the correspondent bit CAIPi=0[2]
ACT_D	53	O	Output of a time stamp, a position and a control signal for a calculated action; SV_i=ACT_D(52:48): ACB bits, directly written from the correspondent PMTR_D signals; ACT_D(47:24) is the calculated position value PSACi for the action in relation to TBU_TS1 or 2 [4] and ACT_D(23:0) is the time stamp value TSACi for the action in relation to TBU_TS0 [4]	Future time stamp with the resolution as TBU_TS0 input, additional position information and additional control bits;

Table 25-46 Interface description of DPLL (cont'd)

Name	Width	I/O	Description	Comment
ACT_V	1	O	ACT_D value is available and valid; blocking read access	for a valid action address: ACT_V reflects the shadow value of ACT_Ni[3)] (ACT_Ni is 1 when new PMTR values are available and the shadow register is updated, when a calculation of the actual PMTR values was done); reset after reading of the ACT_D values
ACT_RA	9	I	ACTION read address;	address bits for selection of all 24 action channels
ACT_RR	1	I	read request of selected action	the action data is demanded from an other module
IRQ	27	O	Interrupt request output	Interrupts of DPLL
SUB_INC1	1	O	Pulse output for TRIGGER input filter	sub-position increment provided continuously
SUB_INC2	1	O	Pulse output for STATE input filter (when TRIGGER and STATE are used for 2 independent devices)	sub-position increment provided continuously
SUB_INC1c	1	O	Pulse output for time base unit 1 in compensation mode (can stop in automatic end mode)	sub-position increment related to TRIGGER input
SUB_INC2c	1	O	Pulse output for time base unit 2 in compensation mode (can stop in automatic end mode)	sub-position increment related to STATE input (when TRIGGER and STATE are used for 2 independent devices)
TS_CLK	1	I	Time stamp clock	used for generation of the time stamps; this clock is used to generate the SUB_INC1,2 pulses

Table 25-46 Interface description of DPLL (cont'd)

Name	Width	I/O	Description	Comment
CMU_CLK0	1	I	CMU clock 0	used for rapid pulse correction of SUB_INC1,2
SYS_CLK	1	I	System clock	High frequency clock
RESET_N	1	I	Asynchronous reset signal	Low active; After Reset he DPLL is available only after performing the RAM reset procedures by the DPLL hardware.
LOW_RES	1	I	low resolution of TBU_TS0 selected; shows which of the 27 bits of TBU_TS0 are connected to the DPLL	LOW_RES=0: TBU_TS0(DPLL)= lower 24 Bits of TBU_TS0(TBU); LOW_RES=1: TBU_TS0(DPLL)= higher 24 Bits of TBU_TS0(TBU); In the case LOW_RES=1 the TS0_HRT and/or TS0_HRS bits can be set 5)
TBU_TS0	24	I	Actual time stamp from TBU; is needed to decide, if a calculated action is already in the past	24 bit time input, with a resolution of the time stamp clock
TBU_TS1	24	I	Actual position/value stamp 1; for calculation of position stamps (TRIGGER/STATE)	24 bit pos./val. input, with a resolution of the SUB_INC1 pulses
TBU_TS2	24	I	Actual position/value stamp 2; to be implemented for an additional independent position	ditto for SUB_INC2 for calculation of position stamps (STATE) for SMC6)=RMO7)=1

Table 25-46 Interface description of DPLL (cont'd)

Name	Width	I/O	Description	Comment
TDIR	1	I	Direction of TRIGGER input values (TDIR=0 does mean a forward direction and TDIR=1 a backward direction)	direction information from multiple sensors valid only for SMC[6)]=1 or IDDS [8)]= 1
SDIR	1	I	Direction of STATE input values (SDIR=0 does mean a forward direction and SDIR=1 a backward direction)	direction information from multiple sensors valid only for SMC[6)]=1
DIR1	1	O	Direction information of SUB_INC1 (count forwards for DIR1=0 and backwards for DIR1=1)	count direction of TBU_TS1; DIR1 changes always after the evaluation of the corresponding valid TRIGGER slope and after incrementing/decremented of the address pointer
DIR2	1	O	Direction information of SUB_INC2 (count forwards for DIR2=0 and backwards for DIR2=1)	count direction of TBU_TS2; DIR2 changes always after the evaluation of the corresponding valid STATE slope and after incrementing/decremented of the address pointer

25.16.5 DPLL Architecture

25.16.5.1 Purpose of the module

The DPLL generates a predefined number of incremental signal pulses within the period between two events of an input TRIGGER or STATE signal, when the corresponding pulse generator is enabled. The resolution of the pulses is restricted by the frequency of the time stamp clock (TS_CLK). Changes in the period length of the predicted time period of the current increment will result in a change of the pulse frequency in order to get the same number of pulses. This adoption can be performed by DPLL hardware, software or with support of DPLL hardware in different modes.

The basic part of a DPLL is to make a prediction of the current period between two TRIGGER and/or STATE signal edges. Disturbances and systematic failures must be considered as well as changes of increment durations caused by acceleration and deceleration of the supervised process. Therefore, a good estimation is to be done using some measuring values from the past. When the process to be predicted takes a steady and differentiable course not only the current increment but also some more increments for the future can be predicted. In utilisation of such calculations actions for the future can be predicted.

25.16.5.2 Explanation of the prediction methodology

As already shown in **Section 25.16.1** the DPLL has to perform different tasks. The basic function for all these tasks is the prediction of the current increment which is based on a relation between increments in the past. Because the relation between two succeeding intervals at a fixed position remains also valid in the case of acceleration or deceleration the prediction of the duration of the current time interval is done by a similarity transformation. Having a good estimation of the current time interval, all the other tasks can be done easily by calculations explained in **Section 25.16.6**.

25.16.5.3 Clock topology

All registers are read using the system clock SYS_CLK. The SUB_INC1,2 pulses generated have the highest frequency not higher then CMU_CLK0 or TS_CLK respectively. All operations can be performed using the system clock.

25.16.5.4 Clock generation

The clock is generated outside the DPLL.

25.16.5.5 Typical frequencies

For system clock a reasonable clock frequency should be applied to give the DPLL module sufficient computational power to calculate all needed values (prediction of next increment, actions) in time.

25.16.5.6 Time stamps and systematic corrections

The time stamps for the input signals TRIGGER and STATE have 24 bits each. These bits represent the value of the 24 bit free running counter running with a clock frequency selected by the configuration of the TBU. Using a typical frequency of 20 MHz the time stamp represents a relative value of time with a resolution of 50 ns.

The input signals have to be filtered. The filter is not part of the DPLL. The time stamps can have a delay caused by the filter algorithm used. There are delayed and undelayed filter algorithms available and the delay value can depend on a time or a position value.

Systematic deviations of TRIGGER inputs can be corrected by a profile, which also considers systematic missing TRIGGERs. The increments containing missing TRIGGERS are divided into the corresponding number of nominal increments whereas the duration of a nominal increment is the greatest divider of all increment durations.

For each increment this number of enclosed nominal increments is stored in a profile as NT value for TRIGGER. When the increment is a nominal increment the NT value is 1.

For the TRIGGER input the value NT is stored in the ADT_T field in RAM region 2C.

In the case of AMT[4] = 1 the ADT_Ti values in the RAM region 2C must also contain the adapting information for the TRIGGER signal, which considers for each increment a systematic physical deviation PD from the perfect increment value with a resolution according to the chosen value of MLT+1, which describes the number of SUB_INC1 pulses for a nominal increment.

The value PD for the TRIGGER describes the amount of missing or surplus pulses with a sint13 value, to be added to MLT+1 directly. The correction value is in this way also applicable in the case of missing TRIGGER inputs for the synchronization gaps. In this case the amount of provided SUB_INC1 pulses for a nominal increment (MLT+1) is multiplied by NT first before the PD value is added.

The NT value of the current increment is stored in the variable SYN_T (see NUTC register in **Section 25.16.11.13**).

In the case of RMO[4] = 1 for SMC[5] =0 (emergency mode) the time stamp of STATE is used to generate the output signal SUB_INC1.

More inaccuracy should be accepted in emergency mode because usually there are only fewer events available for FULL_SCALE according to the value SNU[4].

For the STATE signal the systematic deviations of the increments can be corrected in the same way as for TRIGGER by profile and adaptation information as described below.

Systematic deviations of STATE inputs can be corrected by a profile, which also considers systematic missing STATE events. The increments containing missing STATEs are divided into the corresponding number of nominal increments whereas the duration of a nominal increment is the greatest divider of all increment durations.

For each increment this number of enclosed nominal increments is stored in a profile as NS value for STATE. When the increment is a nominal increment the NS value is 1.

For the STATE input the value NS is stored in the ADT_S field in RAM region 1C3.

In the case of AMS[4] = 1 the ADT_Si values in the RAM region 1C3 must contain the adapting information for the STATE signal, which considers for each increment a systematic physical deviation PD_S from the perfect increment value with a resolution according to the chosen value of MLS1, which describes the number of SUB_INC1 pulses for a nominal increment (see below).

The number of pulses SUB_INC1 for a nominal STATE increment in emergency mode (for SMC=0) is given by the value of MLS1= (MLT + 1)* (TNU + 1) /(SNU + 1) in order to get the same number of pulses in FULL_SCALE for normal and emergency mode. This value has to be configured by the CPU.

The value PD_S for the STATE describes the amount of missing or surplus pulses with a sint16 value, to be added to MLS1 directly. The correction value is in this way also applicable in the case of missing STATE inputs for the synchronization gaps. In this case the amount of provided SUB_INC1 pulses for a nominal increment MLS1 is multiplied by NS first before the PD_S value is added.

The current NS value is stored in the variable SYN_S (see NUSC register in **Section 25.16.11.14**).

6) see DPLL input signal description

25.16.5.7 DPLL Architecture overview

As shown in **Section 25.16.4.1** the DPLL can process different input signals. The signal TRIGGER is the normal input signal which gives the detailed information of the supervised process. It can be for instance the information of water or other liquid level representing the volume of the liquid, where each millimeter increasing results in a TRIGGER signal generation. In order to get a predefined filling level, without overflow also the inertia of the system must be taken into account. Hence, some delay for closing

the inlet valve and also the remaining water amount in the pipe must be considered in order to start the closing action earlier as the filling level will be reached.

A second input signal STATE sends an additional (redundant) information for instance at some centimeters and because of intervals with different distances it gives also information about the system state with the direction of the water flow (in or out), while the TRIGGER signal must not contain information concerning the flow direction. In some applications the inactive slope of TRIGGER can be utilized to transmit a direction information. In the case of faults in the TRIGGER signal the STATE signal is to be processed in order to reach the desired value nevertheless, maybe with some loss of accuracy.

The measuring scale can have some systematic failures, because not all millimeter or centimeter distances measured mean the same value. This could be due to changes in the thickness of the measuring cylinder or the inaccurate position of the marks. These systematic failures are well known by the system and for improvement of the prediction the signals ADT_T and ADT_S for the correction of the systematic failures of TRIGGER and STATE respectively are stored in the internal RAM.

The input signals TRIGGER and STATE are represented as a time stamp signal each, which is stored in the 24 bit TS-part of the corresponding signal.

Information concerning the delay of this signal by filtering of disturbances is stored in the 24 bit FT-part of the signal.

In order to establish the relation of time stamps to the actual time the TBU_TS0[6)] value is also provided showing the actual time value used for prediction of actions in the future.

After reaching the desired water level the water is filled in a bottle by draining. After that the water filling is repeated. The water level at draining is observed by the same sensor signals (the same number of TRIGGER pulses), but the duration of the draining could be different from the filling time. Both times together form the FULL_SCALE region, while one of them is a HALF_SCALE region, which can differ in time but not in the number of pulses, especially for TRIGGER.

For synchronisation purposes some TRIGGER marks can be omitted in order to set the system to a proper synchronisation value (maybe before the upper filling value is reached).

In emergency situations, when the TRIGGER signals are missed the STATE signal is used instead of.

The PMTR_i[6)] signals announce the request for a position minus time calculation for up to 24 events.

All 24 events can be activated using the 24 AENi[1)] (action enable) bits. Each of these enable bits are asked by the routing engine for a read access. The corresponding read request is generated by the AENi bit while CAIPx is zero. CAIP1 and CAIP2 are two bits of the DPLL_STATUS register for 12 actions each with the meaning “calculation of

actions in progress", controlled by the state machine (see **Chapter 25.16.2**) for scheduling the operations.

When such a request is serviced by the ARU (in the case CAIPx=0) the values for position and time are written in the corresponding RAM 1A region (0x0200… 0x025C for the position value and 0x0260… 0x02BC for the delay value), the control bits for the corresponding action are set accordingly. When a new PMTR value arrives, an old value is overwritten without notice and the shadow bit of ACT_Ni is cleared while the ACT_Ni (new action) bit in the DPLL_ACT_STA register is set.The ACT_Ni is cleared, when the currently calculated action value is in the past. Overwriting of old information is possible without data inconsistency because the read request to ARU is suppressed during action calculations by the CAIP1,2 bits. In this way always the last possible PMTR value is used consistently.

For references above the following hints are used:

2) see DPLL_STATUS register

3) see DPLL_ACT_STA register

4) see DPLL_CTRL_0 register

5) see DPLL_CTRL_1 register

6) see DPLL input signal description

25.16.5.8 DPLL Architecture description

The DPLL block diagram **Chapter 25.16.4.1** will now be explained in detail in combination with some example configurations of the control registers. There are different configuration bits available which can adopt the DPLL to the use case (see **Chapter 25.16.11**).

Let for example in HALF_SCALE the TRIGGER number TNU[4)] be 0x3B (which is for TNU+1 = 60 decimal that does mean 120 events in FULL_SCALE) and the number of SUB_INC1 pulses between two TRIGGERs MLT[4)] be 0x257 (this means 600 pulses per TRIGGER event). Than the FULL_SCALE region can be divided into 72000 parts each of them associated with its own SUB_INC1 pulse. For a run through FULL_SCALE all 72000 pulses should appear but maybe with a different pulse frequency between two TRIGGER events. For this example after each 600 pulses at the SUB_INC1 output the next TRIGGER event is to be expected with the corresponding new time stamp.

Missing SUB_INC1 pulses due to acceleration have to be taken into account within the next increment. Not one pulse has to be missed or added because of calculation inaccuracy in average for a sufficient number of FULL_SCALE periods. This means that not one pulse is sent in addition and all missing pulses are to be caught up on afterwards.

For the systematic arrangement of TRIGGER inputs the profile (as already mentioned in **Section 25.16.5.6** is stored in the RAM region 2C (see **Section 25.16.11.100**). In this

field the relative position of gaps can be stored in the NT value and also physical deviations in the PD value.

For the consideration of systematic missing TRIGGERs the actual NT value of the profile is stored in the SYN_T bits of the NUTC register (see **Section 25.16.11.13**).

In normal mode the physical deviation values PD in the ADT_T field could be used to balance the local systematic inaccuracy of the TRIGGER signal. The value of PD (see **Section 25.16.11.100**) is the pulse difference in the corresponding increment and does mean the number of sub pulses to be added to the nominal number of pulses. PD is a signed integer value using 13 bits: up to +/-4096 pulses can be added for each increment.

The NT value of the profile ADT_T has the value 1, when a nominal increment is assumed. An integer number greater than 1 shows the number of nominal increments to be considered for a gap. For the actual increment after synchronization the corresponding NT value is stored in SYN_T of the NUTC register.

Using the STATE input there are similar configuration bits available (see **Section 25.16.11**).

Let for example in HALF_SCALE the STATE number SNU[4)] be 0xB (which is for SNU+1 =12 decimal and while SYSF[4)] =0 that does mean 24 events in FULL_SCALE). In order to get the same number of SUB_INC1 pulses for FULL_SCALE as above for TRIGGERs the value (MLT+1)=600 is divided by 2*(SNU+1)=24 and multiplied with 2*(TNU+1)=120. The result 3000 must be stored in MLS1 by the CPU (see **Section 25.16.11.78**).

For the systematic arrangement of STATE inputs the profile (as already mentioned in **Section 25.16.5.6** is stored in the RAM region 1C3 (see **Section 25.16.11.93**). In this field the relative position of gaps can be stored in the NS value and also physical deviations in the PD_S value.

For the consideration of systematic missing TRIGGERs the actual NS value of the profile is stored in the SYN_S bits of the NUSC register (see **Section 25.16.11.14**).

In emergency mode the physical deviation values PD_S in the ADT_S field could be used to balance the local systematic inaccuracy of the STATE signal. The value of PD_S (see **Section 25.16.11.93**) is the pulse difference in the corresponding increment and does mean the number of sub pulses to be added to the nominal number of pulses. PD_S is a signed integer value using 16 bits: up to +/-32768 pulses can be added for each increment.

The NS value of the profile ADT_S has the value 1, when a nominal increment is assumed. An integer number greater than 1 shows the number of nominal increments to be considered for a gap. For the actual increment after synchronization the corresponding NS value is stored in SYN_S of the NUSC register.

25.16.5.9 Block diagrams of time stamp processing.

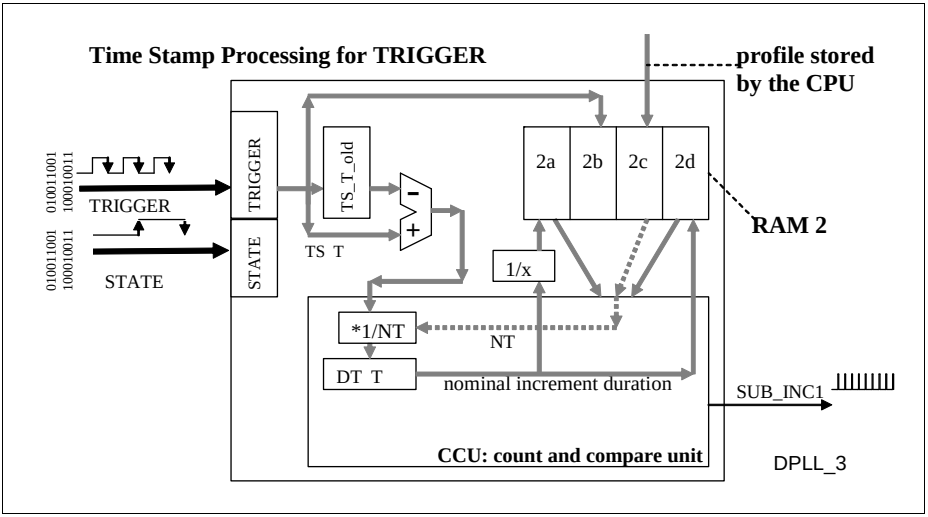

Figure 25-71 Time Stamp Processing

As shown in the block diagram above the time stamp difference of two succeeding input events is calculated. For the prediction of the current increment duration such values from the past are used. For this purpose the measured and calculated values of the last FULL_SCALE period are stored in the RAM. For the TRIGGER input there are 4 different RAM parts in the RAM region 2:

2A stores the reciprocals of each nominal increment duration RDT_T

2B stores the time stamps of each valid input event TSF_T

2C is used for the profile ADT_T and

2D for the nominal increment durations DT_T.

Because the prediction is based on the relations of increments in the past this relation can be calculated easily by the multiplication of increment duration values with the reciprocal value of an other increment. In order not to be forced to distinguish between

gaps and "normal" increment durations also for gaps only the nominal duration and the correspondent reciprocal values are stored in the RAM field. This is possible by consideration of the NT value in the profile: the measured increment duration is divided by NT.

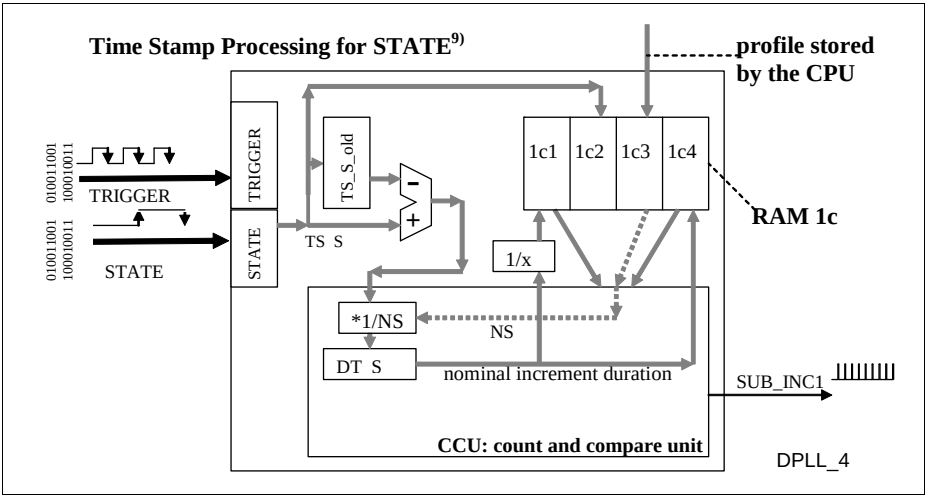

Figure 25-72 Time Stamp Processing for STATE

For the STATE input there are also 4 different RAM parts in the RAM region 1C:

- 1C1 stores the reciprocals of each nominal increment duration RDT_S
- 1C2 stores the time stamps of each valid input event TSF_S
- 1C3 is used for the profile ADT_S and
- 1C4 for the nominal increment durations DT_S.

The calculations are performed similar as for the TRIGGER input. The NS value in the profile shows the appearance of a gap.

25.16.5.10Register and RAM address overview

The address map of the DPLL is divided into register and memory regions as defined in **Table 25-47**. The addresses from 0x0000 to 0x00FC are reserved for registers, from 0x0100 to 0x01FC is reserved for action registers to serve the ARU at immediately read request.

The RAM is divided into 3 independent accessible parts 1A, 1B+C and 2.

The part 1A from 0x0200 to 0x037C is used for PMTR values got from ARU and intermediate calculation values; there is no write access from the CPU possible, while the DPLL is enabled.

The RAM 1B part from 0x0400 to 0x05FC is reserved for RAM variables and the RAM part 1C from 0x0600 to 0x09FC is used for the STATE signal values.

The RAM region 2 from 0x4000 to 0x5FFC is reserved for the TRIGGER signal values. RAM region 1A has a size of 288 bytes, Ram 1B+C uses 1,125 Kbytes while RAM region 2 6 Kbytes, depending on the number of TRIGGER events in FULL_SCALE. The AOSV_2 register is used to determine the beginning of each part.

The table **Table 25-47** in gives the DPLL Address map overview

Register and RAM address map

Registers are used to control the DPLL and to show its status. Also parameters are stored in registers when useful. The table below shows the addresses for status and control registers as well as values stored in additional registers. The register meaning explained in the register overview (**Section 25.16.10**) while the bit positions of the status and control registers are described in detail in **Section 25.16.11**.

Time stamps for TRIGGER and STATE can have either the same resolution as the TBU_TS0 input or 8 times higher. This is configured in the DPLL_CTRL_1 register (see **Section 25.16.11.2**). While the TBU_TS0 is used for action predictions the higher resolution of TRIGGER and STATE inputs can be used for a more accurate pulse generation.

The time stamp fields of TRIGGER and STATE are stored in the corresponding RAM regions in such a way, that for a gap also entries for the virtual increments are provided. This is due to the necessity to calculate time differences between a given number of (real and virtual) input events independent of a gap. Therefore the gap is extended in the RAM fields 2B and 1C2.

For all other RAM regions in RAM 2 and RAM 1C the gap is considered as one increment.

For the access to the RAM fields there must be address pointers. When the device starts all address pointers have a zero value and the first measured and calculated values are stored in the beginning of the corresponding RAM field.

Because the position of the device is usually unknown at the beginning no profile information can be used. The profile regions must have their own address pointers each which are set by the CPU as soon as the position is known. By setting the appropriate value to the address pointer APT_2C of the TRIGGER profile or APT_1C3 of the STATE profile respectively the synchronization bits in the DPLL_STATUS register SYT or SYS are set respectively. In the following the gap information can be used.

Because the time stamp fields are extended at the gaps there must be additional address pointers for these regions: APT_2B for TRIGGER time stamps and APT_1C2 for STATE time stamps. These address pointers must be increment by NT or NS respectively when a gap appears.

Table 25-47 DPLL Register and RAM address map

Addr. range Start	Addr. range End	Value number	Byte #	Content	Indication	Region	RAM size
0x0000	0x0FC	64	256	Register	used/reserved	0	no RAM
0x100	0x1FC	64	192	ACTION registers	direct read from ARU	0	no RAM
0x0200	0x03FC	128	384	PMTR values RAM 1A	CPU rw access, when DPLL disabled; ARU has highest priority	1A with own ports	RAM part 1A: 384 bytes
0x0400	0x05FC	128	384	Variables RAM 1B	r and monitored w access by the CPU	1B	RAM part 1B+C: 1,125 Kbytes
0x0600	0x09FC	256	768	STATE data	r and monitored w access by the CPU	1C	
0x0600	0x06FC	64	192	RDT_Si	STATE reciprocal values	1C1	
0x0700	0x07FC	64	192	TSF_Si	STATE TS values	1C2	

Table 25-47 DPLL Register and RAM address map (cont'd)

Addr. range Start	Addr. range End	Value number	Byte #	Content	Indication	Region	RAM size
0x0800	0x08FC	64	192	ADT_Si	adapt values of STATE	1C3	
0x0900	0x09FC	64	192	DT_Si	nom. STATE inc	1C4	
0x4000	0x5FFC	2048	6144	TRIGGER data	r and monitored w access of CPU	2	RAM part 2: 6Kbytes
0x4000	0x47FC	512	1536	RDT_Ti	TRIGGER reciprocal values	2A	
0x4800	0x4FFC	512	1536	TSF_Ti	TRIGGER TS values	2B	
0x5000	0x58FC	512	1536	ADT_Ti	adapt values of TRIGGER	2C	
0x5800	0x5FFC	512	1536	DT_Ti	nom. TRIGGER increments	2D	

RAM Region 1

RAM region 1 has a size of 1,5 Kbytes and is used to store variables and parameters as well as the measured and calculated values for increments of STATE. The RAM 1 region is divided into two independent accessible RAM parts (A and B+C) with own ports. The address information is shown in the table above and the detailed description is

performed in the following sections. The RAM 1A is used to store the PMTR values got from ARU and in addition some intermediate calculation results of actions. RAM region 1B is used for variables needed for the prediction of increments, while RAM 1C is used to store time stamps, profile and durations for all the STATE inputs of the last FULL_SCALE region. All variables and values of RAM 1B+C part use a data width of up to 24 bits.

The RAM is to be initialized by the DPLL after HW-reset. All RAM cells must have a zero value after performing the initialize procedure. This is performed when setting The Init_RAM bit in the DPLL_RAM_INI register. The DPLL is only available after finishing this procedure. The initialization progress is shown in the status bits of the same register.

- RAM Region 1A: used for storage of PMTR values got from ARU;
  - read and write access by the CPU is only possible, when the DPLL is disabled.
  - The CPU Address range: 0x0200 – 0x03FC
- RAM Region 1B: usable for intermediate calculations and auxiliary values, data width of 3 bytes used for 24 bit values;
  - A write access to this region results in an interrupt to the CPU, when enabled.
  - Address range: 0x0400 – 0x05FC
- RAM Region 1C: Values of all STATE increments in FULL_SCALE, data width of 3 bytes used for 24 bit values;
  - A write access to this region results in an interrupt to the CPU, when enabled.
  - Address range: 0x0600 – 0x09FC

In RAM region 1C there is a difference in the amount of data. While for the RAM regions 1C1, 1C3 and 1C4 there are 2*(SNU+1-SYN_NS) entries for SYSF=0 or 2*(SNU+1) - SYN_NS entries for SYSF=1, for the RAM region 1C2 there are 2*(SNU+1) entries (see DPLL_CTRL_0 and _1 registers). For the latter also the virtual events are considered, that means the gap is divided into equidistant parts each having the same position share as increments without a gap. For that reason the CPU must extend the stored TSF_Si values in the RAM region 1C2 before the APS_1C3 is written. The write access to APS_1C3 sets the SYS bit in the DPLL_Status register in order to show the end of the synchronization process. Only when the SYS bit is set the PMTR values can consider more then the last increment duration for the action prediction by setting NUSE to a corresponding value.

Note: RAM regions 1B and 1C have a common port.

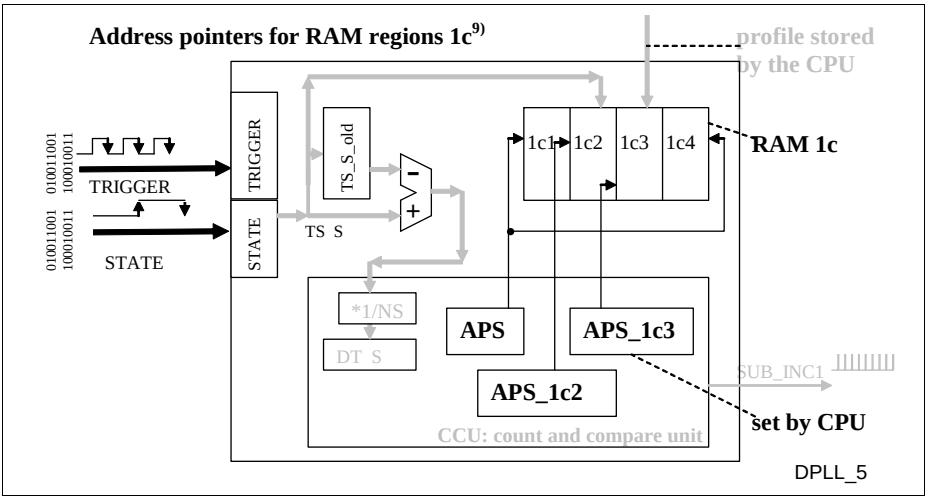

Figure 25-73 Address pointers for RAM regions 1C

The address pointers for RAM region 1C are shown in the diagram above. While the address pointer APS points to the RAM regions 1C1 and 1C4, the address pointer APS_1C2 points to the time stamp field in the region 1C2. This is necessary, because in the time stamp field the gaps are extended to the number of nominal increments (see explanation above and also to the synchronization procedure explained in **Synchronization description**).

The address pointer APS_1C3 is set by the CPU when the position is known and therefore the relation to the other address pointers is calculated. This setting of this profile address pointer synchronizes the RAM fields to one another. The synchronization is shown in the DPLL_STATUS register by the SYS bit.

RAM Region 2

The RAM region 2 has 6 Kbytes and is used to store measured and calculated values for increments of TRIGGER. The address information is explained in **Section 25.16.10** while the meaning is explained in this section.

Because of up to 256 TRIGGER events in HALF_SCALE the fields 2A, B C and D must have up to 512 storage places each. For 3 Bytes word size this does mean6 k Byte of RAM region 2.

In order to save RAM size for configurations with less TRIGGER events the RAM is configurable by the offset switch Register OSW (0x001C) and the address offset value register of RAM region 2 AOSV_2 (0x0020). The RAM is to be initialized by the DPLL after HW-reset. All RAM cells must have a zero value after performing the initialize procedure. The DPLL is only available after finishing this procedure.

In RAM region 2 there is a difference in the amount of data. While for the RAM regions 2A, 2C and 2D there are 2*(TNU+1-SYN_NT) entries, for the RAM region 2B there are 2*(TNU+1) entries (see DPLL_CTRL_0 and _1 registers). For the latter also the virtual events are considered, that means the gap is divided into equidistant parts each having the same position share as increments without a gap. For that reason the CPU must extend the stored TSF_Ti values in the RAM region 2B before the APT_2C is written.

The write access to APT_2C sets the SYT bit in the DPLL_Status register in order to show the end of the synchronization process. Only when the SYT bit is set the PMTR values can consider more then the last increment duration for the action prediction by setting NUTE to a value greater then one.

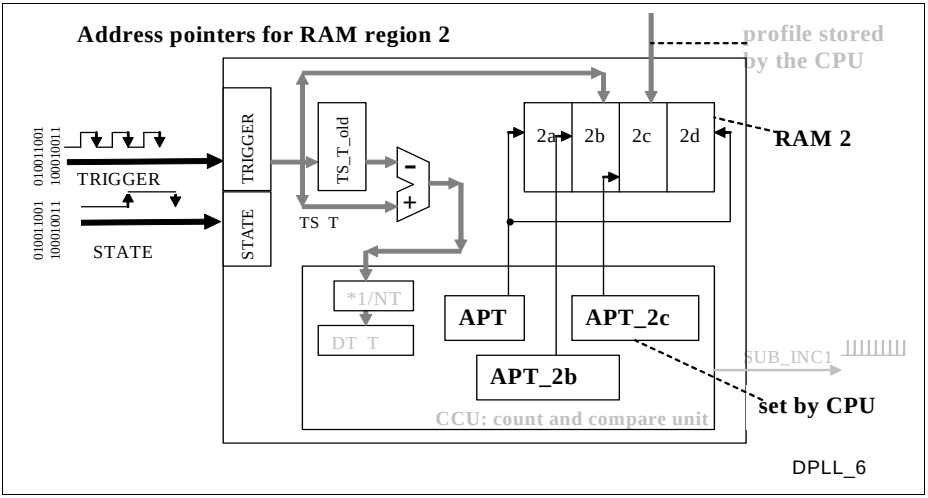

Figure 25-74 Address pointers for RAM region 2

The address pointers for RAM region 2 are shown in the diagram above. While the address pointer APT points to the RAM regions 2A and 2D, the address pointer APT_2B points to the time stamp field in the region 2B. This is necessary, because in the time stamp field the gaps are extended to the number of nominal increments (see explanation above and also to the synchronization procedure explained in **Synchronization description**).

The address pointer APT_2C is set by the CPU when the position is known and therefore the relation to the other address pointers is calculated. This setting of this profile address pointer synchronizes the RAM fields to one another. The synchronization is shown in the DPLL_STATUS register by the SYT bit.

25.16.6 Prediction of the current increment duration

25.16.6.1 The use of increments in the past

Past values to be considered for the prediction of TRIGGER

In order to take into account values of increments for TRIGGERs in the past, the NUTE value is configured to determine the number of past values. In addition the VTN has a value according to the number of virtual increments in the NUTE region. Because gaps come in to the NUTE region or leave it the VTN value must be updated by the CPU until NUTE is set to HALF_SCALE or FULL_SCALE. For the RAM regions 2A and 2D the value NUTE-VTN is to be considered while for the RAM region 2B only the NUTE value is to be considered. This is due to the fact that the time stamp entries in a gap are extended to the number of nominal increments, but duration entries not.

Past values to be considered for the prediction of STATE

In order to take into account values of increments for STATE in the past, the NUSE value is configured to determine the number of past values. In addition the VSN has a value according to the number of virtual increments in the NUSE region. Because gaps come in to the NUSE region or leave it the VSN value must be updated by the CPU until NUSE is set to HALF_SCALE or FULL_SCALE. For the RAM regions 1C1 and 1C4 in the past the value NUSE-VSN is to be considered while for the RAM region 1C2 only the NUSE value is to be considered. This is due to the fact that time stamp entries in a gap are extended to the number of nominal increments, but duration entries not.

25.16.6.2 Increment prediction in Normal Mode forwards (DIR1=0)

For the prediction of increments and actions in normal mode the values are calculated as described in the following equations.

Please note, that the ascending order of calculation must be hold in order not to lose results still needed. It is important for TRIGGER values to calculate and store in the RAM region 2 all values according to equations up to DPLL-14 before DPLL-1a4…7, DPLL-1b1 and DPLL-1C1, while the last one overwrites DT_Ti when NUTE (see **Section 25.16.11.13**) is set to the FULL_SCALE range. Because the old value of DT_Ti is also needed for equation DPLL-10 and DPLL-11 this value is stored temporarily at DT_T_ACT as shown by equation DPLL-1a or DPLL-1b respectively until all prediction calculations are done and after that equation DPLL-1a4…7, DPLL-1b1 and DPLL-1c1 updates DT_Ti: update DT_Ti after calculations of equation DPLL-14. For p=APT calculates in normal mode:

When using filter information of TRIGGER_FT, selected by IDT=1, it must be distinguished by IFP, if this filter information is time or position related:

In order to make possible to perform the automatic resolution corrections of equations DPLL-1a1a the filter unit in TIM module must operate using the time stamp clock.

Equations DPLL-1a to calculate TRIGGER time stamps

Equations DPLL-1a to calculate TRIGGER time stamps

For calculation of time stamps use the filter delay information

TS_T=TRIGGER_TS (unchanged for IDT=0)	**(DPLL-1a0)**
TS_T=TS_T - FTV_T (for IDT=1 and IFP=0)	**(DPLL-1a1)**
with	
FTV_Tx = FTV_T/8 (for LOW_RES = 1 and TS0_HRT = 0)	**(DPLL-1a1a)**
FTV_Tx = FTV_T (for LOW_RES = 0 or TS0_HRT = 1)	**(DPLL-1a1b)**
and	
TS_T= TS_T - FTV_T *(CDT_TX/NMB_T)_old[1)] for (IDT=1 and IFP=1)	**(DPLL-1a2)**

this can be also calculated using the value of ADD_IN_CALN:

TS_T=TS_T - FTV_T *(1/ADD_IN_CALN_old[1)]) for (IDT=1 and IFP=1)	**(DPLL-1a3)**

1) Consider values, calculated for the last increment; position related filter values are only considered up to at least 1 ms time between two TRIGGER events. The reciprocal value is stored using a 32 bit fractional part, while only the 24 lower bits are used - for explanation see note 4) at DPLL_CTRL0 register. The value of 1/ADD_IN_CALN_OLD or (CDT_TX/NMB_T)_old is set to 0xFFFFFF in case of an overflow.

Note: CDT_TX is the predicted duration of the last TRIGGER increment and NMB_T the calculated number of SUB_INC1 events in the last increment, because the new calculations are done by equations DPLL-5 and DPLL-21 for the current increment after that. Therefore in equation DPLL-1a3 the value ADD_IN of the last increment is used (see equation DPLL-25). SYN_T_OLD is the number of TRIGGER events including missing TRIGGERs as specified in the NUTC register for the last increment, with the initial value of 1.

For storage of time stamps in the RAM see also equations DPLL-1a4 ff. after calculation of actions

Equation DPLL-1b to calculate DT_T_ACT (nominal value)

$$DT\_T\_ACT = (TS\_T - TS\_T\_OLD)/SYN\_T\_OLD \quad \textbf{(DPLL-1b)}$$

For the case SYT=0 (still no synchronization to the profile) the values SYN_T and SYN_T_OLD are still assumed as having the value 1.

Equation DPLL-1c to calculate RDT_T_ACT (nominal value)

$$RDT\_T\_ACT = 1/ DT\_T\_ACT \quad \textbf{(DPLL-1c)}$$

Equation DPLL-2a1 to calculate QDT_T_ACT

Relation of the recent last two increment values for APT=p in forward direction (DIR1=0)

$$QDT\_T\_ACT = DT\_T\_ACT * RDT\_T[p-1] \quad \textbf{(DPLL-2a1)}$$

QDT_T_ACT as well as QDT_Ti have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Note: QDT_T_ACT uses a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-3 to calculate the error of last prediction

When q = NUTE-VTN considers for the error calculation only the last valid prediction values for DIR1=0:

Calculate the error of the last prediction when using only RDT_T_FS1, DT_T[p-q] and DT_T[p-1] for the prediction of DT_T[p]:

$$EDT\_T=DT\_T\_ACT-(DT\_T[p-1]*QDT\_T[p-q]) \quad \textbf{(DPLL-3)}$$

with

$$QDT\_T[p-q] = DT\_T[p-q] * RDT\_T[p-q-1] \text{ for FST} = 0 \quad \textbf{(DPLL-2b1)}$$

QDT_T[p-q] = DT_T[p-q] * RDT_T_FS1 for FST = 1 **(DPLL-2b2)**

and
FST has the meaning: NUTE = FULL_SCALE (see NUTC register)
while
QDT_T_ACT as well as QDT_Ti have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Note: QDT_T[p-q] uses a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-4 to calculate the weighted average error

for SYT=1 calculate:

MEDT_T:= (EDT_T + MEDT_T)/2 **(DPLL-4)**

Equations DPLL-5 to calculate the current increment value

nominal increment value:

CDT_TX _nom = (DT_T_ACT + MEDT_T)* QDT_T[p-q+1] **(DPLL-5a)**

with (for q>1):

QDT_T[p-q+1] = DT_T[p-q+1] * RDT_T[p-q] **(DPLL-2c)**

and for q=1 use equation DPLL-2a1.
while
QDT_T_ACT as well as QDT_Ti have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

and the expected duration to the next TRIGGER event

CDT_TX = CDT_TX _nom * SYN_T **(DPLL-5b)**

Note: QDT_T[p-q+1] uses a 6 bit integer part and a 18 bit fractional part.

Note: In the case of an overflow in equations DPLL-5a or b set the value to 0xFFFFFF and the corresponding CTO bit in the DPLL_STATUS register. In the case of negative values set CDT_TX to 0x0 without any effect to the CTO bit.

25.16.6.3 Increment prediction in Emergency Mode forwards (DIR2=0)

Please note, that the ascending order of calculations for STATE and storage of the values in the RAM region 1C must be hold in order not to lose results still needed. The same considerations as done for DT_T_ACT are valid for DT_S_ACT (equation DPLL-6a4…7, DPLL-6b1 and DPLL-6c1): update TD_Si only after calculations of equation DPLL-14.

When using filter information of STATE_FT, selected by IDS=1, it must be distinguished by IFP, if this filter information is time or position related:

In order to make possible to perform the automatic resolution corrections of equations DPLL-6a1a the filter unit in TIM must operate using the time stamp clock.

Equations DPLL-6a to calculate STATE time stamps

For calculation of time stamps use the filter delay information and use p=APS while DIR2=0:

TS_S=STATE_TS (for IDS=0, received unchanged value) **(DPLL-6a0)**

TS_S=TS_S - FTV_Sx (for IDS=1 and IFP=0) **(DPLL-6a1)**

with

FTV_Sx = FTV_S/8 (for LOW_RES = 1 and TS0_HRS = 0) **(DPLL-6a1a)**

FTV_Sx = FTV_S (for LOW_RES = 0 or TS0_HRS = 1) **(DPLL-6a1b)**

and

TS_S=TS_S - FTV_S *(CDT_SX/NMB_S)_old[1)] (for IDS=1 and IFP=1) **(DPLL-6a2)**

this can be also calculated using the value of ADD_IN_CALE:

TS_S=TS_S - FTV_S *(ADD_IN_CALE)_old[1)] (for IDS=1 and IFP=1) **(DPLL-6a3)**

with

see also equations DPLL-6a4 ff. at **Chapter 25.16.6.2** for TRIGGER.

1) Consider values, calculated for the last increment; position related filter values are only considered up to at least 1 ms time between two STATE events. The reciprocal value is stored using a 32 bit fractional part, while only the 24 lower bits are used - for explanation see note 4) at DPLL_CTRL0 register. The value of 1/ADD_IN_CALE_old or (CDT_SX/NMB_S)_old is set to 0xFFFFFF in case of an overflow.

Note: CDT_SX is the predicted duration of the last STATE increment and NMB_S the calculated number of SUB_INC1 events in the last increment, because the new calculations are done by equations DPLL-10 and DPLL-22 respectively for the current increment after that. Therefore in equation DPLL-6a3 the value ADD_IN of the last increment is used (see equation DPLL-26). SYN_S_OLD is the number of increments including missing STATEs as specified in the NUSC register for the last increment with the initial value of 1. The update to the RAM region 1C4 is done after all related calculations (see equation DPLL-6d -after DPLL-14- for this reason).

Equation DPLL-6b to calculate DT_S_ACT (nominal value)

$$DT\_S\_ACT = (TS\_S - TS\_S\_OLD)/SYN\_S\_OLD \quad \textbf{(DPLL-6b)}$$

For the case SYS=0 (still no synchronization to the profile) the values SYN_S and SYN_S_OLD are still assumed as having the value 1.

Equation DPLL-6c to calculate RDT_S_ACT (nominal value)

$$RDT\_S\_ACT = 1/ DT\_S\_ACT \quad \textbf{(DPLL-6c)}$$

Equation DPLL-7a1 to calculate QDT_S_ACT

for APS=p in forward direction (DIR2=0)

$$QDT\_S\_ACT = DT\_S\_ACT * RDT\_S[p-1] \quad \textbf{(DPLL-7a1)}$$

QDT_S_ACT as well as QDT_Si have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Note: QDT_S_ACT uses a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-8 to calculate the error of last prediction

with q= NUSE-VSN when using QDT_S[p-q] and DT_S[p-1] for the prediction of DT_S[p]

EDT_S = DT_S_ACT - (DT_S[p-1] * QDT_S[p-q]) **(DPLL-8)**

and with

QDT_S[p-q] = DT_S[p-q] * RDT_S[p-q-1] for FSS = 0 **(DPLL-7b1)**

QDT_S[p-q] = DT_S[p-q] * RDT_S_FS1 for FSS = 1 **(DPLL-7b1)**

and
FSS has the meaning: NUSE = FULL_SCALE (see NUSC register)

QDT_S_ACT as well as QDT_Si have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Note: QDT_S[p-q] uses a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-9 to calculate the weighted average error

for SYS=1 calculate:

MEDT_S:= (EDT_S + MEDT_S)/2 **(DPLL-9)**

Equations DPLL-10 to calculate the current increment (nominal value)

CDT_SX _nom= (DT_S_ACT + MEDT_S)* QDT_S[p-q+1] **(DPLL-10a)**

with

QDT_S[p-q+1] = DT_S[p-q+1] * RDT_S[p-q] (for q>1) **(DPLL-7c)**

see equation DPLL-7a1 for q=1

while
QDT_S_ACT as well as QDT_Si have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

and the expected duration to the next STATE event

CDT_SX = CDT_SX _nom * SYN_S **(DPLL-10b)**

Note: QDT_S[p-q+1] uses a 6 bit integer part and a 18 bit fractional part.

Note: In the case of an overflow in equations DPLL-10a or b set the value to 0xFFFFFF and the corresponding CSO bit in the DPLL_STATUS register. In the case of negative values set CDT_SX to 0x0 without any effect to the CSO bit.

All 5 steps above (DPLL-6 to DPLL-10) are only needed in emergency mode. For the normal mode the calculations of equations DPLL-6 and DPLL-7 are done solely in order to get the values needed for a sudden switch to emergency mode.

25.16.6.4 Increment prediction in Normal Mode backwards (DIR1=1)

Equations DPLL-2a2 to calculate QDT_T_ACT backwards

QDT_T_ACT = DT_T_ACT * RDT_T[p+1] **(DPLL-2a2)**

QDT_T_ACT as well as QDT_Ti have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-3a to calculate of the error of last prediction

When q = NUTE-VTN and DIR1=1 using only RDT_T[p+q+1], DT_T[p+q] and DT_T[p+1] for the prediction of DT_T[p]

EDT_T=DT_T_ACT-(DT_T[p+1]*QDT_T[p+q] **(DPLL-3a)**

with

QDT_T[p+q] = DT_T[p+q] * RDT_T[p+q+1] for FST = 0 **(DPLL-2b3)**

QDT_T[p+q] = DT_T[p+q] * RDT_T_FS1 for FST = 1 **(DPLL-2b4)**

and

FST has the meaning: NUTE = FULL_SCALE (see NUTC register)

QDT_T_ACT as well as QDT_Ti have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-4 to calculate the weighted average error

For SYT=1 calculate:

$$MEDT\_T := (EDT\_T + MEDT\_T)/2 \quad \textbf{(DPLL-4)}$$

Equation DPLL-5 to calculate the current increment value

$$CDT\_TX\_nom = (DT\_T\_ACT + MEDT\_T) * QDT\_T[p+q-1] \quad \textbf{(DPLL-5a1)}$$

with

$$QDT\_T[p+q-1] = DT\_T[p+q-1] * RDT\_T[p+q] \quad (\text{for } q>1) \quad \textbf{(DPLL-2c1)}$$

for q=1 use equation DPLL-2a1.

while

QDT_T_ACT as well as QDT_Ti have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

and the expected duration to the next TRIGGER event

$$CDT\_TX = CDT\_TX\_nom * SYN\_T \quad \textbf{(DPLL-5b)}$$

Note: In the case of an overflow (or negative values) in equations DPLL-5a1 or b set the value to 0xFFFFFF and the corresponding CTO bit in the DPLL_STATUS register. In case of negative values CDT_TX(_nom) to 0x0.

25.16.6.5 Increment prediction in Emergency Mode backwards (DIR2=1)

Equation DPLL-7a2 to calculate QDT_S_ACT backwards

$$QDT\_S\_ACT = DT\_S\_ACT * RDT\_S[p+1] \quad \textbf{(DPLL-7a2)}$$

QDT_S_ACT as well as QDT_Si have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-8a to calculate the error of the last prediction

While q= NUSE-VSN, use only QDT_S[p+q] and DT_S[p+1] for the prediction of DT_S[p]

EDT_S = DT_S_ACT - (DT_S[p+1] * QDT_S[p+q]) **(DPLL-8a)**

with

QDT_S[p-q] = DT_S[p+q] * RDT_S[p+q+1] for FSS = 0 **(DPLL-7b3)**

QDT_S[p-q] = DT_S[p+q] * RDT_S_FS1 for FSS = 1 **(DPLL-7b4)**

and
FSS has the meaning: NUSE = FULL_SCALE (see NUSC register)

QDT_S_ACT as well as QDT_Si have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-9 to calculate the weighted average error

For SYS=1 calculate:

MEDT_S:= (EDT_S + MEDT_S)/2 **(DPLL-9)**

Equations DPLL-10 to calculate the current increment value

CDT_SX _nom= (DT_S_ACT + MEDT_S)* QDT_S[p+q-1] **(DPLL-10a1)**

with

QDT_S[p+q-1] = DT_S[p+q-1] * RDT_S[p+q] (for q>1) **(DPLL-7c1)**

for q=1 use equation DPLL-7a.

while

QDT_S_ACT as well as QDT_Si have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

and calculate the expected duration to the next STATE event

CDT_SX = CDT_SX _nom * SYN_S **(DPLL-10b)**

Note: In the case of an overflow (or negative values) in equations DPLL-10a1 or b set the value to 0xFFFFFF and the corresponding CSO bit in the DPLL_STATUS register. In case of negative values CDT_TX(_nom) to 0x0.

All 5 steps above (DPLL-6 to DPLL-10) are only needed in emergency mode. For the normal mode the calculations of equations DPLL-6 and DPLL-7 are done solely in order to get the values needed for a sudden switch to emergency mode.

25.16.7 Calculations for actions

As already shown for the calculation of the current interval by equations DPLL-1 to DPLL-10 for the prediction of actions a similar calculation is to be done, as shown by the equations DPLL-11. to DPLL-14. The calculation of actions is also needed when the DPLL is used for synchronous motor control applications (SMC=1, see DPLL_CTRL_1 register). For action prediction purposes the measured time periods of the past (one FULL_SCALE back, when the corresponding NUTE or NUSE values are set properly by the CPU) are used. The calculation can be explained by the following assumptions, which are considerably simple:

Take the corresponding increments for prediction in the past and put the sum of it in relation to the increment (DT_T[k], DT_S[k], with k > 0, which is represented by the time stamp difference) which is exactly one FULL_SCALE period in the past (DPLL-11 or DPLL-13 respectively). Make a prediction for the coming sum of increments using the current measured increment (DT_T_ACT or DT_S_ACT respectively, that means DPLL-1 or DPLL-6 respectively) and add a weighted average error (DPLL-3 and DPLL-4 or DPLL-8 and DPLL-9 respectively, calculated for one increment prediction) before multiplication with the relation of equation DPLL-11 or DPLL-13 respectively in order to get the result as described by equations DPLL-12 or DPLL-14 respectively.

In order to avoid division operations instead of the increment (DT_T[k], DT_S[k] with k > 0) in the past its reciprocal value (RDT_T[k], RDT_S[k] with k > 0) is used, which is stored also in RAM.

For the calculation of actions perform always a new refined calculation as long as the resulting time stamp is not in the past. In the other case the tsac/psac values (time/position stamp of action calculated) is set to the time/position stamp of the last input event (TRIGGER/STATE), the ACT_Ni bit in the DPLL_ACT_STA register is reset, while the corresponding ACT_Ni bit in the DPLL_ACT_STA_shadow register is set. Each new PMTR_i value will set this ACT_Ni bit again and reset the correspondent shadow bit until a new calculation is performed.

Action updates at highest speed

Up to 32 action values can be calculated. For the shortest increment durations (23,4 µs) not all of them can be updated with each valid input event. Please notice the following conditions and parameters for an estimation of possible results.

All time estimation values are given for a system clock frequency of 100 MHz and the assumption, that the calculation of the DPLL is not impeded by a remote read or write access to the DPLL RAMs. Each RAM access is to be considered by an additional delay of about 40 ns (tremote_RAM_access, to be precised later). When using a different system clock frequency the calculation duration is extended accordingly.

1.) Typical time needed for basic operations (RAM update, pointer calculation and SUB_INC generation for normal, emergency mode or one PMSM:

tbasic_0 = 9,9 µs

2.) Typical time needed basic operations (RAM update, pointer calculation and SUB_INC generation for two PMSMs:

tbasic_1 = 11,0 µs

3.) Typical time needed to calculate one action

taction_i = 3,7 µs

Please notice that the above mentioned values are observed worst case values, when the two state machines of TRIGGER and STATE are both in operation.

These values allow the calculation of at least 2 action values for each input event for all specified increment durations. The complete time needed for the basic operation, n action calculations and k remote RAM access operations can be calculated as follows

tcomplete = tbasic_0/1 + n*taction_i + k*tremote_RAM_access.

Typical applications

Normal and emergency mode

For a typical application with the shortest increment duration of 100 µs in normal or emergency mode the calculation of up to 24 action values can be performed for each valid input event.

One PMSM

For one PMSM and a typical shortest increment time of 39 µs there is the calculation of up to 7 action values possible for each input event.

Two PMSMs with restricted action calculations

When only one PMSM uses the action calculation service an the shortest increment duration is 39 µs, there can up to 7 actions served for each valid input event.

Two PMSMs with unrestricted action calculations

When 2 PMSMs are used and both use the action calculation service at a minimal increment duration of 39 µs there are up to 7 action calculations possible for each of the two engines - that means up to 14 action calculations per increment in average.

25.16.7.1 Action calculations for TRIGGER forwards

valid for RMO=0 or for SMC=1 with

p=APT_2B, t=APT, m=NA[i] (part w), mb=NA[i](part b)/1024, NUTE-VTN=q, NUTE=n

Equation DPLL-11a1 to calculate the time prediction for an action

For DIR1=0 and q>m calculate:

PDT_T[i] = (TSF_T[p+m-n] - TSF_T[p-n] + mb* DT_Tx[t-q+1]) * RDT_T[t-q] **(DPLL-11a1)**

with

DT_Tx[t-q+1] = DT_T[t-q+1] for TS0_HRT=0 **(DPLL-11b2)**

or

DT_Tx[t-q+1] = DT_T[t-q+1]/8 for TS0_HRT=1 **(DPLL-11b3)**

and while the multiplication with mb does mean the fractional part of NA[i].

For SMC=0 and RMO=0 calculate for DIR1=0 all 32 actions in forward direction, if requested; in the case SMC=1 calculate up to 16 actions 0 to 15 in dependence of the TRIGGER input.

Equation DPLL-11a2 to calculate the time prediction for an action

For SYT=1, NUTE= 2*(TNU+1), q>m and DIR1=0 equation DPLL-11a2 is equal to

PDT_T[i] = (TSF_T[p+m] - TSF_T[p]+ mb* DT_Tx[t-q+1]) * RDT_T[t] **(DPLL-11a2)**

with

DT_Tx[t-q+1] = DT_T[t-q+1] for TS0_HRT=0 **(DPLL-11b2)**

or

DT_Tx[t-q+1] = DT_T[t-q+1]/8 for TS0_HRT=1 **(DPLL-1b3)**

Equation DPLL-11b to calculate the time prediction for an action

for DIR1=0, NUTE-VTN=q, q (< or =) m, n>1 and t=APT:

PDT_T[i] = (m+mb)*DT_Tx[t-q+1] * RDT_T[t-q] **(DPLL-11b)**

with

DT_Tx[t-q+1] = DT_T[t-q+1] for TS0_HRT=0 **(DPLL-11b2)**

or

DT_Tx[t-q+1] = DT_T[t-q+1]/8 for TS0_HRT=1 **(DPLL-11b3)**

Note: Note: Make the calculations above before updating the TSF_T[i] values according to equations DPLL-1c3 ff.

Equation DPLL-11c to calculate the time prediction for an action

for n=1 (this is always valid for SYT=0)

PDT_T[i] = (m+mb)* DT_T_ax * RDT_T[t-1] **(DPLL-11c)**

with

DT_T_ax = DT_T_ACT for TS0_HRT=0 **(DPLL-1a4a)**

or

DT_T_ax = DT_T_ACT/8 for TS0_HRT=1 **(DPLL-1a4b)**

Note: For the relevant last increment add the fractional part of DT_T_ACT as described in NA[i].

Equation DPLL-12 to calculate the duration value until action

DTA[i] = (DT_T_ACT + MEDT_T)* PDT_T[i] **(DPLL-12)**

Note: All 5 steps in equations DPLL-11 to DPLL-12 are only calculated in normal mode.

25.16.7.2 Action calculations for TRIGGER backwards

valid for RMO=0 or for SMC=1

p=APS_1C2, t=APS, m=Nai(part w) mb=Nai(part b)/1024, NUSE-VSN = q≥m and NUSE=n

For SMC=0 and RMO=0 calculate for DIR1=1 all 32 actions in backward direction for special purposes; in the case SMC=1 calculate up to 16 actions 0 to 15 in dependence of the TRIGGER input.

Equation DPLL-11a3 to calculate the time prediction for an action

For DIR1= 1 and q>m calculate

PDT_T[i] = (TSF_T[p-m+n] - TSF_T[p+n] + mb* DT_Tx[t+q+1]) * RDT_T[t+q] **(DPLL-11a3)**

with

DT_Tx[t+q+1] = DT_T[t+q+1] for TS0_HRT=0 **(DPLL-11b4)**

or

DT_Tx[t+q+1] = DT_T[t+q+1]/8 for TS0_HRT=1 **(DPLL-11b5)**

Equation DPLL-11a4 to calculate the time prediction for an action

For SYT=1 and NUTE = 2*(TNU+1), q>m, VTN=2*SYN_NT and hence NUTE-VTN = 2*(TNU+1-SYN_NT) for DIR1=1 this is equal to

PDT_T[i] = (TSF_T[p-m] - TSF_T[p]+ mb* DT_Tx[t+q+1]) * RDT_T[t] **(DPLL-11a4)**

with

DT_Tx[t+q+1] = DT_T[t+q+1] for TS0_HRT=0 **(DPLL-11b4)**

or

DT_Tx[t+q+1] = DT_T[t+q+1]/8 for TS0_HRT=1 **(DPLL-11b5)**

Note: Make the calculations above before updating the TSF_T[i] values according to equations DPLL-1c3 ff.

Equation DPLL-11b1 to calculate the time prediction for an action

For NUTE-VTN =q, q (< or =) m the following equation is valid for n>1 and t=APT:

PDT_T[i] = (m+mb)*DT_Tx[t+q-1] * RDT_T[t+q] **(DPLL-11b1)**

with

DT_Tx[t+q-1] = DT_T[t+q-1] for TS0_HRT=0 **(DPLL-11b4)**

or

DT_Tx[t+q-1] = DT_T[t+q-1]/8 for TS0_HRT=1 **(DPLL-11b5)**

Equation DPLL-11c1 to calculate the time prediction for an action

for n=1 (this is always valid for SYT=0)

PDT_T[i] = (m+mb)* DT_T_ax * RDT_T[t+1] **(DPLL-11c1)**

with

DT_T_ax = DT_T_ACT for TS0_HRT=0 **(DPLL-1a4a)**

or

DT_T_ax = DT_T_ACT/8 for TS0_HRT=1 **(DPLL-1a4b)**

Note: For the relevant last increment add the fractional part of DT_T_ACT as described in NA[i].

Equation DPLL-12 to calculate the duration value for an action

DTA[i] = (DT_T_ACT + MEDT_T)* PDT_T[i] **(DPLL-12)**

Use the results of equations DPLL-1a, b, DPLL-3 and DPLL-4 for the above calculation

Note: Note: All 5 steps in equations DPLL-11 to DPLL-12 are only calculated in normal mode or when SMC=1.

25.16.7.3 Action calculations STATE forwards

valid for RMO=1

p=APS_1C2, t=APS, m=NA[i](part w) mb=NA[i9](part b)/1024, NUSE-VSN = q and NUSE=n>m

For SMC=0 and RMO=1 calculate for DIR2=0 all 32 actions in forward direction, if requested; in the case SMC=1 and RMO=1 calculate up to 16 actions 16 to 31 in dependence of the STATE input.

Equation DPLL-13a1 to calculate the time prediction for an action

For DIR2=0 and q>m calculate:

PDT_S[i] = (TSF_S[p+m-n] - TSF_S[p-n] + mb* DT_Sx[t-q+1]) * RDT_S[t-q] **(DPLL-13a1)**

with

DT_Sx[t-q+1] = DT_S[t-q+1] for TS0_HRS=0 **(DPLL-13b2)**

or

DT_Sx[t-q+1] = DT_S[t-q+1]/8 for TS0_HRS=1 **(DPLL-13b3)**

Equation DPLL-13a2 to calculate the time prediction for an action

For SYS=1 and NUSE=2*(SNU+1), q>m, SYSF=0, VSN=2*SYN_NS and hence NUSE-VSN = 2*(SNU+1-SYN_NS) equation DPLL-13a1 is equal to

PDT_S[i] = (TSF_S[p+m] - TSF_S[p]+ mb* DT_Sx[t-q+1]) * RDT_S[t] **(DPLL-13a2)**

with

DT_Sx[t-q+1] = DT_S[t-q+1] for TS0_HRS=0 **(DPLL-13b2)**

or

DT_Sx[t-q+1] = DT_S[t-q+1]/8 for TS0_HRS=1 **(DPLL-13b3)**

Equation DPLL-13b to calculate the time prediction for an action

For NUSE-VTN =q, q (< or =) m and n>1:

PDT_S[i] = (m+mb)*DT_Sx[t-q+1] * RDT_S[t-q] **(DPLL-13b)**

with

DT_Sx[t-q+1] = DT_S[t-q+1] for TS0_HRS=0 **(DPLL-13b2)**

or

DT_Sx[t-q+1] = DT_S[t-q+1]/8 for TS0_HRS=1 **(DPLL-13b3)**

Equation DPLL-13c to calculate the time prediction for an action

for n=1

PDT_S[i] = (m+mb)* DT_S_ax * RDT_S[t-1] **(DPLL-13c)**

with

DT_S_ax = DT_S_ACT for TS0_HRS=0 **(DPLL-6a4a)**

or

DT_S_ax = DT_S_ACT/8 for TS0_HRS=1 **(DPLL-6a4b)**

Equation DPLL-14 to calculate the duration value for an action

DTA[i] = (DT_S_ACT + MEDT_S)* PDT_S[i] **(DPLL-14)**

Use the results of DPLL-7, DPLL-8 and DPLL-9 for the above calculation

Note: All 5 steps of equations DPLL-13 to DPLL-14 are only calculated in emergency mode or for SMC=1 in combination with RMO=1.

25.16.7.4 Action calculations for STATE backwards

valid for RMO=1 with

p=APS_1C2, t=APS, m=NA[i](part w) mb=NA[i](part b)/1024, NUSE-VSN = q and NUSE=n

For SMC=0 and RMO=1 calculate for DIR1=1 all 32 actions in backwards mode for special purposes; in the case SMC=1 and RMO=1 calculate up to 16 actions 16 to 31 in dependence of the STATE input.

Equation DPLL-13a3 to calculate the time prediction for an action

For (DIR2= 1 (SMC=1) or DIR1=1 (SMC=0)) and q>m calculate

PDT_S[i] = (TSF_S[p-m+n] - TSF_S[p+n] + mb* DT_Sx[p+q-1]) * RDT_S[t+q] **(DPLL-13a3)**

with

DT_Sx[p+q-1] = DT_S[p+q-1] for TS0_HRS=0 **(DPLL-13B4)**

or

DT_Sx[p+q-1] = DT_S[p+q-1]/8 for TS0_HRS=1 **(DPLL-13b5)**

Equation DPLL-13a4 to calculate the time prediction for an action

For SYS=1, NUSE=2*(SNU+1), q>m, SYSF=0, VSN=2*SYN_NS and hence NUSE-VSN = 2*(SNU+1-SYN_NS) equation DPLL-13a3 is equal to

PDT_S[i] = (TSF_S[p-m] - TSF_S[p]+ mb* DT_Sx[p+q-1]) * RDT_S[t] **(DPLL-13a4)**

with

DT_Sx[p+q-1] = DT_S[p+q-1] for TS0_HRS=0 **(DPLL-13b4)**

or

DT_Sx[p+q-1] = DT_S[p+q-1]/8 for TS0_HRS=1 **(DPLL-13b5)**

Equation DPLL-13b1 to calculate the time prediction for an action

For NUSE-VSN =q, q (< or 0) NUSE=n and n>1:

PDT_S[i] = m*DT_Sx[t+q-1] * RDT_S[t+q] **(DPLL-13b1)**

with

DT_Sx[p+q-1] = DT_S[t+q-1] for TS0_HRS=0 **(DPLL-13b4)**

or

DT_Sx[p+q-1] = DT_S[t+q-1]/8 for TS0_HRS=1 **(DPLL-13b5)**

Equation DPLL-13c1 to calculate the time prediction for an action

for n=1

PDT_S[i] = (m+mb)* DT_S_ax * RDT_S[t+1] **(DPLL-13c1)**

with

DT_S_ax = DT_S_ACT for TS0_HRS=0 **(DPLL-6a4a)**

or

DT_S_ax = DT_S_ACT/8 for TS0_HRS=1 **(DPLL-6a4b)**

Equation DPLL-14 to calculate the duration value until action

DTA[i] = (DT_S_ACT + MEDT_S)* PDT_S[i] **(DPLL-14)**

Use the results of DPLL-7, DPLL-8 and DPLL-9 for the above calculation

Note: All 5 steps of equations DPLL-13 to DPLL-14 are only calculated in emergency mode or for SMC=1 in combination with RMO=1.

25.16.7.5 Update of RAM in Normal and Emergency Mode

After considering the calculations for up to all 24 actions according to equations (DPLL-11, DPLL-12), only when going back to state 1 or 21 (because of a new TRIGGER or STATE event, that means when no further PMTR values are to be considered) set time stamp values and durations of increments in the RAM.

Equation DPLL-1a4 to update the time stamp values for TRIGGER

TSF_T[s]=TS_Tx
using the following equations for the determination of TS_Tx **(DPLL-1a4)**

For TS0_HRT=0:

TS_Tx=TS_T **(DPLL-1a4w)**

DT_T_ax = DT_T_ACT **(DPLL-1a4a)**

For TS0_HRT=1:

TS_Tx(20:0)=TS_T/8 **(DPLL-1a4x)**

TS_Tx(23:21)=TBU_TS0_T(23:21) **(DPLL-1a4y)**

for TBU_TS0_T(20:0) > or = TS_Tx(20:0)

TS_Tx(23:21)=TBU_TS0_T(23:21) -1 **(DPLL-1a4z)**

for TBU_TS0_T(20:0) < TS_Tx(20:0)

DT_T_ax = DT_T_ACT/8 **(DPLL-1a4b)**

Note: The combination of values LOW_RES=0 and TS0_HRT=1 is not possible.

Store the time stamp values in the time stamp field according to the address pointer APT_2B=s, but make this update only after the calculation of actions **Section 25.16.7** because the old TSF_T[i] values are still needed for these calculations. Please note that the address pointer after a gap is still increment by SYN_T_OLD in that case (see state machine step 1 in **Section 25.16.8.6**).

Equation DPLL-1a5-7 to extend the time stamp values for TRIGGER in forward direction

when SYT=1 and SYN_T_OLD=r>1 and DIR1=0

TSF_T[s-1] = TSF_T[s] -DT_T_ax **(DPLL-1a5)**

TSF_T[s-2] = TSF_T[s-1] -DT_T_ax **(DPLL-1a6)**

until

TSF_T[s- r+1] = TSF_T[s- r+2] -DT_T_ax **(DPLL-1a7)**

after the incrementation of the pointer APT_2B by SYN_T_OLD

Equations DPLL-1a5-7 for backward direction

when SYT=1 and SYN_T_OLD=r>1 and DIR1=1

TSF_T[s+1] = TSF_T[s] -DT_T_ax **(DPLL-1a5)**

TSF_T[s+2] = TSF_T[s+1] -DT_T_ax **(DPLL-1a6)**

until

TSF_T[s+r-1] = TSF_T[s+r-2] -DT_T_ax **(DPLL-1a7)**

after the decrementation of the pointer APT_2B by SYN_T_OLD

Equations DPLL-1b1 and DPLL-1c1 to update the RAM after calculation

DT_T[p] = DT_T_ACT **(DPLL-1b1)**

save old reciprocal value from RAM before overwriting:

RDT_T_FS1= RDT_T[p] **(DPLL-1c1)**

after that store new value in RAM

RDT_T[p]= RDT_T_ACT **(DPLL-1c2)**

Store increment duration and reciprocal value in RAM region 2 in normal mode after calculation of actions only when a new valid TRIGGER slope is detected and in emergency mode directly after calculation of DT_T_ACT or RDT_T_ACT respectively.

Equation DPLL-6a4 to update the time stamp values for STATE

TSF_S[s]=TS_Sx
using the following equations for the determination of TS_Sx **(DPLL-6a4)**

For TS0_HRS=0:

TS_Sx=TS_S **(DPLL-6a4)**

DT_S_ax = DT_S_ACT **(DPLL-6a4a)**

For TS0_HRS=1:

TS_Sx(20:0)=TS_S/8 **(DPLL-6a4x)**

TS_Sx(23:21)=TBU_TS0_S(23:21) **(DPLL-6a4y)**

for TBU_TS0_S(20:0) > or = TS_Sx(20:0)

TS_Sx(23:21)=TBU_TS0_S(23:21) -1 **(DPLL-6a4z)**

for TBU_TS0_S(20:0) < TS_Sx(20:0)

DT_S_ax = DT_S_ACT/8 **(DPLL-6a4b)**

Note: The combination of values LOW_RES=0 and TS0_HRS=1 is not possible.

Store the time stamp value in the time stamp field according to the address pointer APS_1C2=s, but make this update only after the calculation of actions (equations DPLL-13a2 or DPLL-13a4, if applicable) because the old TSF_S[i] values are still needed for these calculations. Please note, that the address pointer after a gap is still increment by SYN_S_OLD in that case (see state machine step 21 in **Section 25.16.8.6**).

Equations DPLL-6a5-7 to extend the time stamp values for STATE

When SYS=1 and SYN_S_OLD=r>1 and DIR1=0 respectively calculate

TSF_S[s-1] = TSF_S[s] - DT_S_ax **(DPLL-6a5)**

TSF_S[s-2] = TSF_S[s-1] - DT_S_ax **(DPLL-6a6)**

until

TSF_S[s- r+1] = TSF_S[s- r+2] - DT_S_ax **(DPLL-6a7)**

after incrementation of the pointer APS_2B by SYN_S_OLD

Equations DPLL-6a5-7 for backward direction

When SYS=1 and SYN_S_OLD=r>1 and DIR1=1 respectively calculate

TSF_S[s+1] = TSF_S[s] - DT_S_ax **(DPLL-6a5)**

TSF_S[s+2] = TSF_S[s+1] - DT_S_ax **(DPLL-6a6)**

until

TSF_S[s+r-1] = TSF_S[s+r-2] - DT_S_ax **(DPLL-6a7)**

after the incrementation of the pointer APS_1C2 by SYN_S_OLD

Equations DPLL-6b1 and DPLL-6c1 to update the RAM after calculation

DT_S[p] = DT_S_ACT **(DPLL-6b1)**

save old reciprocal value from RAM before overwriting:

RDT_S_FS1= RDT_S[p] **(DPLL-6c1)**

after that store new value in RAM

RDT_S[p] = RDT_S_ACT **(DPLL-6c2)**

when a new valid STATE slope is detected in emergency mode or in normal mode (SMC=RMO=0) directly after calculation of the values above.

Store increment duration and reciprocal value in RAM region 1C in emergency mode after calculation of actions only when a new valid STATE slope is detected and in normal mode directly after calculation of DT_S_ACT or RDT_S_ACT respectively.

25.16.7.6 Time and position stamps for actions in Normal Mode

Equation DPLL-15 to calculate the action time stamp

TSAC[i]= DTA[i] - DLA[i] + TS_Tx (for DTA[i] > DLA[i] and DTA[i] - DLA[i] < 0x800000) **(DPLL-15a)**

TSAC[i]= TS_Tx (for DTA[i] < DLA[i]) **(DPLL-15b)**

TSAC[i]= 0x7FFFFF + TS_Tx (for DTA[i] > DLA[i] and DTA[i] - DLA[i] > 0x7FFFFF) **(DPLL-15c)**

Note: For TS_Tx see equations (DPLL-1a4 and following).

The calculation is done after the calculation of the current expected duration value according to equation DPLL-12 at **Section** The time stamp of the action can be calculated as shown above in equation DPLL-15 using the delay value of the action and the current time stamp.

Equations DPLL-17 to calculate the position stamp forwards

for DIR1=0 and TS0_HRT=0:

PSAC[i] = PSA[i] - (DLA[i]*RCDT_TX_NOM)*(MLT+1) **(DPLL-17)**

with

RCDT_TX_NOM= RCDT_TX * SYN_T **(DPLL-17a)**

and

RCDT_TX= 1/CDT_TX **(DPLL-17b)**

for DIR1=0 and TS0_HRT=1:

PSAC[i] = PSA[i] - (8*DLA[i]*RCDT_TX_NOM)*(MLT+1) **(DPLL-17d)**

with

RCDT_TX_NOM= RCDT_TX * SYN_T (DPLL-17a)

and

RCDT_TX= 1/CDT_TX **(DPLL-17b)**

replace (MLT+1) in equations (DPLL-17) and (DPLL-17d) by MLS1 for SMC=1

use the calculated value of (DPLL-17b) also for the generation of SUB_INCi

and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D_i

The action is to be updated for each new TRIGGER event until the calculated time stamp is in the past. In this case use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

Equations DPLL-17 to calculate the position stamp backwards

For DIR1=1 and TS0_HRT=0:

PSAC[i] = PSA[i] + (DLA[i]*RCDT_TX_NOM)*(MLT+1) **(DPLL-17c)**

with

RCDT_TX_NOM= RCDT_TX * SYN_T **(DPLL-17a)**

and

RCDT_TX= 1/CDT_TX **(DPLL-17b)**

For DIR1=1 and TS0_HRT=1:

PSAC[i] = PSA[i] + (8*DLA[i]*RCDT_TX_NOM)*(MLT+1) **(DPLL-17e)**

with

RCDT_TX_NOM= RCDT_TX * SYN_T **(DPLL-17a)**

and

RCDT_TX= 1/CDT_TX **(DPLL-17b)**

replace (MLT+1) in equations (DPLL-17c) and (DPLL-17e) by MLS1 for SMC=1

use the calculated value of (DPLL-17b) also for the generation of SUB_INCi

and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D_i
