The action is to be updated for each new TRIGGER event until the calculated time stamp is in the past.In this case use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

25.16.7.7 The use of the RAM

The RAM is used to store the data of the last FULL_SCALE period. The use of single port RAMs is recommended. The data width of the RAM is usual 3 bytes, but could be extended to 4 bytes in future applications. There are 3 different RAMs, each with separate access ports. the RAM 1A is used to store the position minus time requests, got from the ARU. No CPU access is possible to this RAM during operation (when the DPLL is enabled).

Ram 1B is used for configuration parameters and variables needed for calculations. Within RAM 1C the values of the STATE events are stored. RAM 1B and RAM 1C do have a common access port and are also marked as RAM 1BC in order to clarify this fact.

RAM 2 is used for values of the TRIGGER events.

Because of the access of the DPLL internal state machine at the one side and the CPU at the other side the access priority has to be controlled for both RAMs 1BC and 2. The access priority is defined as stated below. The CPU access procedure via AE-interface goes in a wait state (waiting for data valid) while it needs a colliding RAM access during serving a corresponding state machine RAM access. In order not to provoke unexpected behaviour of the algorithms the writing of the CPU to the RAM regions 1B, 1C or 2 will be monitored and results in interrupt requests when enabled.

CPU access is specified at follows:

1. CPU has highest priority for a single read/write access. The DPLL algorithm is stalled during external bus RAM accesses.

2. After serving the CPU access to the RAM the DPLL gets the highest RAM access priority for 8 clock cycles. Afterwards continue with 1.

The RAM address space has to be implemented in the address space of the CPU.

25.16.7.8 Time and position stamps for actions in Emergency Mode

Equation DPLL-18 to calculate the action time stamp

TSAC[i]= DTA[i] - DLA[i] + TS_Sx (for DTA[i] > DLA[i] and DTA[i] - DLA[i] < 0x800000) **(DPLL-18a)**

TSAC[i]= TS_Sx (for DTA[i] < DLA[i]) **(DPLL-18b)**

TSAC[i]= 0x7FFFFF + TS_Sx (for DTA[i] > DLA[i] and DTA[i] - DLA[i] > 0x7FFFFF) **(DPLL-18c)**

Note: For TS_Sx see equations (DPLL-6a4 and following), ***Section*** *.*

The calculation is done after the calculation of the current expected duration value according to equation DPLL-14 at **Section** . The time stamp of the action can be calculated as shown in equation DPLL-18 using the delay value of the action and the current time stamp.

Equations DPLL-20 to calculate the position stamp forwards

for DIR1=0 respectively and TS0_HRS=0:

PSAC[i] = PSA[i] - (DLA[i]*RCDT_SX_NOM)*MLS1 **(DPLL-20)**

with

RCDT_SX_NOM= RCDT_SX * SYN_S **(DPLL-20a)**

and

RCDT_SX= 1/CDT_SX **(DPLL-20b)**

for DIR2=0 or DIR1=0 respectively and TS0_HRS=1:

PSAC[i] = PSA[i] - (8*DLA[i]*RCDT_SX_NOM)*MLS1 **(DPLL-20d)**

with

RCDT_SX_NOM= RCDT_SX * SYN_S **(DPLL-20a)**

and

RCDT_SX= 1/CDT_SX **(DPLL-20b)**

replace MLS1 in equations (DPLL-20) and (DPLL-20d) by MLS2 for (SMC=1 and RMO=1)

use the calculated value of (DPLL-20b) also for the generation of SUB_INCi.

and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D.

The action is to be updated for each new STATE event until the event is in the past. In this case use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

Equations DPLL-20 to calculate the position stamp backwards

For DIR2=1 or DIR1=1 respectively and TS0_HRS=0:

PSAC[i] = PSA[i] + (DLA[i]*RCDT_SX_NOM)*MLS1 **(DPLL-20c)**

with

RCDT_SX_NOM= RCDT_SX * SYN_S **(DPLL-20a)**

and

RCDT_SX= 1/CDT_SX **(DPLL-20b)**

For DIR2=1 or DIR1=1 respectively and TS0_HRS=1:

PSAC[i] = PSA[i] + (8*DLA[i]*RCDT_SX_NOM)*MLS1 **(DPLL-20e)**

with

RCDT_SX_NOM= RCDT_SX * SYN_S **(DPLL-20a)**

and

RCDT_SX= 1/CDT_SX **(DPLL-20b)**

replace MLS1 in equations (DPLL-20c) and (DPLL-20e) by MLS2 for (SMC=1 and RMO=1)

use the calculated value of (DPLL-20b) also for the generation of SUB_INCi.

and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D.

The action is to be updated for each new STATE event until the event is in the past. In this case use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

25.16.8 Signal processing

25.16.8.1 Time stamp processing

Signal processing does mean the computation of the time stamps in order to calculate at which time the outputs have to appear. For such purposes the time stamp values have to be stored in the RAM and by calculating the difference between old and new values the duration of the last time interval is determined simply. This difference should be also stored in the RAM in order to see the changes between the intervals by changing the conditions and the speed of the observed process.

25.16.8.2 Count and compare unit

The count and compare unit processes all input signals taking into account the configuration values. It uses a state machine and provides the output signals as described above.

25.16.8.3 Sub pulse generation for SMC=0

Equation DPLL-21 to calculate the number of pulses to be sent in normal mode using the automatic end mode condition

For RMO=0, SMC=0 and DMO=0

$$NMB\_T = (MLT+1)*SYN\_T + MP + PD\_store + MPVAL1 \quad \textbf{(DPLL-21)}$$

with

$$PD\_store = ADT\_T[12:0], \text{ prefetched during last increment} \quad \textbf{(DPLL-21a)}$$

$$SYN\_T = ADT\_T[18:16], \text{ prefetched during last increment}$$

$$MPVAL1 = \text{pulse correction value for PCM1\_SHADOW\_TRIGGER=1}$$

while the value for PD_store is zero for AMT=0

and

the value of MP is zero for COA=0

In order to get a higher resolution for higher speed a generator for the sub-pulses is chosen using an adder. All missing pulses MP are considered using equation DPLL-21 and are determined by counting the number of pulses of the last increment. The value SYN_T is stored from the last increment using NT of the ADT_T[i] value at RAM region 2C.

Equations DPLL-22-24 to calculate the number of pulses to be sent in emergency mode using the automatic end mode condition for SMC=0

For RMO=1, SMC=0 and DMO=0;

the value for PD_S_store is zero for AMS=0

$$NMB\_S = MLS1 * SYN\_S + MP + PD\_S\_store \quad \text{(DPLL-22)}$$

with

$$MLS1 = (MLT+1) * (TNU+1) / (SNU+1) \quad \text{(DPLL-23)}$$

PD_S_store = ADT_S[15:0], prefetched during last increment

SYN_S = ADT_S[21:16], prefetched during last increment

MPVAL1 = pulse correction value for PCM1_SHADOW_STATE=1

while the value for PD_S_store is zero for AMS=0

and

the value of MP is zero for COA=0

Please note, that these calculations above in equations DPLL-21 and DPLL-22 are only valid for an automatic end mode (DMO = 0).

For calculation of the number of generated pulses a value of 0.5 is added as shown in equations DPLL-25 or DPLL-26 respectively in order to compensate rounding down errors at the succeeding arithmetic operations. Because in automatic end mode the number of pulses is limited by INC_CNT1 it is guaranteed, that not more pulses as needed are generated and in the same way missing pulses are caught up for the next increment.

Equation DPLL-25 to calculate ADD_IN in normal mode for SMC=0

In normal mode (for RMO=0) calculate in the case LOW_RES=TS0_HRT

ADD_IN_CALN= (NMB_T+0.5) *RCDT_TX (DPLL-25)

with

RCDT_TX is the 2^{32} time value of the quotient in equation DPLL-17b

In normal mode (for RMO=0) calculate in the case LOW_RES=1 and TS0_HRT=0

ADD_IN_CALN= (NMB_T+0.5) *(RCDT_TX /8) (DPLL-25a)

with

RCDT_TX is the 2^{32} time value of the quotient in equation DPLL-17b

For RMO=0 and SMC=0:

ADD_IN_CAL1 = ADD_IN_CALN (DPLL-25b)

LOW_RES=0 and TS0_HRT=1 is not possible. For such a configuration the RCT bit in the DPLL_STATUS register is set together with the ERR bit.

In the automatic end mode (DMO = 0) missing pulses should be sent to the input RPCUx (rapid pulse catch up on) in **Adder for generation of SUB_INCx by the carry Cout**, to be caught up on with CMU_CLK0 (for COA = 0).

When normal and rapid pulses are generated simultaneously, the SUB_INCx frequency is doubled at this moment in order to count two pulses at the TBU_CHx_BASE register. In order to make the frequency doubling possible, the CMU_CLK0 should be having a frequency which does not exceed half the frequency of TS_CLK. In addition the ADD_IN value should never exceed the value 0x800000. This limitation is only necessary for DMO = 0 and COA = 0 (see DPLL_CTRL_1 register).

For the normal mode replace ADD_IN of the ADDER (see **Figure 25-75**) by ADD_IN_CAL1 (when calculated, DLM=0) or ADD_IN_LD1 (when provided by the CPU, DLM=1).

The sub-pulse generation in this case is done by the following calculations using a 24 bit adder with a carry out cout and the following inputs:

- ADD_IN
- the second input is the output of the adder, stored one time stamp clock before

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

Enabling of the compensated output for pulses

The cout of the adder influences directly the SUB_INC1 output of the DPLL (see **Figure 25-75**). The compensated output SUB_INCxc is in automatic end mode only enabled by EN_Cxc when INC_CNTx >0.

Equation DPLL-26 to calculate ADD_IN in emergency mode for SMC=0

In emergency mode (RMO=1) calculate in the case LOW_RES=TS0_HRS

$$ADD\_IN\_CALE = (NMB\_S+0.5) * RCDT\_SX \quad \text{(DPLL-26)}$$

while

RCDT_SX is the 2^{32} time value of the quotient in equation DPLL-20b

In emergency mode (RMO=1) calculate in the case LOW_RES=1 and TS0_HRS=0

$$ADD\_IN\_CALE = (NMB\_S+0.5) * RCDT\_SX / 8 \quad \text{(DPLL-26a)}$$

while

RCDT_SX is the 2^{32} time value of the quotient in equation DPLL-20b

For RMO=1 and SMC=0:

$$ADD\_IN\_CAL1 = ADD\_IN\_CALE \quad \text{(DPLL-26b)}$$

LOW_RES=0 and TS0_HRS=1 is not possible. For such a configuration the RCS bit in the DPLL_STATUS register is set together with the ERR bit.

In the automatic end mode (DMO = 0) missing pulses should be sent to the input RPCUx (rapid pulse catch up on) in **Adder for generation of SUB_INCx by the carry Cout**, to be caught up on with CMU_CLK0 (for COA = 0).

When normal and rapid pulses are generated simultaneously, the SUB_INCx frequency is doubled at this moment in order to count two pulses at the TBU_CHx_BASE register. In order to make the frequency doubling possible, the CMU_CLK0 should be having a frequency which does not exceed half the frequency of the system clock. In addition the ADD_IN value should never exceed the value 0x800000 when the TS_CLK frequency exceeds half the frequency of the system clock. This limitation is only necessary for DMO = 0 and COA = 0 (see DPLL_CTRL_1 register).

For the emergency mode replace ADD_IN of the ADDER (see **Figure 25-75**) by ADD_IN_CAL1 (when calculated, DLM=0) or ADD_IN_LD1 (when provided by the CPU, DLM=1).

The sub-pulse generation in this case is done by the following calculations using a 24 bit adder with a carry out cout and the following inputs:

- ADD_IN
- the second input is the output of the adder, stored one time stamp clock before.

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

Adder for generation of SUB_INCx by the carry C_{out}

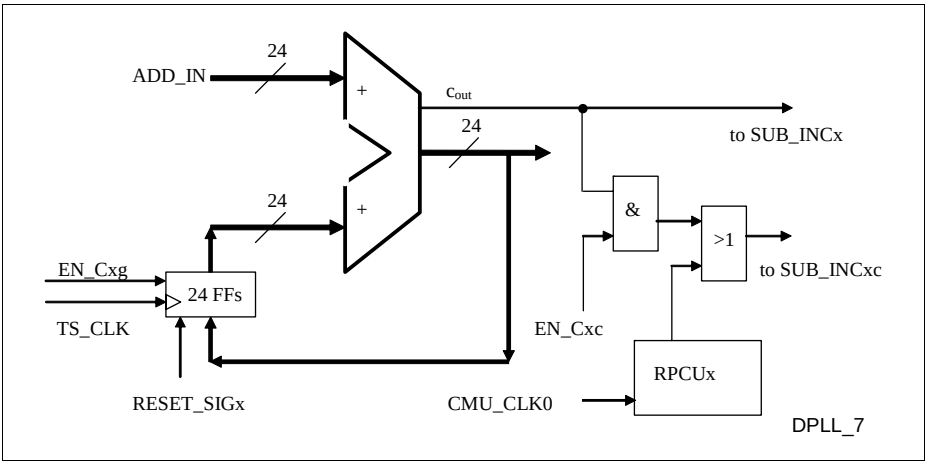

Figure 25-75 Adder for generation of SUB_INCx by the carry C_{out}

Note: The SUB_INC generation by the circuit above has the advantage, that the resolution for higher speed values is better as for a simple down counter.

After RESET and after EN_Cxg=0 the flip-flops (FFs) should have a zero value. EN_Cxg has to be zero until reliable ADD_IN values are available and the pulse generation starts. This is controlled by the configuration bits SGE1,2 in the DPLL_CONTROL_1 register. The calculated values for the increment prediction using equations DPLL-2c (**Equations DPLL-5 to calculate the current increment value**), DPLL-2c1 (**Equation DPLL-5 to calculate the current increment value**), DPLL-7c (**Equations DPLL-10 to calculate the current increment (nominal value)**) or DPLL-7c1 (**Equation DPLL-5 to calculate the current increment value**) respectively are valid only when at least NUTE>1 TRIGGER values or at least NUSE>1 STATE values are available. For NUTE =1 or

NUSE=1 respectively the equations DPLL-25 (**Equation DPLL-25 to calculate ADD_IN in normal mode for SMC=0**) and DPLL-26 (**Equation DPLL-26 to calculate ADD_IN in emergency mode for SMC=0**) use the actual increment value subtracted by the weighted average error.

The generation of SUB_INC1 pulses depends on the configuration of the DPLL.

In automatic end mode the counter INC_CNT1 resets the enable signal EN_C1 when the number of pulses desired is reached. In this case only the uncompensated output SUB_INC1 remains active in order to provide pulses for the input filter unit. A new TRIGGER input in normal mode or a new STATE input in emergency mode respectively resets the FFs and also the enable signal EN_Cxg. In the case of acceleration missing pulses can be determined at the next TRIGGER/STATE event in normal/emergency mode easily. For the correction strategy COA = 0 those missing pulses are sent out with CMU_CLK0 frequency as soon they are determined. During this time period the EN_Cxg remains cleared. After calculation or providing of a new ADD_IN value the FFs are enabled by EN_Cxg. In this way no pulse is lost. The new pulses are sent out afterwards, when INC_CNT1 is set to the desired value, maybe by adding MLT+1 or MLS1 respectively for the new TRIGGER/STATE event.

Because the used DIV procedure of the algorithms results only in integer values, a systematic failure could appear. The pulse generation at SUB_INC1 will stop in automatic end mode when the INC_CNT1 register reaches zero or all remaining pulses at a new increment will be considered in the next calculation. In this way the lost of pulses can be avoided.

When a new TRIGGER/STATE appears the value of SYN_T*(MLT+1) or SYN_S*MLS1 respectively is added to INC_CNT1, when SGE1=1. Therefore for FULL_SCALE 2*(TNU+1)*(MLT+1) pulses SUB_INC1 generated, when INC_CNT1 reaches the zero value. The generation of SUB_INC1 pulses has to be done as fast as possible. The calculations for the ADD_IN value must be done first. Therefore all values needed for calculation are to be fetched in a forecast.

25.16.8.4 Sub pulse generation for SMC=1

Necessity of two pulse generators

The Adder of **Figure 25-75** must be implemented twice in the case of SMC=1: one for SUB_INC1 controlled by the TRIGGER input and (while RMO=1) one for SUB_INC2, controlled by the STATE input. In the case described in the section above for SMC=0 only one Adder is used to generate SUB_INC1 controlled by the TRIGGER in normal mode or by STATE in emergency mode.

Equation DPLL-27 to calculate the number of pulses to be sent for the first device

using the automatic end mode condition

For SMC=1 and DMO=0

$$NMB\_T = MLS1*SYN\_T + MP + PD\_store + MPVAL1 \quad \text{(DPLL-27)}$$

with

PD_store = ADT_T[12:0], prefetched during last increment

SYN_T = ADT_T[18:16], prefetched during last increment

MPVAL1 = pulse correction value for PCM1_STADOW_TRIGGER=1

while the value for PD_store is zero for AMT=0

and

for COA=0 use zero instead of the value of MP

Equation DPLL-28 to calculate the number of pulses to be sent for the second device using the automatic end mode condition

for RMO=1, SMC=1 and DMO=0

$$NMB\_S = MLS2 *SYN\_S+ MP + PD\_S\_store + MPVAL2 \quad \text{(DPLL-28)}$$

with

PD_S_store = ADT_S[15:0], prefetched during last increment

SYN_S = ADT_S[21:16], prefetched during last increment

MPVAL2 = pulse correction value for PCM2_SHADOW_TRIGGER=1

while the value for PD_store is zero for AMS=0

and

for COA=0 use zero instead of the value of MP

Please note, that these calculations above in equations DPLL-27 and DPLL-28 are only valid for an automatic end mode (DMO = 0). In addition the number of generated pulses is added by 0.5 as shown in equations DPLL-30 or DPLL-31 respectively in order to compensate rounding down errors at the succeeding division operation. Because in automatic end mode the number of pulses is limited by INC_CNTx it is guaranteed, that not more pulses as needed are generated and in the same way missing pulses are made up for the next increment.

Equation DPLL-30 to calculate ADD_IN for the first device for SMC=1

The sub-pulse generation in this case is done by the following calculations using a 24 bit adder with a carry out cout and the following inputs:

- ADD_IN
- the second input is the (delayed) output of the adder, stored with each time stamp clock.

Replace ADD_IN by ADD_IN_CAL1 (when calculated, DLM1=0) or ADD_IN_LD1 (when provided by the CPU, DLM1=1) respectively while:

For SMC=1 and LOW_RES=TS0_HRT

$$ADD\_IN\_CAL1 = (NMB\_T + 0.5) * RCDT\_TX \quad \text{(DPLL-30)}$$

When RCDT_TX is the 2^{32} time value of the quotient in equation DPLL-17b.

For SMC=1,LOW_RES= 1 and TS0_HRT=0

$$ADD\_IN\_CAL1 = (NMB\_T + 0.5) * (RCDT\_TX / 8) \quad \text{(DPLL-30a)}$$

When RCDT_TX is the 2^{32} time value of the quotient in equation DPLL-17b.

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

ADD_IN_CAL1 is a 24 bit integer value. The CDT_TX is the expected duration of current TRIGGER increment.

The cout of the adder influences directly the SUB_INC1 output of the DPLL (see **Section**). The SUB_INC1 output is in automatic end mode only enabled by EN_C1 when INC_CNT1 >0.

Equation DPLL-31 to calculate ADD_IN for the second device for SMC=1

Replace ADD_IN by ADD_IN_CAL2 (when calculated, DLM2=0) or ADD_IN_LD2 (when provided by the CPU, DLM2=1) respectively while:

for SMC=1, RMO=1 and LOW_RES=TS0_HRS:

$$ADD\_IN\_CAL2 = (NMB\_S + 0.5) * RCDT\_SX \quad \text{(DPLL-31)}$$

When RCDT_SX is the 2^{32} time value of the quotient in equation DPLL-20b.

for SMC=1, RMO=1, LOW_RES=1 and TS0_HRS=0:

ADD_IN_CAL2= (NMB_S+0.5)* (RCDT_SX/8) (DPLL.31a)

When RCDT_SX is the 2^{32} time value of the quotient in equation DPLL-20b.

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

The cout of the adder2 influences directly the SUB_INC2 output of the DPLL (see **Adder for generation of SUB_INCx by the carry Cout**).

The SUB_INC2 output is in automatic end mode only enabled by EN_C2 when INC_CNT2 >0.

Please note, that after RESET and after EN_Cxc=0 (after stopping in automatic end mode) the flip-flops (FFs) have a zero value and also EN_Cxg has to be zero until reliable ADD_IN values are available and the pulse generation starts. The calculated values for the increment prediction using equations DPLL-2c **Equations DPLL-5 to calculate the current increment value**, DPLL-2c1 **Equation DPLL-5 to calculate the current increment value**, DPLL-7c **Equations DPLL-10 to calculate the current increment (nominal value)** or DPLL-7c1 **Section** respectively are valid only when NUTE>1 or NUSE>1 respectively. For NUTE=1 or NUSE=1 respectively the equations DPLL-30 (see **Equation DPLL-30 to calculate ADD_IN for the first device for SMC=1**) and DPLL-31 (see **Equation DPLL-31 to calculate ADD_IN for the second device for SMC=1**) use the actual increment value subtracted by the weighted average error.

The generation of SUB_INCx pulses depends on the configuration of the DPLL.

In automatic end mode the counter INC_CNTx resets the enable signal EN_Cxcu when the number of pulses desired is reached. In this case only the uncompensated outputs SUB_INCx remain active in order to provide pulses for the input filter units. A new TRIGGER or STATE input respectively can reset the FFs and also ADD_IN, especially when EN_Cxc was zero before. In the case of acceleration missing pulses can be determined at the next TRIGGER/STATE event easily. For the correction strategy COA = 0 those missing pulses are sent out with maximum frequency as soon they are determined. After that the pulse counter INC_CNTx should be always zero and the new pulses are sent out afterwards, when INC_CNTx is set to the desired value by adding MLS1 or MLS2 for the new TRIGGER or STATE event respectively.

Because the used DIV procedure of the algorithms results only in integer values, a systematic failure could appear. The pulse generation will stop when the INC_CNTx register reaches zero or all remaining pulses at a new increment will be considered in the next calculation. In this way the lost of pulses can be avoided.

When a new TRIGGER appears the value of SYN_T*MLS1 is added to INC_CNT1. Therefore for FULL_SCALE 2*(TNU+1)*MLS1 pulses SUB_INC1 generated, when

INC_CNT1 reaches the zero value. The generation of SUB_INC1 pulses has to be done as fast as possible.

When a new STATE appears the value of SYN_S*MLS2 is added to INC_CNT2. Therefore for FULL_SCALE 2*(SNU+1)*MLS2 pulses SUB_INC2 generated, when INC_CNT2 reaches the zero value. The generation of SUB_INC2 pulses has to be done as fast as possible.

25.16.8.5 Calculation of the Accurate Position Values

All appearing TRIGGER and STATE signals do have a time stamp and a position stamp assigned after the input filter procedure. For the calculation of the exact time stamp the filter values are considered in the calculations of equations DPLL-1a **Equations DPLL-1a to calculate TRIGGER time stamps** or DPLL-6a **Equations DPLL-6a to calculate STATE time stamps** respectively. A corresponding calculation is to be performed for the calculation of position values.

The PSTC and PSSC values can be corrected by the CPU, when needed.

After reset, while FTD=0 and no active TRIGGER slope is detected:

$$PSTC = 0 \quad \text{(DPLL-32a)}$$

Calculate the new Position value for each valid TRIGGER event:

$$PSTC = PSTC\_OLD + NMB\_T\_TAR\_old \quad \text{(DPLL-32b)}$$

when FTD=1 and SGE1=1

with

PSTC_OLD is the last PSTC value and

NMB_T_old is the number of pulses which are calculated

and provided for sending out in the last increment.

After reset, while FTD=0 and no active STATE slope is detected:

$$PSSC = 0 \quad \text{(DPLL-33a)}$$

Calculate the new Position value for each valid STATE event:

PSSC= PSSC_OLD + NMB_S_TAR_old (DPLL-33b)

when FTD=1 and SGE1=1 (SMC=0) or SGE2=1 (SMC=1)

respectively with

PSSC_OLD is the last PSSC value and

NMB_S_old is the number of pulses which are calculated

and provided for sending out in the last increment.

25.16.8.6 Scheduling of the Calculation

After enabling the DPLL with each valid TRIGGER or STATE event respectively a cycle of operations is performed to calculate all the results shown in detail in the table below DPLL-2. A state machine controls this procedure and consists of two parts, the first is triggered by a valid slope of the signal TRIGGER, begins at step 1 and ends at step 20 (in normal mode and for SMC=1). The second state machine is controlled by a valid slope of the signal STATE, begins at step 21 and ends at step 40 (in emergency mode and also for SMC=RMO=1). Depending on the mode used all 20 steps are executed or already after 2 steps the jump into the initial state is performed, as shown in the state machine descriptions below. For each new extended cycle (without this jump) all prediction values for actions in the case SMC=0 are calculated once more (with maybe improved accuracy because of better parameters) and all pending decisions are made using these new values when transmitted to the decision device.

In **State description of the State Machine.** the steps of the state machine are described. Please note, that the elaboration of the steps depends on the configuration bits described in the comments. The steps 4 to 17 are only calculated in normal mode (in the state machine explanation below marked yellow in **Section 25.16.2**), but steps 24 to 37 are only calculated in emergency mode (in the state machine explanation below marked cyan in **Section 25.16.2**) when SMC=0.

State machine partitioning for normal and emergency mode.

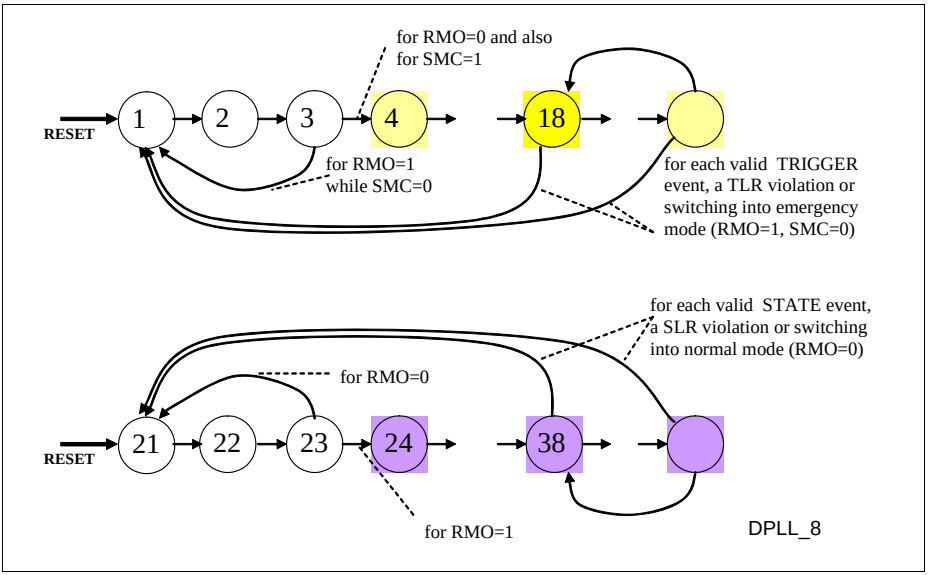

Figure 25-76 State machine partitioning for normal and emergency mode

Synchronization description

TRIGGER:

The APT (address pointer for duration and reciprocal duration values of TRIGGER increments) is initially set to zero and increment with each valid TRIGGER event. Therefore data are stored in the RAM beginning from the first available value. The actual duration of the last increment is stored at DT_T_ACT. For the prediction of the next increment it is assumed, that the same value is valid as long as NUTE is one.

A missing TRIGGER is assumed, when at least after TOV* DT_T_ACT no valid TRIGGER event appears.

The data of equations DPLL-1b1 and DPLL-1c2 **Equations DPLL-1b1 and DPLL-1c1 to update the RAM after calculation** are written in the corresponding RAM regions and APT is increment accordingly up to 2*TNU-2*SYN_NT+1.

The APT_2B (address pointer for the time stamp field of TRIGGER) is initially set to zero and increment with each valid TRIGGER event. When no gap is detected because of the incomplete synchronization process at the beginning, for all TRIGGER events the time stamp values are written in the RAM up to 2*(TNU+1) entries, although only 2*(TNU+1-SYN_NT) events in FULL_SCALE appear. When the current position is detected, the synchronization procedure can be performed as described below:

Before the CPU sets the APT_2C address pointer in order to synchronize to the profile, it writes the corresponding increment value for the necessary extension of the RAM region 2B value APT_2B_EXT into the register APT_2B_sync and sets the status bit APT_2C_status. This value can be e.g. 2*SYN_NT, when all gaps in FULL_SCALE already passed the input data stream of TRIGGER, or less then this value, when up to now e.g. only a single gap is to be considered in the data stream stored already in the RAM region 2B. The number of virtual increments to be considered depends on the number of inputs already got. After writing APT_2C by the CPU, with the next TRIGGER event the APT_2B address pointer is increment (as usual) and then the additional offset value APT_2B_EXT is added to it once (while APT_2B_STATUS=1 and for forward direction). For that reason the APT_2B_STATUS bit is reset after it. The old APT_2B value before adding the offset is stored in the APT_2B_OLD register as information for the CPU where to start the extension procedure. In the following the CPU fills in the time stamp field around the APT_2B_OLD position taking into account the corresponding number of virtual entries stored in the APT_2B_EXT value and the corresponding NT values in the profile. The extension procedure ends when all gaps considered in the APT_2B_EXT value are treated once. In the consequence all storage locations of RAM region 2B up to now do have the corresponding entries. Future gaps are treated by the DPLL.

For a backward direction the APT_2C_ext value is subtracted accordingly.

When the CPU writes the APT_2C address pointer the SYT bit is set simultaneously. For SYT=1 in normal mode (SMC=0) the LOCK1 bit is set with the system clock, when the right number of increments between two synchronization gaps is detected by the DPLL. An unexpected missing TRIGGER or an additional TRIGGER between two synchronization gaps does reset the LOCK1 bit in normal mode. In that case the CPU must correct the SUB_INC pulse number and maybe correct the APT_2C pointer. For this purpose the LL1I interrupt can be used.

When SYT is set the calculations of equations DPLL-1 to DPLL-5 are performed accordingly and the values are stored in (and distributed to) the right RAM positions.

This includes the multiple time stamp storage by the DPLL for a gap according to equations DPLL-1a5 to 7 forwards **Equation DPLL-1a5-7 to extend the time stamp values for TRIGGER in forward direction** or backwards **Equations DPLL-1a5-7 for backward direction**. The APT_2B pointer is for that reason increment or decremented before this operation considering the virtual increments in addition.

Please note, that for the APT and APT_2C pointers the gap is considered as a single increment.

STATE:

The APS (address pointer for duration and reciprocal duration values of STATE) is initially set to zero and increment with each valid STATE event. Therefore data are stored in the RAM field beginning at the first location. The ACT duration of the last

increment is stored at DT_S_ACT. For the prediction of the next increment it is assumed, that the same value is valid as long as NUSE is one.

A missing STATE is assumed, when at least after TOV_S* DT_S_actual no valid STATE event appears.

The data of equations DPLL-6b1 and DPLL-6c2 **Equations DPLL-6b1 and DPLL-6c1 to update the RAM after calculation** is written in the corresponding RAM regions and APS is increment accordingly up to 2*SNU-2*SYN_NS+1 (for SYSF=0).

The APS_1C2 (address pointer for the time stamp field of STATE) is initially set to zero and increment with each valid STATE event. When no gap is detected because of the incomplete synchronization process at the beginning, for all STATE events the time stamp values are written in the RAM up to 2*(SNU+1) entries, although (e.g. for SYSF=0) only 2*(SNU+1-SYN_NS) events in FULL_SCALE appear. When the current position is detected, the synchronization procedure can be performed as described below:

Before the CPU sets the APS_1C3 address pointer in order to synchronize to the profile, it writes the corresponding increment value APS_1C2_EXT for the necessary extension of the RAM region 1C2 into the register DPLL_APS_SYNC and sets the APS_1C2_STATUS bit there. This value can be e.g. 2*SYN_NS (for SYSF=0) or SYN_NS (for SYSF=1), when all gaps in FULL_SCALE already passed the input data stream of STATE. Also less then this value can be considered, when up to now only a single gap is to be considered in the data stream stored already in the RAM region 1C2. The number of increments to be considered depends on the number of inputs already got. After writing APS_1C3 by the CPU, with the next valid STATE slope the APS_1C2 address pointer is increment (as usual) and then the additional offset value APS_1C2_EXT is added to it once (while APS_1C2_STATUS=1 and forward direction). For that reason the APS_1C2_STATUS bit is reset after it. The old APS_1C2 value is stored in the APS_1C2_OLD register as information for the CPU where to start the extension procedure. In the following the CPU extends the time stamp field beginning from the APS_1C2_OLD position taking into account the corresponding number of virtual entries according to the APS_1C2_EXT value and also the correspondent NS values in the profile. The extension procedure ends when all gaps considered in the APS_1C2_EXT value are treated once. In the consequence all storage locations of RAM region 1C2 up to now do have the corresponding entries. Future gaps are treated by the DPLL.

For a backward direction the APS_1C2_EXT value is subtracted accordingly.

When the CPU writes the APS_1C3 address pointer the SYS bit is set simultaneously. For SYS=1 in emergency mode (SMC=0 and DMO=1) the LOCK1 bit is set with the system clock, when the right number of increments between two synchronization gaps is detected by the DPLL. An unexpected missing STATE or an additional STATE between two synchronization gaps does reset the LOCK1 bit in emergency mode. In that

case the CPU must correct the SUB_INC1 pulse number and maybe correct the APS_1C3 pointer. For this purpose the LL1I interrupt can be used.

When SYS is set the calculations of equations DPLL-5 to DPLL-10 are performed accordingly and the values are stored in (and distributed to) the right RAM positions.

This includes the multiple time stamp storage by the DPLL for a gap according to equations DPLL-6a5 to 7 forwards **Equations DPLL-6a5-7 to extend the time stamp values for STATE** or backwards **Equations DPLL-6a5-7 for backward direction**. The APS_1C2 pointer is for that reason increment or decremented before this operation considering the virtual increments in addition.

Please note, that for the APS and APS_2C pointers the gap is considered as a single increment.

SMC=1:

For SMC=1 it is assumed, that the starting position is known by measuring the characteristic of the device. In this way the APT and APT_2C as well the APS and APS_1C3 values are set properly, maybe with an unknown repetition rate. When no gap is to be considered for TRIGGER or STATE signals the APT_2B and APS_1C2 address pointers are set equal to APT or APS respectively. It is assumed, that all missing TRIGGERs and missing STATEs can be also considered from the beginning, when a valid profile with the corresponding adapt values is written in the RAM regions 1C3 and 2C respectively. In that case the TSF_T[i] and TSF_S[i] must be extended by the DPLL according to the profile. Thus the SYT and SYS bits could be set from the beginning and the LOCK1 and LOCK2 bits are set after recognition of the corresponding gaps accordingly. When no gap exists (SYN_NT=0 or SYN_NS=0), the LOCK bits are set immediately. The CPU can correct the APT_2C and APS_1C3 pointer according to the recognized repetition rate later once more without the loss of Lock1,2.

Operation in backward direction in normal and emergency mode (SMC=0)

When for SMC=0 in normal mode a backwards condition is detected for the TRIGGER input signal (e.g. when THMI is not violated), the LOCK1 bit and the FTD (as well as LOCK2 and FSD) in the DPLL_STATUS register is reset, the NUTE value in NUTC register is set to 1 (the same for NUSE in NUSC). The address pointers APT and APT_2C as described below (and after that decremented for each following valid slope of TRIGGER as long as the DIR1 bit shows the backward direction).

Please notice, that in the case of the change of the direction the ITN and ISN bit in the DPLL_STATUS register are reset.

For this transition to the backward direction no change of address pointer APT and APT_2B is necessary.

profile update for TRIGGER when changing direction

The profile address pointer APT_2C is changed step by step in order to update the profile information in SYN_T, SYN_T old and PD_store

- decrement APT_2C, load SYN_T
- decrement APT_2C, load SYN_T
- decrement APT_2C, load SYN_T, PD_store, update SYN_T_OLD
- decrement APT_2C, make calculations, load SYN_T and PD_store, update SYN_T_OLD and PD_store_old and wait for a new TRIGGER event.

Note: The update of SYN_T_OLD and the loading of PD_store can be performed in all steps above. The value APT_2B needs not to be corrected. for a direction change from backwards to forwards make the same corrections by imcrementing APT_2C.

Make calculations does mean: the operation of the state machine starts in normal mode at step 1 with the calculations and results in an update of the SYN_T value including the automatic update of SYN_T_OLD at state 17 using the actual APT_2C address pointer value, see **Section 25.16.2**.

The TBU_TB1 value is to be corrected by the number of pulses sent out in the wrong direction mode during the last and current increment. This correction is done by sending out SUB_INC1 pulses for decrementing TBU_TB1 (while DIR1=1).

The amount of pulses is determined by calculation of the difference between NMB_T and INC_CNT1. This difference is multiplied by 2 and added to INC_CNT1. In addition the pulses for the new increment SYN_T_OLD*(MLT+1) are sent. All pulses are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction.

Save inc_cnt1 value at direction change to inc_cnt1_save.

Calculate the new inc_cnt1 value as follows:

1. Stop sending pulses and save inc_cnt1 at the moment of direction change as inc_cnt1_save.

2. Set inc_cnt1 to the target value of the last increment

nmb_t_tar_old

3. Add the number of trigger which were calculated for the current increment when this value was already added to inc_cnt1 before the direction change is detected

+ nmb_t

4. Subtract the value of still not sent pulses (remaining value at inc_cnt1_save)

- inc_cnt1_save

5. Calculate the new target pulses to be sent considering the new values of SYN_T and PD_store and add them:

+ nmb_t_tar_new

This does mean the following equation:

inc_cnt1 = nmb_t_tar_old + nmb_t - inc_cnt1_save + nmb_t_tar_new

All pulses summarized at inc_cnt1 are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Please notice that no pulse correction using PCM1 of DPLL_CTRL1 is possible during direction change.

When PSTC was incremented/decremented at the active slope and after that the direction change was detected at the same input event, correct PSTC once by

- nmb_t_tar_old when changed to backwards

+ nmb_t_tar_old when changed to forwards

in order to compensate the former operation. When the direction information is known before an intended change of PSTC, do not change them.

Store the new calculated value nmb_t_tar_new at nmb_t_tar for the correct calculation of PSTC at the next input event.

consequences for STATE

With the next valid STATE event the direction information is already given. The profile pointer APS_1C3 is to be corrected by a two times decrement in order to point to the profile of the next following increment. In the following it is decremented with each STATE event while DIR1=1. The SYN_S and PD_S_store values must be updated accordingly, including SYN_S_OLD and PD_S_store_old.

Because the right direction is already known when an input event appears, make the following corrections:

- decrement APS_1C3, load SYN_S and PD_S_store, update SYN_S_OLD and PD_S_store_old
- decrement APS_1C3, make calculations, load SYN_S and PD_S_store, update SYN_S_OLD and PD_S_store_old, wait for a new STATE event

Note: The update of SYN_S_OLD and the loading of PD_S_store can be performed in all steps above. The value of APS_1C2 needs not to be corrected.

When a new STATE event occurs, all address pointers are decremented accordingly as long as DIR1=1.

In emergency mode the pulses are corrected as follows:

Save inc_cnt1 value at direction change to inc_cnt1_save.

Calculate the new inc_cnt1 value as follows:

1. Stop sending pulses and save inc_cnt1 at the moment of direction change as inc_cnt1_save.

2. Set inc_cnt1 to the target value of the current increment

nmb_s_tar

Please notice, that in difference to the normal mode, nmb_s_tar is to be used instead of nmb_s_tar_old, because direction information in emergency mode is only given from the TRIGGER input and occurs independent of a STATE event.

That means: The calculations at the last STATE event were done for the correct former direction.

3. Do not add the calculated number of state pulses because no new STATE event occurred.

4. Subtract the value of still not sent target pulses (remaining value at inc_cnt1_save)

- inc_cnt1_save

5. Add the new calculated target pulses for the current increment

+ nmb_s_tar_new

when for the calculation all new conditions of PD_S_store and SYN_S are considered.

inc_cnt1 = nmb_s_tar_old - inc_cnt1_save + nmb_s_tar_new

All pulses summarized at inc_cnt1 are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Please notice that no pulse correction using PCM1 of DPLL_CTRL1 is possible during direction change.

Do not change PSSC and suppress incrementing/decrementing of PSSC at the event directly following to the direction change information.

Store the new calculated value nmb_s_tar_new at nmb_s_tar for the correct calculation of PSTC at the next input event.

repeated change to forward direction for TRIGGER

The DIR1 bit remains set as long as the THMI value remains none violated for the following TRIGGER events and is reset when for an invalid TRIGGER slope the THMI is violated.

Resetting the DIR1 to 0 results (after repeated reset of LOCK1, NIT, NIS) in the opposite correction of the profile address pointer considered.

This does mean four increment operations of the address pointer APS_1C3 including the update of SYN_S and PD_S_store with the automatic update of SYN_S_OLD and PD_S_store_old four increment operations of the address pointer APT_2C including the update of SYN_T and PD_store with the automatic update of SYN_S_OLD and PD_S_store_old.

The correction of TBU_TS1 is done by sending out the correction pulses with the highest possible frequency at SUB_INC1 while DIR1=0. The number of pulses is calculated as shown above.

consequences for STATE

For DIR1=0: DIR2 is reset to 0 after the next valid STATE event and after a last decrementing of APS, APS_1C3 as well as APS_1C2. After that the address pointers are increment again with each following valid STATE event as long as DIR1=0.

Operation in backward direction for TRIGGER (SMC=1)

When for SMC=1 a backwards condition is detected for the TRIGGER input signal (TDIR=1, resulting in DIR1=1), the LOCK1 bit and the FTD in the DPLL_STATUS register is reset, the NUTE value in NUTC register is set to 1. The address pointers APT and APT_2C as well as APT_2B are increment for a last time (and after that decremented for each following valid slope of TRIGGER as long as the DIR1 bit shows the backward direction.

Please notice, that in the case of the change of the direction the ITN bit in the DPLL_STATUS register is reset.

profile update for TRIGGER

Make the same update steps for the profile address pointer as shown in **Operation in backward direction in normal and emergency mode (SMC=0)**: Decrement APT_2C for 2 times with the update of the SYN_T and PD_store values at each step with an automatic update of SYN_T_OLD and PD_store_old.

- decrement APT_2C, load SYN_T, PD_store, update SYN_T_OLD
- decrement APT_2C, make calculations, load SYN_T and PD_store, update SYN_T_OLD and PD_store_old and wait for a new TRIGGER event.

In the normal case no correction of wrong pulses sent is necessary, because the direction change is detected by the pattern immediately.

Nevertheless a correction is necessary as shown below. In the other case: see treatment of pulses TBU_TS1 in normal mode at **Operation in backward direction in normal and emergency mode (SMC=0)**.

Save inc_cntx value at direction change to inc_cnt1_save.

Calculate the new inc_cnt1 value as follows:

1. Clear inc_cnt1.

2. Set inc_cnt1 to the target value of the last increment

nmb_t_tar

Please notice, that in difference to the normal mode, nmb_t_tar is to be used instead of nmb_t_tar_old, because the direction information is known before the calculation takes place.

3. Do not add the calculated number of trigger pulses because it is not calculated yet before the direction change information is known.

4. Subtract the value of still not sent pulses (remaining value at inc_cnt1_save)

- inc_cnt1_save

5. Add the new calculated target pulses for the current increment

+ nmb_t_tar_new

when for the calculation all new conditions of PD_S_store and SYN_S are considered.

inc_cnt1 = nmb_t_tar_old - inc_cnt1_save + nmb_t_tar_new

All pulses summarized at inc_cnt1 are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Please notice that no pulse correction using PCM1 of DPLL_CTRL1 is possible during direction change.

Suppress changing of PSTC for the TRIGGER event when a direction change is detected.

Store the new calculated value nmb_t_tar_new at nmb_t_tar for the correct calculation of PSTC at the next input event.

repeated change to forward direction for TRIGGER

The DIR1 bit remains set as long as the TDIR bit is set for the following TRIGGER events and is reset when for a valid TRIGGER slope the TDIR is zero.

Resetting the DIR1 to 0 results (after repeated reset of LOCK1 and ITN) in the opposite correction of the address pointer use.

This does mean two increment operations of the address pointer including the update of SYN_T and PD_store.

A complex correction of TBU_TS1 and INC_CNT1 is in the normal case not necessary, when all increments are equal (SYN_NT=0) and no adapt information is used. In this case only the MLS1 value is added to INC_CNT1 in order to backcount the value for the last increment. In the other case: see treatment of pulses TBU_TS1 and ICN_CNT1 in normal mode at **Operation in backward direction in normal and emergency mode (SMC=0)**.

Operation in backward direction for STATE (SMC=1)

When for SMC=1 a backwards condition is detected for the STATE input signal (SDIR=1, resulting in DIR2=1), the LOCK2 bit and the FSD in the DPLL_STATUS register is reset, the NUSE value in NUSC register is set to 1 and the address pointers APS and APS_1C3_f and APS_1C2 are increment for a last time (and after that decremented for each following valid slope of STATE as long as the DIR2 bit shows the backward direction.

Please notice, that in the case of the change of the direction the ISN bit in the DPLL_STATUS register is reset.

For this transition to the backward direction no change of address pointer APS and APC_1C2 is necessary.

profile update for STATE

Make the same update steps for the profile address pointer as shown in **Operation in backward direction in normal and emergency mode (SMC=0)**: Decrement APS_1C3 for 2 times with the update of the SYN_S, SYN_S_OLD and PD_S_store and PD_S_store_old values at each step:

A correction of TBU_TS2 and INC_CNT2 is in the normal case not necessary, because no pulses are sent out with the wrong direction information. In the other case: see treatment of pulses TBU_TS1 and ICN_CNT1 in normal mode at **Operation in backward direction in normal and emergency mode (SMC=0)**.

- decrement APT_1C3, load SYN_S, PD_S_store, update SYN_S_OLD
- decrement APT_1C3, make calculations, load SYN_S and PD_S_store, update SYN_S_OLD and PD_S_store_old and wait for a new STATE event.

A complex correction of TBU_TS2 and INC_CNT2 is in the normal case not necessary, when all increments are equal (SYN_NS=0) and no adapt information is used. In this case only the MLS2 value is added to INC_CNT2 in order to backcount the value for the last increment. In the other case: see treatment of pulses TBU_TS1 and ICN_CNT1 in normal mode at **Operation in backward direction in normal and emergency mode (SMC=0)**.

For the second PMSM the pulses are corrected as follows:

Save inc_cnt2 value at direction change to inc_cnt2_save.

Calculate the new inc_cnt2 value as follows:

1. Clear inc_cnt2.

2. Set inc_cnt2 to the target value of the last increment

nmb_s_tar

Please notice, that in difference to the normal mode, nmb_s_tar is to be used instead of nmb_s_tar_old, because no new calculation is performed so far.

3. Do not add the calculated number of state pulses because it is not calculated yet before the direction change information is known.

4. Subtract the value of still not sent pulses (remaining value at inc_cnt2_save)

- inc_cnt2_save

5. Add the new calculated target pulses for the current increment

+ nmb_s_tar_new

when for the calculation all new conditions of PD_S_store and SYN_S are considered.

inc_cnt2 = nmb_s_tar_old - inc_cnt2_save + nmb_s_tar_new

All pulses summarized at inc_cnt2 are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Please notice that no pulse correction using PCM2 of DPLL_CTRL1 is possible during direction change.

Do not change PSSC for a STATE event when a direction change is detected.

Store the new calculated value nmb_s_tar_new at nmb_s_tar for the correct calculation of PSTC at the next input event.

repeated change to forward direction for STATE

The DIR2 bit remains set as long as the SDIR bit is set for the following STATE events and is reset when for a valid STATE slope SDIR is zero.

Resetting the DIR2 to 0 results (after repeated reset of LOCK2 and FSD) in the opposite correction of the address pointer use.

After a last decrementing of all address pointers the APS_1C3 is increment 2 times with a repeated update of SYN_S, SYN_S_OLD and PD_S_store after each increment.

DPLL reaction in the case of non plausible input signals

When the DPLL is synchronized concerning the TRIGGER signal by setting the FTD, SYT and LOCK1 bits in the DPLL_STATUS register, the number of valid TRIGGER events between the gaps is to be checked continuously.

When additional events appear while a gap is expected, the LOCK1 bit is reset and the ITN bit in the DPLL_STATUS register is set.

When an unexpected gap appears (missing TRIGGERS), the NUTE value in the NUTC register is set to 1, the LOCK1 bit is reset and the ITN bit in the DPLL_STATUS register is set. The address pointers are increment with the next valid TRIGGER slope accordingly.

When the TRIGGER locking range TLR is violated 8),

the state machine 1 will remain in state 1 and the address pointer APT, APT_2B and APT_2C will remain unchanged until the CPU sets the APT_2C accordingly. In this case also the NUTE value in the NUTC register is set to 1. The DPLL stops the generation of the SUB_INC1 pulses and will perform no other actions - remaining in step1 of the first state machine (see **Section 25.16.2**).

8) The TOR Bit in the DPLL_STATUS register is set, when the time to the next active TRIGGER slope exceeds the value of the last nominal TRIGGER duration multiplied with the value of the TLR register (see **Section 25.16.11.75**). In this case also the TORI interrupt is generated, when enabled.

When in the following the direction DIR1 changes as described in the sections above the ITN bit in the DPLL_STATUS register is reset, the use of the address pointers APT_2C is switched and the pulse correction takes place as described above.

In all other cases the CPU can interact to leave the instable state. This can be done by setting the APT_2C address pointer which results in a reset of the ITN bit. In the following NUTE can also be set to higher values.

When the DPLL is synchronized concerning the STATE signal by setting the FSD, SYS and LOCK1 (for SMC=0) or LOCK2 (for SMC=1) bits in the DPLL_STATUS register, the number of valid STATE events between the gaps is to be checked continuously.

When additional events appear while a gap is expected or while an unexpected missing STATE event appears, the LOCK1,2 bit is reset and the ISN bit in the DPLL_STATUS register is set.

When an unexpected gap appears for RMO=SMC=1 (missing STATEs for synchronous motor control), the NUSE value in the NUSC register is set to 1, the LOCK2 bit is reset and the ISN bit in the DPLL_STATUS register is set. The address pointers are increment with the next valid STATE slope accordingly.

When the STATE locking range SLR is violated 7),

the state machine 2 will remain in state 21 and the address pointer APS, APS_1C2 and APS_1C3 will remain unchanged until the CPU sets the APS_1C3 accordingly. In this case also the NUSE value in the NUSC register is set to 1. The DPLL stops the generation of the SUB_INC1,2 pulses respectively and will perform no other actions - remaining in step21 of the second state machine (see **Section 25.16.2**).

7) The SOR Bit in the DPLL_STATUS register is set, when the time to the next active STATE slope exceeds the value of the last nominal STATE duration multiplied with the value of the SLR register (see **Section 25.16.11.76**).

In this case also the SORI interrupt is generated, when enabled.

When in the following the direction DIR2 changes as described in the sections above the ISN bit in the DPLL_STATUS register is reset, the use of the address pointers APS_1C3 is switched and the pulse correction takes place as described above. In all other cases the CPU must interact to leave the instable state. This can be done by setting the APS_1C3 address pointers which results in a reset of the ISN bit. In the following NUSE can also be set to higher values.

State description of the State Machine.

Table 25-48 State description of the State Machine

Step	Description	Comments

always for DEN=1	for each inactive TRIGGER slope:
	generate the TISI interrupt; calculate the time stamp difference ΔT to the last valid event, store this value at THVAL;
	when THMI >0 is violated (ΔT < THMI):
	generate TINI interrupt,
	set DIR1=0 (forwards)
	set BWD1=0 (see DPLL_STATUS register)
	else (only for THMI >0):
	set DIR1= 1 (backwards);
	set BWD1=1 (see DPLL_STATUS register)
	after changing the direction correct the pulses WP sent with wrong direction information and send the pulses for the actual increment in addition with highest possible frequency:
	WP=NMB_T-DPLL_INC_CNT1;
	correct INC_CNT1 by addition of 2*WP before sending the correction pulses;
	check THMA, when THMA is violated, generate the TAXI interrupt;
	go to step 1
	for each inactive STATE slope:
	set DIR2=DIR1
		for SMC=0;
		set DIR1 always after inc./decr. the address pointers APT, APT_x;
		go to step 1;
		stop output of SUB_INC1 and correct pulses after changing DIR1 after incr./decr. of APS_x
		set DIR2 always after incr./decr. the address pointers APS, APS_x;
		go to step 1

Table 25-48 State description of the State Machine (cont'd)

Step	Description	Comments
always for DEN=1	set DIR1=BWD1=TDIR, set DIR2=BWD2=SDIR; for each change of TDIR go to step 1 after performing the following calculations: correct INC_CNT1 correct the pulses (WP, see above) sent with wrong direction information and send the pulses for the actual increment in addition with highest possible frequency. For each change of SDIR go to step 21 after performing the following calculations: update of SYN_S, PD_S_store according to **Operation in backward direction in normal and emergency mode (SMC=0)** correct INC_CNT1,2 correct the pulses sent with wrong direction information and send the pulses for the actual increment in addition with highest possible frequency.	**for SMC=1;** set the direction bits always after incr./decr. the corresponding address pointers;
1	When DEN = 0 or TEN=0: stay in step 1 until DEN=1, TEN=1 and at least one valid TRIGGER has been detected (FTD=1); the following steps are performed always (not necessarily in step 1, but also in steps 18 to 20 (when waiting for new PMTR values to be calculated): compare TRIGGER_S with TSL (valid slope); **When no valid TRIGGER appears** and when TS_T_CHECK time is reached: • send missing TRIGGER INT, also when a Gap is expected according to the profile; set MT=1 (missing TRIGGER bit) in the DPLL_STATUS register; do not leave the active step, until a valid TRIGGER appears.	Depending on TSL, TEN, DEN the leaving of step one is done with the next TRIGGER input; Note: Step 1 is also left in emergency mode when a valid TRIGGER event appears in order to make a switch back to normal mode possible; _old - values are values valid at the last but one valid TRIGGER event; for the whole table: use always MLS1 instead of (MLT+1) for the case SMC=1;

Table 25-48 State description of the State Machine (cont'd)

Step	Description	Comments
1	**When a valid TRIGGER appears check PVT** - **when the PVT value is violated:** generate the PWI interrupt, ignore the TRIGGER input and wait for the next valid TRIGGER slope (ignore each invalid slope); do not store any value - **When the PVT value is fulfilled:** store actual position stamp at PSTM (value at the TRIGGER event) update the RAM region 2 by equation DPLL-a-c (see **Chapter 25.16.7.5**) store the actual INC_CNT1 value at MP1 as missing pulses (instead of calculating in step 5) store all relevant configuration bits X of the DPLL_CTRL(0,1) Registers in shadow registers and consider them for all corresponding calculations of steps 2 to 20 accordingly; the relevant bits are explained in the registers itself generate the TASI interrupt; for FTD=0: • set PSTC=PSTM • set FTD (first TRIGGER detected) • do not change PSTC,APT, APT_2B • for (RMO=0 or SMC=1) and SGE1=1: increment INC_CNT1 by (MLT+1)*) + MPVAL1***) • send SUB_INC1 pulses with highest possible frequency when SGE1=1 for SYT=0 and FTD =1: • dir_crement APT and APT_2B by one; • dir_crement for SGE1_delay****)=1 and TOR=0 PSTC by NMB_T_TAR**) • for (RMO=0 or SMC=1) and SGE1=1. 1	for SYT=1 and TOR=0: • dir_crement APT, APT_2C, dir_crement APT_2B by SYN_T_OLD • dir_crement for SGE1_delay****)=1 PSTC by NMB_T_TAR**) • for (RMO=0 or SMC=1) and SGE1=1: increment INC_CNT1 by SYN_T*(MLT+1)*) + PD_store*****) + MPVAL1***) PD_store is 0 for AMT=0 within the DPLL_STATUS register: • set LOCK1 bit accordingly;	*****)PD_store=0 for AMT=0 (see DPLL_CTRL_0 register)
2	calculate TS_T according to equations DPLL-1a; calculate DT_T_ACT = TS_T - TS_T_old calculate RDT_T_ACT calculate QDT_TX according to equation DPLL-2	
3	send CDTI interrupt when NTI_CNT is zero or decrement NTI_CNT when not zero; calculate EDT_T and MEDT_T according to equations DPLL-3 and DPLL-4 for (RMO=1 and SMC=0): update SYN_T, PD_store and go back to step 1	Note: There are different behaviours of Reference Model and hardware: For the hardware the values of SYN_T and PD_store are not updated until a new valid TRIGGER slope occurs.
4	calculate CDT_TX according to equation DPLL-5a and b;	for RMO=0 or SMC=1;
5	calculate missing pulses: MP1 = INC_CNT1(at the moment of a valid TRIGGER slope) calculate target pulses: NMB_T_TAR = (MLT+1)*)*SYN_T + PD_store + MPVAL1 (instead of PD_store use zero in the case AMT=0)	for RMO=0 or SMC=1 *)replace (MLT+1) by MLS1 for SMC=1 add MPVAL1 only for PCM=1; add MPVAL1 once to INC_CNT1 and reset PCM1 after that;
6	sent MP with highest possible frequency and set NMB_T = NMB_T_TAR	for RMO=0 or SMC=1, DMO=0 and COA=0

Table 25-48 State description of the State Machine (cont'd)

Step	Description	Comments
7	calculate the number of pulses to be sent NMB_T = NMB_T_TAR + MP (see equations DPLL-21 or DPLL-27 respectively)	for RMO=0 or SMC=1, DMO=0 and COA=1
8	NMB_T = SYN_T*CNT_NUM1	for RMO=0 or SMC=1, DMO=1
9	update SYN_T and PD_store;	Note: There are different behaviours of Reference Model and hardware: For the hardware the values of SYN_T and PD_store are not updated until a new valid TRIGGER slope occurs.
10	calculate ADD_IN_CAL1 according to equation DPLL-25 and DPLL-25b or DPLL-31 and store this value in RAM use ADD_IN_CAL1 as ADD_IN value for the case DLM=0 use ADD_IN_LD1 as ADD_IN for the case DLM=1, but do this update immediately (without waiting for this step 10); for DMO=DLM=0 and EN_C1u=0: reset the FlipFlops in the SUB_INC1 generator; start sending SUB_INC1;	for RMO=0 or SMC=1 for DLM=0 for DLM=1
11	calculate TS_T_CHECK = TS_T + DT_T_ACT *(TOV) ;	for RMO=0 or SMC=1;
12	automatic setting of actions masking bits in the DPLL_STATUS register: for SMC=0: set CAIP1=CAIP2=1 for SMC=1: set only CAIP1=1	steps 12 to 16 are not valid for the combination: (SMC=0 and RMO=1)

Table 25-48 State description of the State Machine (cont'd)

Step	Description	Comments
13	for all correspondent actions with ACT_N[i]=1 calculate: NA[i] = (PSA[i] - PSTC)/(MLT+1)*)for forward direction with w= integer part and b = remainder of the division (fractional part); for backward direction use NA[i] = (PSTC - PSA[i])/(MLT+1)*) and consider in both cases the time base overflow in order to get a positive difference	actions 0…11 for SMC=1 actions 0…23 for SMC=0 depending on ACT_Ni in DPLL_ACT_STA register; replace MLT+1 by MLS1 for SMC=1
14	calculate PDT_T[i] and DTA[i] for up to 24 action values according to equations DPLL-11 and DPLL-12;	actions 0…11 for SMC=1 actions 0…23 for SMC=0
15	calculate TSAC[i] according to equation DPLL-15 and PSAC[i] according to equation DPLL-17	actions 0…11 for SMC=1 actions 0…23 for SMC=0
16	automatic resetting of actions masking bits in the DPLL_STATUS register: for SMC=0: set CAIP1=CAIP2=0 for SMC=1: set only CAIP1=0; set the corresponding ACT_Ni bits in the DPLL_ACT_STA register	Set ACT_Ni for all enabled actions concerned: 0…11 for SMC=1 0…23 for SMC=0
17	check the relation of the last increment to its predecessor according to the profile and taking into account TOV: set the ITN status bit and reset the corresponding LOCK bit, when not plausible; go to step 18, when no valid TRIGGER appears for all following steps 18 to 20: go immediately back to step 1, when a valid TRIGGER event occurs, interrupt all calculations there and reset all CAIP in that case; when going back to step 1: store TS_T in RAM 2B according to APT_2B; update RAM 2A and RAM 2D	for all conditions

Table 25-48 State description of the State Machine (cont'd)

Step	Description	Comments
18	wait for a new PMTR value; set the corresponding CAIPx values and go to step 19 in that case	go immediately to step 1 and update the RAM according to step 17 when a valid TRIGGER event occurs
19	make the requested action calculation according to new PMTR values	go immediately to step 1 and update the RAM according to step 17 when a valid TRIGGER event occurs
20	reset CAIPx and go back to step 18	go immediately to step 1 and update the RAM according to step 17 when a valid TRIGGER event occurs

Table 25-48 State description of the State Machine (cont'd)

Step	Description	Comments

21	When DEN = 0 or SEN=0:
	stay in step 1 until DEN=1, SEN=1 and at least one valid STATE has been detected (FSD=1);
	
	the following steps are performed always (not necessarily in step 21, but also in steps 38 to 40 (when waiting for new PMTR values to be calculated):
	compare STATE_S with SSL (valid slope); for each invalid slope: generate a SISI interrupt; send missing STATE INT when TS_S_CHECK time is reached and set MS=1 (missing STATE bits) in that case; do not leave step 21 while no valid STATE appears.
	When a valid STATE appears:
	store the actual position stamp at PSSM (value at the STATE event) update RAM by equation DPLL-7c (see **Chapter 25.16.7.5**);
	store the actual INC_CNT1/2 at MP1/MP2 respectively as missing pulses (instead of calculations in step 25)
	
	store all relevant configuration bits X of the DPLL_CTRL(0,1) Registers in shadow registers and consider them for all corresponding calculations of steps 22 to 37 accordingly; the relevant bits are explained in the registers itself
	for FSD=0:
	set PSSC=PSSM
	set FSD (first STATE detected)
	do not increment PSSC
	for (RMO=1 and SMC=0) and SGE1=1:
	increment INC_CNT1 by MLS1+MPVAL1**)
	for (RMO=1 and SMC=1) and SGE2=1:
	increment INC_CNT2 by MLS2+MPVAL2**)
		Depending on SSL, SEN, DEN the leaving of step 21 one is done with the next STATE input;
		
		for the steps 22-37: for SMC=1 replace:
		MLS1 by MLS2,
		LOCK1 by LOCK2;
		SUB_INC1 by SUB_INC2;
		CNT_NUM1 by CNT_NUM2;
		MPVAL1 by MPVAL2;
		EN_C1u by EN_C2u;
		
		dir_crement does mean: increment for DIR2=0 decrement for DIR2=1 or DIR1 respectively
		
		*) target number of pulses of the last increment (see step 25ff)
		
		**) add MPVAL1 or MPVAL2 only once, that means as long as PCM1 or PCM2 is set respectively

Table 25-48 State description of the State Machine (cont'd)

Step	Description	Comments

21	for SYS=0, FSD =1 and SOR=0:
	dir_crement PSSC by NMB_S_TAR*) for (SMC=0 and SGE1=1) or (SMC=1 and SGE2=1)
	increment INC_CNT1 by MLS1+MPVAL1**) (for SMC=0, SGE1=1 and RMO=1);
	increment INC_CNT2 by MLS2+MPVAL2**) (for SMC=1, SGE2=1 and RMO=1);
	dir_crement APS and APS_1C3
	
	for SYS=1 and SOR=0:
	dir_crement APS and APS_1C3
	dir_crement APS_1C2 by SYN_S_OLD
	for RMO=1 and SMC=0: for SGE1_delay***)=1
	dir_crement PSSC by NMB_S_TAR*); for SGE1=1 increment INC_CNT1 by SYN_S*MLS1 + PD_S_store + MPVAL1**)
	for RMO=1 and SMC=1: for SGE2_delay****)=1
	dir_crement PSSC by NMB_S_TAR*); for SGE2=1 increment INC_CNT2 by SYN_S*MLS2 + PD_S_store*****) +MPVAL2**)
	within the DPLL_STATUS register:
	set LOCK1 or 2 bit accordingly;
		***) SGE1_delay is the value of SGE1 delayed by one valid STATE event
		
		****) SGE2_delay is the value of SGE2 delayed by one valid STATE event
		
		*****) PD_S_store=0 for AMS=0 (see DPLL_CTRL_0 register)

22	calculate TS_S according to equations DPLL-6a; calculate DT_S_ACT = TS_S - TS_S_old calculate RDT_S_ACT calculate QDT_SX	
23	send CDSI interrupt; calculate EDT_S and MEDT_S according to equations DPLL-8 and DPLL-9 for RMO=0: go back to step 21 for RMO=0 and update SYN_S and PD_S_store using the current ADT_S[i] values in that case;	Note: There are different behaviours of Reference Model and hardware: For the hardware the values of SYN_T and PD_store are not updated until a new valid TRIGGER slope occurs.
24	calculate CDT_SX according to equation DPLL-10a and b;	only for RMO=1

Table 25-48 State description of the State Machine (cont'd)

Step	Description	Comments
25	calculate missing pulses: - for TBU_CH1: MP1 = INC_CNT1(valid STATE slope) - for TBU_CH2: MP2 = INC_CNT2(valid STATE slope) calculate target number of pulses: NMB_S_TAR = MLS1*SYN_S + PD_S_store +MPVAL1 (for SMC=0) NMB_S_TAR = MLS2*SYN_S + PD_S_store + MPVAL2 (for SMC=1) (instead of PD_S_store use zero in the case AMS=0)	only for RMO=1 for SMC=0 instead of MPVAL1=0 use zero for PCM1=0 for SMC=1 instead of MPVAL2=0 use zero for PCM2=0; add MPVAL1/2 once to INC_CNT1/2 and reset PCM1/2 after that
26	sent MPx with highest possible frequency and set NMB_S = NMB_S_TAR	only for RMO=1, DMO=0 and COA=0
27	calculate number of pulses to be sent according to DPLL-22 or NMB_S = NMB_S_TAR + MPx	only for RMO=1, DMO=0 and COA=1
28	NMB_S = SYN_S*CNT_NUM1 (SMC=0) NMB_S = SYN_S*CNT_NUM2 (SMC=1)	only for RMO=1, DMO=1
29	update SYN_S and PD_S_store;	Note: There are different behaviours of Reference Model and hardware: For the hardware the values of SYN_T and PD_store are not updated until a new valid TRIGGER slope occurs.

Table 25-48 State description of the State Machine (cont'd)

Step	Description	Comments
30	calculate ADD_IN_CAL2 according to equation DPLL-26 and DPLL-26b or DPLL-31 respectively and store this value in RAM use ADD_IN_CAL2 as ADD_IN value for the case DLM=0 use ADD_IN_LD2 as ADD_IN for the case DLM=1, but do this update immediately (without waiting for this step 30); for RMO=1, DMO=DLM=0 and EN_C1u=0 (EN_C1u=0): reset the FlipFlops in the SUB_INC1 or SUB_INC2 generator respectively; start sending SUB_INC1 / SUB_INC2;	only for RMO=1 for DLM=0 for DLM=1
31	calculate TS_S_CHECK = TS_S + DT_S _ACT * (TOV_S);	only for RMO=1;
32	automatic setting of actions masking bits in the DPLL_STATUS register: CAIP1 and CAIP2 for SMC=0 only CAIP2 for SMC=1	for RMO=1
33	for all actions with ACT_N[i]=0 calculate: NA[i] = (PSA[i] - PSSC)/MLS1 for forward direction with w = integer part and b = remainder of the division (fractional part) for backward direction use NA[i] = (PSSC - PSA[i])/(MLS1) and consider in both cases the time base overflow in order to get a positive difference use MLS2 as divider in the case of SMC=1	for SMC=0: 24 actions, for SMC=1: 12 actions; depending on ACT_Ni in DPLL_ACT_STA register
34	calculate PDT_S[i] and DTA[i] for up to 24 action values according to equations DPLL-13 and DPLL-14;	only for RMO=1; for SMC=0 actions 0…23 for SMC=1 actions 1223
35	calculate TSAC[i] according to equation DPLL-18 and PSAC[i] according to equation DPLL-20	for the relevant actions (see above) and RMO=1

Table 25-48 State description of the State Machine (cont'd)

Step	Description	Comments
36	automatic reset of the actions masking bit CAIP in the DPLL_STATUS register: CAIP1=CAIP2=0 for SMC=0 and only CAIP2=0 for SMC=1 set the corresponding ACT_Ni bits in the DPLL_ACT_STA register	for the relevant actions (see above) and RMO=1 Set ACT_Ni and reset ACT_WRi for all enabled actions
37	check the duration of the last increment to its predecessor according to the profile and taking into account TOV_S: set the ISN status bit and reset the corresponding LOCK bit, when not plausible; go to step 38, when no valid STATE appears **for all following steps 38 to 40:** **go immediately back to step 21, when a valid STATE event occurs, interrupt all calculations there and reset all CAIPx in that case;** **when going back to step 21:** store TS_S in RAM 1C2 according to APS_1C2; update RAM 1C1 and RAM 1C4	for all conditions
38	wait for a new PMTR value; set the corresponding CAIPx values and go to step 39 in that case	go immediately to step 21 and update the RAM according to step 37 when a valid STATE event occurs
39	make the requested action calculation according to new PMTR values	go immediately to step 21 and update the RAM according to step 37 when a valid STATE event occurs
40	reset CAIP and go back to step 38	go immediately to step 21 and update the RAM according to step 37 when a valid STATE event occurs

25.16.9 DPLL Interrupt signals

The DPLL provides 27 interrupt lines. These interrupts are shown below.

25.16.9.1 DPLL Interrupt signals

interrupt signals of table

Table 25-49 DPLL Interrupt signals

Signal	Description
DPLL_SORI_IRQ	STATE is out of range
DPLL_TORI_IRQ	TRIGGER is out of range
DPLL_CDSI_IRQ	STATE duration calculated for last increment
DPLL_CDTI_IRQ	TRIGGER duration calculated for last increment
DPLL_TE4_IRQ	TRIGGER event interrupt 4 request[1)]
DPLL_TE3_IRQ	TRIGGER event interrupt 3 request[1)]
DPLL_TE2_IRQ	TRIGGER event interrupt 2 request[1)]
DPLL_TE1_IRQ	TRIGGER event interrupt 1 request[1)]
DPLL_TE0_IRQ	TRIGGER event interrupt 0 request[1)]
DPLL_LL2_IRQ	Lost of lock interrupt for SUB_INC2 request
DPLL_GL2_IRQ	Get of lock interrupt for SUB_INC2 request
DPLL_E_IRQ	Error interrupt request
DPLL_LL1_IRQ	Lost of lock interrupt for SUB_INC1 request
DPLL_GL1_IRQ	Get of lock interrupt for SUB_INC1 request
DPLL_W1_IRQ	Write access to RAM region 1B or 1C interrupt request
DPLL_W2_IRQ	Write access to RAM region 2 interrupt request
DPLL_PW_IRQ	Plausibility window violation interrupt of TRIGGER request
DPLL_TAS_IRQ	TRIGGER active slope while NTI_CNT is zero interrupt request
DPLL_SAS_IRQ	STATE active slope interrupt request
DPLL_MT_IRQ	Missing TRIGGER interrupt request
DPLL_MS_IRQ	Missing STATE interrupt request
DPLL_TIS_IRQ	TRIGGER inactive slope interrupt request
DPLL_SIS_IRQ	STATE inactive slope interrupt request
DPLL_TAX_IRQ	TRIGGER maximum hold time violation interrupt request
DPLL_TIN_IRQ	TRIGGER minimum hold time violation interrupt request

Table 25-49 DPLL Interrupt signals (cont'd)

Signal	Description
DPLL_PE_IRQ	DPLL enable interrupt request
DPLL_PD_IRQ	DPLL disable interrupt request

1) see TINT value in the corresponding ADT_T[i] section of RAM region 2

Note: TEi_IRQ depends on the TINT value in ADT_T[i][1] and is only active when SYT[2]

1) see RAM region 2 explanations

2) see DPLL STATUS register

25.16.10 DPLL Register overview

Table 25-50 DPLL register overview

Address offset	Name	Description	Init value	Page
0x0000	DPLL_CTRL_0	DPLL Control Register 0	0x003B_BA57	25-509
0x0004	DPLL_CTRL_1	DPLL Control Register 1	0xB000_0000	25-513
0x0008	DPLL_CTRL_2	DPLL Control Register 2 (actions 0-7 enable)	0x0000_0000	25-521
0x000C	DPLL_CTRL_3	DPLL Control Register 3 (actions 8-15 enable)	0x0000_0000	25-523
0x0010	DPLL_CTRL_4	DPLL Control Register 4 (actions 16-23 enable)	0x0000_0000	25-525
0x0018	DPLL_ACT_STA	DPLL ACTION Status Register with connected shadow register	0x0000_0000	25-527
0x001C	DPLL_OSW	DPLL Offset and switch old/new address register	0x0000_0200	25-529
0x0020	DPLL_AOSV_2	DPLL Address offset register for APT in RAM region 2	0x1810_0800	25-531
0x0024	DPLL_APT	DPLL Actual RAM pointer to RAM regions 2A, b and d	0x0000_0000	25-532
0x0028	DPLL_APS	DPLL Actual RAM pointer to RAM regions 1C1, 1C2 and 1C4	0x0000_0000	25-535
0x002C	DPLL_APT_2C	DPLL Actual RAM pointer to RAM region 2C	0x0000_0000	25-538
0x0030	DPLL_APS_1C3	DPLL Actual RAM pointer to RAM region 1C3	0x0000_0000	25-540
0x0034	DPLL_NUTC	DPLL Number of recent TRIGGER events used for calculations (mod 2*(TNU +1-SYN_NT))	0x0001_2001	25-541

Table 25-50 DPLL register overview (cont'd)

Address offset	Name	Description	Init value	Page
0x0038	DPLL_NUSC	Number of recent STATE events used for calculations (e.g. mod 2*(SNU +1-SYN_NS) for SYSF=0)	0x0001_2081	25-544
0x003C	DPLL_NTI_CNT	DPLL Number of active TRIGGER events to interrupt	0x0000_0000	25-547
0x0040	DPLL_IRQ_NOTIFY	DPLL Interrupt notification register	0x0000_0000	25-548
0x0044	DPLL_IRQ_EN	DPLL Interrupt enable register	0x0000_0000	25-551
0x0048	DPLL_IRQ_FORCINT	DPLL Interrupt force register	0x0000_0000	25-555
0x004C	DPLL_IRQ_MODE	DPLL Interrupt mode register	0x0000_0000	25-557
0x0050	DPLL_EIRQ_EN	DPLL Error Interrupt enable register	0x0000_0000	
0x00B0	INC_CNT1	DPLL Counter for pulses for TBU_TS1 to be sent in automatic end mode	0x0000_0000	25-562
0x00B4	INC_CNT2	DPLL Counter for pulses for TBU_TS2 to be sent in automatic end mode when SMC=RMO=1	0x0000_0000	25-563
0x00B8	DPLL_APT_SYNC	DPLL old RAM pointer and offset value for TRIGGER	0x0000_0000	25-564
0x00BC	DPLL_APS_SYNC	DPLL old RAM pointer and offset value for STATE	0x0000_0000	25-567
0x00C0	TBU_TS0_T	DPLL TBU_TS0 value at last TRIGGER event	0x0000_0000	25-570
0x00C4	TBU_TS0_S	DPLL TBU_TS0 value at last STATE event	0x0000_0000	25-570
0x00C8	ADD_IN_LD1	DPLL direct load input value for SUB_INC1	0x0000_0000	25-572

Table 25-50 DPLL register overview (cont'd)

Address offset	Name	Description	Init value	Page
0x00CC	ADD_IN_LD2	DPLL direct load input value for SUB_INC2	0x0000_0000	25-573
0x00FC	DPLL_STATUS	Status register	0x0000_0000	
0x0100 + x * 0x04	DPLL_ID_PMTR_x	DPLL 9-bit ID Information For Input Signal PMT_x[8:0] Register (x:023)	0x0000_01FE	25-581
0x01E0	DPLL_CTRL_0_SHADOW_TRIGGER	shadow register of DPLL_CTRL_0	0x0000_0000	25-582

Name	Description	Address offset in relation to DPLL start address	Page
Region 2D	Uncorrected last increment values of TRIGGER (DT_T); measuring raw data of increments		
DT_Tx	DT_Tx (x:0511)	AOSV_2D + x* 0x04	**25-650**

25.16.11 DPLL Register and Memory description

All of the following registers are 32-bit only accessible.

Description of registers beginning from register DPLL_CTRL_0.

Description of RAM regions beginning from RAM 1A (see below):
Bits 31 down to 24 in each RAM region are not implemented and therefore always read as zero (reserved). Other bits which are declared as reserved are not protected against writing. Reserved address regions are not protected against writing.

Description of memory region RAM 1A beginning from memory PSAi
The RAM region 1A is writable only for DEN=0 (see DPLL_CTRL_1 register).

Description of memory region RAM 1B beginning from memory TS_T.

Description of memory region RAM 1C beginning from memory RDT_S.

Description of memory region RAM 2 beginning from memory RDT_T.

25.16.11.1Register DPLL_CTRL_0

Control register 0.

GTM_DPLL_CTRL_0
DPLL Control Register 0 **(28000_H)** **Reset Value: $003BBA57_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RMO	TEN	SEN	IDT	IDS	AMT	AMS	TNU								
rw	rw	rw	rw	rw	rw	rw					rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SNU					IFP	MLT									
		rw			rw						rw				

Field	Bits	Type	Description
MLT[1)]	[9:0]	rw	**Multiplier for TRIGGER** MLT+1 is number of SUB_INC1 pulses between two TRIGGER events in normal mode (1…1024); For emergency mode the number of SUB_INC1 pulses between two STATE events is calculated by the CPU using the formula MLS1=(MLT+1)* (TNU+1) / (SNU+1) in order to get the same number of SUB_INC1 pulses for FULL_SCALE. This value is stored in RAM at 0x05C0. Change of MLT by the CPU must result in the corresponding change of MLS1 by the CPU for SMC=0. Note: The number of MLT events is the binary value plus 1. The value MLT+1 is replaced by MLS1 in the case of SMC=1 (see DPLL_CTRL_1 register) for all relevant calculations.
IFP[1)2)3)]	10	rw	**Input filter position** Value contains position or time related information. 0_B TRIGGER_FT and STATE_FT mean time related values, that means the number of time stamp clocks 1_B TRIGGER_FT and STATE_FT mean position related values, that means the number of SUB_INC1 (or SUB_INC2 in the case SMC=1) pulses respectively
SNU[4)]	[15:11]	rw	**STATE number** SNU+1 is number of STATE events in HALF_SCALE (1…32). Note: The number of nominal STATE events is the binary value plus 1. Set by DEN=0 only. This value can only be written when the DPLL is disabled.
TNU[4)]	[24:16]	rw	**TRIGGER number** TNU+1 is number of TRIGGER events in HALF_SCALE (1…512). Note: The number of nominal TRIGGER events is the binary value plus 1. Set by DEN=0 only. This value can only be written when the DPLL is disabled.

Field	Bits	Type	Description
AMS[2]	25	rw	**Adapt mode STATE** Use of adaptation information of STATE. 0_B No adaptation information is used for STATE 1_B Immediate adapting mode; the values ADT_S[i] are considered to calculate SUB_INC1 pulses in emergency mode (SMC=0) or SUB_INC2 pulses for SMC=1
AMT[1]	26	rw	**Adapt mode TRIGGER** Use of adaptation information of TRIGGER. 0_B No adaptation information for TRIGGER is used 1_B Immediate adapting mode; the values ADT_T[i] are considered to calculate the SUB_INC1 pulses in normal mode and for SMC=1
IDS[2]	27	rw	**Input delay STATE** Use of input delay information transmitted in FT part of the STATE signal. 0_B Delay information is not used 1_B Up to 24 bits of the FT part contain the delay value of the input signal, concerning the corresponding edge
IDT[1]	28	rw	**Input delay TRIGGER** use of input delay information transmitted in FT part of the TRIGGER signal. 0_B Delay information is not used 1_B Up to 24 bits of the FT part contain the delay value of the input signal, concerning the corresponding edge
SEN	29	rw	**STATE enable** 0_B STATE signal is not enabled (no signal considered) 1_B STATE signal is enabled
TEN	30	rw	**TRIGGER enable** 0_B TRIGGER signal is not enabled (no signal considered) 1_B TRIGGER signal is enabled

Field	Bits	Type	Description
RMO[1)2)]	31	rw	**Reference mode** Selection of the relevant the input signal for generation of SUB_INC1. 0_B Normal mode; the signal TRIGGER is used to generate the SUB_INC1 signals 1_B Emergency mode for SMC=0; signal STATE is used to generate the SUB_INC1 signals; Double synchronous mode for SMC=1: signal TRIGGER is used to generate the SUB_INC1 signals and STATE is used to generate the SUB_INC2 signals Note: for SMC=0: TRIGGER and STATE are prepared to calculate SUB_INC1. The RMO bit gives a decision only, which of them is used. For changing from normal mode to emergency mode at the following TRIGGER slope (according to the RMO value in the shadow register)1) the PSSC value is calculated by PSSC = PSSM + correction_value (forward direction) or PSSC = PSSM - correction value (backward direction) with the correction_value = inc_cnt1 - nmb_t. For changing from emergency mode to normal mode at the following STATE slope (according to the RMO value in the shadow register)2) the PSTC value is calculated by PSTC = PSTM + correction_value (forward direction) or PSTC = PSTM - correction value (backward direction) with the correction_value = inc_cnt1 - nmb_s. In the case of no further TRIGGER or STATE events appearing the CPU has to perform the corrections above accordingly.

1) stored in an independent shadow register for a valid TRIGGER event and for DEN = 1.

2) stored in an independent shadow register for a valid STATE event and for DEN = 1.

3) for IFP=1 the time between two valid TRIGGER or STATE events must be always greater then 2,34 µs and the value x of MLT, MLS1 or MLS2 must be chosen such that the number of time stamps pules between two SUB_INC events must be less then 65536. This is fulfilled when x is greater then 256.

4) the time between two valid STATE or TRIGGER events must be always greater then 23,4 ms; in addition the TS_CLK and the resolution must be chosen such that for each nominal increment the time stamps differ at least in the value of 257.

25.16.11.2Register DPLL_CTRL_1

Control register 1.

GTM_DPLL_CTRL_1
DPLL Control Register 1 **(28004_H)** **Reset Value: $B0000000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TSL		SSL		SMC	TS0_HRT	TS0_HRS	SYSF	SWR	LCD	Reserved	SYN_NT				
rw		rw		rw	rw	rw	rw	w	rw	r	rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SYN_NS					PCM2	DLM2	SGE2	PCM1	DLM1	SGE1	PIT	COA	IDDS	DEN	DMO
		rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
DMO[1) 2)]	0	rw	**DPLL mode select** 0_B Automatic end mode; if the number of pulses for a increment is reached, no further pulse is generated until the next valid TRIGGER/STATE is received; in the case of getting a new valid TRIGGER/STATE before the defined number of pulses is reached, the pulse frequency is changed according to the conditions described below (COA) 1_B Continuous mode; in this mode a difference between the predefined number of pulses and the actual number of generated pulses can influence the pulse frequency by writing a corresponding pulse number into CNT_NUM1 or CNT_NUM2 respectively in RAM region 1B.

Field	Bits	Type	Description
DEN	1	rw	**DPLL enable** 0_B The DPLL is not enabled; Disabling the DPLL will result in a reset state of the DPLL_STATUS register which remains in this state until DEN=1. No DPLL related interrupt will be generated in that case. 1_B The DPLL is enabled; Note: The bits 31 down to 0 of the DPLL STATUS register are cleared, when the DPLL is disabled. Some bits of the control registers can be set only when DEN=0. The protected bits in the DPLL_CTRL_1 register can not be written when simultaneously DEN is set to 1.
IDDS	2	rw	**Input direction detection strategy in case of SMC = 0** 0_B The input direction is detected comparing the THMI value with the duration between valid and invalid slope of TRIGGER 1_B The input direction is detected using TDIR input signal also in the case SMC=0 *Note: This bit can only be written when the DPLL is disabled and be fixed to zero, when not needed for an implementation. Independent of the value of IDDS is the direction information for TRIGGER in the case SMC=0 always considered at the moment when the invalid slope appears.*

Field	Bits	Type	Description
COA[1)2)]	3	rw	**Correction strategy in automatic end mode (DMO=0)** 0_B The maximum pulse frequency of the system clock will be used to make up for missing pulses from last increment; the output of the calculated new pulses will be delayed accordingly and the FFs in the pulse generation unit will be reset before sending new pulses 1_B missing pulses of the last increment are distributed evenly to the next increment, calculations are done when the next valid input event appears. The number of missing sub-pulses will be determined by the pulse counter difference between the last two valid TRIGGER/STATE events respectively; the FFs in the pulse generation unit are not reset before sending new pulses. Note: For SMC=RMO=1: COA is used for SUB_INC1 and SUB_INC2.
PIT[1)]	4	rw	**Plausibility value PVT to next valid TRIGGER is time related** 0_B the plausibility value is position related (PVT contains the number of SUB_INC1 pulses) 1_B the plausibility value is time related (the PVT value is to be multiplied with the duration of the last increment DT_T_ACT and divided by 1024)
SGE1[1)2)]	5	rw	**SUB_INC1 generator enable** 0_B The SUB_INC1 generator is not enabled 1_B The SUB_INC1 generator is enabled
DLM1[1)2)]	6	rw	**Direct Load Mode for SUB_INC1 generation** 0_B the DPLL uses the calculated ADD_IN_CAL value for the SUB_INC1 generation 1_B the ADD_IN_LD value is used for the SUB_INC1 generation and is provided by the CPU; the value remains valid until the CPU writes a new one; the calculated ADD_IN values are stored as ADD_IN_CAL in the RAM at different locations for normal and emergency mode

Field	Bits	Type	Description
PCM1[1)2)3)]	7	rw	**Pulse Correction Mode for SUB_INC1 generation** 0_B the DPLL does not use the correction value stored in MPVAL1 1_B the DPLL uses the correction value stored in MPVAL1 in normal and emergency mode
SGE2[2)]	8	rw	**SUB_INC2 generator enable** 0_B The SUB_INC2 generator is not enabled 1_B The SUB_INC2 generator is enabled
DLM2[2)]	9	rw	**Direct Load Mode for SUB_INC2 generation** 0_B the DPLL uses the calculated ADD_IN_CAL value for the SUB_INC2 generation 1_B the ADD_IN_LD value is used for the SUB_INC2 generation and is provided by the CPU; the value remains valid until the CPU writes a new one; the calculated ADD_IN values are stored as ADD_IN_CAL in the RAM at different locations for normal and emergency mode
PCM2[2)3)]	10	rw	**Pulse Correction Mode for SUB_INC2 generation** 0_B the DPLL does not use the correction value stored in MPVAL2 1_B the DPLL uses the correction value stored in MPVAL2

Field	Bits	Type	Description
SYN_NS	[15:11]	rw	**Synchronization number of STATE** Summarized number of virtual increments in HALF_SCALE sum of all systematic missing STATE events in HALF_SCALE (for SYSF=0) or FULL SCALE (for SYSF=1); the SYN_NS missing STATES can be divided up to an arbitrary number of blocks. The pattern of events and missing events in FULL_SCALE is shown in RAM region 1C3 as value NS in addition to the adapt values. The number of stored increments in FULL_SCALE must be equal to 2*(SNU+1-SYN_NS) for SYSF=0 or 2*(SNU+1)-SYN_NS for SYSF=1. This pattern is written by the CPU beginning from a fixed reference point (maybe beginning of the FULL_SCALE region). The relation to the actual increment is established by setting of the profile RAM pointer APS_1C3 in an appropriate relation to the RAM pointer APS of the actual increment by the CPU. Note: This value can only be written when the DPLL is disabled.
SYN_NT	[20:16]	rw	**Synchronization number of TRIGGER** Summarized number of virtual increments in HALF_SCALE. Sum of all systematic missing TRIGGER events in HALF_SCALE; the SYN_NT missing TRIGGER can be divided up to an arbitrary number of blocks. The pattern of events and missing events in FULL_SCALE is shown in RAM region 2C as value NT in addition to the adapt values. The number of stored increments in FULL_SCALE must be equal to 2*(TNU-SYN_NT). This pattern is written by the CPU beginning from a fixed reference point (maybe beginning of the FULL_SCALE region). The relation to the actual increment is established by setting of the profile RAM pointer APT_2C in an appropriate relation to the RAM pointer APT of the actual increment by the CPU. Note: This value can only be written when the DPLL is disabled.
Reserved	21	r	**Reserved** Read as zero, should be written as zero.

Field	Bits	Type	Description
LCD	22	rw	**Locking condition definition** 0_B locking condition definition is one times missing TRIGGERs as expected by the profile in HALF_SCALE (one gap) 1_B locking condition definition is n-1 times missing TRIGGERs as expected by the profile in HALF_SCALE (one additional tooth) *Note: This bit can only be written when the DPLL is disabled and be fixed to zero, when not needed for an implementation.*
SWR	23	w	**Software Reset** resets all register and internal states of the DPLL 0_B no software reset enabled 1_B software reset enabled Setting the SWR bit results only in a software reset when the DPLL is not enabled (DEN=0). Read as zero.
SYSF	24	rw	**SYN_NS for FULL_SCALE** The value SYN_NS does mean the sum of all systematic missing STATE events in HALF_SCALE (for SYSF=0) or FULL SCALE (for SYSF=1) 0_B the SYN_NS value is valid for HALF_SCALE 1_B the SYN_NS value is valid for FULL_SCALE Note: This value can only be written when the DPLL is disabled.
TS0_HRS	25	rw	**TS0_HRS** 0_B the resolution of the used DPLL input TBU_TS0 bits is equal to the STATE input time stamp resolution 1_B the STATE input time stamps have a 8 times higher resolution as the TBU_TS0 DPLL input Note: This bit can only be written when the DPLL is disabled.

Field	Bits	Type	Description
TS0_HRT	26	rw	**TS0_HRT** 0_B the resolution of the used DPLL input TBU_TS0 bits is equal to the TRIGGER input time stamp resolution 1_B the TRIGGER input time stamps have a 8 times higher resolution as the TBU_TS0 input Note: This bit can only be written when the DPLL is disabled.
SMC	27	rw	**Synchronous Motor Control** 0_B the TRIGGER and STATE inputs are used for a control to SMC 1_B the TRIGGER input reflects a combined sensor signal for SMC and in the case of RMO=1 also STATE reflects a different combined sensor signal Note: This bit can only be written when the DPLL is disabled.
SSL	[29:28]	rw	**STATE slope select** Definition of active slope for signal STATE each active slope is an event defined by SNU. Set by DEN=0 only. 00_B No slope of STATE will be used; this value makes only sense in normal mode 01_B Low high slope will be used as active slope, only inputs with a signal value of “1” will be considered 10_B High low slope will be used as active slope, only inputs with a signal value of “0” will be considered 11_B Both slopes will be used as active slopes Note: This bits can only be written when the DPLL is disabled.
TSL	[31:30]	rw	**Definition of active slope for signal TRIGGER each active slope is an event defined by TNU** Set by DEN=0 only. 00_B No slope of TRIGGER will be used; this value makes only sense in emergency mode 01_B Low high slope will be used as active slope, only inputs with a signal value of “1” will be considered 10_B High low slope will be used as active slope, only inputs with a signal value of “0” will be considered 11_B Both slopes will be used as active slopes Note: This bits can only be written when the DPLL is disabled.

1) stored in an independent shadow register for a valid TRIGGER event and for DEN = 1.
2) stored in an independent shadow register for a valid STATE event and for DEN = 1.
3) Bit is cleared, when transmitted to shadow register

Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

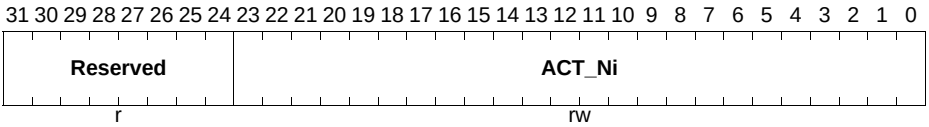
25.16.11.6Register DPLL_ACT_STA

Action status register including shadow register.

GTM_DPLL_ACT_STA
DPLL ACTION Status Register With Shadow Register
(28018_H) **Reset Value: 00000000_H**



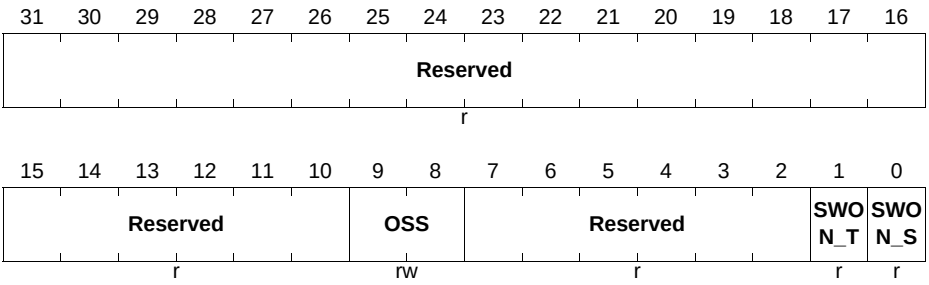
Field	Bits	Type	Description
ACT_Ni	[23:0]	rw	**New output data values concerning to action i provided** 0_B no new output data available after a recent PMT request or actual event value is in the past or invalid 1_B new PMTR data received or calculation is to be precise by taking into account new TRIGGER or STATE values Note: ACT_Ni is • set (for AENi=1 and a new valid PMTR), that means when new action data are to be calculated for the correspondent action. After each calculation of the new actions values the ACT_Ni bit updates the corresponding bit in the connected shadow register. The status of the ACT_Ni bits in the shadow register is reflected by the corresponding DPLL output signal ACT_V (valid bit). • reset together with the corresponding shadow register bit for AENi=0; • reset without the corresponding shadow register bit when the calculated event is in the past • the corresponding shadow register bit is reset, when new PMTR data are written or when the provided action data are read (blocking read) • writable for debugging purposes together with the corresponding shadow register when DEN=0 Note: This bit can only be written when the DPLL is disabled.

Field	Bits	Type	Description
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.7Register DPLL_OSW

Offset and switch old/new address register.

GTM_DPLL_OSW
DPLL Offset And Switch Old/New Address Register
(2801C$_H$) **Reset Value: 00000200$_H$**



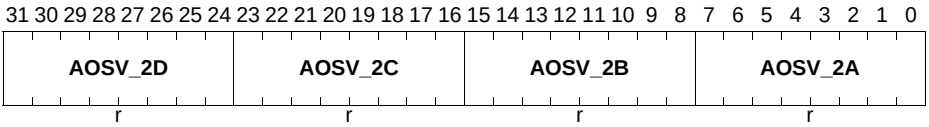
Field	Bits	Type	Description
SWON_S	0	r	**Switch of new STATE** Switch bit for LSB address of STATE. This bit is changed for each write access to TS_S/TS_S_OLD. Using this unchanged address bit SWON_S for any access to TS_S results always in an access to TS_S_OLD. For writing to this address the former old (TS_S_OLD_OLD) value is overwritten by the new one while the SWON_S bit changes. Thus the former new one is now the old one and the next access is after changing SWON_S directed to this place. Therefore write to TS_S first and after that immediately to FTV_S and PSSM, always before a new TS_S value is to be written. Note: After writing TS_S, FTV_S and PSSM in this order the address pointer AP with LSB(AP)=SWON_S shows for the corresponding address to TS_S_OLD, FTV_S and PSSM while LSB(AP)=/SWON_S results in an access to TS_S, FTV_S_OLD and PSSM_OLD respectively. The value can be read only. This bit is reset when disabling the DPLL (DEN = 0).

Field	Bits	Type	Description
SWON_T	1	r	**Switch of new TRIGGER** Switch bit for LSB address of TRIGGER. This bit is changed for each write access to TS_T/TS_T_OLD. Using this unchanged address bit SWON_T for any access to TS_T results always in an access to TS_T_OLD. For writing to this address the former old (TS_T_OLD_OLD) value is overwritten by the new one while the SWON_T bit changes. Thus the former new one is now the old one and the next access is after changing SWON_T directed to this place. Therefore write to TS_T first and after that immediately to FTV_T and PSTM, always before a new TS_T value is to be written. Note: After writing TS_T, FTV_T and PSTM in this order the address pointer AP with LSB(AP)=SWON_T shows for the corresponding address to TS_T_OLD, FTV_T and PSTM while LSB(AP)=/SWON_T results in an access to TS_T, FTV_T_OLD and PSTM_OLD respectively. The value can be read only. This bit is reset when disabling the DPLL (DEN = 0).
Reserved	[7:2]	r	**Reserved** Read as zero, should be written as zero.
OSS	[9:8]	rw	**Offset size of RAM region 2** 00_B Offset size 128 of RAM region 2. 01_B Offset size 256 of RAM region 2. 10_B Offset size 512 of RAM region 2. 11_B Offset size 1024 of RAM region 2. Note: At least 128 and at most 1024 values can be stored in each of the RAM 2 regions a to d accordingly. The value can be set only for DEN=0. The change of the OSS value results in an automatic change of the offset values in the DPLL_AOSV_2 register. Note: This bits can only be written when the DPLL is disabled.
Reserved	[31:10]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.8Register DPLL_AOSV_2

Address offset register of RAM 2 regions

GTM_DPLL_AOSV_2
DPLL Address Offset Register For APT In RAM Region 2
(28020_H) **Reset Value: 18100800_H**



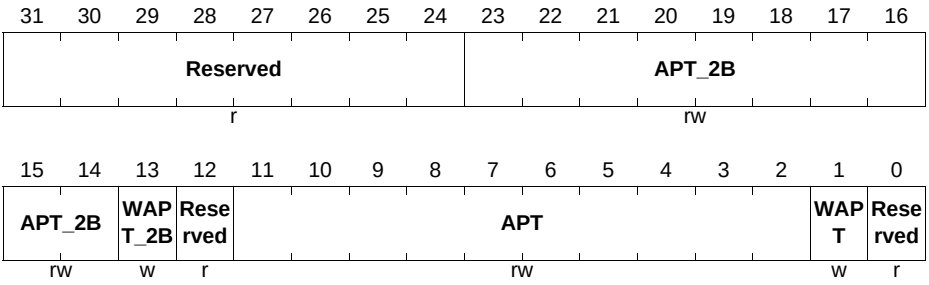
Field	Bits	Type	Description
AOSV_2A	[7:0]	r	**Address offset value of the RAM 2A region** The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2A. When the APT value is added to this start address, the current RAM cell RDT_Tx is addressed.
AOSV_2B	[15:8]	r	**Address offset value of the RAM 2B region** The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2B. When the APT value is added to this start address, the current RAM cell TSF_Tx is addressed.
AOSV_2C	[23:16]	r	**Address offset value of the RAM 2C region** The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2C. When the APT value is added to this start address, the current RAM cell ADT_Tx is addressed.

Field	Bits	Type	Description
AOSV_2D	[31:24]	r	**Address offset value of the RAM 2D region** The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2D. When the APT value is added to this start address, the current RAM cell DT_Tx is addressed. Note: The offset values are needed to support a scalable RAM size of region 2 from 1,5 Kbytes to 12 Kbytes. The values above must be in correlation with the offset size defined in the OSW register. All offset values are set automatically in accordance to the OSS value in the DPLL_OSW register. This value can be set only for DEN=0.

25.16.11.9Register DPLL_APT

Actual RAM pointer address for TRIGGER.

GTM_DPLL_APT
DPLL Actual RAM Pointer to RAM Regions 2A, B and D
(28024_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
Reserved	0	r	**Reserved** Read as zero, should be written as zero.

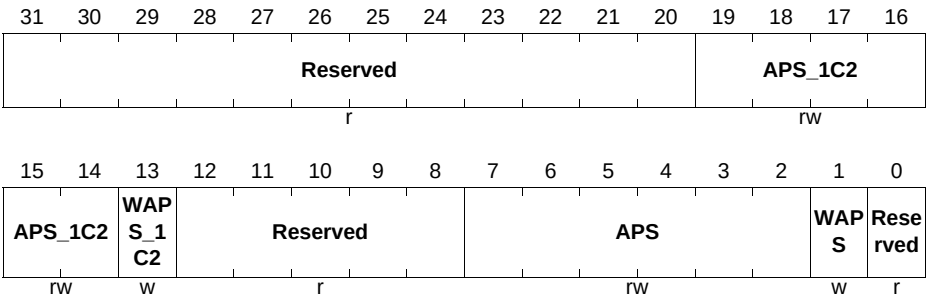
Field	Bits	Type	Description
WAPT	1	w	**Write bit for address pointer APT** read as zero 0_B the APT is not writable 1_B the APT is writable Note: This bit is cleared automatically after write.
APT	[11:2]	rw	**Address pointer TRIGGER** Actual RAM pointer address value offset for DT_T[i] and RDT_T[i] in FULL_SCALE for 2*(TNU+1-SYN_NT) TRIGGER events This pointer is used for the RAM region 2 subsections 2A and 2D. The pointer APT is increment for each valid TRIGGER event (simultaneously with APT_2B, APT_2C) for DIR1=0. For DIR1=1 the APT is decremented. The APT offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region Note: The APT pointer value is directed to the RAM position, in which the data values are to be written, which corresponds to the last increment. The APT value is not to be changed, when the direction (shown by DIR1) changes, because it points always to a storage place after the considered increment. Changing of DIR1 takes place always after a valid TRIGGER event and the resulting increment/decrement. Note: This value can only be written when the WAPT bit is set.
Reserved	12	r	**Reserved** Read as zero, should be written as zero.
WAPT_2B	13	w	**Write bit for address pointer APT_2B** read as zero 0_B the APT_2B is not writable 1_B the APT_2B is writable Note: This bit is cleared automatically after write.

Field	Bits	Type	Description
APT_2B	[23:14]	rw	**Address pointer TRIGGER for RAM region 2B** Actual RAM pointer address value for TSF_T[i] Actual RAM pointer address of TRIGGER events in FULL_SCALE for 2*(TNU+1) TRIGGER periods; this pointer is used for the RAM region 2B. The RAM pointer is initially set to zero. For SYT = 1: The pointer APT_2B is increment by SYN_T_OLD for each valid TRIGGER event (simultaneously with APT and APT_2C) for DIR1=0 when a valid TRIGGER input appears. For DIR1=1 (backwards) the APT is decremented by SYN_T_OLD. For SYT = 0: APT_2B is incremented or decremented by 1. In addition when the APT_2C value is written by the CPU - in order to synchronize the DPLL- with the next valid TRIGGER event the APT_2B_EXT value is added/subtracted (while APT_2B_STATUS is one; see DPLL_APT_SYNC register at **Chapter 25.16.11.23**). Note: This value can only be written when the WAPT_2B bit is set.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.10Register DPLL_APS

Actual RAM pointer address for STATE.

GTM_DPLL_APS
DPLL Actual RAM Pointer to RAM Regions 1C1, 1C2 and 1C4
(28028_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
Reserved	0	r	**Reserved** Read as zero, should be written as zero.
WAPS	1	w	**Write bit for address pointer APS** read as zero 0_B the APS is not writable 1_B the APS is writable Note: This bit is cleared automatically after write.

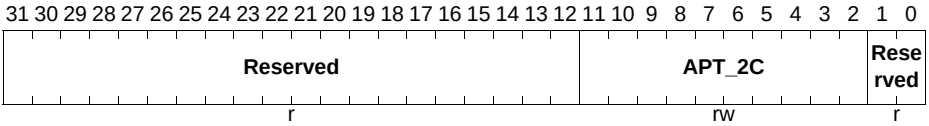
Field	Bits	Type	Description
APS	[7:2]	rw	**Address pointer STATE** Actual RAM pointer address value for DT_S[i] and RDT_S[i] Actual RAM pointer and synchronization position/value of STATE events in FULL_SCALE for up to 64 STATE events but limited to 2*(SNU+1-SYN_NS) in normal and emergency mode for SYSF=0 or to 2*(SNU+1)-SYN_NS for SYSF=1 respectively; this pointer is used for the RAM region 1C1 and 1C4. APS is incremented (decremented) by one for each valid STATE event and DIR2=0 DIR2=1). The APS offset value is added in the above shown bit position with the subsection offset of the RAM region. Note: The APS pointer value is directed to the RAM position, in which the data values are to be written, which correspond to the last increment. The APS value is not to be changed, when the direction (shown by DIR2) changes, because it points always to a storage place after the considered increment. Changing of DIR2 takes place always after a valid STATE event and the resulting increment/decrement. Note: This value can only be written when the WAPS bit is set.
Reserved	[12:8]	r	**Reserved** Read as zero, should be written as zero.
WAPS_1C2	13	w	**Write bit for address pointer APS_1C2** read as zero 0_B the APS_1C2 is not writable 1_B the APS_1C2 is writable Note: This bit is cleared automatically after write.

Field	Bits	Type	Description
APS_1C2	[19:14]	rw	**Address pointer STATE for RAM region 1C2** Actual RAM pointer address value for TSF_S[i] Initial value: zero (0x00). Actual RAM pointer and synchronization position/value of STATE events in FULL_SCALE for up to 64 STATE events but limited to 2*(SNU+1) in normal and emergency mode; this pointer is used for the RAM region 1C2. For SYS=1:APS_1C2 is increment (decremented) by SYN_S_OLD for each valid STATE event and DIR2=0 (DIR2=1). The APS_1C2 offset value is added in the above shown bit position with the subsection offset of the RAM region. For SYS=0: APT_1C2 is incremented or decremented by 1 respectively. In addition when the APS_1C3 value is written by the CPU - in order to synchronize the DPLL- with the next valid STATE event the APS_1C2_EXT value is added/subtracted (while APS_1C2_STATUS is one; see DPLL_APT_SYNC register at **Section 25.16.11.24**). Note: This value can only be written when the WAPS_1C2 bit is set.
Reserved	[31:20]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.11Register DPLL_APT_2C

Actual RAM pointer address for region 2C.

GTM_DPLL_APT_2C
DPLL Actual RAM Pointer to RAM Region 2C
($2802C_H$) **Reset Value: 00000000_H**



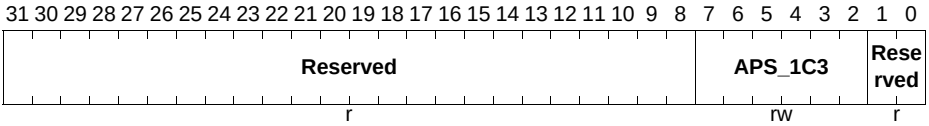
Field	Bits	Type	Description
Reserved	[1:0]	r	**Reserved** Read as zero, should be written as zero.
APT_2C	[11:2]	rw	**Address pointer TRIGGER for RAM region 2C** Actual RAM pointer address value for ADT_T[i] Actual RAM pointer address value of TRIGGER adapt events in FULL_SCALE for 2*(TNU+1-SYN_NT) TRIGGER periods depending on the size of the used RAM 2; this pointer is used for the RAM region 2 for the subsection 2C only. The RAM pointer is initially set to zero. The APT_2C value is set by the CPU when the synchronization condition was detected. Within the RAM region 2C initially the conditions for synchronization gaps and adapt values are stored by the CPU.

Field	Bits	Type	Description
Reserved	[31:12]	r	**Reserved** Read as zero, should be written as zero. Note: The APT_2C pointer values are directed to the RAM position of the profile element in RAM region 2C, which correspond to the current increment. For DIR1=0 (DIR1=1) the pointers APT_2C_x are increment (decremented) by one simultaneously with APT. For SMC=0 the change of DIR1 takes place always after a valid TRIGGER event (by evaluation of the invalid slope) and the resulting increment/decrement. In the case SMC=1 the direction change is known before the input event is processed. The correction of the APT_2C pointer differs: for SMC=0 correct 4 times and for SMC=1 correct only 2 times. The APT_2C_x offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region.

25.16.11.12Register DPLL_APS_1C3

Actual RAM pointer address for RAM region 1C3.

GTM_DPLL_APS_1C3
DPLL Actual RAM Pointer to RAM Region 1C3
(28030_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
Reserved	[1:0]	r	**Reserved** Read as zero, should be written as zero.
APS_1C3	[7:2]	rw	**Address pointer STATE for RAM region 1C3** Initial value: zero (0x00). Actual RAM pointer and synchronization position/value of STATE events in FULL_SCALE for up to 64 STATE events but limited to 2*(SNU+1-SYN_NS) in normal and emergency mode for SYSF=0 or to 2*(SNU+1)-SYN_NS for SYSF=1 respectively; this pointer is used for the RAM region 1C3. The RAM pointer is set by the CPU accordingly, when the synchronization condition was detected.
Reserved	[31:8]	r	**Reserved** Read as zero, should be written as zero. Note: The APS_1C3 pointer value is directed to the RAM position of the profile element in RAM region 1C2, which corresponds to the current increment. When changing the direction DIR1 or DIR2 respectively, this is always known before a valid STATE event is processed. This is because of the pattern recognition in SPE (for PMSM) or because of the direction change recognition by TRIGGER. This direction change results in an automatic increment (forwards) or decrement (backwards) when the input event occurs in addition with a 2 times correction. The APS_1C3_x offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region.

25.16.11.13Register DPLL_NUTC

number of recent TRIGGER events used for calculations.

GTM_DPLL_NUTC
DPLL Number of Recent TRIGGER Events Used for Calculations
(28034$_H$) **Reset Value: 00012001$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WVTN	WSYN	WNUT	Reserved				VTN						SYN_T_OLD		
w	w	w	r				rw						rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SYN_T			Reserved		FST	NUTE									
rw			r		rw	rw									

Field	Bits	Type	Description
NUTE	[9:0]	rw	**Number of recent TRIGGER events used for SUB_INC1 and action calculations modulo 2*(TNUmax+1)** NUTE: number of last nominal increments to be considered for the calculations. No gap is considered in that case for this value, but in the VTN value (see below): This register is set by the CPU, but reset automatically to “1” by a change of direction or lost of LOCK. Each other value can be set by the CPU, maybe FULL_SCALE, HALF_SCALE or parts of them. For FULL_SCALE set NUTE=2*(TNU+1) and fir HALF_SCALE NUTE=TNU+1.The relation values QDT_Tx are calculated using NUTE values in the past with its maximum value of 2*(TNU +1). The value zero (in combination with the value FST=1) does mean 211 values in the past. Note: This value can only be written when the WNUT bit is set.

Field	Bits	Type	Description
FST	10	rw	**this value is to be set, when NUTE is set to FULL_SCALE** 0= the NUTE value is less then FULL_SCALE 1= the NUTE value is equal to FULL_SCALE Note: This value can only be written when the WNUT bit is set.
Reserved	[12:11]	r	**Reserved** Read as zero, should be written as zero.
SYN_T	[15:13]	rw	**Number of real and virtual events to be considered for the current increment** This value reflects the NT value of the last valid increment, stored in ADT_T[i]; to be updated after all calculations in step 17 of **Table 25-48**. Note: This value can only be written when the WSYN bit is set.
SYN_T_OLD	[18:16]	rw	**Number of real and virtual events to be considered for the last increment** This value reflects the NT value of the last but one valid increment, stored in ADT_T[i]; is updated automatically when writing SYN_T. Note: This value is updated by the SYN_T value when the WSYN bit is set.

Field	Bits	Type	Description
VTN	[24:19]	rw	**Virtual TRIGGER number** Number of virtual increments in the current NUTE region This value reflects the number of virtual increments in the current NUTE region; for NUTE=1 this value is zero, when the CPU sets NUTE to a value > 1, it must also set VTN to the correspondent value; for NUTE is set to FULL_SCALE including NUTE=zero (211 modulo 211) the VTN is to be set to 2* SYN_NT. the VTN value is subtracted from the NUTE value in order to get the corresponding APT value for the past; the VTN value is not used for the APT_2B pointer. VTN is to be updated by the CPU when a new gap is to be considered for NUTE or a gap is leaving the NUTE region; for this purpose the TINT values in the profile can be used to generate an interrupt for the CPU at the corresponding positions; no further update of VTN is necessary when NUTE is set to FULL_SCALE Note: This value can only be written when the WVTN bit is set.
Reserved	[28:25]	r	**Reserved** Read as zero, should be written as zero.
WNUT	29	w	**Write control bit for NUTE and FST** read as zero 0_B the NUTE value is not writable 1_B the NUTE value is writable Note: This bit is cleared automatically after write.
WSYN	30	w	**Write control bit for SYN_T and SYN_T_OLD** read as zero 0_B the SYN_T value is not writable 1_B the SYN_T value is writable Note: This bit is cleared automatically after write.
WVTN	31	w	**Write control bit for VTN** read as zero 0_B the VTN value is not writable 1_B the VTN value is writable Note: This bit is cleared automatically after write.

25.16.11.14Register DPLL_NUSC

Number of recent STATE events used for calculations.

GTM_DPLL_NUSC
DPLL Number of Recent STATE Events Used for Calculations

(28038_H) **Reset Value: 00002081_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	r				rw						rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SYN_S_OLD			SYN_S						FSS	NUSE					
rw			rw						rw	rw					

Field	Bits	Type	Description
NUSE	[5:0]	rw	**Number of recent STATE events used for SUB_INCx calculations modulo 2*(SNUmax+1)** No gap is considered in that case for this value, but in the VSN value (see below): This register is set by the CPU but reset automatically to “1” by a change of direction or lost of LOCK. Each other value can be set by the CPU, maybe FULL_SCALE, HALF_SCALE or parts of them. The relation values QDT_Sx are calculated using NUSE values in the past with its maximum value of 2*SNU+1. Note: This value can only be written when the WNUS bit is set.
FSS	6	rw	**this value is to be set, when NUSE is set to FULL_SCALE** 0= the NUSE value is less then FULL_SCALE 1= the NUSE value is equal to FULL_SCALE Note: This value can only be written when the WNUT bit is set.

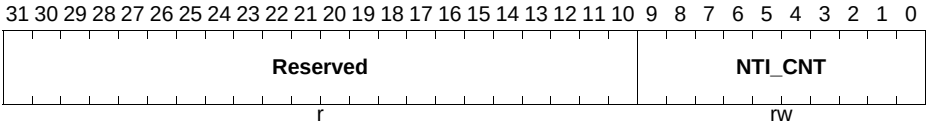
Field	Bits	Type	Description
SYN_S	[12:7]	rw	**Number of real and virtual events to be considered for the current increment** This value reflects the NS value of the last valid increment, stored in ADT_S[i]; to be updated after all calculations in step 37 of **Table 25-48**. Note: This value can only be written when the WNUS bit is set.
SYN_S_OLD	[18:13]	rw	**Number of real and virtual events to be considered for the last increment** This value reflects the NS value of the last but one valid increment, stored in ADT_S[i]; is updated automatically when writing SYN_S. Note: This value is updated by the SYN_S value when the WSYN bit is set.
VSN	[24:19]	rw	**Virtual STATE number** Number of virtual state increments in the current NUSE region This value reflects the number of virtual increments in the current NUSE region; for NUSE=1 this value is zero, when the CPU sets NUSE to a value > 1 or zero(27 modulo 27), it must also set VSN to the correspondent value; the VSN value is subtracted from the NUSE value in order to get the corresponding APS value for the past; the VSN value is not used for the APS_1C2 pointer. VSN is to be updated by the CPU when a new gap is to be considered for NUSE or a gap is leaving the NUSE region; for this purpose the SASI interrupt can be used; no further update of VSN is necessary when NUSE is set to FULL_SCALE. Note: This value can only be written when the WVSN bit is set.
Reserved	[28:25]	r	**Reserved** Read as zero, should be written as zero.
WNUS	29	w	**Write control bit for NUSE; read as zero** 0_B the NUSE value is not writable 1_B the NUSE value is writable Note: This bit is cleared automatically after write.

Field	Bits	Type	Description
WSYN	30	w	**Write control bit for SYN_S and SYN_S_OLD; read as zero** 0_B the SYN_S value is not writable 1_B the SYN_S value is writable Note: This bit is cleared automatically after write.
WVSN	31	w	**Write control bit for VSN; read as zero** 0_B the VSN value is not writable 1_B the VSN value is writable Note: This bit is cleared automatically after write.

25.16.11.15Register DPLL_NTI_CNT

Number of active TRIGGER events to interrupt.

GTM_DPLL_NTI_CNT
DPLL Number of Active TRIGGER Events to Interrupt
(2803C$_H$) **Reset Value: 00000000$_H$**



Field	Bits	Type	Description
NTI_CNT	[9:0]	rw	**Number of TRIGGERs to interrupt** Number of active TRIGGER events to the next DPLL_CDTI interrupt. This value shows the remaining TRIGGER events until an active TRIGGER slope results in a DPLL_CDTI interrupt; the value is to be count down for each valid TRIGGER event.
Reserved	[31:10]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.16Register DPLL_IRQ_NOTIFY

Interrupt register.

GTM_DPLL_IRQ_NOTIFY
DPLL Interrupt Notification Register (28040_H) **Reset Value: 00000000_H**

APT_2B_OLD		Reserved							APT_2B_STATUS	APT_2B_EXT					
rw		r							rw	rw					

Field	Bits	Type	Description
APT_2B_EXT	[5:0]	rw	**Address pointer 2B extension** Set by CPU before the synchronization is performed This offset value is the number of virtual increments to be considered for an imminent intended synchronization; the CPU sets its value dependent on the gaps until the synchronization time taking into account the considered NUTE value to be set and including the next future increment (when SYN_T_OLD is still 1). When the synchronization takes place, this value is to be added to the APT_2B address pointer (for forward direction, DIR1=0) and the APT_2B_STATUS bit is cleared after it. For backward direction subtract APT_2B_EXT accordingly. Note: When the synchronization is intended and the NUTE value is to be set to FULL_SCALE after it, the APT_2B_EXT value must be set to 2*SYN_NT in order to be able to fill all gaps in the extended TSF_T with the corresponding values by the CPU. When still not all values for FULL_SCALE are available, the APT_2B_EXT value considers only a share according to the corresponding NUTE value to be set after the synchronization.
APT_2B_STATUS	6	rwh	**Address pointer 2B status** Set by CPU before the synchronization is performed The value is cleared when the APT_2B_OLD value is written status bit 0_B APT_2B_EXT is not to be considered. 1_B APT_2B_EXT has to be considered for time stamp field extension.
Reserved	[13:7]	r	**Reserved** Read as zero, should be written as zero.

Field	Bits	Type	Description
APT_2B_OLD	[23:14]	rw	**Address pointer TRIGGER for RAM region 2B at synchronization time** This value is set by the current APT_2B value when the synchronization takes place for the first valid TRIGGER event after writing APT_2C but before adding the offset value APT_2B_EXT (that means when APT_2B_STATUS=1) Address pointer APT_2B value at the moment of synchronization, before the offset value is added, that means the pointer with this value points to the last value before the additional inserted gap
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.24Register DPLL_APS_SYNC

STATE time stamp field offset at synchronization time.

GTM_DPLL_APS_SYNC
DPLL Old RAM Pointer and Offset Value for STATE
(280BC$_H$) **Reset Value: 00000000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

APS_1C2_OLD		Reserved							APS_1C2_STATUS	APS_1C2_EXT					
rw		r							rw	rw					

Field	Bits	Type	Description
APS_1C2_EXT	[5:0]	rw	**Address pointer 1C2 extension** set by CPU before the synchronization is performed This offset value is the number of virtual increments to be considered for an imminent intended synchronization; the CPU sets its value dependent on the gaps until the synchronization time taking into account the considered NUSE value to be set and include the next future increment (when SYN_S_OLD is still 1). When the synchronization takes place, this value is to be added to the APS_1C2 address pointer (for forward direction, DIR2=0) and the APT_1C2_status bit is cleared after it. For backward direction subtract APS_1C2_EXT accordingly. Note: When the synchronization is intended and the NUSE value is to be set to FULL_SCALE after it, the APS_1C2_EXT value must be set to SYN_NS (for SYSF=1) or 2*SYN_NS (for SYSF=0) in order to be able to fill all gaps in the extended TSF_S with the corresponding values by the CPU. When still not all values for FULL_SCALE are available, the APS_1C2_EXT value considers only a share according to the NUSE value to be set after the synchronization.
APS_1C2_STATUS	6	rwh	**Address pointer 1C2 status** set by CPU before the synchronization is performed The value is cleared automatically when the APS_1C2_OLD value is written 0_B APT_2B_EXT is not to be considered. 1_B APT_2B_EXT has to be considered for time stamp field extension.
Reserved	[13:7]	r	**Reserved** Read as zero, should be written as zero.

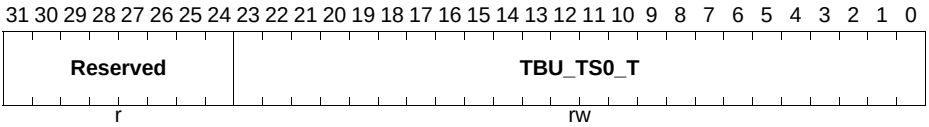
Field	Bits	Type	Description
APS_1C2_OLD	[19:14]	rw	**Address pointer STATE for RAM region 1C2 at synchronization time** This value is set by the current APS_1C2 value when the synchronization takes place for the first valid STATE event after writing APS_1C3 but before adding the offset value APS_1C2_EXT (that means when APS_1C2_STATUS=1) Address pointer APS_1C2 value at the moment of synchronization, before the offset value is added, that means the pointer with this value points to the last value before the additional inserted gap
Reserved	[31:20]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.25Register DPLL_TBU_TS0_T

Time stamp value for the last valid TRIGGER.

GTM_DPLL_TBU_TS0_T
DPLL TBU_TS0 Value at last TRIGGER Event

(280C0$_H$) **Reset Value: 00000000$_H$**



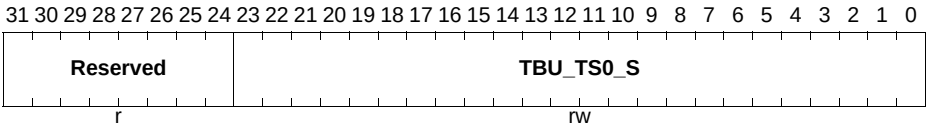
Field	Bits	Type	Description
TBU_TS0_T	[23:0]	rw	**value of TBU_TS0 at the last TRIGGER event** For each T_VALID the value of TBU_TS0 is stored in this register; The register is writable only for test purposes when DEN=0. Note: This value can only be written when the DPLL is disabled.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.26Register DPLL_TBU_TS0_S

Time stamp value for the last valid STATE.

GTM_DPLL_TBU_TS0_S
DPLL TBU_TS0 Value at last STATE Event

(280C4$_H$) **Reset Value: 00000000$_H$**

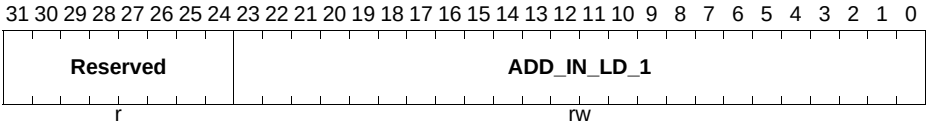


Field	Bits	Type	Description
TBU_TS0_S	[23:0]	rw	**value of TBU_TS0 at the last STATE event** For each S_VALID the value of TBU_TS0 is stored in this register; The register is writable only for test purposes when DEN=0. Note: This value can only be written when the DPLL is disabled.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.27Register DPLL_ADD_IN_LD1

ADD_IN value in direct load mode for TRIGGER.

GTM_DPLL_ADD_IN_LD1
DPLL Direct Load Input Value for SUB_INC1
($280C8_H$) **Reset Value: 00000000_H**

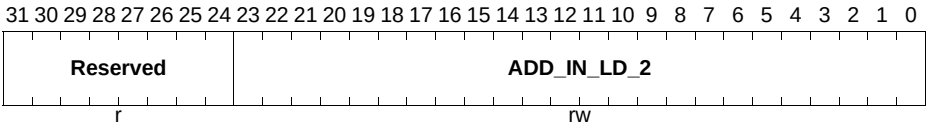


Field	Bits	Type	Description
ADD_IN_LD_1	[23:0]	rw	**Input value for SUB_INC1 generation** given by CPU This value can be used in normal and emergency mode (SMC=0) as well as for SMC=1 *Note: The value is loaded by the CPU but used by the DPLL only for DLM1=1 (see DPLL_CRTL_1 register). When switching DLM1 to 1, the value in the register is used for the SUB_INC1 generation beginning from the next valid TRIGGER or STATE event respectively independently if new values are written by the CPU or not.* *Note: When a new value is written the output frequency changes according to the given value beginning immediately from the moment of writing. Do not wait for performing step 10 in the state machine for ADD_in calculations.* *Note: If ADD_IN_LD1 value is zero all pules are sent with the highest possible frequency.*
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.28Register DPLL_ADD_IN_LD2

ADD_IN value in direct load mode STATE.

GTM_DPLL_ADD_IN_LD2
DPLL Direct Load Input Value for SUB_INC1
(280CC$_H$) **Reset Value: 00000000$_H$**



Field	Bits	Type	Description
ADD_IN_LD_2	[23:0]	rw	**Input value for SUB_INC2 generation** given by CPU This value can be used for SMC=1 while RMO=1 *Note: The value is loaded by the CPU but used by the DPLL only for DLM2=1 (see DPLL_CRTL_1 register). When switching DLM2 to 1, the value in the register is used for the SUB_INC2 generation beginning from the next valid STATE event respectively independently if new values are written by the CPU or not.* *Note: When a new value is written the output frequency changes according to the given value beginning immediately from the moment of writing. Do not wait for performing step 30 in the state machine for ADD_in calculations.* *Note: If ADD_IN_LD2 value is zero all pules are sent with the highest possible frequency.*
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.29Register DPLL_STATUS

Status register.

The DPLL_STATUS register is reset, when the DPLL is disabled (switching DEN from 1 to 0).

GTM_DPLL_STATUS
DPLL Status Register **($280FC_H$)** **Reset Value: 00000000_H**

Field	Bits	Type	Description
Reserved	0	r	**Reserved** Read as zero, should be written as zero.
CSO	1	rwh	**Calculated STATE duration overflow** Bit is set when equations DPLL-10a or DPLL-10b lead to an overflow. 0_B No overflow at equation DPLL-10a or b 1_B overflow at equation DPLL-10a or b
Reserved	2	r	**Reserved** Read as zero, should be written as zero.
CTO	3	rwh	**Calculated TRIGGER duration overflow** Bit is set when equations DPLL-5a or DPLL-5b lead to an overflow. 0_B No overflow at equation DPLL-5a or b 1_B overflow at equation DPLL-5a or b *Note: When one of the above bits is set the corresponding register contains the maximum value 0xFFFFFF.*

Field	Bits	Type	Description
CRO	4	rwh	**Calculated Reciprocal value overflow** Bit is set when the calculation of RDT_T_actual or RDT_S_actual leads to an overflow. 0_B No overflow at any reciprocal calculation 1_B overflow for at least one reciprocal calculation *Note: An overflow in calculation of reciprocal values can occur, when the condition of Note 3) to the DPLL_CTRL_0 register is violated (see chapter 16.11.1). Such an overflow can occur according to the calculations in equations (DPLL-1c) or (DPLL-6c).* The overflow is detected when after the calculation and shifting left 32 bits at least one of the bits 31 to 24 is not zero. In that case the corresponding register is set to 0xFFFFFF.
RCS	5	rh	**RCS** 0_B No resolution conflict detected 1_B the TS0_HRT value is set to 1 while LOW_RES=0
RCT	6	rwh	**RCT** 0_B No resolution conflict detected 1_B the TS0_HRS value is set to 1 while LOW_RES=0
PSE	7	rwh	**Prediction space configuration error** 0_B No prediction space error detected 1_B Configured offset value of RAM2 is too small in order to store all TNU+1 values twice in FULL_SCALE
SOR	8	rh	**STATE out of range** 0_B all STATE signal events appear within SLR interval or a direction change was detected 1_B at least one STATE signal event is out of SLR; address pointers APS, APS_1C2, and APS_1C3 are frozen and generated of pulse SUB_INC1,2 respectively is stopped The SOR bit is set, when the time to the next active STATE slope exceeds the value of the last nominal STATE duration multiplied with the value of the SLR register (see chapter 16.13.37) and is reset, when at the current or last valid input event a direction change was detected. the SYS bit is not influenced by setting the SOR bit.

Field	Bits	Type	Description
MS	9	rh	**Missing STATE detected according to TOV_S** 0_B No missing STATE detected or a new valid STATE slope occurred 1_B At least one missing STATE detected after the last valid slope
TOR	10	rh	**TRIGGER out of range** 0_B all TRIGGER signal events appear within TLR interval or a direction change was detected 1_B at least one TRIGGER signal event is out of TLR; address pointers APT, APT_2B, and APT_2C are frozen and generated of pulse SUB_INC1 respectively is stopped The TOR bit is set, when the time to the next active TRIGGER slope exceeds the value of the last nominal TRIGGER duration multiplied with the value of the TLR register (see chapter 16.13.36) and is reset, when at the current or last valid input event a direction change was detected. The SYT bit is not influenced by setting the TOR bit.
MT	11	rwh	**Missing TRIGGER detected according to TOV** 0_B No missing TRIGGER detected or a new valid TRIGGER slope occurred 1_B At least one missing TRIGGER detected after the last valid slope
RAM2_ERR	12	rwh	**DPLL internal access to not configured RAM2** 0_B No access to not configured RAM2 memory space 1_B access to not configured RAM2 memory space
Reserved	[14:13]	r	**Reserved** Read as zero, should be written as zero.
LOW_RES	15	rwh	**Low resolution of TBU_TS0 is used for DPLL input** This value reflects the input signal LOW_RES. 0_B the lower 24 Bits of TBU_TS0 are used as input for the DPLL 1_B the higher 24 Bits of TBU_TS0 are used as input for the DPLL
CSVS	16	rh	**Current signal value STATE** 0_B the last STATE_S value was 0 1_B the last STATE_S value was 1
CSVT	17	rh	**Current signal value TRIGGER** 0_B the last TRIGGER_S value was 0 1_B the last TRIGGER_S value was 1

Field	Bits	Type	Description
CAIP2	18	rh	**Calculation of actions 12 to 23 in progress (2nd part)** 0_B currently no action calculation, new data requests possible 1_B action calculation in progress, no new data requests possible
CAIP1	19	rh	**Calculation of actions 0 to 11 in progress (1st part)** 0_B currently no action calculation, new data requests possible 1_B action calculation in progress, no new data requests possible
ISN	20	rh	**Number of STATE is not plausible** Bit is set when the number of STATES is different to profile. 0_B the number of STATE events between synchronization gaps is plausible, a direction change is detected or the APS_1C3 pointer is written 1_B after setting LOCK1 in emergency mode (SMC=0 and RMO=1) or LOCK2 for SMC=RMO=1 missing or additional STATE signals detected; bit is cleared when a direction change is detected or the APS_1C3 is written
ITN	21	rh	**Increment number of TRIGGER is not plausible** Bit is set when the number of TRIGGERS is different to profile. 0_B the number of TRIGGER events between synchronization gaps is plausible, a direction change is detected or the address pointer APT_2C is written 1_B after setting LOCK1 in normal mode (for SMC=0 or SMC=1) or in emergency mode (only for SMC=0) for missing or additional TRIGGER signals detected; bit is cleared when a direction change is detected or the APT_2C is written
BWD2	22	rh	**Backwards drive of SUB_INC2** 0_B forward direction 1_B backward direction
BWD1	23	rh	**Backwards drive of SUB_INC1** 0_B forward direction 1_B backward direction
Reserved	24	r	**Reserved** Read as zero, should be written as zero.

Field	Bits	Type	Description
LOCK2	25	rh	**DPLL Lock status concerning SUB_INC2** 0_B The DPLL is not locked concerning STATE for SMC=1 1_B The DPLL is locked concerning STATE for SMC=1 *Note: Locking of SUB_INC2 appears* for RMO=SMC=1: Bit is set, when SYS is set and the number of events between two missing STATEs is as expected by the SYN_S values. *Note: LOCK2 is set* for SMC=RMO=1: for a valid STATE event when SYS is set and SYN_NS=0 for a valid STATE event when SYS is set and SYN_NS=0 or when SYS is set and the profile stored in the ADT_Si field matches once between two gaps. *Note: LOCK2 is reset: for SMC=RMO=1* *- when a missing STATE event occurs while SYN_S=1. This does mean an unexpected missing STATE.* *- when the corresponding input signal STATE is out of locking range SLR.*
SYS	26	rh	**Synchronization condition of STATE fixed** This bit is set when the CPU writes to the APS_1C3 address pointer.
SYT	27	rh	**Synchronization condition of TRIGGER fixed** This bit is set when the CPU writes to the APT_2C address pointer.
FSD	28	rh	**STATE detected** 0_B Still no valid STATE event was detected after enabling DPLL 1_B At least one valid STATE event was detected after enabling DPLL *Note: No change of FSD for switching from normal to emergency mode or vice versa.*
FTD	29	rh	**First TRIGGER detected** 0_B No valid TRIGGER event was detected after enabling DPLL 0_B At least one valid TRIGGER event was detected after enabling DPLL *Note: No change of FTD for switching from normal to emergency mode or vice versa.*

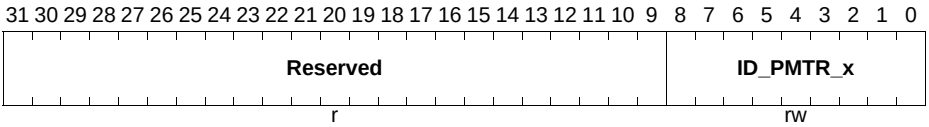
Field	Bits	Type	Description
LOCK1	30	rh	**DPLL Lock status concerning SUB_INC1** 0_B The DPLL is not locked for TRIGGER (while SMC=RMO=0 or SMC=1) or for STATE (while SMC=0 and RMO=1) 1_B The DPLL is locked for TRIGGER (while SMC=RMO=0 or SMC=1) or for STATE (while SMC=0 and RMO=1) LOCK1 is set: - in normal mode (for RMO=SMC=0, LCD=0): Bit is set for a valid TRIGGER event when SYT is set and the number of events between two gaps is as expected by the profile (NT values in the ADT_T[i] field) or when SYN_NT=0 and SYT=1. - in normal mode (for RMO=SMC=0, LCD=1): Bit is set for a valid TRIGGER event when SYT is set and the number of events between two increments without missing TRIGGER (no gap) is as expected by profile (NT values in the ADT_Ti filed). - in emergency mode (for RMO=1 and SMC=0): Bit is set for a valid STATE event, when SYS is set and the received events are in correspondence to the profile (NS values in the ADT_S[i] field) for at least two expected missing STATE events or when SYN_NS=0. - for SMC=1: Bit is set for a valid TRIGGER even when SYT is set and SYN_NT=0 or when SYT is set and the profile stored in the ADT_T[i] field matches once between two gaps. LOCK1 is reset for RMO=SMC=0: - when a corresponding missing TRIGGER event occurs while SYN_T=1. this does mean an unexpected missing TRIGGER. - when the corresponding input signal TRIGGER is out of locking range TLR, - when a corresponding direction change is detected for RMO=1 and SMC=0: - when a corresponding missing STATE event occurs while SYN_S=1. This does mean an unexpected missing STATE. - when the corresponding input signal STATE is out of locking range TLR for SMC=1: - when a corresponding missing TRIGGER event occurs while SYN_T=1. This does mean an unexpected missing TRIGGER. - when the corresponding input signal TRIGGER is out of locking range TLR - when a corresponding direction change is detected

Field	Bits	Type	Description
ERR	31	rh	**Error during configuration or operation resulting in unexpected values** 0_B when all bits in position 8 to 0 and 10 and 12 are zero 1_B when at least one bit in position 8 to 0 or 10 or 12 is one

25.16.11.30Register DPLL_ID_PMTR_x

ID information for input signal PMTRx (position minus time request), x=0…23.

GTM_DPLL_ID_PMTR_x (x=0-23)
DPLL ID Information For Input Signal PMTR x Register
(28100_H+x*04_H) **Reset Value: $000001FE_H$**

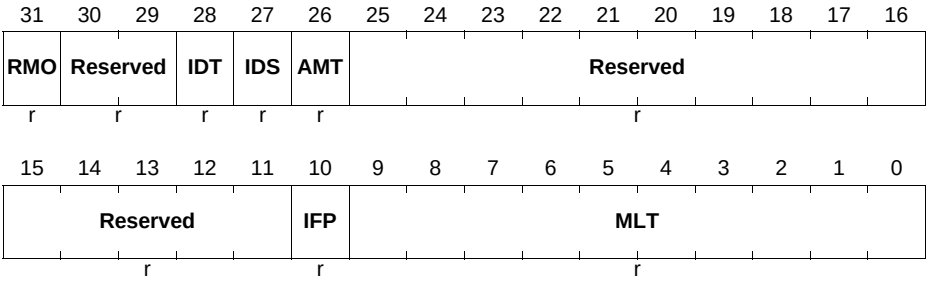


Field	Bits	Type	Description
ID_PMTR_x	[8:0]	rw	**ID information to the input signal PMTR_x from the ARU** *Note: The DPLL_ID_PMTR_x can be changed also when the DPLL is enabled.*
Reserved	[31:9]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.31Register DPLL_CTRL_0_SHADOW_TRIGGER

Shadow register of DPLL_CTRL_0 controlled by valid TRIGGER slope.

GTM_DPLL_CTRL_0_SHADOW_TRIGGER
DPLL Control0 Shadow Trigger Register(281E0$_H$) **Reset Value: 00000257$_H$**



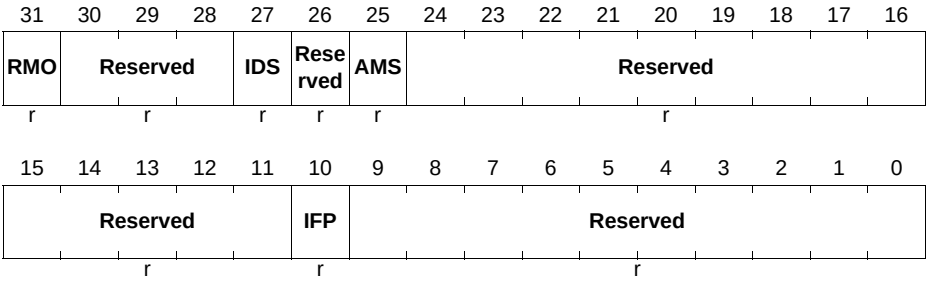
Field	Bits	Type	Description
MLT [1)]	[9:0]	r	**multiplier for TRIGGER** MLT+1 is number of SUB_INC1 pulses between two TRIGGER events in normal mode (11024).
IFP [1)]	10	r	**Input filter position** Value contains position or time related information.
Reserved	[25:11]	r	**Reserved** Read as zero, should be written as zero.
AMT [1)]	26	r	**Adapt mode TRIGGER** Use of adaptation information of TRIGGER.
IDS	27	r	**Input delay STATE** Use of input delay information transmitted in FT part of the STATE signal.
IDT [1)]	28	r	**Input delay TRIGGER** Use of input delay information transmitted in FT part of the TRIGGER signal.
Reserved	[30:29]	r	**Reserved** Read as zero, should be written as zero.
RMO [1)]	31	r	**Reference mode; selection of the relevant the input signal for generation of SUB_INC1**

1) Only the values are stored for a valid TRIGGER slope. All other values remain 0. When DEN=0 the relevant bit values of the original register DPLL_CTRL_0 are transferred without any input event at the next system clock. This results in the above reset value.

25.16.11.32Register DPLL_CTRL_0_SHADOW_STATE

Shadow register of DPLL_CTRL_0 controlled by a valid STATE slope.

GTM_DPLL_CTRL_0_SHADOW_STATE
DPLL Control 0 Shadow STATE Register(281E4$_H$) **Reset Value: 00000000$_H$**



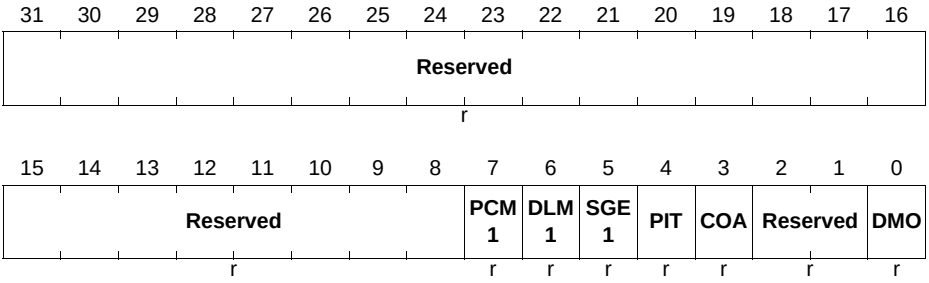
Field	Bits	Type	Description
Reserved	[9:0]	r	**Reserved** Read as zero, should be written as zero.
IFP [1)]	10	r	**Input filter position** Value contains position or position or time related information.
Reserved	[24:11]	r	**Reserved** Read as zero, should be written as zero.
AMS [1)]	25	r	**Adapt mode STATE** Use of adaptation information of STATE.
Reserved	26	r	**Reserved** Read as zero, should be written as zero.
IDS [1)]	27	r	**Input delay STATE** Use of input delay information transmitted in FT part of the STATE signal.
Reserved	[30:28]	r	**Reserved** Read as zero, should be written as zero.
RMO [1)]	31	r	**Reference mode; selection of the relevant the input signal for generation of SUB_INC1**

1) Only the values are stored for a valid TRIGGER slope. All other values remain 0. When DEN=0 the relevant bit values of the original register DPLL_CTRL_0 are transferred without any input event at the next system clock. This results in the above reset value.

25.16.11.33Register DPLL_CTRL_1_SHADOW_TRIGGER

Shadow register of DPLL_CTRL_1 controlled by a valid TRIGGER slope.

GTM_DPLL_CTRL_1_SHADOW_TRIGGER
DPLL Control 1 Shadow TRIGGER Register(281E8$_H$) **Reset Value: 00000000$_H$**



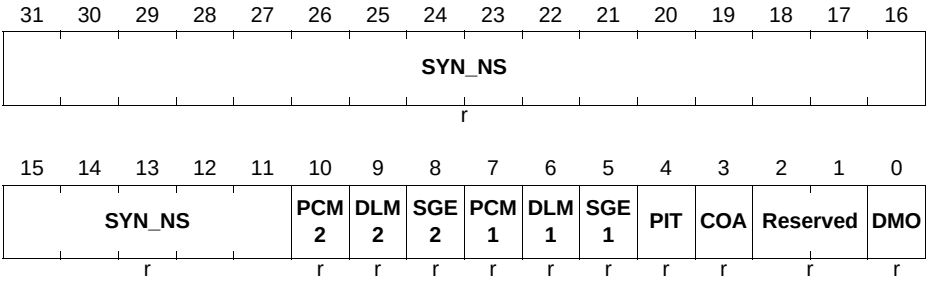
Field	Bits	Type	Description
DMO [1]	0	r	**DPLL mode select**
Reserved	[2:1]	r	**Reserved** Read as zero, should be written as zero.
COA [1]	3	r	**Correction strategy in automatic end mode (DMO=0)**
PIT [1]	4	r	**Plausibility** value PVT to next valid TRIGGER is time related
SGE1 [1]	5	r	**SUB_INC1 generator enable**
DLM1 [1]	6	r	**Direct Load Mode** for SUB_INC1 generation
PCM1 [1]	7	r	**Pulse Correction Mode** for SUB_INC1 generation
Reserved	[31:8]	r	**Reserved** Read as zero, should be written as zero.

1) Only the values are stored for a valid TRIGGER slope. All other values remain 0. When DEN=0 the relevant bit values of the original register DPLL_CTRL_1 are transferred without any input event at the next system clock. This results in the above reset value.

25.16.11.34Register DPLL_CTRL_1_SHADOW_STATE

Shadow register of DPLL_CTRL_1 controlled by a valid STATE slope.

GTM_DPLL_CRTL_1_SHADOW_STATE
DPLL Control 1 Shadow STATE Register(281EC$_H$) **Reset Value: 00000000$_H$**



Field	Bits	Type	Description
DMO [1)]	0	r	**DPLL mode select**
Reserved	[2:1]	r	**Reserved** Read as zero, should be written as zero.
COA [1)]	3	r	**Correction strategy in automatic end mode (DMO=0)**
PIT	4	r	**Plausibility** value PVT to next valid TRIGGER is time related
SGE1 [1)]	5	r	**SUB_INC1 generator enable**
DLM1 [1)]	6	r	**Direct Load Mode** for SUB_INC1 generation
PCM1 [1)]	7	r	**Pulse Correction Mode** for SUB_INC1 generation
SGE2 [1)]	8	r	**SUB_INC2 generator enable**
DLM2 [1)]	9	r	**Direct Load Mode** for SUB_INC2 generation
PCM2 [1)]	10	r	**Pulse Correction Mode** for SUB_INC2 generation
SYN_NS	[31:11]	r	**Synchronization number of STATE** Summarized number of virtual increments in HALF_SCALE

1) Only the values are stored for a valid TRIGGER slope. All other values remain 0. When DEN=0 the relevant bit values of the original register DPLL_CTRL_1 are transferred without any input event at the next system clock. This results in the above reset value.

25.16.11.35Register DPLL_RAM_INI

Register to control the RAM initialisation.

GTM_DPLL_RAM_INI

DPLL RAM Initatlisation Register (281FC$_H$) **Reset Value: 00000000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r											w	r	r	r	r

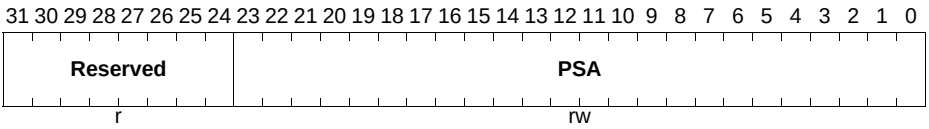
Field	Bits	Type	Description
INIT_1A	0	r	**RAM region 1A initialization in progress** 0_B No initialization of considered RAM region in progress 1_B Initialization of considered RAM region in progress
INIT_1B	1	r	**RAM region 1B initialization in progress** see bit 0
INIT_2	2	r	**RAM region 2 initialization in progress** see bit 0
Reserved	3	r	**Reserved** Read as zero, should be written as zero.

Field	Bits	Type	Description
INIT_RAM	4	w	**RAM regions 1A, 1B and 2 are to be initialized** 0_B Do not start initialization of all RAM regions 1_B Start initialization of all RAM regions Note: Setting the INIT_RAM bit results only in a RAM reset when the DPLL is not enabled (DEN=0). Note: Depending on the vendor configuration the connected RAM regions are initialized to zero in the case of a module HW reset or for setting the RST bit in the GTM_RST register. Note: In the case of no RAM initialization it must be ensured that all relevant parameters are configured correctly. Otherwise there is no guarantee to get a predictable behaviour.
Reserved	[31:5]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.36Memory DPLL_PSA[i]

Position request for action i, RAM1A.

GTM_DPLL_PSAi (i=0-23)
DPLL ACTION_i Position/Value Action Request Register
(28200_H + i * 04_H) **Reset Value: 00000000_H**



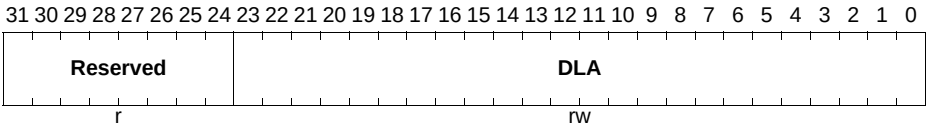
Field	Bits	Type	Description
PSA	[23:0]	rw	**Position information of a desired action (i=0…23)** Get position values via ARU Note: This value can only be written when the DPLL is disabled.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.37Memory DPLL_DLA[i]

Time to react for action i, RAM1A

GTM_DPLL_DLAi (i=0-23)
DPLL ACTION_i Time To React Before PSAi Register

(28280_H + i * 04_H) **Reset Value: 00000000_H**



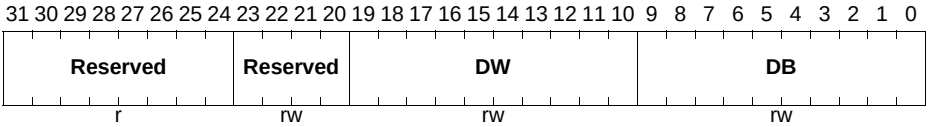
Field	Bits	Type	Description
DLA	[23:0]	rw	**Time to react before the corresponding position value of a desired action is reached** In case of LOW_RES=1 (see **Chapter 25.16.4.2**) this delay value must be also given as low resolution value. Note: This value can only be written when the DPLL is disabled.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.38Memory DPLL_NA[i]

Calculated number of TRIGGER / STATE increments to action i, RAM1A.

GTM_DPLL_NAi (i=0-23)
DPLL Calculated Number Of TRIGGER/STATE Increments To ACTION_i

(28300_H + i * 04_H) **Reset Value: 00000000_H**



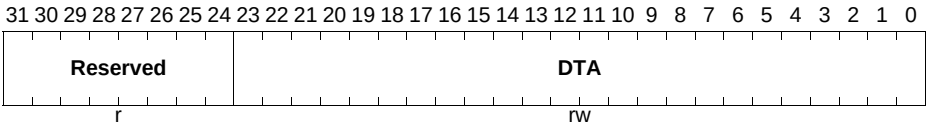
Field	Bits	Type	Description
DB	[9:0]	rw	**Number of events to Action_i (fractional part)** Note: This value can only be written when the DPLL is disabled.
DW	[19:10]	w	**Number of events to Action_i (integer part)** Note: This value can only be written when the DPLL is disabled.

Field	Bits	Type	Description
Reserved	[23:20]	rw	**Reserved** Note: must be written as zero.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero. Note: Use the maximum value for DW=0x3FF in the case of a calculated value which exceeds the represent able value.

25.16.11.39Memory DPLL_DTA[i]

Calculated relative time to action i, RAM1A.

GTM_DPLL_DTAi (i=0-23)
DPLL Calculated Relative Time To ACTION_i Register
(28380_H + i * 04_H) **Reset Value: 00000000_H**

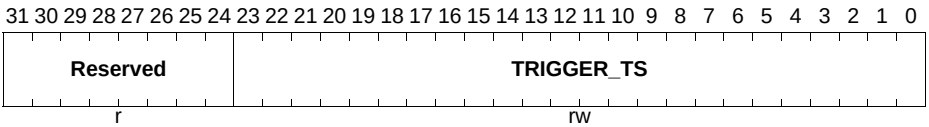


Field	Bits	Type	Description
DTA	[23:0]	rw	**Calculated relative time to ACTION_i** Note: This value can only be written when the DPLL is disabled. The DTA value is a positive integer value. When calculations using equations DPLL-12 or DPLL-14 result in a negative value, it is replaced by zero.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.40Memory DPLL_TS_T

Actual TRIGGER time stamp value.

GTM_DPLL_TS_T_0
DPLL Actual Signal TRIGGER Time Stamp Register
(28400_H) **Reset Value: 00000000_H**
GTM_DPLL_TS_T_1
DPLL Actual Signal TRIGGER Time Stamp Register
(28404_H) **Reset Value: 00000000_H**



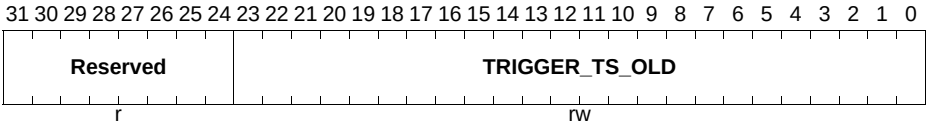
Field	Bits	Type	Description
TRIGGER_TS	[23:0]	rw	**Time stamp value of the last valid TRIGGER input** measured TRIGGER time stamp Note: The LSB address is determined using the SWON_T value in the OSW register (see **Section 25.16.11.7**).
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.41Memory DPLL_TS_T_OLD

Previous TRIGGER time stamp value.

GTM_DPLL_TS_T_OLD_0
DPLL Previous Signal TRIGGER Time Stamp Register
(28400_H) **Reset Value: 00000000_H**

GTM_DPLL_TS_T_OLD_1
DPLL Previous Signal TRIGGER Time Stamp Register
(28404_H) **Reset Value: 00000000_H**

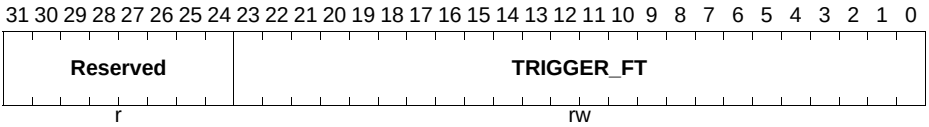


Field	Bits	Type	Description
TRIGGER_TS_old	[23:0]	rw	**Time stamp value of the last but one valid TRIGGER input** previous measured TRIGGER time stamp Note: The LSB address is determined using the SWON_T value in the OSW register (see **Section 25.16.11.7**).
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.42Memory DPLL_FTV_T

Actual TRIGGER filter value.

GTM_DPLL_FTV_T
DPLL Actual Signal TRIGGER Filter Value Register
(28408_H) **Reset Value: 00000000_H**



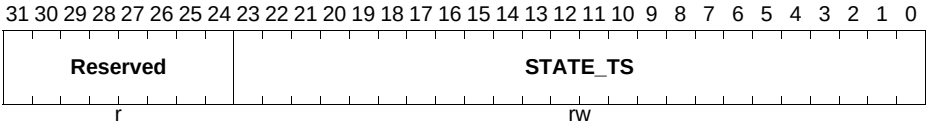
Field	Bits	Type	Description
TRIGGER_FT	[23:0]	rw	**Filter value of the last valid TRIGGER input** transmitted filter value Note: The LSB address is determined using the SWON_T value in the OSW register (see **Section 25.16.11.7**).
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.43Memory DPLL_TS_S

Actual STATE time stamp register.

GTM_DPLL_TS_S_0
DPLL Actual Signal STATE Time Stamp Register
(28410_H) **Reset Value: 00000000_H**

GTM_DPLL_TS_S_1
DPLL Actual Signal STATE Time Stamp Register
(28414_H) **Reset Value: 00000000_H**



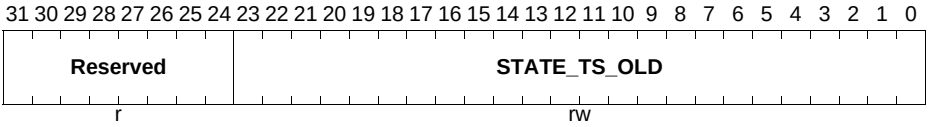
Field	Bits	Type	Description
STATE_TS	[23:0]	rw	**Time stamp value of the last valid STATE input** Note: The LSB address is determined using the SWON_S value in the OSW register (see **Section 25.16.11.7**).
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.44Memory DPLL_TS_S_OLD

Previous STATE time stamp register.

GTM_DPLL_TS_S_OLD_0
DPLL Previous Signal STATE Time Stamp Register
(28410_H) **Reset Value: 00000000_H**

GTM_DPLL_TS_S_OLD_1
DPLL Previous Signal STATE Time Stamp Register
(28414_H) **Reset Value: 00000000_H**

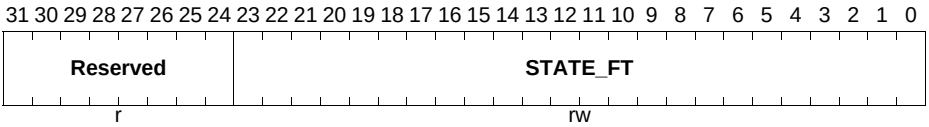


Field	Bits	Type	Description
STATE_TS_OLD	[23:0]	rw	**Time stamp value of the last valid STATE input** Note: The LSB address is determined using the SWON_S value in the OSW register (see **Section 25.16.11.7**).
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.45Memory DPLL_FTV_S

Actual STATE filter value.

GTM_DPLL_FTV_S
DPLL Actual Signal STATE Filter Value Register
(28418_H) **Reset Value: 00000000_H**

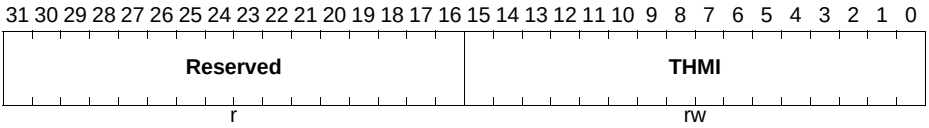


Field	Bits	Type	Description
STATE_FT	[23:0]	rw	**Filter value of the last valid STATE input** transmitted filter value Note: The LSB address is determined using the SWON register (see **Section 25.16.11.7**).
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.46Memory DPLL_THMI

TRIGGER hold time min value.

GTM_DPLL_THMI
DPLL TRIGGER hold time min value (28420_H) **Reset Value: 00000000_H**

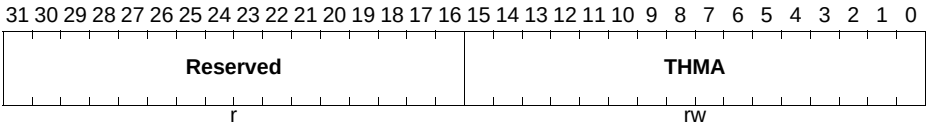


Field	Bits	Type	Description
THMI	[15:0]	rw	**Minimal time between active and inactive TRIGGER slope (uint16)** the time value corresponds to the time stamp clock counts; this does mean the clock selected for the TBU_CH0_BASE (see TBU_CH0CTRL register). set min value; generate the TINI interrupt in the case of a violation for THMI>0. Note: Typical retention time values after a valid slope can be e.g. between 45 µs (forwards) and 90 µs (backwards). When THMI is zero, consider always a THMI violation (forwards).
Reserved	[31:16]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.47Memory DPLL_THMA

TRIGGER hold time max value.

GTM_DPLL_THMA
DPLL TRIGGER Hold Time Max Value(28424_H) **Reset Value: 00000000_H**

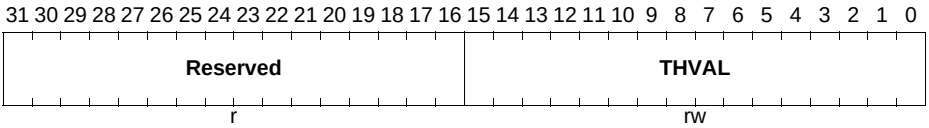


Field	Bits	Type	Description
THMA	[15:0]	rw	**Maximal time between active and inactive TRIGGER slope (uint16)** the time value corresponds to the time stamp clock counts; this does mean the clock selected for the TBU_CH0_BASE (see TBU_CH0_CTRL register). max value to be set; generate the TAX interrupt in the case of a violation for THMA>0.
Reserved	[31:16]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.48Memory DPLL_THVAL

Measured TRIGGER hold time value.

GTM_DPLL_THVAL
DPLL Measured Last Pulse Time from Valid to Invalid TRIGGER Slope (28428_H) **Reset Value: 00000000_H**



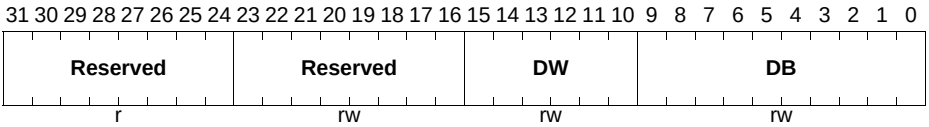
Field	Bits	Type	Description
THVAL	[15:0]	rw	**Measured time from the last valid slope to the next inactive TRIGGER slope in time stamp clock counts: this does mean the clock selected for the TBU_CH0_BASE (uint16)** measured value
Reserved	[31:16]	r	**Reserved** Read as zero, should be written as zero.

Note: In the case of LOW_RES=1 and TBU_HRT=0 the difference between the time stamps of valid and invalid slope is multiplied by 8. The register contains this value.

25.16.11.49Memory DPLL_TOV

Time out value active TRIGGER slope (for missing TRIGGER generation).

GTM_DPLL_TOV
DPLL Time Out Value of active TRIGGER Slope
(28430_H) **Reset Value: 00000000_H**

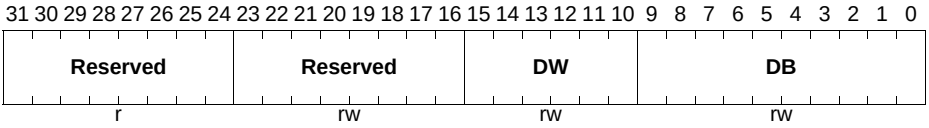


Field	Bits	Type	Description
DB	[9:0]	rw	**Decision value (fractional part) for missing TRIGGER interrupt**
DW	[15:10]	rw	**Decision value (integer part) for missing TRIGGER interrupt** TOV(15:0) is to be multiplied with the duration of the last increment and divided by 1024 in order to get the timeout time value for a missing trigger event. Note: For the case of LOW_RES=1 (see DPLL_STATUS register) consider for the calculation of the time out value the following cases: LOW_RES=1 and DPLL_CTRL_1/TS0_HRT=1: multiply the TBU_TS0 value by 8 LOW_RES=1 and DPLL_CTRL_1/TS0_HRT=0: multiply the TBU_TS0 value by 8 multiply the estimated time point value (using TS_T, dt_t_ACT and TOV) by 8 LOW_RES=0 and DPLL_CTRL_1/TS0_HRT=0: use TBU_TS0 and the estimated time point value unchanged.
Reserved	[23:16]	r	**Reserved** Must be written as zero.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.50Memory DPLL_TOV_S

Time out value of active STATE slope (for a missing STATE generation).

GTM_DPLL_TOV_S
DPLL Time Out Value of active STATE Slope
(28434_H) **Reset Value: 00000000_H**

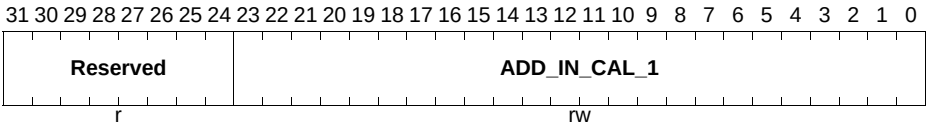


Field	Bits	Type	Description
DB	[9:0]	rw	**Decision value (fractional part) for missing STATE interrupt**
DW	[15:10]	rw	**Decision value (integer part) for missing STATE interrupt** TOV_S (15:0) is to be multiplied with the duration of the last increment and divided by 1024 in order to get the timeout time value for a missing STATE event. Note: For the case of LOW_RES=1 (see DPLL_STATUS register) consider for the calculation of the time out value the following cases: LOW_RES=1 and DPLL_CTRL_1/TS0_HRS=1: multiply the TBU_TS0 value by 8 LOW_RES=1 and DPLL_CTRL_1/TS0_HRS=0: multiply the TBU_TS0 value by 8 multiply the estimated time point value (using TS_T, dt_s_ACT and TOV_S) by 8 LOW_RES=0 and DPLL_CTRL_1/TS0_HRS=0: use TBU_TS0 and the estimated time point value unchanged.
Reserved	[23:16]	r	**Reserved** Must be written as zero.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.51Memory DPLL_ADD_IN_CAL1

Calculated ADD_IN value for SUB_INC1 generation.

GTM_DPLL_ADD_IN_CAL1
DPLL Calculated ADD_IN Value for SUB_INC1 Generation
(28438$_H$) **Reset Value: 00000000$_H$**

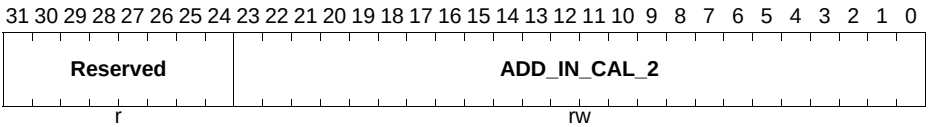


Field	Bits	Type	Description
ADD_IN_CAL_1	[23:0]	rw	**Calculated input value for SUB_INC1 generation, calculated by the DPLL** calculated value The update of the ADD_IN value by the new calculated value ADD_IN_CAL1 is suppressed for one increment when an unexpected missing TRIGGER (SMC = 1 or RMO = 0) or an unexpected STATE(RMO = 1 and SMC = 0) is detected.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.52Memory DPLL_ADD_IN_CAL2

Calculated ADD_IN value for SUB_INC2 generation.

GTM_DPLL_ADD_IN_CAL2
DPLL Calculated ADD_IN Value for SUB_INC2 Generation
(2843C$_H$) **Reset Value: 00000000$_H$**

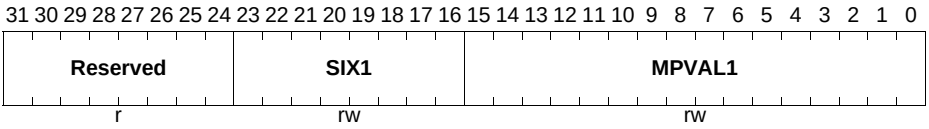


Field	Bits	Type	Description
ADD_IN_CAL_2	[23:0]	rw	**Input value for SUB_INC2 generation, calculated by the DPLL for SMC=RMO=1** calculated value The update of the ADD_IN value by the calculated value ADD_IN_CAL2 is suppressed for one increment when an unexpected missing STATE(RMO = SMC = 1) is detected.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.53Memory DPLL_MPVAL1

Missing pluses to be added or subtracted directly.

GTM_DPLL_MPVAL1
DPLL Missing Pulses to be Added/Subtracted Directly to SUB_INC1 and INC_CNT1 Once **(28440_H)** **Reset Value: 00000000_H**

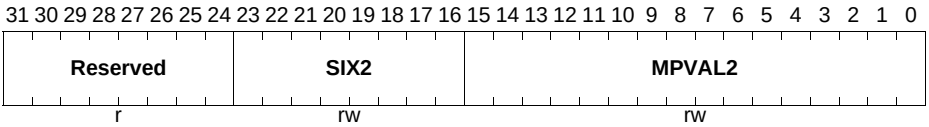


Field	Bits	Type	Description
MPVAL1	[15:0]	rw	**Missing pulses for direct correction of SUB_INC1 pulses by the CPU (sint16)** used only for RMO=0 or SMC=1 for the case PCM1=1. Add MPVAL1 once to INC_CNT1 and reset PCM1 after applying once Note: Do not provide negative values which exceed the amount of NT*(MLT+1) or MLS1 respectively; when considered negative PD values the sum of both should not exceed the amount of NT*(MLT+1) or MLS1 respectively.
SIX1	[23:16]	rw	**sign extension for MPVAL1** 0x00 =MPVAL1 is a positive number 0xFF =MPVAL1 is a negative number Note: All bits must be written to either all zeros or all ones.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero. Note: Do not provide negative values which exceed the amount of NT*(MLT+1) or MLS1 respectively; when considered negative PD values the sum of both should not exceed the amount of NT*(MLT+1) or MLS1 respectively.

25.16.11.54Memory DPLL_MPVAL2

Missing pulses to be added or subtracted directly.

GTM_DPLL_MPVAL2
DPLL Missing Pulses to be Added/Subtracted Directly to SUB_INC2 and INC_CNT2 Once **(28444_H)** **Reset Value: 00000000_H**

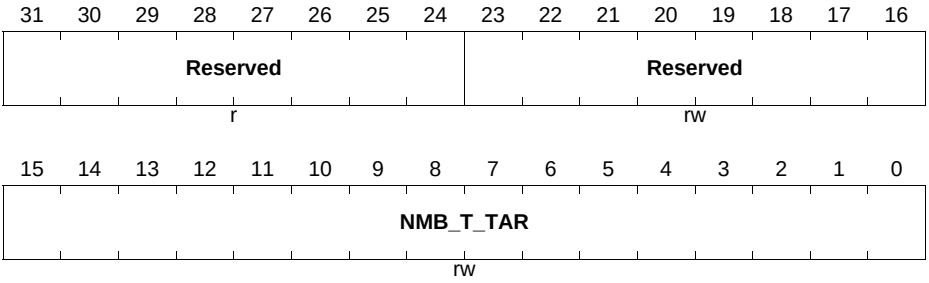


Field	Bits	Type	Description
MPVAL2	[15:0]	rw	**missing pulses for direct correction of SUB_INC2 pulses by the CPU (sint16)** used only for SMC=RMO=1 for the case PCM2=1. Add MPVAL2 once to INC_CNT2 and reset PCM2 after applying once Note: Do not provide negative values which exceed the amount of MLS2; when considered negative PD_S values the sum of both should not exceed the amount of MLS2.
SIX2	[23:16]	rw	**sign extension for MPVAL2** 0x00 =MPVAL2 is a positive number 0xFF =MPVAL2 is a negative number Note: All bits must be written to either all zeros or all ones.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.55Memory DPLL_NMB_T_TAR

target number of pluses to be sent in normal mode.

GTM_DPLL_NMB_T_TAR
DPLL Target Number of Pulses to be sent in normal mode Register (28448$_H$) **Reset Value: 00000000$_H$**

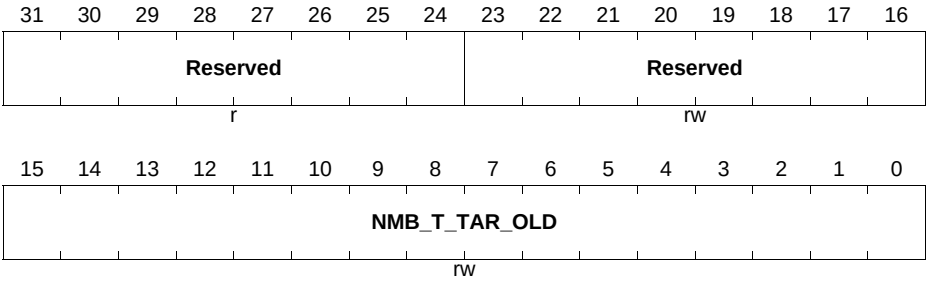


Field	Bits	Type	Description
NMB_T_TAR	[15:0]	rw	**Target Number of pulses for TRIGGER** Calculated number of pulses in normal mode for the current TRIGGER increment without missing pulses. calculated target pulse number *Note: The LSB address is determined using the SWON_S value in the OSW register (see **Chapter 25.16.11.7**).*
Reserved	[23:16]	rw	**Reserved** Note: must be written to zero.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.56Memory DPLL_NMB_T_TAR_OLD

Last but one target number of pulses to be sent in normal mode.

GTM_DPLL_NMB_T_TAR_OLD
DPLL Target Number of Pulses to be sent in normal mode Register (2844C$_H$) **Reset Value: 00000000$_H$**

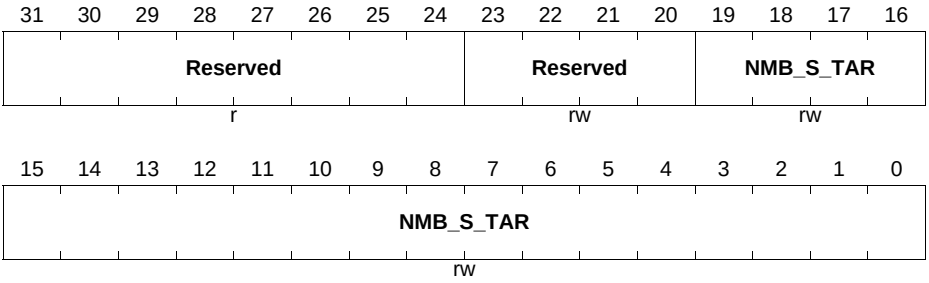


Field	Bits	Type	Description
NMB_T_TAR_OLD	[15:0]	rw	**Target Number of pulses for TRIGGER** Calculated number of pulses in normal mode for the current TRIGGER increment without missing pulses. calculated target pulse number *Note: The LSB address is determined using the SWON_S value in the OSW register (see **Chapter 25.16.11.7**).*
Reserved	[23:16]	rw	**Reserved** Note: must be written to zero.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.57Memory DPLL_NMB_S_TAR

Target number of pulses to be sent in emergency mode.

GTM_DPLL_NMB_S_TAR
DPLL Target Number of Pulses to be sent in emergency mode Register (28450$_H$) **Reset Value: 00000000$_H$**

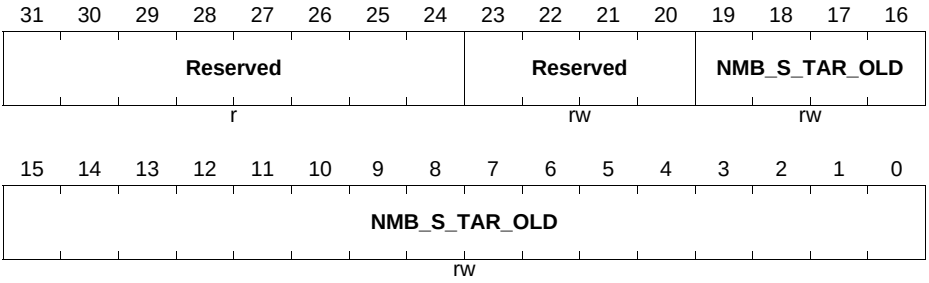


Field	Bits	Type	Description
NMB_S_TAR	[19:0]	rw	**Target Number of pulses for STATE** Calculated number of pulses in emergency mode for the current STATE increment without missing pulses. calculated target pulse number. *Note: The LSB address is determined using the SWON_S value in the OSW register (see **Chapter 25.16.11.7**).*
Reserved	[23:20]	rw	**Reserved** Note: must be written to zero.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.58Memory DPLL_NMB_S_TAR_OLD

Last but one target number of pulses to be sent in emergency mode.

GTM_DPLL_NMB_S_TAR_OLD
DPLL Target Number of Pulses to be sent in emergency mode Register (28454$_H$) **Reset Value: 00000000$_H$**

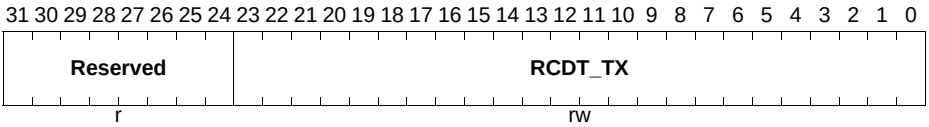


Field	Bits	Type	Description
NMB_S_TAR_OLD	[19:0]	rw	**Target Number of pulses for STATE** Calculated number of pulses in emergency mode for the current STATE increment without missing pulses. calculated target pulse number. *Note: The LSB address is determined using the SWON_S value in the OSW register (see **Chapter 25.16.11.7**).*
Reserved	[23:20]	rw	**Reserved** Note: must be written to zero.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.59Memory DPLL_RCDT_TX

reciprocal value of the expected increment duration of TRIGGER.

GTM_DPLL_RCDT_TX
DPLL Reciprocal Value of Expected Increment Duration TRIGGER
(28460_H) **Reset Value: 00000000_H**

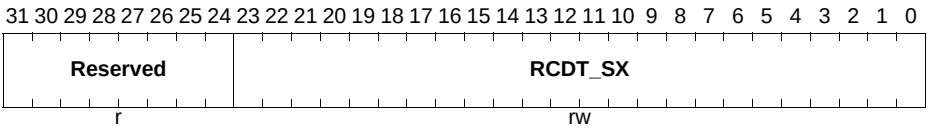


Field	Bits	Type	Description
RCDT_TX	[23:0]	rw	**Reciprocal value of expected increment duration *2^{32} while only the lower 24 bits are used** calculated value; when an overflow occurs in calculation the value is set to 0xFFFFFF.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.60Memory DPLL_RCDT_SX

Reciprocal value of the expected increment duration of STATE.

GTM_DPLL_RCDT_SX
DPLL Reciprocal Value of Expected Increment Duration STATE
(28464_H) **Reset Value: 00000000_H**



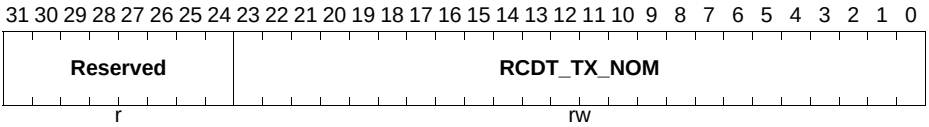
Field	Bits	Type	Description
RCDT_SX	[23:0]	rw	**Reciprocal value of expected increment duration *2^{32} while only the lower 24 bits are used** calculated value; when an overflow occurs in calculation the value is set to 0xFFFFFF.

Field	Bits	Type	Description
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.61Memory DPLL_RCDT_TX_NOM

Reciprocal value of the expected nominal increment duration of TRIGGER.

GTM_DPLL_RCDT_TX_NOM
DPLL Reciprocal Value of the Expected Nominal Increment Duration TRIGGER
(28468_H) **Reset Value: 00000000_H**

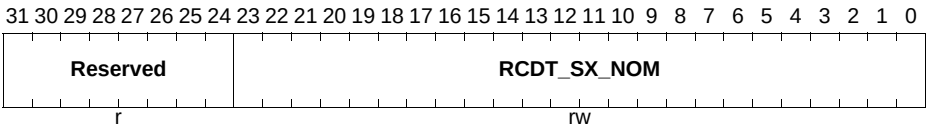


Field	Bits	Type	Description
RCDT_TX_NOM	[23:0]	rw	**Reciprocal value of nominal increment duration *2^{32} while only the lower 24 bits are used** calculated value; when an overflow occurs in calculation the value is set to 0xFFFFFF.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.62Memory DPLL_RCDT_SX_NOM

Reciprocal value of the expected nominal increment duration of STATE.

GTM_DPLL_RCDT_SX_NOM
DPLL Reciprocal Value of the Expected Nominal Increment Duration STATE
($2846C_H$) **Reset Value: 00000000_H**



Field	Bits	Type	Description
RCDT_SX_NOM	[23:0]	rw	**Reciprocal value of nominal increment duration *2^{32} while only the lower 24 bits are used** calculated value; when an overflow occurs in calculation the value is set to 0xFFFFFF.

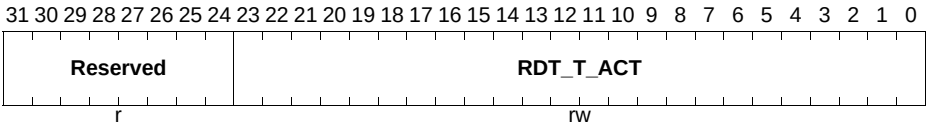
Field	Bits	Type	Description
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

Note: RCDT_TX_NOM and RCDT_SX_NOM are calculated by the values RCDT_TX and RCDT_SX to be multiplied with SYN_T or SYN_S respectively.

25.16.11.63Memory DPLL_RDT_T_ACT

Reciprocal value of the last increment of TRIGGER.

GTM_DPLL_RDT_T_ACT
DPLL Actual Reciprocal Value of TRIGGER
(28470_H) **Reset Value: 00000000_H**

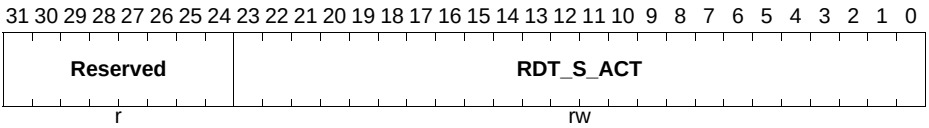


Field	Bits	Type	Description
RDT_T_ACT	[23:0]	rw	**Reciprocal value of last TRIGGER increment *2^{32} while only the lower 24 bits are used** the LSB is rounded up when the next truncated bit is 1. calculated value; when an overflow occurs in calculation the value is set to 0xFFFFFF and the CRO bit in the DPLL_STATUS register is set.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.64Memory DPLL_RDT_S_ACT

Reciprocal value of the last increment of STATE.

GTM_DPLL_RDT_S_ACT
DPLL Actual Reciprocal Value of STATE(28474_H) **Reset Value: 00000000_H**

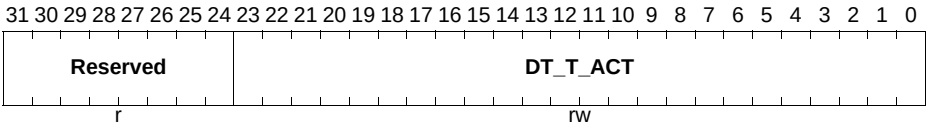


Field	Bits	Type	Description
RDT_S_ACT	[23:0]	rw	**Reciprocal value of last STATE increment *2^{32}** while only the lower 24 bits are used and the LSB is rounded up when the next truncated bit is 1. calculated value; when an overflow occurs in calculation the value is set to 0xFFFFFF and the CRO bit in the DPLL_STATUS register is set.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.65Memory DPLL_DT_T_ACT

Duration of the last TRIGGER increment.

GTM_DPLL_DT_T_ACT
DPLL Duration of Last TRIGGER Increment (28478$_H$) **Reset Value: 00000000$_H$**

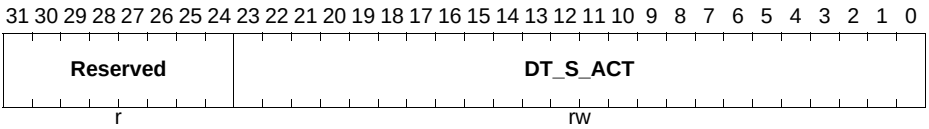


Field	Bits	Type	Description
DT_T_ACT	[23:0]	rw	**Calculated duration of the last TRIGGER increment** calculated duration of the last increment; Value will be written into the corresponding RAM field, when all calculations for the considered increment are done and APT is valid.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.66Memory DPLL_DT_S_ACT

Duration of the last STATE increment.

GTM_DPLL_DT_S_ACT
DPLL Duration of Last STATE Increment [DT_S_ACT] **(2847C$_H$)** **Reset Value: 00000000$_H$**



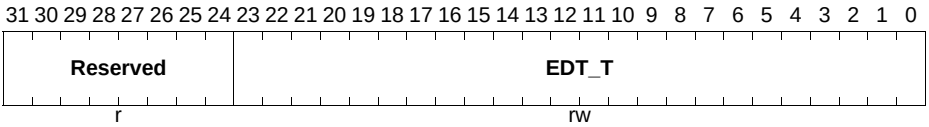
Field	Bits	Type	Description
DT_S_ACT	[23:0]	rw	**Calculated duration of the last STATE increment** Calculated increment duration Value will be written into the corresponding RAM field, when all calculations for the considered increment are done and APS is valid.

Field	Bits	Type	Description
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.67Memory DPLL_EDT_T

Difference of prediction to actual value of the last TRIGGER increment.

GTM_DPLL_EDT_T
DPLL Difference of prediction to actual value of the last TRIGGER increment (28480$_H$) **Reset Value: 00000000$_H$**

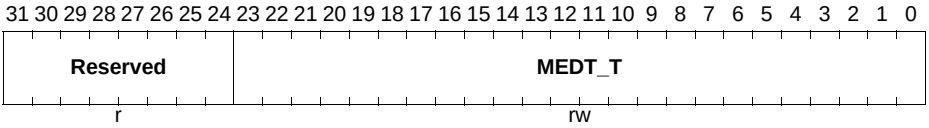


Field	Bits	Type	Description
EDT_T	[23:0]	rw	**Signed difference between actual value and a simple prediction of the last TRIGGER increment: sint24** calculated error value
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.68Memory DPLL_MEDT_T

Weighted difference of prediction errors of TRIGGER.

GTM_DPLL_MEDT_T
DPLL Weighted difference of Prediction up to the Last TRIGGER Increment (28484$_H$) **Reset Value: 00000000$_H$**

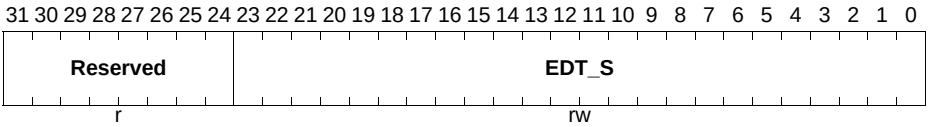


Field	Bits	Type	Description
MEDT_T	[23:0]	rw	**Signed middle weighted difference between actual value and prediction of the last TRIGGER increments: sint24** only calculated for SYT=1 calculated medium error value The value is calculated only after synchronization (SYT=1) and the update is suppressed for one increment when an unexpected missing TRIGGER is detected.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.69Memory DPLL_EDT_S

Difference of prediction to actual value of the last STATE increment.

GTM_DPLL_EDT_S
DPLL Difference of Prediction to actual value for Last STATE Increment (28488$_H$) **Reset Value: 00000000$_H$**

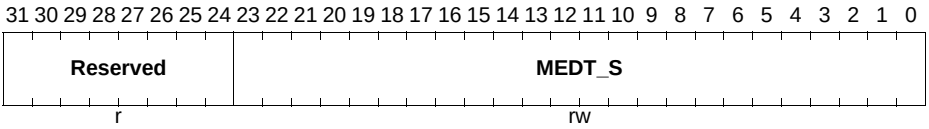


Field	Bits	Type	Description
EDT_S	[23:0]	rw	**Signed difference between actual value and prediction of the last STATE increment: sint24** calculated error value
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.70Memory DPLL_MEDT_S

Weighted difference of prediction errors of STATE.

GTM_DPLL_MEDT_S
DPLL Weighted difference of Prediction up to the Last STATE Increment (2848C$_H$) **Reset Value: 00000000$_H$**

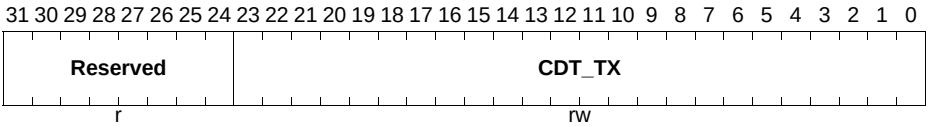


Field	Bits	Type	Description
MEDT_S	[23:0]	rw	**Signed middle weighted difference between actual value and prediction of the last STATE increments: sint24** only calculated for SYS=1 calculated medium error value The value is calculated only after synchronization (SYS=1) and the update is suppressed for one increment when an unexpected missing STATE is detected.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.71Memory DPLL_CDT_TX

Prediction of the actual TRIGGER duration.

GTM_DPLL_CDT_TX
DPLL Prediction of the actual TRIGGER Increment
(28490$_H$) **Reset Value: 00000000$_H$**

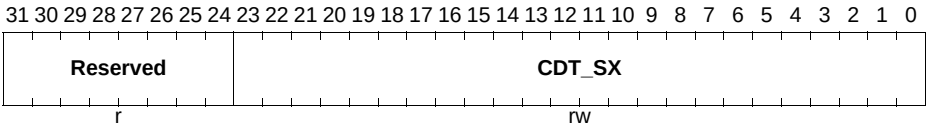


Field	Bits	Type	Description
CDT_TX	[23:0]	rw	**Calculated duration of the current TRIGGER increment** calculated value
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.72Memory DPLL_CDT_SX

Prediction of the actual STATE increment duration.

GTM_DPLL_CDT_SX
DPLL Prediction of the actual STATE Increment
(28494$_H$) **Reset Value: 00000000$_H$**



Field	Bits	Type	Description
CDT_SX	[23:0]	rw	**Calculated duration of the current STATE increment** calculated value
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

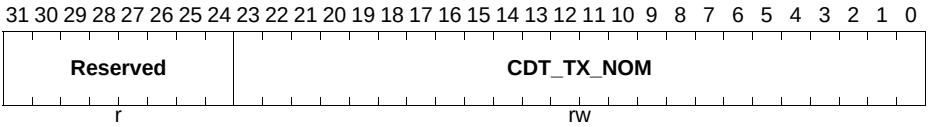
25.16.11.73Memory DPLL_CDT_TX_NOM

Prediction of the nominal TRIGGER increment duration.

GTM_DPLL_CDT_TX_NOM

DPLL Prediction of the nominal TRIGGER Increment duration

(28498$_H$) **Reset Value: 00000000$_H$**



Field	Bits	Type	Description
CDT_TX_NOM	[23:0]	rw	**Calculated duration of the current nominal TRIGGER event** calculated value
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

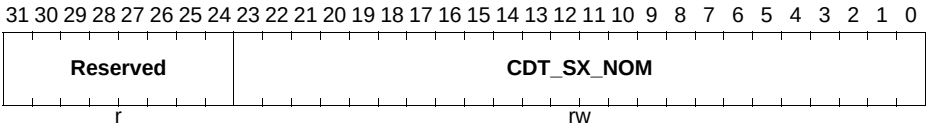
25.16.11.74Memory DPLL_CDT_SX_NOM

Prediction of the nominal STATE increment duration.

GTM_DPLL_CDT_SX_NOM

DPLL Prediction of the nominal STATE increment duration

(2849C$_H$) **Reset Value: 00000000$_H$**

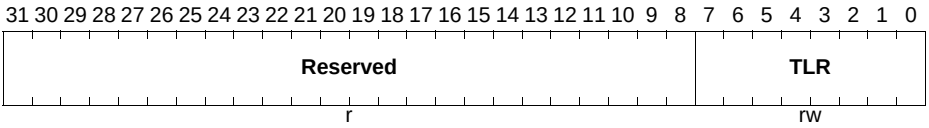


Field	Bits	Type	Description
CDT_SX_NOM	[23:0]	rw	**Calculated duration of the current t nominal STATE event** calculated value
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.75Memory DPLL_TLR

TRIGGER locking range.

GTM_DPLL_TLR
DPLL TRIGGER locking range (284A0$_H$) Reset Value: 00000000$_H$

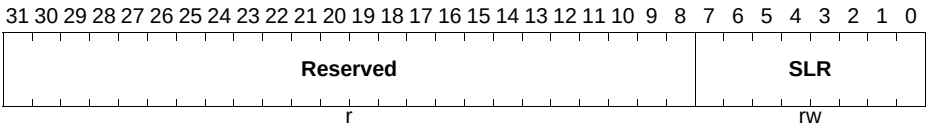


Field	Bits	Type	Description
TLR	[7:0]	rw	**Value is to be multiplied with the last nominal TRIGGER duration in order to get the range for the next TRIGGER event without setting TOR in the DPLL_STATUS register** multiply value with the last nominal increment duration and check violation; when TLR=0 don't perform the check
Reserved	[31:8]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.76Memory DPLL_SLR

STATE locking range.

GTM_DPLL_SLR
DPLL STATE Locking Range (284A4$_H$) Reset Value: 00000000$_H$

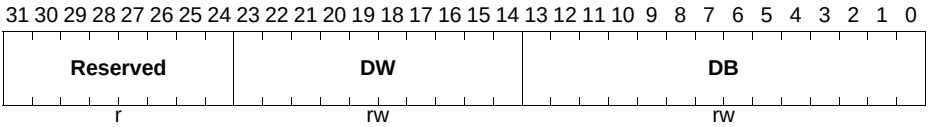


Field	Bits	Type	Description
SLR	[7:0]	rw	**Value is to be multiplied with the last nominal STATE duration in order to get the range for the next STATE event without setting SOR in the DPLL_STATUS register** multiply value with the last nominal increment duration and check violation; when SLR=0 don't perform the check
Reserved	[31:8]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.77Memory DPLL_PDT[i]

Projected increment sum relations for action i.

GTM_DPLL_PDT_Ti (i=0-23)
DPLL Projected TRIGGER Increment Sum Relations for Action_i
(28500_H + i * 04_H) **Reset Value: 00000000_H**

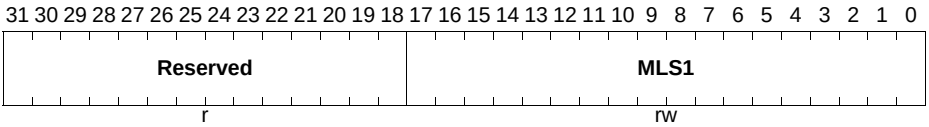


Field	Bits	Type	Description
DB	[13:0]	rw	**Fractional part of relation between TRIGGER or STATE increments**
DW	[23:14]	rw	**Integer part of relation between TRIGGER or STATE increments** Definition of relation values between TRIGGER or STATE increments PDT[i] according to Equation DPLL-11 or DPLL-13.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.78Memory DPLL_MLS1

Calculated number of sub-pulses between two STATE events for SMC=0.

GTM_DPLL_MLS1
DPLL Calculated Number of Sub-Pulses between Two STATE Events
($285C0_H$) **Reset Value: 00000000_H**

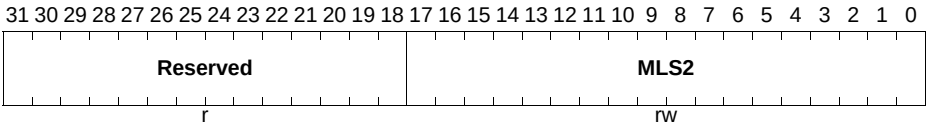


Field	Bits	Type	Description
MLS1	[17:0]	rw	**Number of pulses between two STATE events (to be set and updated by the CPU)** For SMC=0 the value of MLS1 is calculated once by the CPU for fixed values in the DPLL_CTRL_0 register by the formula MLS1 = ((MLT+1)*(TNU+1)/(SNU+1)) and set accordingly FOR SMC=1 the value of MLS1 represents the number of pulses between two TRIGGER events (to be set and updated by the CPU)
Reserved	[31:18]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.79Memory DPLL_MLS2

Calculated number of sub-pulses between two STATE events for SMC=1 and RMO=1.

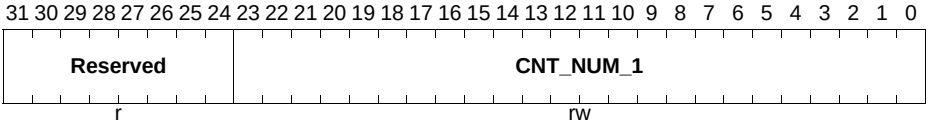
GTM_DPLL_MLS2
DPLL Calculated Number of Sub-Pulses between Two STATE Events
($285C4_H$) **Reset Value: 00000000_H**



Field	Bits	Type	Description
MLS2	[17:0]	rw	**Counter for number of SUB_INC2 pulses** Number of pulses between two STATE events (to be set and updated by the CPU). Using adapt information and the missing STATE event information SYN_S, this value can be corrected for each increment automatically.
Reserved	[31:18]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.80Memory DPLL_CNT_NUM1

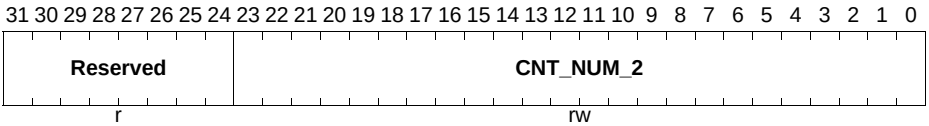
GTM_DPLL_CNT_NUM1
DPLL Number of Sub-Pulses of SUB_INC1 in Continuous Mode
(285C8$_H$) **Reset Value: 00000000$_H$**



Field	Bits	Type	Description
CNT_NUM_1	[23:0]	rw	**Counter for number of SUB_INC1 pulses** Number of pulses in continuous mode for a nominal increment in normal and emergency mode for SUB_INC1 given and updated by CPU only count value for continuous mode
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.81Memory DPLL_CNT_NUM2

GTM_DPLL_CNT_NUM2
DPLL Number of Sub-Pulses of SUB_INC2 in Continuous Mode
(285CC$_H$) **Reset Value: 00000000$_H$**

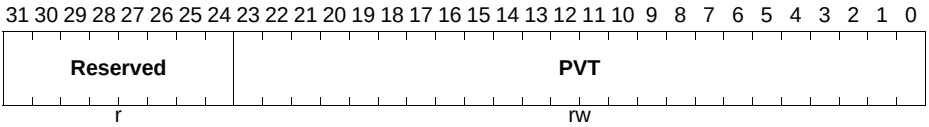


Field	Bits	Type	Description
CNT_NUM_2	[23:0]	rw	**Counter for number of SUB_INC2 pulses** Number of pulses in continuous mode for a nominal increment in normal and emergency mode for SUB_INC2, given and updated by CPU only count value for continuous mode
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.82Memory DPLL_PVT

Plausibility value of next TRIGGER slope.

GTM_DPLL_PVT
DPLL Plausibility Value of Next Active TRIGGER Slope
(285D0$_H$) **Reset Value: 00000000$_H$**

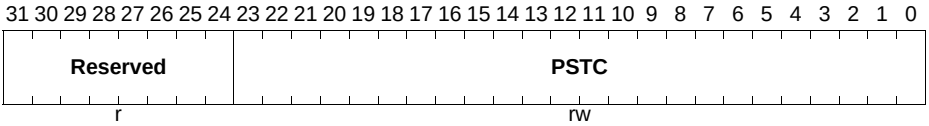


Field	Bits	Type	Description
PVT	[23:0]	rw	**Plausibility value of next valid TRIGGER slope** The meaning of the value depends on the value of the PIT value in the DPLL_CTRL_1 register. For PIT=0: the number of SUB_INC1 pulses to be waited for until a next valid TRIGGER event is accepted. For PIT=1: PVT is to be multiplied with the last nominal increment time DT_T_ACT and divided by 1024 and reduced to a 24 bit value in order to get the time to be waited for until the next valid TRIGGER event is accepted. The wait time must be exceeded for a valid slope. Note: When a valid TRIGGER slope is detected while the wait condition is not fulfilled the interrupt PWI is generated. Please note, that the SGE1 must be set, when PIT=0 in order to provide the necessary SUB_INC1 pulses for checking. After an unexpected missing TRIGGER the plausibility check is suppressed for the following increment.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.83Memory DPLL_PSTC

Actual calculated position stamp of TRIGGER.

GTM_DPLL_PSTC
DPLL Actual Calculated Position Stamp of Last TRIGGER Input
(285E0$_H$) **Reset Value: 00000000$_H$**

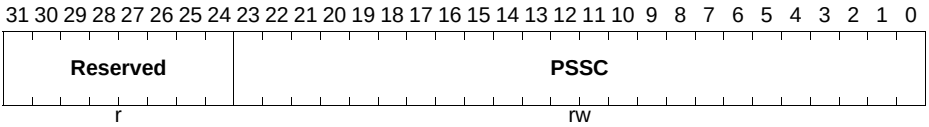


Field	Bits	Type	Description
PSTC	[23:0]	rw	**Calculated position stamp of last TRIGGER input** value is set by the DPLL and can be updated by the CPU when filter values are to be considered for the exact position (see DPLL_STATUS and DPLL_CTRL registers for explanation of the status and control bits used): For each valid slope of TRIGGER in normal and emergency mode • when FTD=0: PSTC is set from actual position value, for the first valid TRIGGER event (no filter delay considered) the CPU must update the value once, taking into account the filter value • when FTD=1: PSTC is increment at each TRIGGER event by • SMC=0: (MLT+1)*(SYN_T) +PD; while PD=0 for AMT=0 • SMC=1: (MLS1)*(SYN_T) +PD; while PD=0 for AMT=0
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.84Memory DPLL_PSSC

Actual calculated position stamp of STATE.

GTM_DPLL_PSSC
DPLL Accurate Calculated Position Stamp of Last STATE Input
($285E4_H$) **Reset Value: 00000000_H**



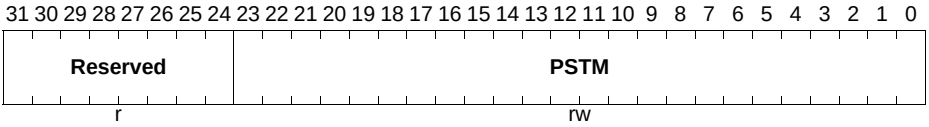
Field	Bits	Type	Description
PSSC	[23:0]	rw	**Calculated position stamp for the last STATE input** first value is set by the DPLL and can be updated by the CPU when the filter delay is to be considered. For each valid slope of STATE in normal and emergency mode • when FSD=0: PSSC is set from actual position value (no filter delay considered), • the CPU must update the value once, taking into account the filter value • when FSD=1: at each valid slope of STATE (PD_S_store=0 for AMS=0): • SMC=0: add MLS1*(SYN_S) + PD_S_store; • SMC=1: add MLS2*(SYN_S) + PD_S_store;
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.85Memory DPLL_PSTM

Measured position stamp at last TRIGGER input.

GTM_DPLL_PSTM_0
DPLL Measured Position Stamp of Last TRIGGER Input
($285E8_H$) **Reset Value: 00000000_H**

GTM_DPLL_PSTM_1
DPLL Measured Position Stamp of Last TRIGGER Input
($285EC_H$) **Reset Value: 00000000_H**



Field	Bits	Type	Description
PSTM	[23:0]	rw	**Position stamp of TRIGGER, measured** Measured position stamp of last TRIGGER input, measured at processing the input signal. Store the value TBU_TS1 at the moment when T_VALID is set in an intermediate register, but transmit this value to PSTM only, when the plausibility value (according to PVT) is passed.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

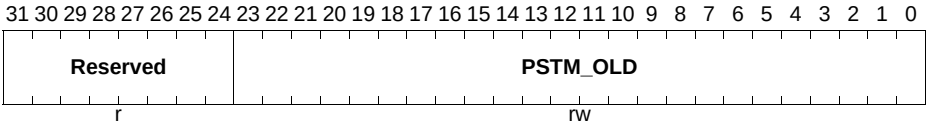
*Note: The LSB address is determined using the SWON_T value in the OSW register (see **Section 25.16.11.7**).*

25.16.11.86Memory DPLL_PSTM_OLD

Measured position stamp at last but one TRIGGER input.

GTM_DPLL_PSTM_OLD_0
DPLL Measured Position Stamp of Last But One TRIGGER Input
($285EC_H$) **Reset Value: 00000000_H**

GTM_DPLL_PSTM_OLD_1
DPLL Measured Position Stamp of Last But One TRIGGER Input
($285E8_H$) **Reset Value: 00000000_H**



Field	Bits	Type	Description
PSTM_OLD	[23:0]	rw	**Last but one position stamp of TRIGGER, measured** Measured position stamp of last but one TRIGGER input, measured at processing the input signal. (because of the input and transmission delay the value of PSTM_OLD can be higher than the exact value PSTC_OLD)
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

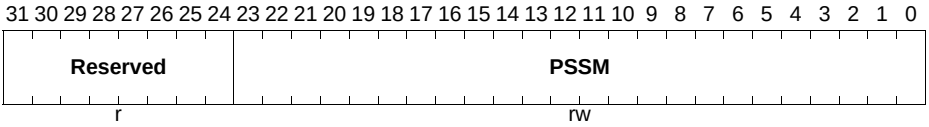
*Note: The LSB address is determined using the SWON_T value in the OSW register (see **Section 25.16.11.7**).*

25.16.11.87Memory DPLL_PSSM

Measured position stamp at last STATE input.

GTM_DPLL_PSSM_0
DPLL Measured Position Stamp of Last STATE Input
(285F0$_H$) **Reset Value: 00000000$_H$**

GTM_DPLL_PSSM_1
DPLL Measured Position Stamp of Last STATE Input
(285F4$_H$) **Reset Value: 00000000$_H$**



Field	Bits	Type	Description
PSSM	[23:0]	rw	**Position stamp of STATE, measured** Measured position stamp of last STATE input, measured at processing the input signal. Store the value TBU_TS1 or TBU_TS2 respectively at the moment when S_VALID is set in PSSM.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

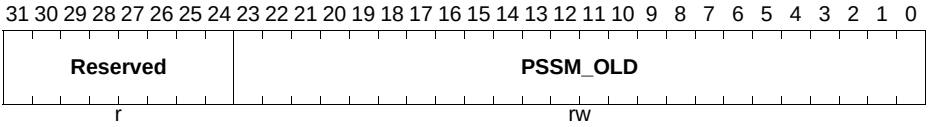
*Note: The LSB address is determined using the SWON_S value in the OSW register (see **Section 25.16.11.7**).*

25.16.11.88Memory DPLL_PSSM_OLD

Measured position stamp at last but one STATE.

GTM_DPLL_PSSM_OLD_0
DPLL Measured Position Stamp of Last But One STATE Input
($285F4_H$) **Reset Value: 00000000_H**

GTM_DPLL_PSSM_OLD_1
DPLL Measured Position Stamp of Last But One STATE Input
($285F0_H$) **Reset Value: 00000000_H**



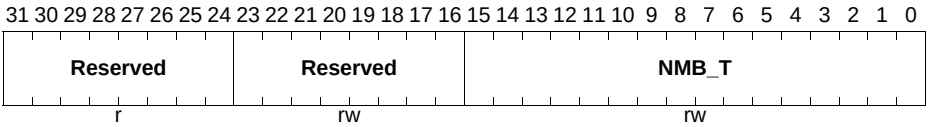
Field	Bits	Type	Description
PSSM_OLD	[23:0]	rw	**Last but one position stamp of STATE, measured** Measured position stamp of last but one STATE input, measured at processing the input signal. (because of the input and transmission delay the value of PSSM_OLD can be higher than the exact value PSSC_OLD).
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

*Note: The LSB address is determined using the SWON_S value in the OSW register (see **Section 25.16.11.7**).*

25.16.11.89Memory DPLL_NMB_T

Number of pulses to be sent in normal mode.

GTM_DPLL_NMB_T
DPLL Number of Pulses of Current Increment in Normal Mode
(285F8$_H$) **Reset Value: 00000000$_H$**

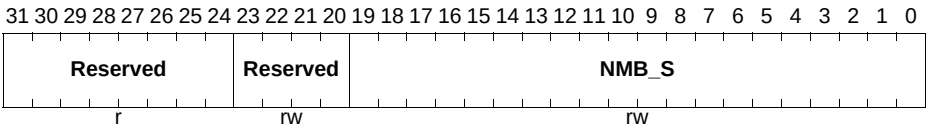


Field	Bits	Type	Description
NMB_T	[15:0]	rw	**Number of pulses for TRIGGER** Calculated number of pulses in normal mode for the current TRIGGER increment. calculated pulse number
Reserved	[23:16]	rw	**Reserved** Must be written as zero.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.90Memory DPLL_NMB_S

Number of pulses to be sent in emergency mode.

GTM_DPLL_NMB_S
DPLL Number of Pulses of Current Increment in Emergency Mode
(285FC$_H$) **Reset Value: 00000000$_H$**

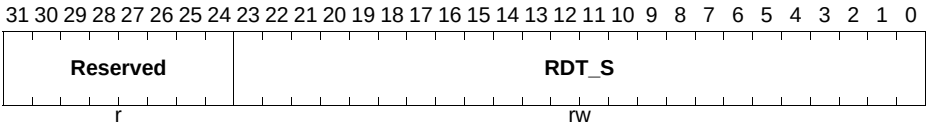


Field	Bits	Type	Description
NMB_S	[19:0]	rw	**Number of pulses for STATE** Calculated number of pulses in emergency mode for the current STATE increment. calculated pulse number
Reserved	[23:20]	rw	**Reserved** Must be written as zero.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.91Memory DPLL_RDT_Sx

Reciprocal values of normal STATE increment durations in FULL_SCALE.

GTM_DPLL_RDT_Sx (x=0-63)
DPLL Nominal STATE x Reciprocal Values in FULL_SCALE
(28600_H + x * 04_H) **Reset Value: 00000000_H**



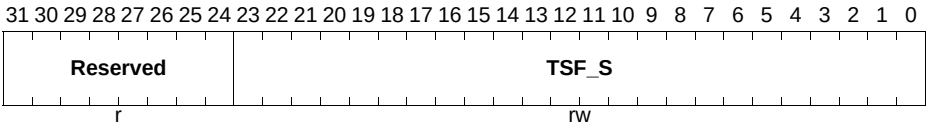
Field	Bits	Type	Description
RDT_S	[23:0]	rw	**Reciprocal difference time of TRIGGER** Nominal reciprocal value of the number of time stamp clocks measured in the corresponding increment *2^{32} while only the lower 24 bits are used; no gap considered. The LSB is rounded up when the next truncated bit is 1. Note: There are 2*(SNU+1-SYN_NS) entries for SYSF=0 or 2*(SNU+1)-SYN_NS entries for SYSF=1 respectively.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.92Memory DPLL_TSF_S[i]

Time stamp of normal STATE events in FULL_SCALE.

GTM_DPLL_TSF_Sx (x=0-63)
DPLL Time Stamp Field of STATE x Events

(28700_H + x * 04_H) **Reset Value: 00000000_H**



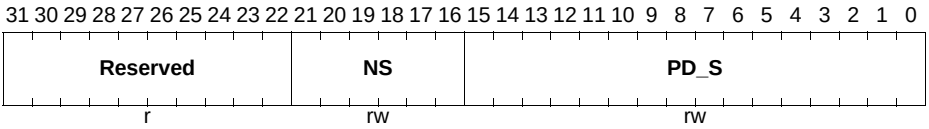
Field	Bits	Type	Description
TSF_S	[23:0]	rw	**Time stamp field of STATE** Time stamp value of each valid STATE event. Note: There are 2* (SNU+1) entries.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.93Memory DPLL_ADT_S[i]

Adapt and profile values of the STATE increments in FULL_SCALE

GTM_DPLL_ADT_Sx (x=0-63)
DPLL Adapt Values for All STATE x Increments

(28800_H + x * 04_H) **Reset Value: 00000000_H**



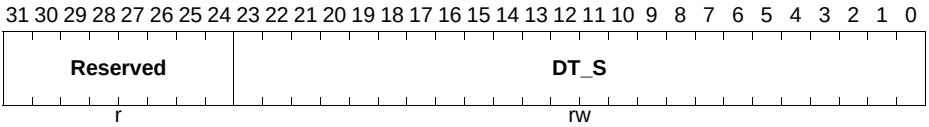
Field	Bits	Type	Description
PD_S	[15:0]	rw	**Physical deviation of STATE** Adapt values for each STATE increment in FULL_SCALE (sint16); This value represents the number of pulses to be added to the correspondent increment.

Field	Bits	Type	Description
NS	[21:16]	rw	**Number of STATEs** number of nominal STATE parts in the corresponding increment. Note: There are 2* (SNU+1-SYN_NS) entries.
Reserved	[31:22]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.94Memory DPLL_DT_S[i]

Nominal STATE increment durations in FULL_SCALE.

GTM_DPLL_DT_Sx (x=0-63)
DPLL Nominal STATE x Increment Values for FULL_SCALE
(28900_H + x * 04_H) **Reset Value: 00000000_H**

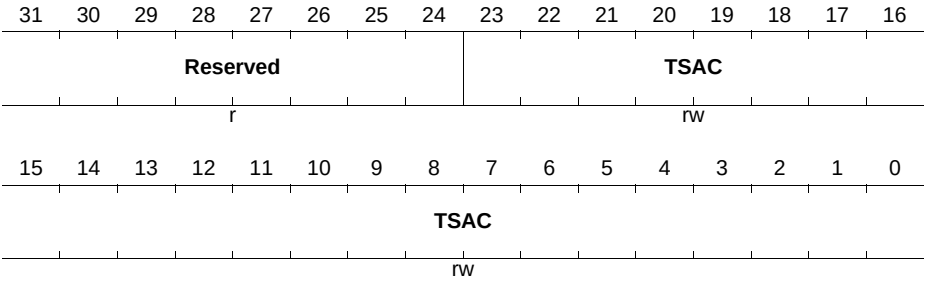


Field	Bits	Type	Description
DT_S	[23:0]	rw	**Difference time of STATE** nominal increment duration values for each STATE increment in FULL_SCALE (considering no gap). Note: There are 2* (SNU+1-SYN_NS) entries.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.95Memory DPLL_TSAC[i]

Calculated time value to start action i.

GTM_DPLL_TSACi (i=0-23)
DPLL Calculate Time Stamp Register($28E00_H$ + i * 04_H) Reset Value: $007FFFFF_H$



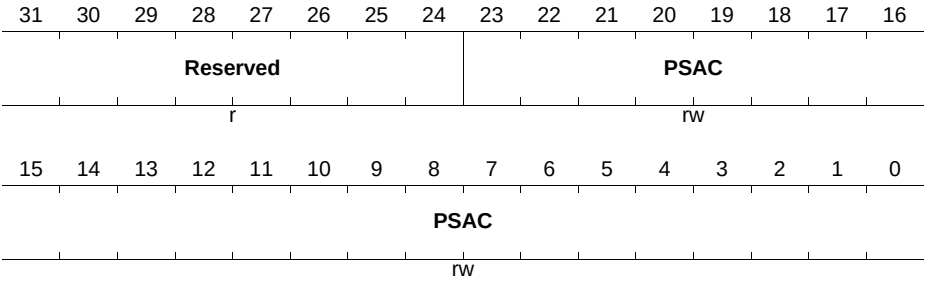
Field	Bits	Type	Description
TSAC	[23:0]	rw	**calculated time stamp for ACTION_i** Note: This value can only be written when the DPLL is disabled.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.96Memory DPLL_PSAC[i]

Calculated position to start action i.

GTM_DPLL_PSACi (i=0-23)
DPLL Calculated Position Value Register

($28E80_H$ + i * 04_H) **Reset Value: $007FFFFF_H$**

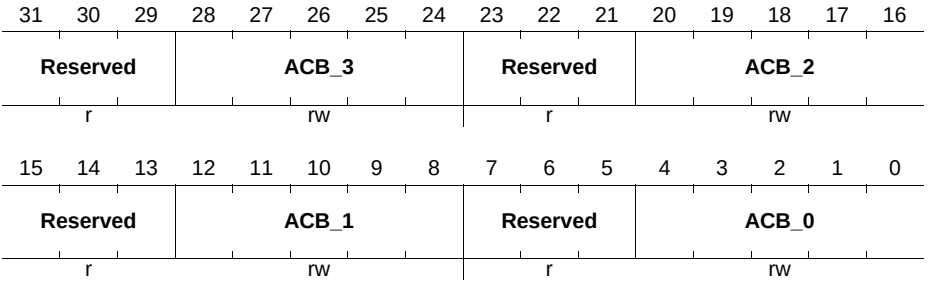


Field	Bits	Type	Description
PSAC	[23:0]	rw	**calculated position value for the start of ACTION_i in normal or emergency mode according to equations DPLL-17 or DPLL-20 respectively** Note: This value can only be written when the DPLL is disabled.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.97Memory DPLL_ACBi

Control bits for actions.

GTM_DPLL_ACBi (i=0-5)
DPLL Action Control i Register (28F00$_H$ + i * 04$_H$) **Reset Value: 00000000$_H$**



Field	Bits	Type	Description
ACB_0	[4:0]	rw	**Action Control Bits of ACTION_j** reflects ACT_D[j](52:48), j=4*i Note: This value can only be written when the DPLL is disabled.
Reserved	[7:5]	r	**Reserved** Read as zero, should be written as zero.
ACB_1	[12:8]	rw	**Action Control Bits of ACTION_(j + 1)** reflects ACT_D[j+1](52:48), j=4*i Note: This value can only be written when the DPLL is disabled.
Reserved	[15:13]	r	**Reserved** Read as zero, should be written as zero.
ACB_2	[20:16]	rw	**Action Control Bits of ACTION_(j + 2)** reflects ACT_D[j+2](52:48), j=4*i Note: This value can only be written when the DPLL is disabled.
Reserved	[23:21]	r	**Reserved** Read as zero, should be written as zero.
ACB_3	[28:24]	rw	**Action Control Bits of ACTION_(j + 3)** reflects ACT_D[j+3](52:48), j=4*i Note: This value can only be written when the DPLL is disabled.

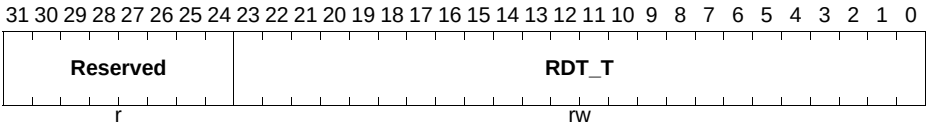
Field	Bits	Type	Description
Reserved	[31:29]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.98Memory DPLL_RDT_T[i]

Reciprocal values of the nominal TRIGGER increment durations in FULL_SCALE.

DPLL_RDT_Tx (x=0-511)
DPLL TRIGGER x Nominal Increment Reciprocals in FULL_SCALE

(AOSV_2A + x * 04_H) **Reset Value: 00000000_H**



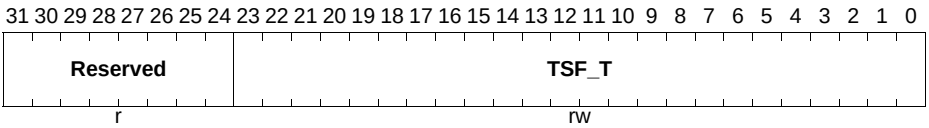
Field	Bits	Type	Description
RDT_T	[23:0]	rw	**Reciprocal difference time of TRIGGER** 2* (TNU+1- SYN_NT) stored values nominal reciprocal value of the number of time stamp clocks measured in the corresponding increment (which is divided by the number of nominal increments); multiplied by 2^{32} while only the lower 24 bits are used; the LSB is rounded up, when the next truncated bit is 1. Note: There are 2* (TNU+1- SYN_NT) entries. The maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.99Memory DPLL_TSF_T[i]

Time stamp values of the nominal TRIGGER increments in FULL_SCALE.

DPLL_TSF_Tx (x=0-511)
DPLL Time Stamp Field of TRIGGER x Events

(AOSV_2B + x * 04_H) **Reset Value: 00000000_H**



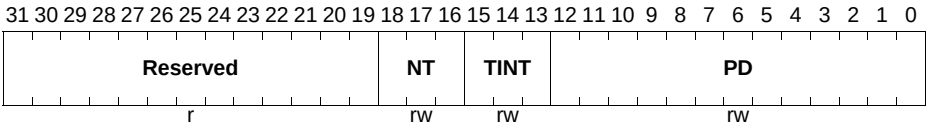
Field	Bits	Type	Description
TSF_T	[23:0]	rw	**Time stamp field of valid TRIGGER slopes** Note: There are 2* (TNU+1) entries. The maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.100Memory DPLL_ADT_T[i]

Adapt and profile values of the TRIGGER increments in FULL_SCALE.

DPLL_ADT_Tx (x=0-511)
DPLL Adapt Value x for All Increments

(AOSV_2C + x * 04_H) **Reset Value: 00000000_H**

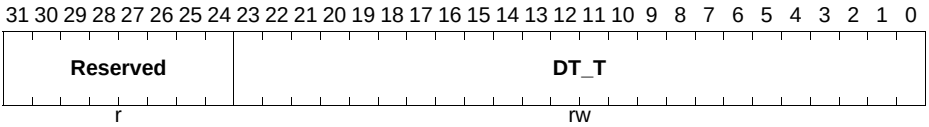


Field	Bits	Type	Description
PD	[12:0]	rw	**Physical deviation** Adapt values for each TRIGGER increment in FULL_SCALE (sint13); the PD value does mean the number of SUB_INC1 pulses to be added to NT*(MLT+1); the absolute value of a negative PD must not exceed nt*(MLT+1) or MLS1 respectively; systematic missing TRIGGER events must not be considered for the value of PD;
TINT	[15:13]	rw	**TRIGGER Interrupt information** depending on the value up to 7 different interrupts can be generated. In the current version the 5 interrupts TE0_IRQ … TE4_IRQ are supported by TINT=”001”, “010”, "011", “100”, “101” respectively. For the values "000", "110" and "111" no interrupt is generated and no other reaction is performed. The corresponding interrupt is activated, when the TINT value is read by the DPLL together with the other values (PD, NT) according to the profile.
NT	[18:16]	rw	**Number of TRIGGERs** number of nominal TRIGGER parts in the corresponding increment. Note: There are 2* (TNU+1- SYN_NT) entries. The maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.
Reserved	[31:19]	r	**Reserved** Read as zero, should be written as zero.

25.16.11.101Memory DPLL_DT_T[i]

Nominal TRIGGER increment durations in FULL_SCALE.

DPLL_DT_Tx (x=0-511)
DPLL Nominal TRIGGER Increment Values for FULL_SCALE
(AOSV_2D + x * 04_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
DT_T	[23:0]	rw	**Difference time of TRIGGER** Increment duration values for each TRIGGER increment in FULL_SCALE divided by the number of nominal increments (nominal value). Note: There are 2* (TNU+1- SYN_NT) entries. The maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero.

25.16.12 Terms and Abbreviations

The following terms and abbreviations are used for DPLL:

- FULL_SCALE; Range in which all positions / values depend on the information of TRIGGER and STATE signals
- HALF_SCALE; Range in which all positions / values depend on the information of TRIGGER signal only, two consecutive HALF_SCALE periods from a FULL_SCALE period
- TS; Time stamp representation
- PS; Position (or value) stamp representation, common description

25.17 Sensor Pattern Evaluation (SPE)

25.17.1 Overview

The Sensor Pattern Evaluation (SPE) submodule can be used to evaluate three hall sensor inputs and together with the TOM module to support the drive of BLDC engines. Thus, the input signals are filtered already in the connected TIM channels. In addition, the SPE submodule can be used as an input stage to the MAP submodule if the DPLL should be used to calculate the rotation speed of one or two electric engine(s). The integration of the SPE submodule into the overall GTM architecture concept is shown in **Figure 25-77**.

25.17.1.1 SPE Submodule integration concept into GTM

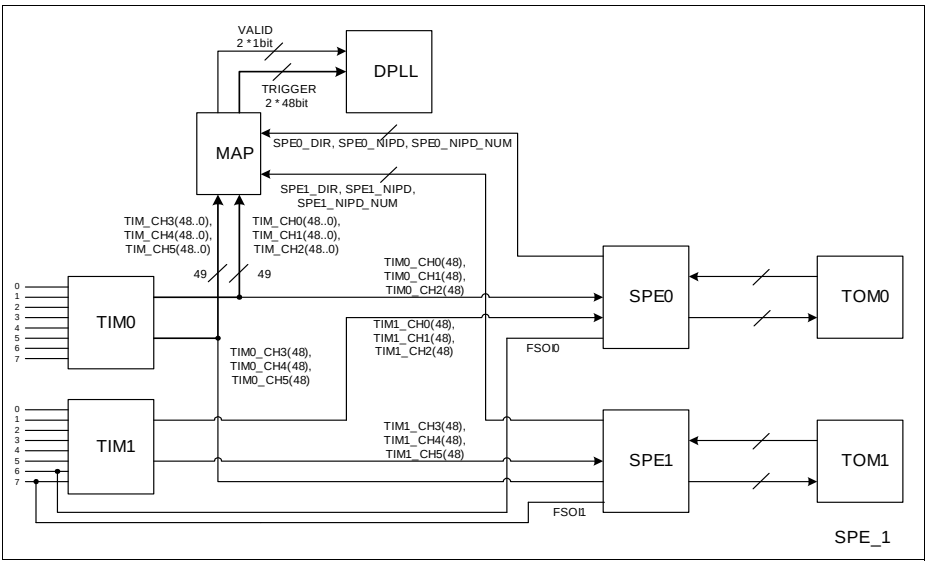


Figure 25-77 SPE integration

As mentioned above, the SPE submodule can determine a rotation direction out of the combined TIM[i]_CHx(48), TIM[i]_CHy(48) and TIM[i]_CHz(48) signals. On this input signals a pattern matching algorithm is applied to generate the SPEx_DIR signal on behalf of the temporal relation between these input patterns. A possible sample pattern of the three input signals is shown in **Figure 25-78**. In general, the input pattern is programmable within the SPE submodule.

25.17.1.2 SPE Sample input pattern for

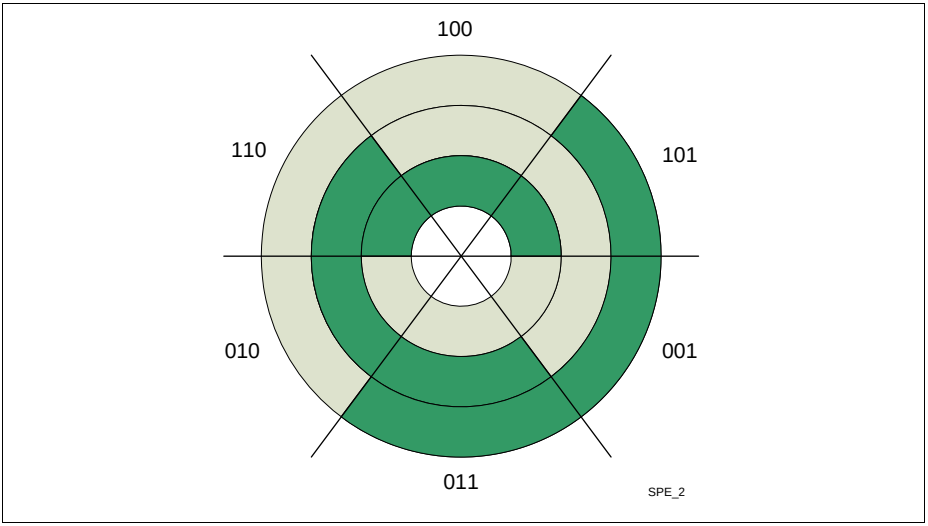

Figure 25-78 SPE sample input pattern

In **Figure 25-78** the input signals define the pattern from the input sensors which have a 50% high and 50% low phase. The pattern according to **Figure 25-79** is as follows:

100 – 110 – 010 – 011 – 001 – 101 – 100

where the first bit (smallest circle) represents TIM[i]_CH[x](48), the second bit represents TIM[i]_CH[y](48), and the third bit (greatest circle) represents TIM[i]_CH[z](48).

Note that the SPE module expects that with every new pattern only one of the three input signals changes its value.

25.17.2 SPE Submodule description

The SPE submodule can handle sensor pattern inputs. Every time if one of the input signals TIM[i]_CH[x](48),TIM[i]_CH[y](48) or TIM[i]_CH[z](48) changes its value, a sample of all three input signals is made. Derived from the sample of the three inputs the encoded rotation direction and the validity of the input pattern sequence can be detected and signalled. When a valid input pattern is detected, the SPE submodule can control the outputs of a dedicated connected TOM submodule. This connection is shown in **Figure 25-79**.

25.17.2.1 SPE to TOM Connections

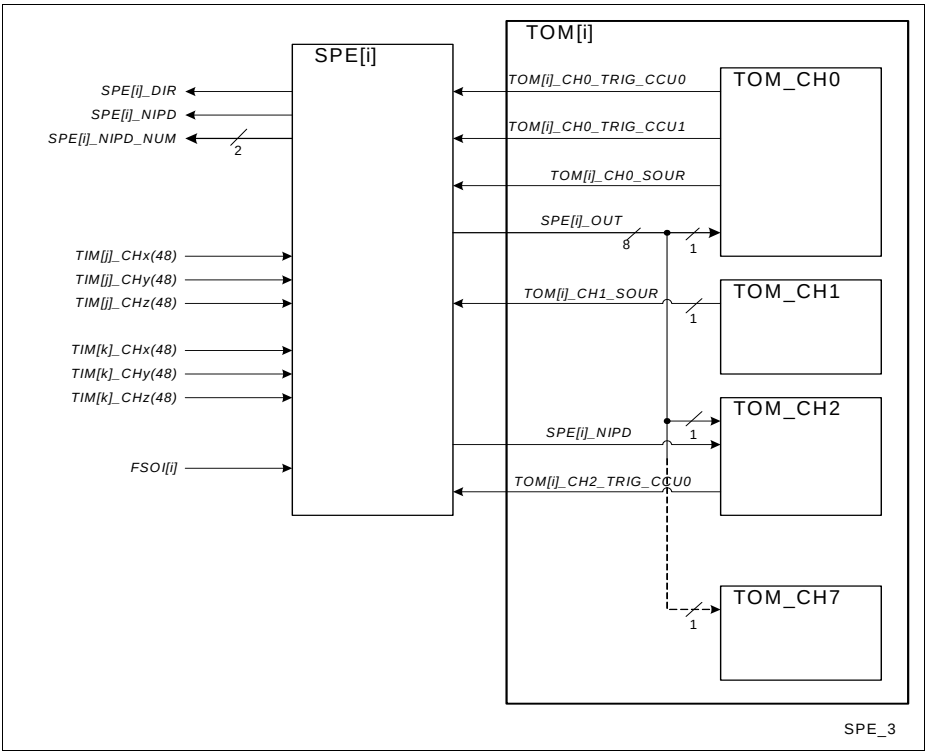

Figure 25-79 SPE to TOM Connections

The TOM[i]_CH0_TRIG_CCU[x] and TOM[i]_CH[x]_SOUR signal lines are used to evaluate the current state of the TOM outputs, whereas the SPE[i]_OUT output vector is used to control the TOM output depending on the new input pattern. The SPE[i]_OUT output vector is defined inside the SPE submodule in a pattern definition table SPEi_OUT_PATx. The internal SPE submodule architecture is shown in **Figure 25-80**.

25.17.2.2 SPE Submodule architecture

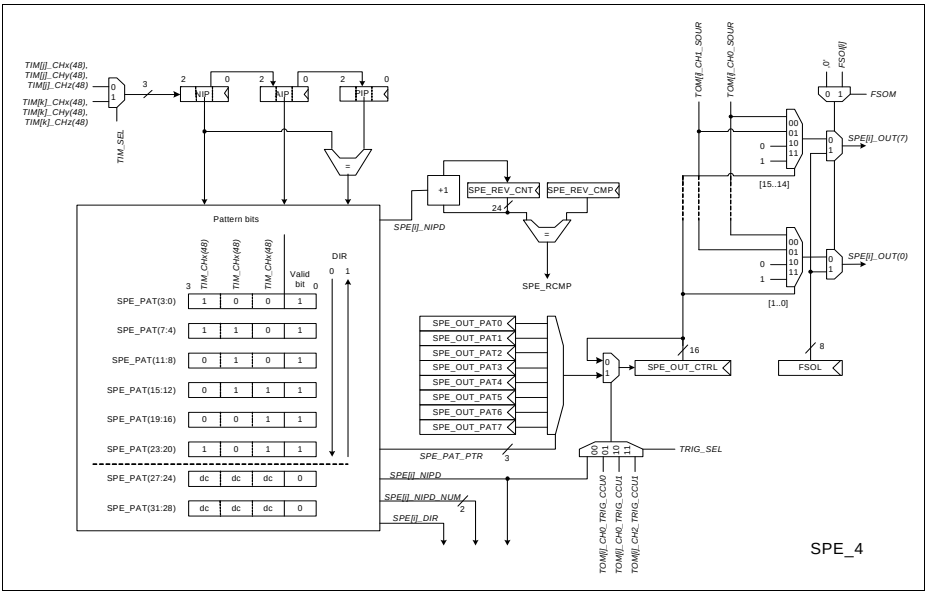

Figure 25-80 SPE Submodule architecture

The SPEi_PAT register holds the valid input pattern for the three input patterns TIM[i]_CH[x](48), TIM[i]_CH[y](48) and TIM[i]_CH[z](48). The input pattern is programmable. The valid bit shows if the programmed pattern is a valid one. **Figure 25-80** shows the programming of the SPEi_PAT register for the input pattern defined in **Figure 25-79**.

The rotation direction is determined by the order of the valid input pattern. This rotation direction defines if the SPE_PAT_PTR is increment (DIR = 0) or decremented (DIR = 1). Whenever a valid input pattern is detected, the NIPD signal is raised, the SPE_PAT_PTR is increment/decremented and a new output control signal SPE[i]_OUT(x) is send to the corresponding TOM submodule.

The TOM[i]_CH2 with i=0…3 can be used together with the SPE module to trigger a delayed update of the SPE_OUT_CTRL register after new input pattern detected by SPE (signalled by SPE[i]_NIPD).

To do this, the TOM[i]_CH2 has to be configured to work in one-shot mode (set bit OSM in register TOM[i]_CH2_CTRL). The SPE mode of this channel has to be enabled, too (set bit SPEM in register TOM[i]_CH2_CTRL). The SPE module has to be configured to update SPE_OUT_CTRL on TOM[i]_CH2_TRIG_CCU1 (set in SPEi_CTRL_STAT bits TRIG_SEL to '11'). Then, on new input detected by SPE, the signal SPE[i]_NIPD triggers the start of the TOM channel 2 to generates one PWM period by resetting CN0 to 0. On

second PWM edge triggered by CCU1 of TOM channel 2, the signal TOM[i]_CH2_TRIG_CCU1 triggers the update of SPE_OUT_CTRL.

According to **Figure 25-80**, the two input patterns “000” and “111” are not allowed combinations and will end in a SPE[i]_PERR interrupt. These two patterns can be used to determine a sensor input error. A SPE[i]_PERR interrupt will also be raised, if the input patterns occur in a wrong order, e.g. if the pattern "010" does not follow the pattern "110" or "011".

The register SPE[i]_IN_PAT bit field inside the SPEi_CTRL_STAT register is implemented, where the input pattern history is stored by the SPE submodule. The CPU can determine a broken sensor when the SPE[i]_PERR interrupt occurs by analyzing the bit pattern NIP inside the SPEi_CTRL_STAT register. The input pattern in the SPEi_CTRL_STAT register is updated whenever a valid edge is detected on one of the input lines TIM[i]_CH[x](48), TIM[i]_CH[y](48) or TIM[i]_CH[z](48). The pattern bit fields are then shifted. The input pattern history generation inside the SPEi_CTRL_STAT register is shown in **Figure 25-81**.

Additionally to the sensor pattern evaluation the SPE module also provides the feature of fast shut-off for all TOM channels controlled by the SPE module. The feature is enabled by setting bit FSOM in register SPEi_CTRL_STAT. The fast shut-off level itself is defined in the bit field FSOL of register SPEi_CTRL_STAT. The TIM input used to trigger the fast shut-off is either TIM channel 6 or TIM channel 7 depending on the TIM instance connected to the SPE module. For details of connections please refer to **Figure 25-77**.

25.17.2.3 SPE[i]_IN_PAT register representation

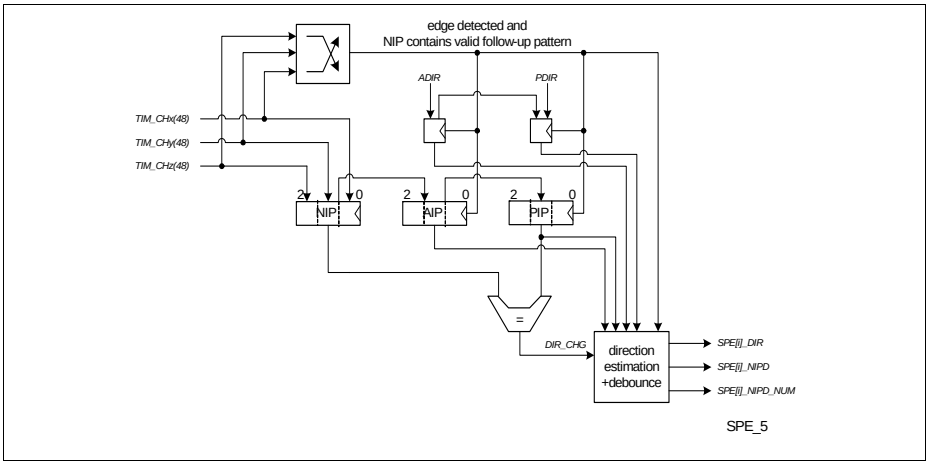

Figure 25-81 Register SPE_IN_PAT implementation

The CPU can disable one of the three input signals, e.g. when a broken input sensor was detected, by disabling the input with the three input enable bits SIE inside the SPEi_CTRL_STAT register.

Whenever at least one of the input signal TIM[i]_CH[x](48), TIM[i]_CH[y](48) or TIM[i]_CH[z](48) changes the SPE submodule stores the new bit pattern in an internal register NIP (New Input Pattern). If the current input pattern in NIP is the same as in the Previous Input Pattern (PIP) the direction of the engine changed, the SPE[i]_DCHG interrupt is raised, the direction change is stored internally and the pattern in the PIP bit field is filled with the AIP bit field and the AIP bit field is filled with the NIP bit field. The SPE[i]_DIR bit inside the SPEi_CTRL_STAT register is toggled and the SPE[i]_DIR signal is changed.

If the SPE encounters that with the next input pattern detected new input pattern NIP the direction change again, the input signal is categorized as bouncing and the bouncing input signal interrupt SPE[i]_BIS is raised.

Immediately after update of register NIP, when the new detected input pattern doesn't match the PIP pattern (i.e. no direction change was detected), the SPE shifts the value of register AIP to register PIP and the value of register NIP to register AIP. The SPE[i]_NIPD interrupt is raised.

The number of the channel that has been changed and thus leads to the new input pattern is encoded in the signal SPE[i]_NIPD_NUM.

If a sensor error was detected, the CPU has to define upon the pattern in the SPEi_CTRL_STAT register, which input line comes from the broken sensor. The faulty signal line has to be masked by the CPU and the SPE submodule determines the rotation direction on behalf of the two remaining TIM[i]_CH[x] input lines.

The pattern history can be determined by the CPU by reading the two bit fields AIP and PIP of the SPEi_CTRL_STAT register. The AIP register field holds the actual detected input pattern at TIM[i]_CH[x](48), TIM[i]_CH[y](48) and TIM[i]_CH[z](48) and the PIP holds the previous detected pattern.

After reset the register NIP, AIP and PIP as well as the register SPEi_PAT_PTR and SPEi_OUT_CTRL will not contain valid startup values which would allow correct behaviour after enabling SPE and detecting the first input patterns.

Thus, it is necessary to initialize these register to correct values.

To do this, before enabling the SPE, the bit field NIP of register SPEi_CTRL_STAT can be read and depending on this value the initialization values for the register AIP, PIP, SPT_PAT_PTR and SPEi_OUT_CTRL can be determined.

25.17.2.4 SPE Revolution detection

The SPE submodule is able to detect and count the number of valid input patterns detected at the specified input ports. This is done with a 24bit revolution counter SPE_CNT. The counter is incremented by a value of one (1) when a new valid input pattern indicating forward direction is detected. The counter is decremented by a value of one (1) when a new valid input pattern indicating backward direction is detected.

In addition there exists a 24 bit SPE_CMP register. The user can initialize this register with a compare value, where an interrupt SPEi_RCMP is raised, when the revolution counter equals the compare value either in forward or backward direction.

Both register may be written by software at any time.

25.17.3 SPE Interrupt signals

The following table describes SPE interrupt signals:

Table 25-54 SPE Interrupt signals

Signal	Description
SPE[i]_NIPD	SPE New valid input pattern detected.
SPE[i]_DCHG	SPE Rotation direction change detected on behalf of input pattern.
SPE[i]_PERR	SPE Invalid input pattern detected.
SPE[i]_BIS	SPE Bouncing input signal detected at input.

25.17.4 SPE Register overview

The following table shows an overview about the SPE register set.

Table 25-55 SPE Register overview

Register name	Description	Details in Section
SPEi_CTRL_STAT	SPE Control status register	Section 25.17.5.1
SPEi_PAT	SPE Input pattern definition register	Section 25.17.5.2
SPEi_OUT_PATx	SPE Output definition registers. (x: 07)	Section 25.17.5.3
SPEi_OUT_CTRL	SPE output control register	Section 25.17.5.4
SPEi_CNT	SPE input revolution counter	Section 25.17.5.5
SPEi_CMP	SPE revolution counter compare value	Section 25.17.5.6
SPEi_IRQ_NOTIFY	SPE Interrupt notification register	Section 25.17.5.7
SPEi_IRQ_EN	SPE Interrupt enable register	Section 25.17.5.8
SPEi_EIRQ_EN	SPE Error interrupt enable register.	Section 25.17.5.11
SPEi_IRQ_FORCINT	SPE Interrupt generation by software	Section 25.17.5.9
SPEi_IRQ_MODE	IRQ mode configuration register	Section 25.17.5.10

25.17.5 SPE Register description

All of the following registers are 32-bit only accessible.

25.17.5.1 Register SPEi_CTRL_STAT

GTM_SPEi_CTRL_STAT (i=0-1)
SPEi Control Status Register **(00800_H+i*80_H)** **Reset Value: 00000000_H**

rw			rw	rw			rw	rw			rw	rw			rw

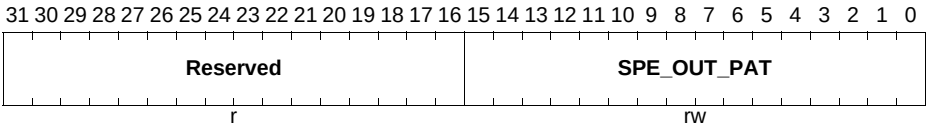
Field	Bits	Type	Description
IP0_VAL	0	rw	**Input pattern 0 is a valid pattern** 0_B Pattern invalid. 1_B Pattern valid.
IP0_PAT	[3:1]	rw	**Input pattern 0** Bit field defines the first input pattern of the SPE input signals. Bit 1 defines the TIM[i]_CHx(48) input signal. Bit 2 defines the TIM[i]_CHy(48) input signal. Bit 3 defines the TIM[i]_CHz(48) input signal.
IP1_VAL	4	rw	**Input pattern 1 is a valid pattern** See bit 0.
IP1_PAT	[7:5]	rw	**Input pattern 1** See bits 3:1.
IP2_VAL	8	rw	**Input pattern 2 is a valid pattern** See bit 0.
IP2_PAT	[11:9]	rw	**Input pattern 2** See bits 3:1.
IP3_VAL	12	rw	**Input pattern 3 is a valid pattern** See bit 0.
IP3_PAT	[15:13]	rw	**Input pattern 3** See bits 3:1.

Field	Bits	Type	Description
IP4_VAL	16	rw	**Input pattern 4 is a valid pattern** See bit 0.
IP4_PAT	[19:17]	rw	**Input pattern 4** See bits 3:1.
IP5_VAL	20	rw	**Input pattern 5 is a valid pattern** See bit 0.
IP5_PAT	[23:21]	rw	**Input pattern 5** See bits 3:1.
IP6_VAL	24	rw	**Input pattern 6 is a valid pattern** See bit 0.
IP6_PAT	[27:25]	rw	**Input pattern 6** See bits 3:1.
IP7_VAL	28	rw	**Input pattern 7 is a valid pattern** See bit 0.
IP7_PAT	[31:29]	rw	**Input pattern 7** See bits 3:1.

Note: Only the first block of valid input patterns defines the commutator. All input pattern following the first marked invalid input pattern are ignored.

25.17.5.3 Register SPEi_OUT_PATx (x: 07)

GTM_SPE0_OUT_PATx (x=0-7)
SPE0 Output Definition Register x (808_H+x*04_H) **Reset Value: 00000000_H**
GTM_SPE1_OUT_PATx (x=0-7)
SPE1 Output Definition Register x (888_H+x*04_H) **Reset Value: 00000000_H**

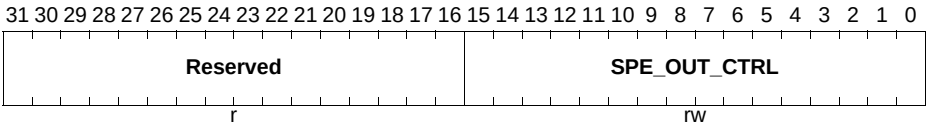


Field	Bits	Type	Description
SPE_OUT_PAT	[15:0]	rw	**SPE output control value for TOM_CH0 to TOM_CH7** SPE_OUT_PAT[n+1:n] defines output select signal of TOM[i]_CH[n] 00_B set SPE_OUT(n) to TOM_CH0_SOUR 01_B set SPE_OUT(n) to TOM_CH1_SOUR 10_B set SPE_OUT(n) to '0' 11_B set SPE_OUT(n) to '1' with n = 0…7
Reserved	[31:16]	r	**Reserved** Read as zero, should be written as zero

Note: Note: Register SPEi_OUT_PATx defines the output selection for TOM[i]_CH0 to TOM[i]_CH7 depending on actual input pattern IP[x]_PAT with x=0-7.

25.17.5.4 Register SPEi_OUT_CTRL

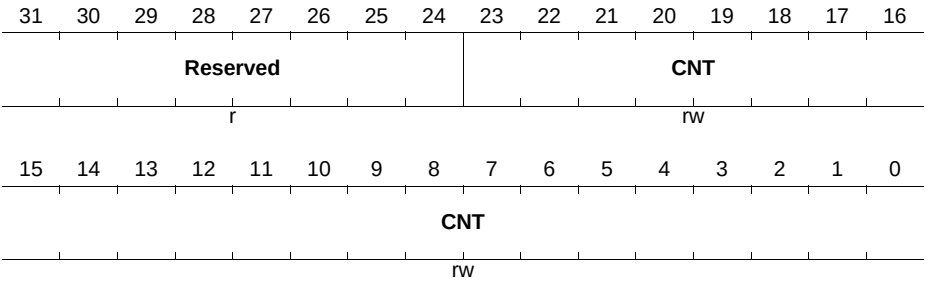
GTM_SPEi_OUT_CTRL (i=0-1)
SPEi Output Control Register **(828_H+i*80_H)** **Reset Value: 00000000_H**



Field	Bits	Type	Description
SPE_OUT_CTRL	[15:0]	rw	**SPE output control value for TOM_CH0 to TOM_CH7** SPE_OUT_CTRL[n+1:n] defines output select signal of TOM_CHn 00_B set SPE_OUT(n) to TOM_CH0_SOUR 01_B set SPE_OUT(n) to TOM_CH1_SOUR 10_B set SPE_OUT(n) to '0' 11_B set SPE_OUT(n) to '1' with n = 0…7
Reserved	[31:16]	r	**Read as zero, should be written as zero** Note: Current output control selection for SPE[i]_OUT(0…7).

25.17.5.5 Register SPEi_CNT

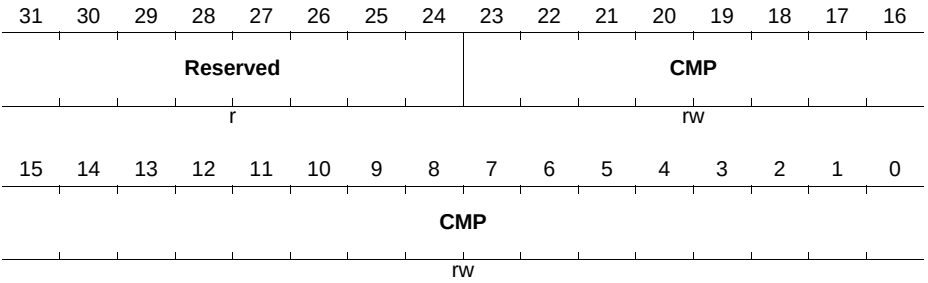
GTM_SPEi_CNT (i=0-1)
SPEi Revolution Counter Register (840_H+i*80_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
CNT	[23:0]	rw	**Input signal revolution counter** The counter is running if SPE module is enabled (bit SPE_EN). CNT is incrementing if SPE_PAT_PTR is incrementing CNT is decrementing if SPE_PAT_PTR is decrementing
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

25.17.5.6 Register SPEi_CMP

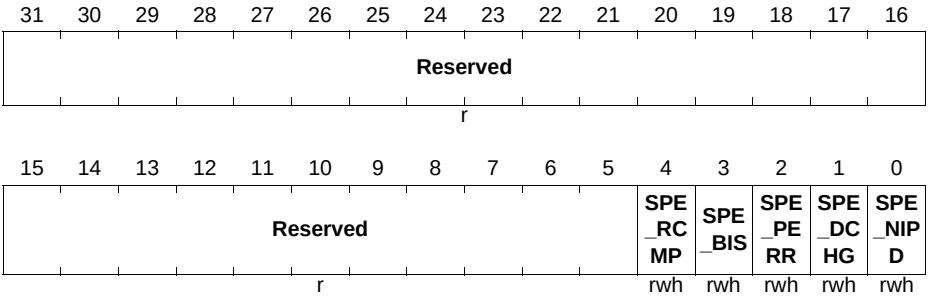
GTM_SPEi_CMP (i=0-1)
SPEi Revolution Compare Register(844_H+i*80_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
CMP	[23:0]	rw	**Input signal revolution counter compare value** The interrupt SPEi_RCMP is raised when the SPEi_CNT value equals the SPEi_CMP register. It should be noted that SPEi_RCMP is only raised if an incrementation or decrementation of SPEi_CNT is applied, due to a input signal change. Any update of SPEi_CNT or SPEi_CMP via AEI does not raise an SPEi_RCMP interrupt.
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

25.17.5.7 Register SPEi_IRQ_NOTIFY

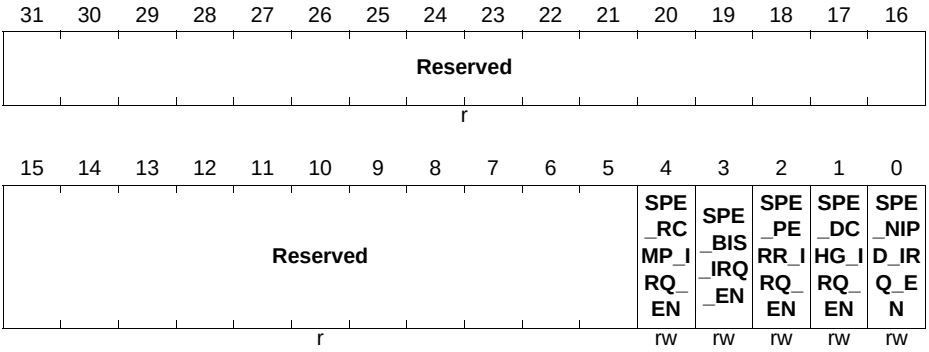
GTM_SPEi_IRQ_NOTIFY (i=0-1)
SPEi Interrupt Notification Register($82C_H$+i*80_H) **Reset Value: 00000000_H**



Field	Bits	Type	Description
SPE_NIPD	0	rwh	**New input pattern interrupt occurred** 0_B No interrupt occurred. 1_B New input pattern detected interrupt occurred. Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
SPE_DCHG	1	rwh	**SPE_DIR bit changed on behalf of new input pattern** See bit 0.
SPE_PERR	2	rwh	**Wrong or invalid pattern detected at input** See bit 0.
SPE_BIS	3	rwh	**Bouncing input signal detected** See bit 0.
SPE_RCMP	4	rwh	**SPE revolution counter match event** See bit 0.
Reserved	[31:5]	r	**Reserved** Read as zero, should be written as zero

25.17.5.8 Register SPEi_IRQ_EN

GTM_SPEi_IRQ_EN (i=0-1)
SPEi Interrupt Enable Register **(830_H+i*80_H)** **Reset Value: 00000000_H**



Field	Bits	Type	Description
SPE_NIPD_IRQ_EN	0	rw	**SPE_NIPD_IRQ interrupt enable** 0_B Disable interrupt, interrupt is not visible outside GTM. 1_B Enable interrupt, interrupt is visible outside GTM.
SPE_DCHG_IRQ_EN	1	rw	**SPE_DCHG_IRQ interrupt enable** See bit 0.
SPE_PERR_IRQ_EN	2	rw	**SPE_PERR_IRQ interrupt enable** See bit 0.
SPE_BIS_IRQ_EN	3	rw	**SPE_BIS_IRQ interrupt enable** See bit 0.
SPE_RCMP_IRQ_EN	4	rw	**SPE_RCMP_IRQ interrupt enable** See bit 0.
Reserved	[31:5]	r	**Reserved** Read as zero, should be written as zero

25.17.5.9 Register SPEi_IRQ_FORCINT

GTM_SPEi_IRQ_FORCINT (i=0-1)
SPEi Interrupt Generation by Software

25.18 Interrupt Concentrator Module (ICM)

25.18.1 Overview

The Interrupt Concentrator Module (ICM) is used to bundle the GTM interrupt lines of the individual submodules in a reasonable manner into interrupt groups. By this bundling a smaller amount of interrupt lines is visible at the outside of the GTM.

The individual interrupts of the GTM submodules and channels have to be enabled or disabled inside the submodules and channels.

The feed through architecture of bundled interrupt lines is used for the submodules AEI, ARU, BRC, CMP, SPE, PSM, TIM, DPLL, TOM, ATOM and MCS.

To determine the detailed interrupt source the microcontroller has to read the submodule/channel interrupt notification register NOTIFY and serve the channel individual interrupt.

Please note, that the interrupts are only visible inside the ICM and in consequence outside of the GTM, when the interrupt is enabled inside the submodules themselves.

25.18.2 Bundling

The GTM submodule individual interrupt sources are connected to the ICM. There, the individual interrupt lines are either feed through and signalled to the outside world or bundled a second time into groups and are then signalled to the outside world.

The ICM interrupt bundling is described in the following sections.

25.18.2.1 GTM Infrastructure Interrupt Bundling

The first interrupt group contains interrupts of the infrastructure and safety components of the GTM. This interrupt group includes therefore interrupt lines coming from the AEI, ARU, BRC, PSM, SPE and CMP submodules. In this interrupt group each individual channel of the submodules has its own interrupt line to the outside world.

Thus, the active interrupt line can be used by the CPU to determine the GTM submodule channel that raised the interrupt. The interrupts are also represented in the ICM_IRQG_0 register. This register is typically not read by the CPU, but it is readable.

25.18.2.2 DPLL Interrupt Bundling

The DPLL Interrupt group handles the interrupts coming from the DPLL submodule of the GTM. Each of the individual DPLL interrupt lines has its own dedicated interrupt line to the outside world. The interrupts are additionally identified in the ICM_IRQG_1 interrupt group register. This register is typically not read out by the CPU, but it is readable.

25.18.2.3 TIM Interrupt Bundling

Inside this group submodules which handle GTM input signals are treated. This is the case for the TIM[i] submodules. Each TIM submodule channel is able to generate six (6) individual interrupts if enabled inside the TIM channel. This six interrupts are bundled into one interrupt per TIM channel connected to the ICM.

The ICM does no further bundling. Thus, for the GTM 32 interrupt lines TIM[i]_IRQ[y] are provided for the external microcontroller. The channel responsible for the interrupt can be determined by the raised interrupt line.

In addition, the ICM_IRQG_2 register a mirror for the TIM submodule channel interrupts and typically not read out by the CPU, but it is readable.

25.18.2.4 MCS Interrupt Bundling

For complex signal output generation, the MCS submodules are used inside the GTM. Each of these MCS submodules has eight channels with one interrupt line. This interrupt line is connected to the ICM submodule and is feed through directly to the outside world.

In addition the interrupt line status is shown in the ICM_IRQG_4 register. Typically, the interrupt source is determined by the corresponding interrupt line and the ICM_IRQ4 register is typically not read out by the CPU, but it is readable.

25.18.2.5 TOM and ATOM Interrupt Bundling

For the TOM and ATOM submodules, the interrupts are bundled within the ICM submodule a second time to reduce external interrupt lines. The interrupts are OR-ed in a manner that one GTM external interrupt line represents two adjacent TOM or ATOM channel interrupts. For TOM[i] and ATOM[i] the bundling is shown in **TOM and ATOM interrupt bundling within ICM**.

TOM and ATOM interrupt bundling within ICM

TOM[i]-input IRQs [i]=0..number of TOM's-1	TOM-output IRQs (OR-ed)		ATOM[i]-input IRQs [i]=0..number of ATOM's-1	ATOM-output IRQs (OR-ed)

TOM[i]_CH15_IRQ				

ICM_1

Figure 25-82 TOM and ATOM interrupts

The interrupts coming from the TOM[i] submodules are registered in the ICM_IRQG_6 / ICM_IRQG_7 register. Always two TOM's are bundled in one ICM register, TOM0 and TOM1 are bundled in ICM_IRQG_6. To identify the TOM submodule channel where the interrupt occurred, the CPU has to read out the ICM_IRQG_6(/_7) register first before it goes to the TOM submodule channel itself.

The ICM_IRQG_6(/_7) register bits are cleared automatically, when their corresponding interrupt in the submodule channels is cleared.

The interrupts coming from the ATOM[i] submodules are registered in the ICM_IRQG_9 / ICM_IRQG_10 register. Always four ATOM's are bundled in one ICM register, ATOM0,ATOM1, ATOM2 and ATOM3 are bundled in ICM_IRQG_9. To identify the ATOM submodule channel where the interrupt occurred, the CPU has to read out the ICM_IRQG_9(/_10) register first before it goes to the ATOM submodule channel itself.

The interrupts coming from the ATOM[i] submodules are registered in the ICM_IRQG_9 register. ATOM0, ATOM1 and ATOM2 are bundled in ICM_IRQG_9. Ti identify the

ATOM submodule channel where the interrupt occurred, the CPU has to read out the ICM_IRQG_9 register first before it goes to the ATOM submodule channel itself.

The ICM_IRQG_9(/_10) register bits are cleared automatically, when their corresponding interrupt in the submodule channels is cleared.

Module Error Interrupt Bundling

The Module Error Interrupt group handles the error interrupts coming from the BRC, FIFO, TIM, MCS, SPE, CMP, DPLL submodules of the GTM. The Module Error interrupts are additionally identified in the ICM_IRQ_MEI error interrupt group register. This register is typically not read out by the CPU, but it is readable.

The ICM_IRQG_MEI register bits are cleared automatically, when their corresponding error interrupt in the submodule is cleared.

FIFO Channel Error Interrupt Bundling

The FIFO Channel Error Interrupt group handles the error interrupts coming from the FIFO channel of the GTM. The FIFO Channel Error interrupts are additionally identified in the ICM_IRQ_CEI0 error interrupt group register. This register is typically not read out by the CPU, but it is readable.

The ICM_IRQG_CEI0 register bits are cleared automatically, when their corresponding error interrupt in the submodule channel is cleared.

TIM Channel Error Interrupt Bundling

The TIM Channel Error Interrupt group handles the error interrupts coming from the TIM channel of the GTM. The TIM Channel Error interrupts are additionally identified for the submodules TIM0, TIM1, TIM2, and TIM3 in the ICM_IRQ_CEI1 error interrupt group register and for TIM4, TIM5, and TIM6 in the ICM_IRQ_CEI2 error interrupt group register. This register is typically not read out by the CPU, but it is readable.

The ICM_IRQG_CEI1 and ICM_IRQG_CEI2 register bits are cleared automatically, when their corresponding error interrupt in the submodule channel is cleared.

MCS Channel Error Interrupt Bundling

The MCS Channel Error Interrupt group handles the error interrupts coming from the MCS channel of the GTM. The MCS Channel Error interrupts are additionally identified for the submodules MCS0, MCS1, MCS2, and MCS3 in the ICM_IRQ_CEI3 error interrupt group register and for MCS4, MCS5, and MCS6 in the ICM_IRQ_CEI4 error interrupt group register. This register is typically not read out by the CPU, but it is readable.

The ICM_IRQG_CEI4 and ICM_IRQG_CEI4 register bits are cleared automatically, when their corresponding error interrupt in the submodule channel is cleared.

25.18.3 ICM Interrupt Signals

Following table shows the GTM interrupt lines that are visible at the outside of the GTM.

Table 25-56 ICM Interrupt Signals

Signal	Description
GTM_AEI_IRQ	AEI Shared interrupt
GTM_ARU_IRQ[2:0]	[0]: ARU_NEW_DATA0 Interrupt [1]: ARU_NEW_DATA1 Interrupt [2]: ARU_ACC_ACK Interrupt
GTM_BRC_IRQ	BRC Shared interrupt
GTM_CMP_IRQ	CMP Shared interrupt
GTM_SPE[i]_IRQ	SPE Shared interrupt (i: 0…number of SPE's-1)
GTM_PSM[i]_IRQ[x]	PSM Shared interrupts (x: 0…7) (i: 0…number of PSM's-1)
GTM_DPLL_IRQ[0]	DPLL_DCGI: DPLL TRIGGER direction change detected
GTM_DPLL_IRQ[1]	DPLL_EDI: DPLL enable/disable interrupt
GTM_DPLL_IRQ[2]	DPLL_TIN: DPLL TRIG. min. hold time (THMI) viol. detected
GTM_DPLL_IRQ[3]	DPLL_TAX: DPLL TRIG. max. hold time (THMA) viol. detected
GTM_DPLL_IRQ[4]	DPLL_SIS: DPLL STATE inactive slope detected
GTM_DPLL_IRQ[5]	DPLL_TIS: DPLL TRIGGER inactive slope detected
GTM_DPLL_IRQ[6]	DPLL_MSI: DPLL Missing STATE interrupt
GTM_DPLL_IRQ[7]	DPLL_MTI: DPLL Missing TRIGGER interrupt
GTM_DPLL_IRQ[8]	DPLL_SAS: DPLL STATE active slope detected
GTM_DPLL_IRQ[9]	DPLL_TAS: DPLL TRIG. active slope det. while NTI_CNT is 0
GTM_DPLL_IRQ[10]	DPLL_PWI: DPLL Plausibility window (PVT) viol. int. of TRIG
GTM_DPLL_IRQ[11]	DPLL_W2I: DPLL Write access to RAM region 2 interrupt
GTM_DPLL_IRQ[12]	DPLL_W1I: DPLL Write access to RAM region 1B or 1C int
GTM_DPLL_IRQ[13]	DPLL_GLI: DPLL Get of lock interrupt for SUB_INC1
GTM_DPLL_IRQ[14]	DPLL_LLI: DPLL Lost of lock interrupt for SUB_INC1
GTM_DPLL_IRQ[15]	DPLL_EI: DPLL Error interrupt
GTM_DPLL_IRQ[16]	DPLL_GL2I: DPLL Get of lock interrupt for SUB_INC1
GTM_DPLL_IRQ[17]	DPLL_LL2I: DPLL Lost of lock interrupt for SUB_INC2
GTM_DPLL_IRQ[18]	DPLL_TE0: DPLL TRIGGER event interrupt 0

Table 25-56 ICM Interrupt Signals (cont'd)

Signal	Description
GTM_DPLL_IRQ[19]	DPLL_TE0: DPLL TRIGGER event interrupt 1
GTM_DPLL_IRQ[20]	DPLL_TE0: DPLL TRIGGER event interrupt 2
GTM_DPLL_IRQ[21]	DPLL_TE0: DPLL TRIGGER event interrupt 3
GTM_DPLL_IRQ[22]	DPLL_TE0: DPLL TRIGGER event interrupt 4
GTM_DPLL_IRQ[23]	DPLL_CDIT: DPLL calculated duration interrupt for trigger
GTM_DPLL_IRQ[24]	DPLL_CDIS: DPLL calculated duration interrupt for state
GTM_DPLL_IRQ[25]	DPLL_TORI: trigger out of range interrupt
GTM_DPLL_IRQ[26]	DPLL_SORI: status out of range interrupt
GTM_TIM[i]_IRQ[x]	TIM Shared interrupts (i: 0…number of TIM's-1) (x: 0…7)
GTM_MCS[i]_IRQ[x]	MCS Interrupt for channel x (x: 0…7) (i: 0…number of MCS's-1)
GTM_TOM[i]_IRQ[x]	TOM Shared interrupts for x:0…7 = {ch0||ch1,,ch14||ch15} (i: 0…number of TOM's-1)
GTM_ATOM[i]_IRQ[x]	ATOM Shared interrupts for x:0…3 = {ch0||ch1,,ch6||ch7} (i: 0…number of ATOM's-1)
GTM_ERR_IRQ	GTM Error Interrupt

25.18.4 ICM Configuration Registers Overview

ICM contains following configuration registers:

Table 25-57 ICM Configuration Registers Overview

Register Name	Description	Details in Section
ICM_IRQG_0	ICM Interrupt group register covering infrastructural and safety components (ARU, BRC, AEI, PSM[i], MAP, CMP,SPE)	Section 25.18.5.1
ICM_IRQG_1	ICM Interrupt group register covering DPLL	Section 25.18.5.2
ICM_IRQG_2	ICM Interrupt group register covering TIM0, TIM1, TIM2, TIM3	Section 25.18.5.3
ICM_IRQG_4	ICM Interrupt group register covering MCS0 to MCS3 submodules	Section 25.18.5.4
ICM_IRQG_6	ICM Interrupt group register covering GTM output submodules TOM0 and TOM1	Section 25.18.5.5
ICM_IRQG_7	ICM Interrupt group register covering GTM output submodule TOM2	Section 25.18.5.6
ICM_IRQG_9	ICM Interrupt group register covering GTM output submodules ATOM0, ATOM1, ATOM2 and ATOM3	Section 25.18.5.7
ICM_IRQG_10	ICM Interrupt group register covering GTM output submodule ATOM4	Section 25.18.5.8
ICM_IRQG_MEI	ICM Interrupt group register for module error interrupt information	Section 25.18.5.9
ICM_IRQG_CEI0	ICM Interrupt group register 0 for channel error interrupt information	Section 25.18.5.10
ICM_IRQG_CEI1	ICM Interrupt group register 1 for channel error interrupt information	Section 25.18.5.11
ICM_IRQG_CEI3	ICM Interrupt group register 3 for channel error interrupt information	Section 25.18.5.12

25.18.5 ICM Configuration Registers Description

All of the following registers are 32-bit only accessible.

25.18.5.1 Register ICM_IRQG_0

GTM_ICM_IRQG_0
GTM Infrastructure Interrupt Group (600_H) **Reset Value: 00000000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								PSM0_CH7_IRQ	PSM0_CH6_IRQ	PSM0_CH5_IRQ	PSM0_CH4_IRQ	PSM0_CH3_IRQ	PSM0_CH2_IRQ	PSM0_CH1_IRQ	PSM0_CH0_IRQ
r								rh	rh	rh	rh	rh	rh	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								SPE1_IRQ	SPE0_IRQ	CMP_IRQ	AEI_IRQ	BRC_IRQ	ARU_ACC_ACK_IRQ	ARU_NEW_DATA1_IR	ARU_NEW_DATA0_IR
r								rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
ARU_NEW_DATA0_IRQ	0	rh	**ARU_NEW_DATA0 interrupt** 0_B no interrupt occurred 1_B interrupt was raised by the corresponding submodule Note: This bit is only set, when the interrupt is enabled in the interrupt enable register of the corresponding submodule. The bit is cleared automatically, when the corresponding interrupt in the submodule channels is cleared.
ARU_NEW_DATA1_IRQ	1	rh	**ARU_NEW_DATA1 interrupt** See bit 0.
ARU_ACC_ACK_IRQ	2	rh	**ARU_ACC_ACK interrupt** See bit 0.
BRC_IRQ	3	rh	**BRC shared submodule interrupt** See bit 0.

Field	Bits	Type	Description
AEI_IRQ	4	rh	**AEI_IRQ interrupt** See bit 0.
CMP_IRQ	5	rh	**CMP shared submodule interrupt** See bit 0.
SPE0_IRQ	6	rh	**SPE0 shared submodule interrupt** See bit 0.
SPE1_IRQ	7	rh	**SPE1 shared submodule interrupt** See bit 0.
Reserved	[15:8]	r	**Reserved** Read as zero, should be written as zero
PSM0_CH0_IRQ	16	rh	**PSM0 shared submodule channel 0 interrupt** 0_B no interrupt occurred 1_B interrupt was raised by the corresponding submodule Note: This bit is only set, when the interrupt is enabled in the interrupt enable register of the corresponding submodule. Note: When set this bit represents one of the four interrupt sources FIFO_[x]_EMPTY, FIFO_[x]_FULL, FIFO_[x]_LOWER_WM or FIFO_[x]_UPPER_WM The bit is cleared automatically, when the corresponding interrupt in the submodule channels is cleared.
PSM0_CH1_IRQ	17	rh	**PSM0 shared submodule channel 1 interrupt** **See bit 16**
PSM0_CH2_IRQ	18	rh	**PSM0 shared submodule channel 2 interrupt** See bit 16
PSM0_CH3_IRQ	19	rh	**PSM0 shared submodule channel 3 interrupt** See bit 16
PSM0_CH4_IRQ	20	rh	**PSM0 shared submodule channel 4 interrupt** See bit 16
PSM0_CH5_IRQ	21	rh	**PSM0 shared submodule channel 5 interrupt** See bit 16
PSM0_CH6_IRQ	22	rh	**PSM0 shared submodule channel 6 interrupt** See bit 16
PSM0_CH7_IRQ	23	rh	**PSM0 shared submodule channel 7 interrupt** See bit 16

Field	Bits	Type	Description
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero

25.18.5.2 Register ICM_IRQG_1 (DPLL Interrupt Group)

GTM_ICM_IRQG_1
GTM DPLL Interrupt Group **(604_H)** **Reset Value: 00000000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

25.19 Output Compare Unit (CMP)

25.19.1 Overview

The Output Compare Unit (CMP) is designed for the use in safety relevant applications. The main idea is to have the possibility to duplicate outputs in order to be compared in this unit. Because of the simple EXOR function used it is necessary to ensure the total cycle accurate output behaviour of the output modules to be compared. This is given when two ATOM units produce output signals at the same time stamp or when two TOMs have the same configuration and start their output generation at the same time. This is possible by means of the trigger mechanisms TRIG_x provided by the TOMs as shown in the **Section 25.11.1.1** (TOM Block Diagram). It is not necessary to compare each output channel with each other.

The CMP enables the comparison of 2x24 channels of the TOM and ATOM units respectively and is restricted to neighbor channels. Thus, channel 0 is compared with channel 1, channel 2 with 3 and so on until the comparison of channel 22 with channel 23.

25.19.1.1 Architecture of the Compare Unit

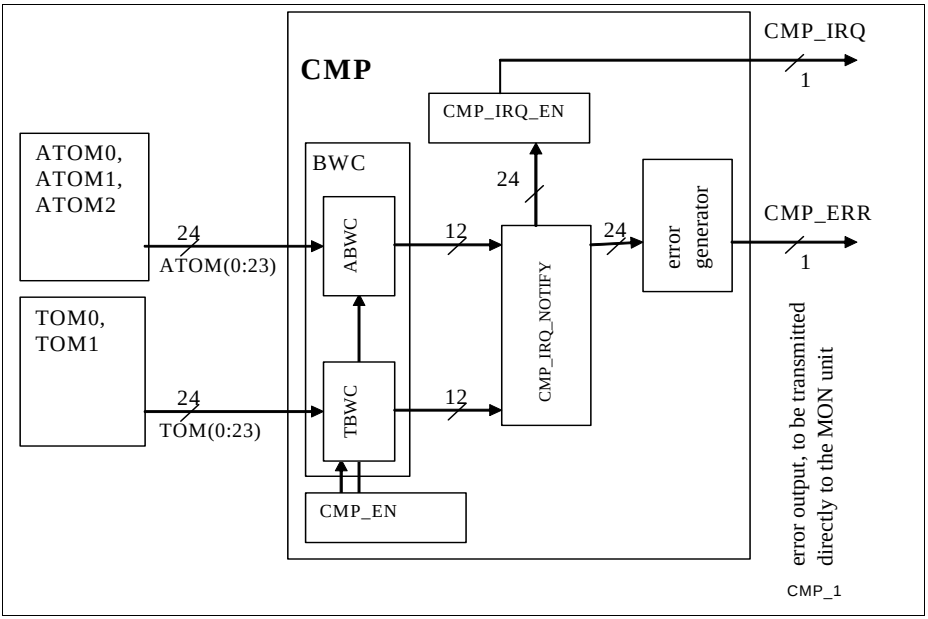

Figure 25-83 Architecture of the Compare Unit

25.19.2 Bitwise Compare Unit (BWC)

The Bitwise Compare Unit compares in pairs the combinations shown in following table

Table 25-58 Bitwise compare

TBWC/ABWC Comparator Number	Compare TOM/ATOM Bit Number one	Compare TOM/ATOM Bit Number Two	Output Number
0	0	1	0
1	2	3	1
2	4	5	2
3	6	7	3
4	8	9	4
5	10	11	5

Table 25-58 Bitwise compare (cont'd)

TBWC/ABWC Comparator Number	Compare TOM/ATOM Bit Number one	Compare TOM/ATOM Bit Number Two	Output Number
6	12	13	6
7	14	15	7
8	16	17	8
9	18	19	9
10	20	21	10
11	22	23	11

25.19.3 Configuration of the Compare Unit

Because of the restrictions described in the section above the Compare Unit consists of 24 antivalence (EXOR) elements, a select register CMP_EN which selects the corresponding comparisons and a status register CMP_IRQ_NOTIFY which shows and stores each mismatching result, when selected.

For each with CMP_IRQ_EN enabled mismatching error an interrupt signal on CMP_IRQ is generated.

For each with CMP_EIRQ_EN enabled mismatching error an interrupt signal on CMP_EIRQ is generated.

25.19.4 Error Generator

The error generator generates an error signal to be transmitted directly to the MON unit and independently from the CMP_IRQ and CMP_EIRQ. The error is set when in the CMP_IRQ_NOTIFY register at least one bit is set. The CMP_IRQ_NOTIFY bits are not maskable for this purpose.

The CMP_ERR output reflects its status in the status register of the Monitor Unit, which is to be polled by the CPU.

25.19.5 CMP Interrupt Signal

The CMP submodule has two interrupt signals, one normal interrupt and one error interrupt. The source of both interrupts can be determined by reading the CMP_IRQ_NOTIFY register for under consideration of CMP_IRQ_EN register and CMP_EIRQ_EN register. Each source can be forced separately for debug purposes using the interrupt force CMP_IRQ_FORCINT register. CMP_IRQ_MODE configures interrupt output characteristic. All interrupt modes are described in detail in **Section 25.2.5**.

Table 25-59 CMP interrupt interface

Signal	Description
CMP_EIRQ	Mismatching interrupt of outputs to be compared, when enabled
CMP_IRQ	Mismatching interrupt of outputs to be compared, when enabled

25.19.6 CMP Configuration Registers Overview

CMP contains following configuration registers:

Table 25-60 CMP Configuration Registers Overview

Register Name	Description	Details in Section
CMP_EN	Comparator enable register	Section 25.19.7.1
CMP_IRQ_NOTIFY	Event notification register	Section 25.19.7.2
CMP_IRQ_EN	Interrupt enable register	Section 25.19.7.3
CMP_IRQ_FORCINT	Interrupt force register	Section 25.19.7.4
CMP_IRQ_MODE	IRQ mode configuration register	Section 25.19.7.5
CMP_EIRQ_EN	Error interrupt enable register	Section 25.19.7.6

25.19.7 CMP Configuration Registers Description

All of the following registers are 32-bit only accessible.

25.19.7.1 Register CMP_EN

25.20 Monitor Unit (MON)

25.20.1 Overview

The Monitor Unit (MON) is designed for the use in safety relevant applications. The main idea is to have a possibility to supervise common used circuitry and resources. In this way the activity of the clocks is supervised. In addition the characteristics of output signals can be checked in a MCS channel by a re-read-in via TIM and routing to the MCS. When the comparison fails an error signal is generated in MCS and sent to the monitor unit. One error signal per MCS summarizes the errors of all channels. By generating of an activity signal per channel for each such performed comparison, the activity of TIM, ARU and the used clocks is checked implicitly.

In addition the ARU cycle time could be also compared in a MCS channel to given values.

25.20.1.1 MON Block Diagram

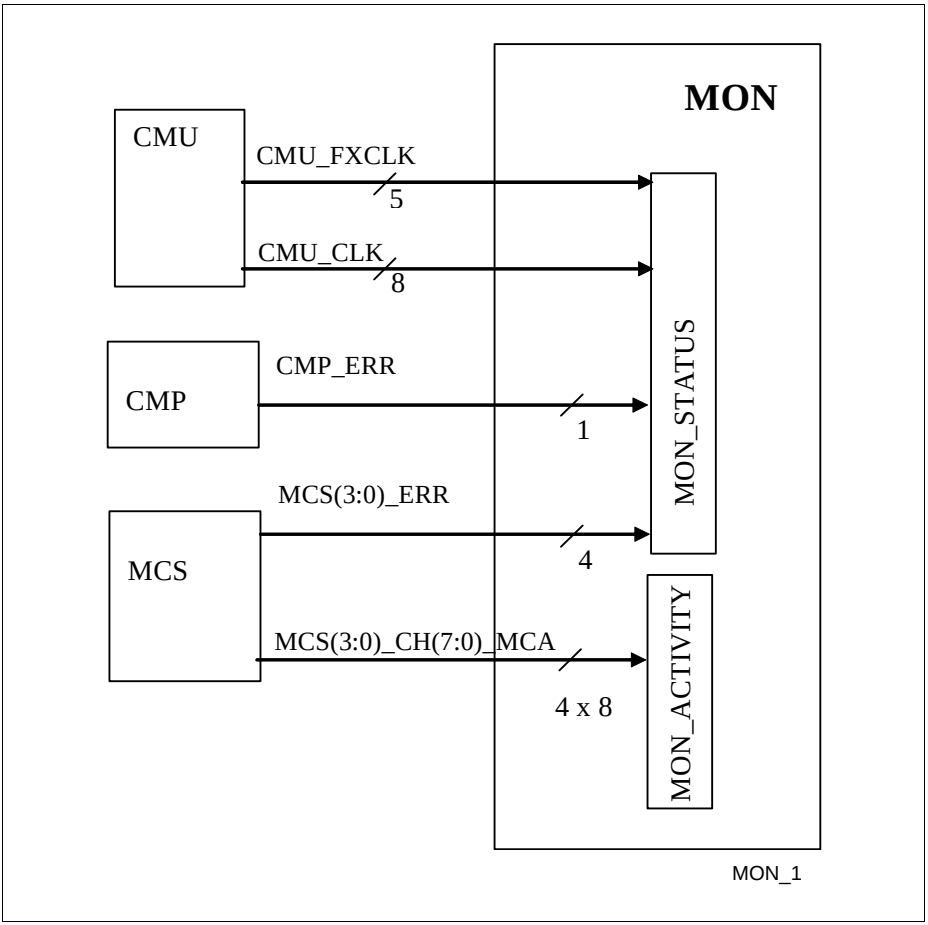

Figure 25-84 MON Block Diagram

25.20.1.2 Realization without Activity Checker of the clock signals

An activity checker of the clock signals used is not needed because these signals are only enables to be used in combination with the system clock. Therefore the clock enables are to be checked to have a high value.

25.20.2 Clock Monitoring

The monitor unit has a connection to each of the 8 clocks CMU_CLK[x] (x=0…7), provided by the CMU. Some of these clocks can be used for special tasks (see **Section 25.3**).

In addition the 5 clock inputs of the TOMs CMU_FXCLK[y] (y=0…4) are also connected to the MON unit.

The supervising of the clocks is done by scanning for activity of each clock.

A high value is defined as the state to be monitored.

When a high value of the clock enable is detected, the corresponding bit in the status register MON_STATUS is set.

The status register bits are reset by writing a one.

When the register is polled by the CPU and the time between two read accesses is higher than the period of the slowest clock, all bits of the corresponding clocks must have been set.

When polling in shorter time distances, not for all clocks an activity can be shown, although they are still working.

Because of the realization without a select register for the clock signals only the bits of the status register are to be considered for which the clock signal is enabled in the CMU.

25.20.3 CMP error Monitoring

The signal CMP_ERR is to be received directly from module CMP and is set if an error occurred.

25.20.4 Checking the Characteristics of Signals by MCS

By use of the MCS some given properties of signals can be checked. Such signals can be generated output signals of TOM or ATOM channels, which are re-read in into a TIM and the time stamp information is routed via ARU to the MCS module.

The corresponding MCS signal performs the check according to given properties. In this way signal high or low time as well as signal periods can be checked, also taking into account tolerances. When the check fails a MCS internal error signal is generated and ORed with the error signals of the other channels of the MCS module to an summarized error signal MCS[z]_ERR (z=0…35).

For each MCS a summarized error signal is transmitted to MON and monitored in the MON_STATUS register.

In order to check the execution of the comparison for each MCS channel an activity signal is generated. In the MCA_i_x (x=0…7) vector always for each MCS 8 bits for each channels are combined. The activity signals are stored in the MON_ACTIVITY_0 register

for MCS0 to MCS3. The bits are set by a one signal and reset by writing a one to it (preferably after polling the status of the register).

Because the activity signal shows the execution of a comparison, the involved units for providing the signals and execution of comparison (like TIM, ARU and MCS itself) are checked implicitly to work accordingly. Also the involved clocks and time bases are checked in this way.

25.20.5 Checking ARU Cycle Time

The cycle time of the ARU can be checked, when this is essential for safety purposes. This check can be performed by an MCS channel. It should be noted that the MCS program for measuring the ARU round trip time must add a tolerance value.

The resulting error is reported to the MON unit using the summarized error signal MCS[z]_ERR for each MCS module in addition to an interrupt, generated in MCS. The same signals and status bits are used as in the case of checking the signal characteristics.

The corresponding MCS is programmed to get a fixed data value at address 0x1FF. The data value is always zero and is not blocked. When getting the access the time stamp value TBU_TS0 is stored in a register. The next time getting the access the new TBU_TS0 value is stored and the difference between both values is compared with a given value. When the comparison fails, an error flag is set in the MCS internal status register, an interrupt is generated and the error signal MCS[z]_ERR is provided.

When the check is performed, an activity signal MCA_x (x=0...31) is provided for each channel x for each MCSi (i=0...6) together with an summarized interrupt MCS[z]_ERR for each MCS.

The activity signal sets a bit in the MON_ACTIVITY register.

The bits in the MON_ACTIVITY register are reset by writing a one.

When the check fails, an interrupt is generated and the error signal MCS[z]_ERR is provided for the MON unit.

Figure 25-84 shows the block diagram of the Monitor Unit.

25.20.6 MON Interrupt Signals

The MON submodule has no interrupt signals.

25.20.7 MON Registers Overview

Following configuration registers are considered in MON sub module

Table 25-61 MON Registers Overview

Register Name	Description	Details in Section
MON_STATUS	Monitor Status register	Section 25.20.8.1
MON_ACTIVITY_0	Monitor activity register 0	Section 25.20.8.2

25.20.8 MON Configuration Registers Description

All of the following registers are 32-bit only accessible.

25.20.8.1 Register MON_STATUS

GTM_MON_STATUS
Monitor Status Register **(180_H)** **Reset Value: 00000000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								MCS3_ERR	MCS2_ERR	MCS1_ERR	MCS0_ERR	Reserved			CMP_ERR
r								r	r	r	r	r			r

Reserved			ACT_CMUFX4	ACT_CMUFX3	ACT_CMUFX2	ACT_CMUFX1	ACT_CMUFX0	ACT_CMU7	ACT_CMU6	ACT_CMU5	ACT_CMU4	ACT_CMU3	ACT_CMU2	ACT_CMU1	ACT_CMU0
r			rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
ACT_CMU0	0	rwh	**CMU_CLK0 activity** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
ACT_CMU1	1	rwh	**CMU_CLK1 activity** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
ACT_CMU2	2	rwh	**CMU_CLK2 activity** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
ACT_CMU3	3	rwh	**CMU_CLK3 activity** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
ACT_CMU4	4	rwh	**CMU_CLK4 activity** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
ACT_CMU5	5	rwh	**CMU_CLK5 activity** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Field	Bits	Type	Description
ACT_CMU6	6	rwh	**CMU_CLK6 activity** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
ACT_CMU7	7	rwh	**CMU_CLK7 activity** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
ACT_CMUFX0	8	rwh	**CMU_CLKFX0 activity** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
ACT_CMUFX1	9	rwh	**CMU_CLKFX1 activity** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
ACT_CMUFX2	10	rwh	**CMU_CLKFX2 activity** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
ACT_CMUFX3	11	rwh	**CMU_CLKFX3 activity** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
ACT_CMUFX4	12	rwh	**CMU_CLKFX4 activity** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged. Note: Bits 0 to 12 are set, when a high low slope is detected at the considered clock
Reserved	[15:13]	r	**Reserved** Read as zero, should be written as zero
CMP_ERR	16	r	**Error detected at CMP** Note: This bit will be readable only.
Reserved	[19:17]	r	**Reserved** Read as zero, should be written as zero
MCS0_ERR	20	r	**Error detected at MCS[0]** Note: This bit will be readable only.
MCS1_ERR	21	r	**Error detected at MCS[1]** Note: This bit will be readable only.
MCS2_ERR	22	r	**Error detected at MCS[2]** Note: This bit will be readable only.
MCS3_ERR	23	r	**Error detected at MCS[3]** Note: This bit will be readable only.

Field	Bits	Type	Description
Reserved	[31:24]	r	**Reserved** Read as zero, should be written as zero Note: Bits16 and 20 to 23 are set, when the corresponding unit reports an error Note: The MCS can be programmed to generate an error, when the comparison of signal values (duty time, cycle time) fails or also when the cycle time of the ARU (checking of the TBU_TS0 between two periodic accesses) is out of the expected range.

25.20.8.2 Register MON_ACTIVITY_0

GTM_MON_ACTIVITY_0
Monitor Activity Register 0 **(184_H)** **Reset Value: 00000000_H**

Field	Bits	Type	Description
MCA_0_0	0	rwh	**Activity of check performed in module MCS0 at channel 0** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_0_1	1	rwh	**Activity of check performed in module MCS0 at channel 1** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_0_2	2	rwh	**Activity of check performed in module MCS0 at channel 2** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Field	Bits	Type	Description
MCA_0_3	3	rwh	**Activity of check performed in module MCS0 at channel 3** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_0_4	4	rwh	**Activity of check performed in module MCS0 at channel 4** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_0_5	5	rwh	**Activity of check performed in module MCS0 at channel 5** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_0_6	6	rwh	**Activity of check performed in module MCS0 at channel 6** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_0_7	7	rwh	**Activity of check performed in module MCS0 at channel 7** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_1_0	8	rwh	**Activity of check performed in module MCS1 at channel 0** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_1_1	9	rwh	**Activity of check performed in module MCS1 at channel 1** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_1_2	10	rwh	**Activity of check performed in module MCS1 at channel 2** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_1_3	11	rwh	**Activity of check performed in module MCS1 at channel 3** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Field	Bits	Type	Description
MCA_1_4	12	rwh	**Activity of check performed in module MCS1 at channel 4** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_1_5	13	rwh	**Activity of check performed in module MCS1 at channel 5** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_1_6	14	rwh	**Activity of check performed in module MCS1 at channel 6** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_1_7	15	rwh	**Activity of check performed in module MCS1 at channel 7** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_2_0	16	rwh	**Activity of check performed in module MCS2 at channel 0** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_2_1	17	rwh	**Activity of check performed in module MCS2 at channel 1** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_2_2	18	rwh	**Activity of check performed in module MCS2 at channel 2** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_2_3	19	rwh	**Activity of check performed in module MCS2 at channel 3** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_2_4	20	rwh	**Activity of check performed in module MCS2 at channel 4** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Field	Bits	Type	Description
MCA_2_5	21	rwh	**Activity of check performed in module MCS2 at channel 5** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_2_6	22	rwh	**Activity of check performed in module MCS2 at channel 6** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_2_7	23	rwh	**Activity of check performed in module MCS2 at channel 7** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_3_0	24	rwh	**Activity of check performed in module MCS3 at channel 0** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_3_1	25	rwh	**Activity of check performed in module MCS3 at channel 1** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_3_2	26	rwh	**Activity of check performed in module MCS3 at channel 2** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_3_3	27	rwh	**Activity of check performed in module MCS3 at channel 3** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_3_4	28	rwh	**Activity of check performed in module MCS3 at channel 4** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_3_5	29	rwh	**Activity of check performed in module MCS3 at channel 5** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Field	Bits	Type	Description
MCA_3_6	30	rwh	**Activity of check performed in module MCS3 at channel 6** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
MCA_3_7	31	rwh	**Activity of check performed in module MCS3 at channel 7** Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

25.22 GTM Implementation

This chapter describes product specific implementation of the Generic Timer Module (GTM).

Note: After a module reset the outputs of the (A)TOMs are high (see (A)TOMi_CHx_CRTL.SL) and could cause unexpected triggers in other modules.

25.22.1 GTM Registers

MCS3 RAM1	512	32 Bit	0x51000	0x517FF

GTM Address Ordering

The GTM address area start at F010 0000_H and ends at F019 $FFFF_H$. All given address for registers (beside for the DPLL part) are offset addresses to the GTM base address of F010 0000_H and need to be added. DPLL addresses for the CPU access are offset addresses to the DPLL base address of $0x00028000_H$, independent if with address is located in a DPLL RAM or not. For the DPLL base address of course the GTM base address have to be added.

Table 25-66 Address Overview

Submodule	Base address (to be added to GTM based address)
BRIDGE	0x00000030
MAP	0x00000F00

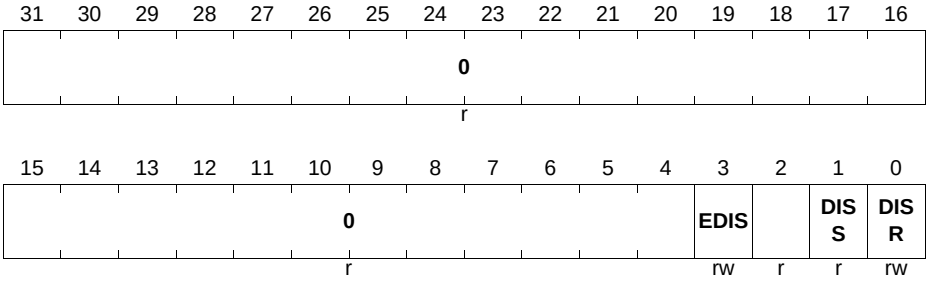
The clock control register is used to switch the GTM on or off and to control its input clock rate. The GTM can be disabled by setting bit DISR to 1.

CLC
Clock Control Register **(9FD00$_H$)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the GTM module. 0_B No disable requested 1_B Disable requested
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the GTM module. 0_B GTM module is enabled 1_B GTM module is disabled
EDIS	3	rw	**Sleep Mode Enable Control** Used for module sleep mode control.
0	2, [31:4]	r	**Reserved** Read as 0; should be written with 0.

OCDS Control and Status Register (OCS)

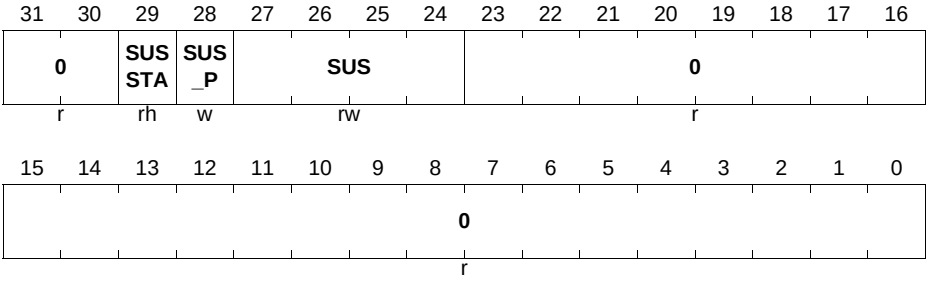
The OCDS Control and Status (OCS) register is cleared by Debug Reset and by each System Reset when OCDS is disabled. It is not touched by System Reset when OCDS is enabled.

The OCS register includes the module related control bits for the ODDS Trigger Bus (OTGB).

The OCS control register bits are only effective while the system is in debug mode. While not in debug mode, OCS reset values/modes are effective.
Write access is 32 bit wide only and requires Supervisor Mode.

OCS

OCDS Control and Status **(9FDE8$_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. In Hard suspend no registers beside the registers documented in the Implementation section of this chapter could be read or written. 2_H Soft suspend (GTM Halt Mode). In Soft suspend registers could be read or written, for details see **Chapter 25.2.6**. **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ,EN31 -> TAG ID 011111_B.

All registers and memories of the GTM are protected beside the following registers:

ACCEN0 and ACCEN1.

ACCEN0

Access Enable Register 0 **($9FDFC_H$)** **Reset Value: $FFFF\ FFFF_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register (ACCEN1)

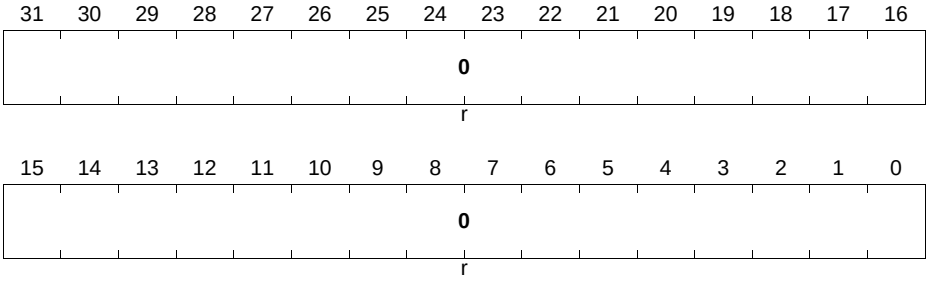
The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID master peripheral mapping).

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001_B, , EN31 -> TAG ID 111111_B.

All registers and memories of the GTM are protected beside the following registers:

ACCEN0 and ACCEN1.

ACCEN1
Access Enable Register 1 **(9FDF8$_H$)** **Reset Value: 0000 0000$_H$**



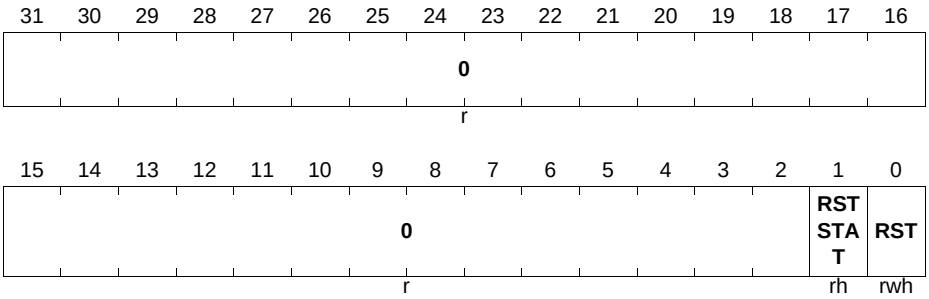
Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

The Kernel Reset Register 0 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers related to the module kernel that should be reset (kernel 0 or kernel 1). In order support modules with two kernel the BPI_FPI provides two set of kernel reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing to it with ´1´.

Note: This reset function has the effect as bit RST.RST.

KRST0
Kernel Reset Register 0 **(9FDF4$_H$)** **Reset Value: 0000 0000$_H$**

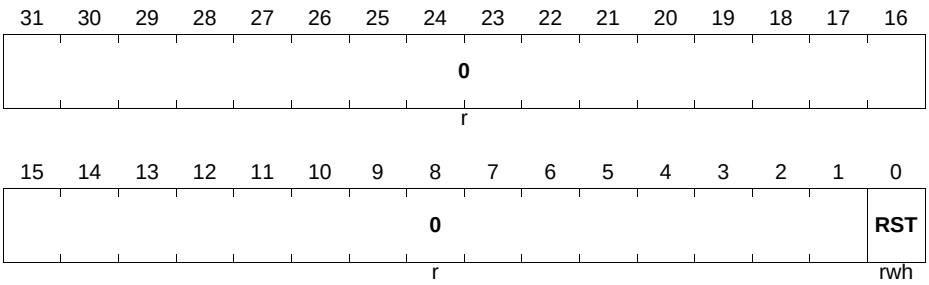


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rw	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the GTM kernel. GTM kernel registers related to the Debug Reset (Class 1) are not influenced. To reset the GTM kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be cleared with the end of the BPI kernel reset sequence.

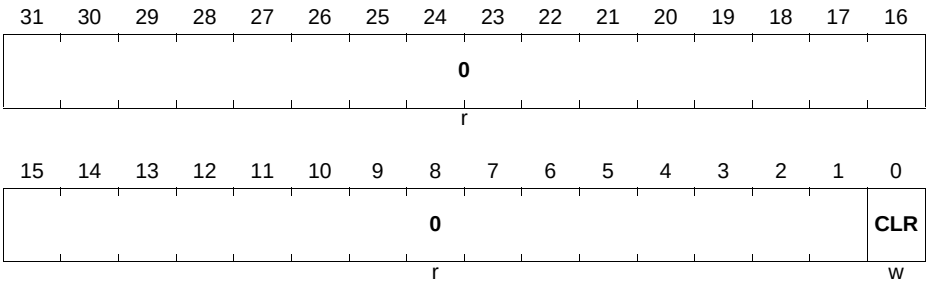
KRST1
Kernel Reset Register 1 **(9FDF0$_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR
Kernel Reset Status Clear Register (9FDEC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

25.22.2 Port Connections

The sections summarize the port connections which defined the boundary of the GTM for the TC27x.

Table 25-67 GTM to Port Mapping for QFP-176

The GTM outputs *cmu_eclk[2:0]* are connected directly to dedicated ports.

Table 25-69 GTM clock to Port Mapping

GTM Clock Output	Alternate Output of Pin
cmu_eclk0	P23.1
cmu_eclk1	P32.4
cmu_eclk2	P11.12

25.22.2.1 Port to GTM Control Registers

The inputs to the GTM TIM modules (*gtm_timx_in[7:0]*) are not connected directly to the port input path. Each timed GPIO is connectable to two TIMs via an input multiplexer. In addition the inputs from the on chip peripherals are connected here too.

TIMnINSEL (n = 0-3)
TIMn Input Select Register **($9FD10_H+n*4_H$)** **Reset Value: $0000\ 0000_H$**

25.22.2.2 GTM to Port Control Registers

The outputs of the GTM TOM and ATOM modules are not connected directly to the port output path. Each TOM and ATOM is connectable to several port alternate inputs via an output multiplexer.

The output signals to the mux are called *gtm_tout_x*, where x is running number.

TOUTSELn (n = 0-14)

Field	Bits	Type	Description
SELx (x = 0-15)	[x*2+1: x*2]	rw	**TOUT(n*16+x) Output Selection** This bit defines which timer out is connected as TOUT(n*16+x). The mapping for each pin is defined by **Table 25-67Table 25-68**. 00_B Timer A form **Table 25-67Table 25-68** is connected as TOUT(n*16+x) to the ports 01_B Timer B form **Table 25-67Table 25-68** is connected as TOUT(n*16+x) to the ports 10_B Timer C form **Table 25-67Table 25-68** is connected as TOUT(n*16+x) to the ports 11_B Timer D form **Table 25-67Table 25-68** is connected as TOUT(n*16+x) to the ports *Note: If TOUT(n*16+x) is not defined in **Table 25-67Table 25-68** this bit field has to be treated as reserved.*

25.22.3 MSC Connections

The sections summarize the connections to the MSC modules for the TC27x. The MSC interfaces (MSC0 and MSC1) provide a serial communication link typically used to connect power switches or other peripheral devices.

The outputs of the signal names are defined in **Table 25-79** and **Table 25-80**.

25.22.4 DSADC Connections

This register defines the DSADC to GTM connections of TC27x.
The 16 to 1 multiplexer is implemented once per TIM0 / 1 / 2 module / channel. The input signal from the DSADC is called *dsadcx_trig_in*_y x = number of DSADC, y = SRM / SAUL / SBLL. The output of the multiplexer is called *timy_muxout_x*, (y = 0,1,2)(x = 0...7).

Register DSADCOUTSELxy defines the GTM to DSADC connections of TC27x.
The DSADC trigger inputs (one per DSADC) 8 to 1 multiplexer is implemented twice per DSADC module / channel. The output signal to the DSADC is called *dsadcx_trig0* and *dsadcx_trig1*, The inputs of the multiplexer are called *dsadc_x_muxin[7:0]*, x = number of DSADCs.

Which of the possible trigger inputs is used by the DSADC can be selected in the VADC module.

Field	Bits	Type	Description
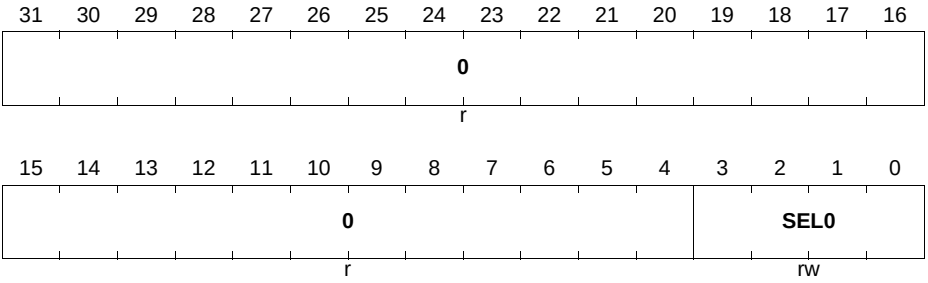
SELx (x = 0-7)	[x*4+3: x*4]	rw	**Output Selection for ADCx GTM connection** This bit field defines which TOM / ATOM channel output is used as ADCx trigger 0. The decoding is defined by **Table 25-81**, **Table 25-82**, or **Table 25-83** depending on the ADC.

ADCTRIG0OUT1

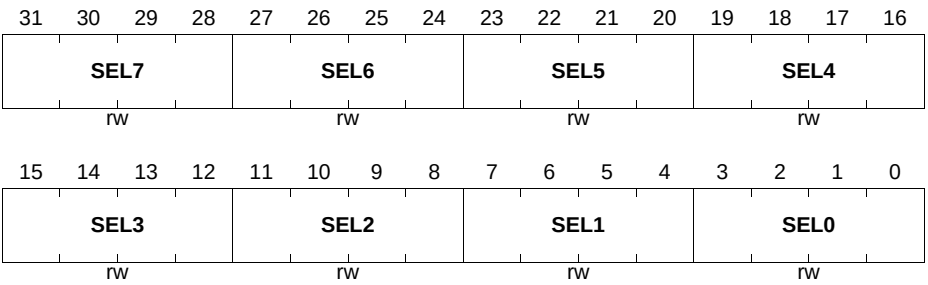
ADC Trigger 0 Output Select 1 Register(9FDB4$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SEL0	[3:0]	rw	**Output Selection for ADCx GTM connection** This bit field defines which TOM / ATOM channel output is used as ADCx+8 trigger 0. The decoding is defined by **Table 25-84** depending on the ADC.
0	[31:4]	r	**Reserved** Read as 0; should be written with 0.

ADCTRIG1OUT0

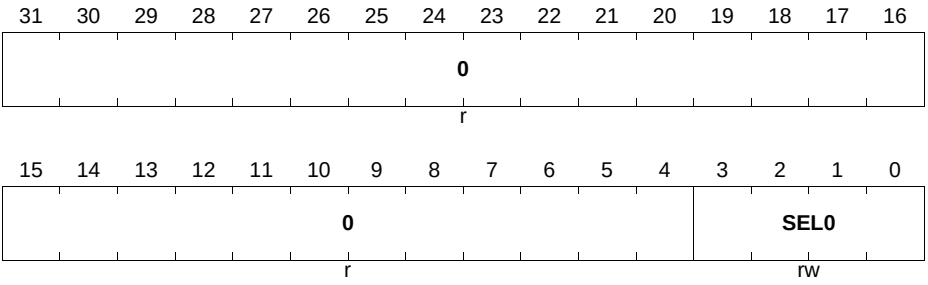
ADC Trigger 1 Output Select 0 Register(9FDB8$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SELx (x = 0-7)	[x*4+3: x*4]	rw	**Output Selection for ADCx GTM connection** This bit field defines which TOM / ATOM channel output is used as ADCx trigger 1. The decoding is defined by **Table 25-81**, **Table 25-82** or **Table 25-83** depending on the ADC.

ADCTRIG1OUT1

ADC Trigger 1 Output Select 1 Register(9FDBC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SEL0	[3:0]	rw	**Output Selection for ADCx GTM connection** This bit field defines which TOM / ATOM channel output is used as ADCx+7 trigger 1. The decoding is defined by **Table 25-84** depending on the ADC.

Field	Bits	Type	Description
0	[31:4]	r	**Reserved** Read as 0; should be written with 0.

25.22.6 SENT Connections

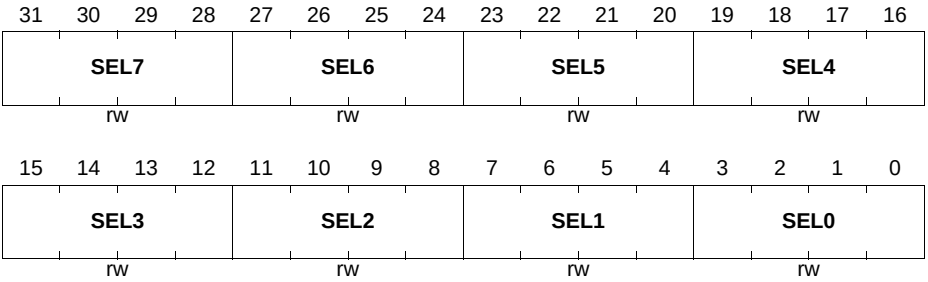
This register defines the GTM to SENT connections of TC27x.
The trigger generation 16 to 1 multiplexer is implemented twice per ADC module / channel. The output signal to the ADC is called *adcx_trig0* and *adcx_trig1*. As the SENT channels overlay and replace ADC channels the ADC triggers will be also reused for the SENT channels. Therefore no additional outputs for separate operation are defined here.

adcx_trig0 is connected to sent_trig_x.

In addition DSADC trig0 to DSADC0 is connected to sent_trig_9.

25.22.7 CAN Connection

CANOUTSEL
CAN Output Select Register (9FDA0$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description

25.22.9 PSI5 Connections

This register defines the GTM to PSI5 connections of TC27x.
The PSI5 trigger inputs are generated by 16 to 1 multiplexer that are implemented twice per PSI5 module / channel plus 3 combined for all PSI5 channels together. The output signal to the PSI5 is called *psi5x_trig0*, The inputs of the multiplexer are called *psi5_x_muxin[7:0]*, x = number of PSI5 triggers, TC27x has 6 triggers.

Mapping of PSI5 Triggers

Table 25-91 PSI5 Timer Triggers

SELx	Trigger 0 to 5
0000_B	No trigger is generated
0001_B	TOM2 Channel 6 output
0010_B	TOM2 Channel 7 output
0011_B	TOM2 Channel 13 output
0100_B	TOM2 Channel 14 output
0101_B	ATOM2 Channel 4 output
0110_B	ATOM2 Channel 5 output
0111_B	ATOM2 Channel 6 output
1000_B	ATOM2 Channel 7 output
1001_B	TOM0 Channel 6 output
1010_B	TOM0 Channel 7 output
1011_B	TOM0 Channel 13 output
1100_B	TOM0 Channel 14 output
1101_B	Reserved
1110_B	Reserved
1111_B	Reserved

Table 25-92 PSI5-S Timer Triggers

SELx	Trigger 0 / 4	Trigger 1 / 5	Trigger 2 / 6	Trigger 3 / 7
0000_B	No trigger is generated	No trigger is generated	No trigger is generated	No trigger is generated
0001_B	TOM0_6	TOM1_6	TOM1_6	TOM2_6
0010_B	TOM0_7	TOM1_7	TOM1_7	TOM2_7

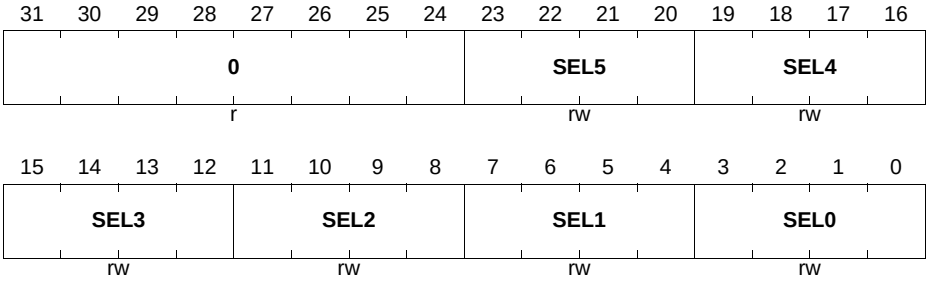
PSI5OUTSEL0
PSI5 Output Select 0 Register (9FDA4$_H$) Reset Value: 0000 0000$_H$

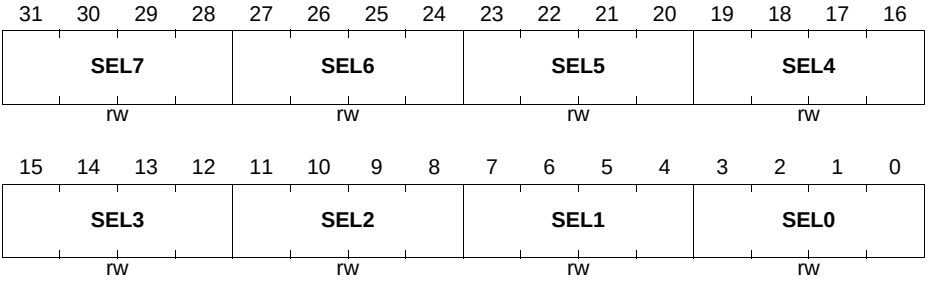


Field	Bits	Type	Description
SELx (x = 0-5)	[x*4+3: x*4]	rw	**Output Selection for PSI5x GTM connection** This bit field defines which TOM / ATOM channel output is used as PSI5x trigger 0. Decoding is defined by **Table 25-91**.

Field	Bits	Type	Description
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

PSI5SOUTSEL

PSI5-S Output Select Register (9FDA8$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
SELx **(x = 0-7)**	[x*4+3: x*4]	rw	**Output Selection for PSI5-S GTM connection** This bit field defines which TOM / ATOM channel output is used as PSI5-S trigger 0. Decoding is defined by **Table 25-92**.

25.22.10 GTM Data Exchange Registers

The registers defines additional data exchange and control options for GTM towards the on-chip system of TC27x.

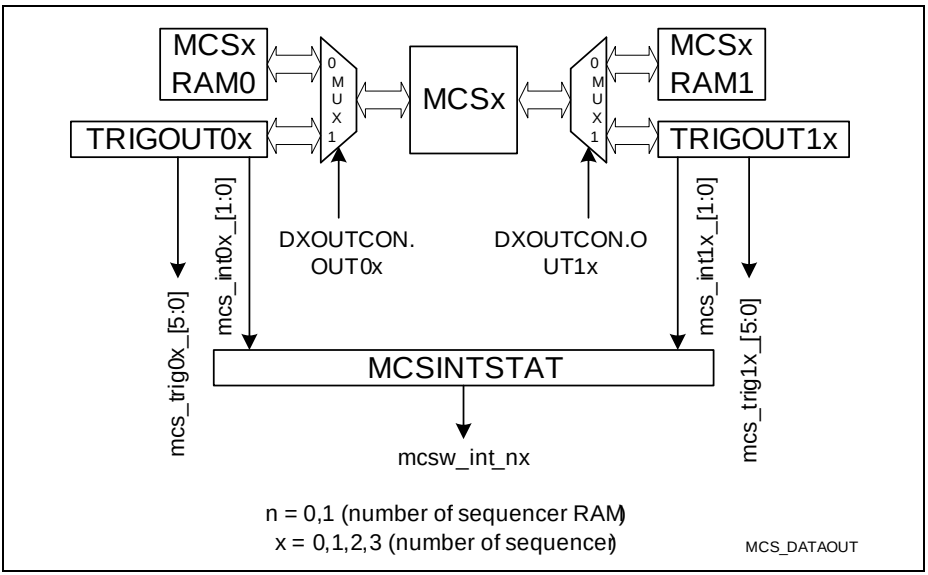


Figure 25-87 MCS Trigger Output Path

The TRIGOUT registers enable the GTM internal sequencers to generate dedicated interrupts or triggers from the sequence flow by writing to this register. The TRIGOUT registers are mirrored to address 0x0000 for each of the two sequencer RAMs. If a write for address 0x0000 updates the RAM or the TRIGOUT register is controlled by the bus accessable register DXOUTCON in central for all sequencers and there RAMs. This need to be configured only once when setting up the GTM with the reminder of the system.

Register MCSINTSTAT contains interrupt status flags and register MCSINTCLR provides the option to clear these status flags from the system bus. Both registers are optional register.

DXOUTCON

Data Exchange Output Control Register ($9FE00_H$) **Reset Value: $0000\ 0000_H$**

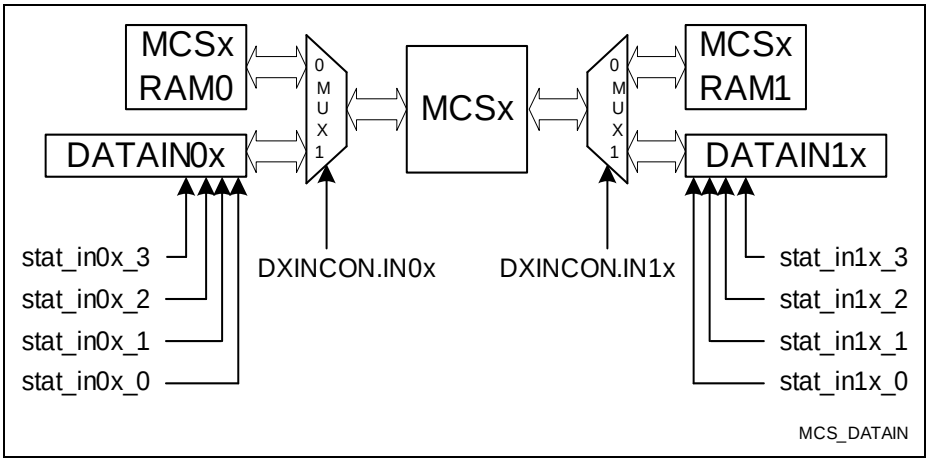

Figure 25-88 MCS Data Input path

The DATAIN registers enable the GTM internal sequencers to access data provided by other masters in the system directly in the sequencer data flow without ARU interaction. In addition the status of dedicated system triggers could also be observed here. The DATAIN registers are mirrored to address 0x0001 for each of the two sequencer RAMs. If a read for address 0x0001 fetch data from the RAM or the DATAIN register is controlled by the bus accessable register DXINCON in central for all sequencers and there RAMs. In addition register DATAIN contains the control if the 4 LSB of the DATAIN register contains data or the status of the four system signals. This need to be configured only once when setting up the GTM with the reminder of the system.

GTM Output	SCU Input
TOM0_12	Input41
TOM1_12	Input51

25.22.12 GTM Debug Interface

OTGB0/1 are 16-bit trigger busses, OTGB2 is 32 bit wide. Further information is available in the OTGM (OCDS Trigger Mux) section of the device specification.

Note: If triggering or tracing is to be used the GTM clock must not be faster than the SPB clock.

25.22.12.1OCDS Trigger Bus (OTGB) Interface

GTM OTGB Features

- IO signals
  - TIM input signals (after filter)
  - TOM output signals
  - ATOM output signals
  - SPE NIPD and DIR signals
  - Groups of 8 signals (e.g. all inputs of a specific TIM, etc.)
  - Two arbitrary groups on one 16 bit OTGB0/1
  - OTGB0 and/or OTGB1 can be used for 2-4 groups in parallel (e.g. both with one TIM 8, one ATOM 8 and one TOM 16)
- MCS
  - Channel number, PC and data access type (read or write)
  - Data value on OTGB2
  - Only one 16 bit OTGB0/1 needed if no data trace. Other free for IO signals.
- ARU
  - ARU_DBG_DATA0/1_H/L on 32 bit OTGB2 (time multiplexed)
- DPLL
  - TASI and SASI signals
  - Accesses to RAM1A/1BC/2 (only one at a time)
- TBUs
  - Trace one selected TBU
  - Trigger signals for individual TBU comparators

The GTM module has five 16 bit and eight 32 bit Trigger Sets (**Table 25-103**) which are selected with the **OTSS** register.

Table 25-103 GTM Trigger Sets

Trigger Set	Details
TS16_IOS Trigger Set IO and Other Signals	**Table 25-105**
TS16_MCA MCS Channel, Address and PC	**Table 25-106**
TS32_MCD MCS Data	**Table 25-107**
TS32_ARU Trigger Set ARU	**Table 25-108**
TS16_DRA1A/1BC/2 DPLL RAM Access Address (3 Sets)	**Table 25-109**
TS32_DRD1A/1BC/2 DPLL RAM Access Data (3 Sets)	**Table 25-110**
TS32_TTB0/1/2 TBU Time Stamps (3 Sets)	**Table 25-111**

Table 25-104 shows all sensible Trigger Set mapping options. Simple permutations of OTGB0/1 are omitted. If OTGB0 and/or OTGB1 is not used for GTM, Trigger Sets of other sources can be added in the OTGM module. The Trigger Sets which will initiate the writing of a 32 or 64 bit data word to the MCDS trace are marked with bold letters. This is by design always the case for OTGB2 Trigger Sets. Independent OTGB0/1 Trigger Sets need an independent own sensitivity to their signal changes, configured in the OTGM module.

Table 25-104 Trigger Set Mapping Options

Width	OTGB0	OTGB1	OTGB2
32 Bit	**TS16_IOS** or **MCA**		
	TS16_IOS or **MCA**	**TS16_IOS**	
64 Bit			**TS32_ARU** or **TTB0/1/2**
	TS16_IOS or **MCA**		
	TS16_IOS or **MCA**	**TS16_IOS**	
	TS16_MCA		**TS32_MCD**
	TS16_MCA	**TS16_IOS**	
	TS16_DRA1A/1BC/2		**TS32_DRD1A/1BC/2**
	TS16_DRA1A/1BC/2	**TS16_IOS**	

The GTM trigger signals relate to the GTM internal clock, which can be slower or equal to the OTGB/OTGM clock.

IO and Other Signals Trigger Sets

IO Trigger Sets consist of the most important TIM, TOM and ATOM signals in groups of 8. In addition there is a group of SPE signals and one group for miscellaneous signals. The multiplexer allows to map arbitrary and different signal groups to the high and the low byte of a 16 bit Trigger Set. In addition it is possible to use one or two 16 bit Trigger Sets with this flexibility. All this is controlled with **OTSC0**.

Table 25-105 TS16_IOS Trigger Set IO and Other Signals

Bits	Name	Description	
[7:0]	SG0	A group of 8 signals from a selected TIM, TOM, ATOM or SPE	
		TIM	All 8 input signals after filter F_OUT
		TOML	Lower 8 output signals TOM_OUT
		TOMH	Higher 8 output signals TOM_OUT
		ATOM	All 8 output signals ATOM_CHx_OUT
		SPE	Bits 0,1: SPE0_NIPD, SPE_DIR0 Bits 2,3: SPE1_NIPD, SPE_DIR1 Bits 4,5: Reserved Bits 6,7: Reserved
		MISC	Bit 0: DPLL TASI Bit 1: DPLL SASI Bit 4: TBU0 trigger (OTBU0T) Bit 5: TBU1 trigger (OTBU1T) Bit 6: TBU2 trigger (OTBU2T) Others: reserved
[15:8]	SG1	Independent selection with same options as for Bits [7:0]	

MCS Trigger Sets

There are two MCS Trigger Sets: TS16_MCA (**Table 25-106**) and TS32_MCD (**Table 25-107**). TS16_MCA allows to observe the PC of all or a selected MCS Channel. If only one Channel is selected, the TS16_MCA value will stay stable until the MCS executes this Channel again. In case of data access by CPU or by a Channel, it represents the data address. With TS32_MCD the associated data value and even the fetched instruction opcode can be traced. Usually the latter is avoided to reduce the trace bandwidth. All this is controlled with **OTSC1**.

Table 25-106 TS16_MCA MCS Channel, Address and PC

Bits	Name	Description
[11:0]	ADDR	PC of MCS Channel or address of data access (32 bit word address)
[15:12]	AQ	Address Qualifier with Channel information 0_H ADDR is PC of MCS Channel 0 $_H$ ADDR is PC of MCS Channel 7_H ADDR is PC of MCS Channel 7 C_H reserved D_H reserved E_H ADDR is address of Channel data read access F_H ADDR is address of Channel data write access Others: reserved

Table 25-107 TS32_MCD MCS Data

Bits	Description
[31:0]	Read or written data value of current channel instruction

ARU Trigger Sets

There are four 29 bit ARU data words with debug information (ARU_DBG_DATA0_L/H and ARU_DBG_DATA1_L/H). These words may get valid in the same GTM kernel clock cycle but they will never change in consecutive cycles. This property is used to transmit them with time multiplexing over the OTGB2 bus. ARU_NEW_DATA0/1_IRQ controls the OTGB2 valid signal.

The implementation of TS32_ARU has to capture the ARU_NEW_DATA0/1_IRQ signals and clear these capture bits, when the associated ARU data has been output on OTGB2. The ARU data itself doesn't need to be captured because it will be valid long enough. If both ARU_NEW_DATA0/1_IRQ signals become active in the same cycle, the ARU data is output in four consecutive cycles with the sequence ARU_DBG_DATA0_L, DATA0_H, DATA1_L, DATA1_H.

Table 25-108 TS32_ARU Trigger Set ARU

Bits	Name	Description
[28:0]	DATA	ARU_DBG_DATA

Table 25-108 TS32_ARU Trigger Set ARU (cont'd)

Bits	Name	Description
29		Reserved
[31:30]	DQ	Qualifier for DATA 0_D Is ARU_DBG_DATA0_L 1_D Is ARU_DBG_DATA0_H 2_D Is ARU_DBG_DATA1_L 3_D Is ARU_DBG_DATA1_H

DPLL Trigger Sets

The TASI and SASI signals are part of the MISC signal group of TS16_IOS (**Table 25-105**).

The following tables **Table 25-109** and **Table 25-110** define six additional DPLL Trigger Sets for observing the DPLL RA

M accesses. Only one of the three DPLL (1A, 1B+C, 2) RAMs can be observed at a time. The Trigger Set selection is done with **OTSS**.

Table 25-109 TS16_DRA1A/1BC/2 DPLL RAM Access Address

Bits	Name	Description
[13:0]	ADDR	Address of data access. Range starts with address 0 for the selected RAM (1A, 1B+C or 2). Effective width depends on selected RAM
[15:14]	AQ	Address Qualifier 0_H DPLL data read access 1_H DPLL data write access 2_H CPU read access 3_H CPU write access

Table 25-110 TS32_DRD1A/1BC/2 DPLL RAM Access Data

Bits	Name	Description
[23:0]	DATA	Read or written data
[31:24]		Reserved

TBU Trigger Sets

Table 25-111 defines the Trigger Sets for the observation of the different time bases. The Trigger Set selection (one at a time) is done with **OTSS**.

Table 25-111 TS32_TTB0/1/2 TBU Time Stamps

Bits	Name	Description
[26:0]	TS	Current TBU_TS0/1/2 time stamp. Effective width depends on selected time base.
[31:27]		Reserved

25.22.12.2GTM Debug Registers

All debug control registers are cleared by Debug Reset.

OCDS Trigger Bus (OTGB)

Access are only supported for byte, halfword and word data and requires Supervisor Mode.

OTSS

OCDS Trigger Set Select Register (9FDD0$_H$) **Reset Value: 0000 0000$_H$**

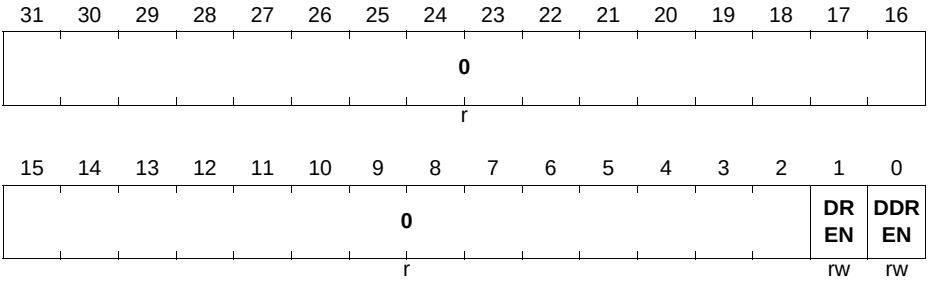
0	8	rw	**Reserved** Should be written with 0.
MOE	9	rw	**MCS Opcode Trace Enable** Required by TS32_MCD 0_B Trigger Set TS32_MCD excludes opcode fetches 1_B Trigger Set TS32_MCD includes opcode fetches

Field	Bits	Type	Description
0	[31:10]	r	**Reserved** Read as 0; must be written with 0.

ODA
OCDS Debug Access Register (9FDDC$_H$) Reset Value: 0000 0000$_H$



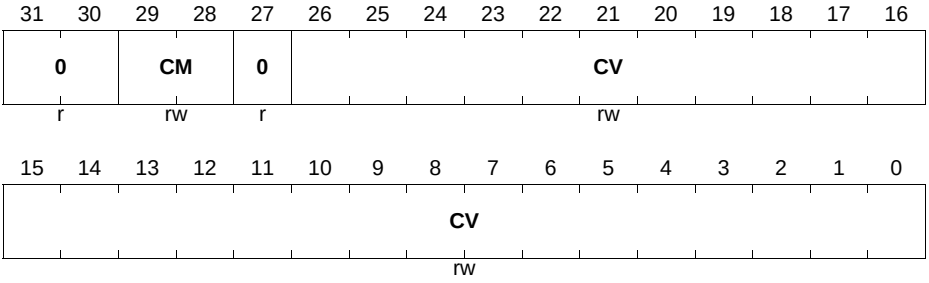
Field	Bits	Type	Description
DDREN	0	rw	**Detructive Debug Read Enable** For details see**Table 25-112**.
DREN	1	rw	**Detructive Read Enable** For details see**Table 25-112**.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Table 25-112 Destructive Read Control encoding

ODA.DREN	ODA.DDREN	Description
0	0	Destructive read access are enabled for all masters beside the OCDS master
0	1	Destructive read access are enabled for all masters
1	0	Destructive read access are disabled for all masters
1	1	Destructive read access are disabled for all masters

OTBU0T

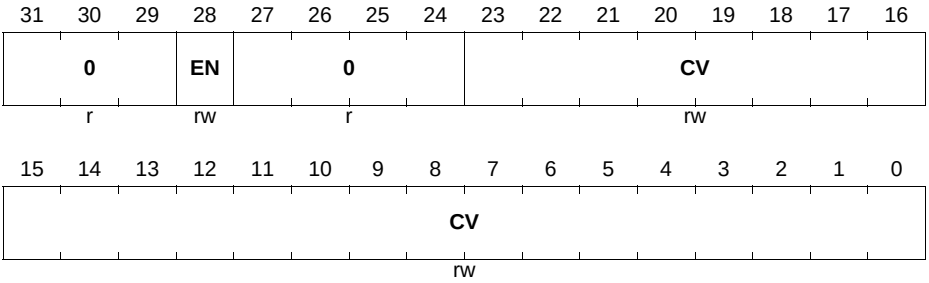
OCDS TBU0 Trigger Register (9FDC4$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
CV	[26:0]	rw	**Compare Value** This value is compared to TBU_CH0_BASE register. As long as both match the associated TS16_IOS.MISC bit (**Table 25-105**) is active.
CM	[29:28]	rw	**Compare Mode** 0_H Disabled 1_H Compare lower 24 bits 2_H Compare upper 24 bits 3_H Compare all 27 bits
0	27, [31:30]	r	**Reserved** Read as 0; must be written with 0.

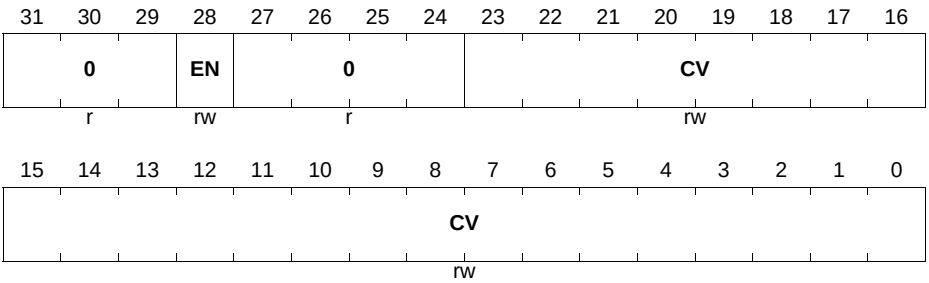
OTBU1T

OCDS TBU1 Trigger Register (9FDC8$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
CV	[23:0]	rw	**Compare Value** This value is compared to TBU_CH0_BASE register. As long as both match the associated TS16_IOS.MISC bit (**Table 25-105**) is active.
EN	28	rw	**Enable** 0_B Disabled 1_B Enabled
0	[27:24], [31:29]	r	**Reserved** Read as 0; must be written with 0.

OTBU2T
OCDS TBU2 Trigger Register (9FDCC$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
CV	[23:0]	rw	**Compare Value** This value is compared to TBU_CH0_BASE register. As long as both match the associated TS16_IOS.MISC bit (**Table 25-105**) is active.
EN	28	rw	**Enable** 0_B Disabled 1_B Enabled
0	[27:24], [31:29]	r	**Reserved** Read as 0; must be written with 0.

25.23 ision History

Changes from version 0.3 to 1.0

- 2.2.1 Updated list of registers that drive value “illegal module access”
- 2.5 Fixed bugs in IRQ Specification
- 4.2 Clarified register bit settings in case of Trashbin functionality
- 4.5.2 Clarified register bit settings in case of Trashbin functionality
- 5.5.12,13 Fixed bad naming of register labels
- 10.4.2.5 Clarified modified behaviour of ECNT in mode TBCM
- 10.8.1,2 Clarified behaviour if bad TIM modes are selected
- 11.3.6 Clarified one shot mode in case of writing to CN0 while CN0 is counting
- 12.2.2 Clarified ATOM channel startup behaviour when ARU_EN is set and channel is enabled
- 12.3.1.1, 12.3.2.3, 12.3.3.5, 12.3.4.1 Not used bits can be written in any mode, but should be written as zero when not used
- 12.3.4 Clarified interrupt behaviour in SOMS mode: in SOMS mode only CCU1TC IRQ possible
- 12.6.2 Corrected some bit manipulation properties for bits OSM, TRIGOUT, CLK_SRC/CLK_SRC_SR
- 13.1.1ff Fixed declaration of maximum address range and clarified priorities of register accesses
- 14.1.1ff Documented additional memory layout parameters for the case that two large RAMs are connected to MCS
-
- 16.4.2 LOW_RES options
- 16.7.1 VTN
- 16.8.3ff NMB_T/S: MPVAL1/2 added
- 16.8.5ff PSTC/PSSC = 0 for FTD/FSD=0
- 16.8.6.7ff NMB_T/S calculation and use
- 16.11.1 Note 3): restriction for resolution choices
- 16.11.2 SWR and DEN
- 16.11.6 CRO, PSE, TOR, SOR, LOCK1/2
- 16.11.8/9 OSW and AOSV_2
- 16.11.28/29 old ADD_IN value used
- 16.13 no write protection of available RAM bits
- 16.13.9 THVAL for LOW_RES and !TSO_HRT
- 16.13.16ff all reciprocal values: SHL 32
- 16.14ff resolution of reciprocal values
- 20.1.1ff Activity checker removed
-
- 2.2.1 Updated list of registers that drive value “illegal module access”
- 2.5.4 Changed IRQ behaviour in single pulse mode on simultaneous clear and interrupt event
- 2.9.2 Protected write information

- 3.6.1 Clarified usage of ARU_ACCESS register
- 4.5.1 ARU read address only writeable if channel disabled
- 7.4.2 ARU read address only writeable if channel disabled
- 8.3, 8.5, 8.6: Removed confusing reset description
- 12.3 Clarified CN0 behaviour at channel enable
- 12.3.2ff SOMC mode description restructured
- 12.3.4ff SOMS mode description restructured
- 12.6.4 ARU read address only writeable if channel disabled
- 13.2.1 Specified behaviour in the case of bad opcode decoding
- 13.2.3 Added two non blocking ARU read instructions (NARD/NARDI)
- 13.2.4 Clarified behaviour on flags CY and V in arithmetic inctructions
- 13.4.5 Added write protection to register MCS[i]_CH[x]_R6
- 16.6.2.1 higher reciprocal resolution TRIGGER
- 16.6.3.1 higher reciprocal resolution STATE
- 16.8.3.6 QDT is zero at the beginning
- 16.8.6.7 Store INC_CNTx when a valid event occurs and use it as MPx in step 5 or 25
- 16.11.1 condition for pulse number per increment
- 16.11.6 refined definitions of CRO, RCS, RCT, MT, MS, FTD, FSD and LOCKx
- 16.11.21 DPLL_ID_PMTR_x is now RPW
- 16.12.3 Bits 24:31 are read only
- 16.13.7ff Bits 24:31 are read only
- 16.13.12ff suppress update for unexpected missing TRIGGER or STATE respectively
- 16.13.16ff calculation of reciprocal values from predicted durations do not influence RCO
- 16.13.32ff Bits 24:31 are read only
- 16.13.43ff minor changes in formulations
- 16.13.47ff Bits 24:31 are read only
- 16.14.3 Bits 24:31 are read only
- 16.15.3 Bits 24:31 are read only
-
- 2.2.1 Updated list of registers that drive value “illegal module access”
- 9.4.3ff Address offset corrected
- 12.3.2ff SOMC mode description restructured
- 16.11.17 refined definitions of TINI and TAXI
-
- 2.2.1 Updated list of registers that may drive an aei_status signal with value “10”
- 2.5.4 Added note in single pulse mode
- 2.6ff Extended description of software debugger support (e.g. added lists of registers with special behaviour in the case of debugger access)
- 2.9.1 ision ID updated
- 2.9.3 Reset force protection includes SW RAM reset

- 2.9.9-11 Moved register description of AEI_bridge from module integration guide to this document. Added control and status information for diagnosis of the bridge status.
- 3.3.2 Clarified usage of debug mechanism
- 3.6.1 Extended functionality of ARU_ACCESS register
- 4.5.1 Note added
- 9.4.2 Second note added
- 11.2.2 Note to trigger signal added
- 11.8.2 Meaning of bits in ENDIS_CTRL changed
- 11.8.5 Meaning of bits in OUTEN_CTRL changed
- 12.2.2 Clarified ATOM channel startup behaviour in case of ARU_EN=1
- 12.3.2.1 Added note that less/equal compare only applies for comparisons against TBU_TS1/2
- 12.3.2.2.1 Added ACBI=00111 behaviour in table
- 12.3.2.3.3 Clarified WR_REQ and WRF bit behaviour for ATOM SOMC late update mechanism
- 12.3.2.4 Fixed ACB10 bit description
- 12.3.3.5 Clarified CLK_SRC_SR register description
- 12.3.4 Global ATOM SOMS mode behaviour update
- 12.3.4.6 Update SL and CLK_SRC_SR register description
- 12.6.2 Update SL and CLK_SRC_SR register description
- 13.4.11 Added feature to reset connected RAMs by software
- 15.1.1 Fixed minor specification issues
- 15.4.1 Completed SSL bit field description
- 16.5.10.2 Influence of SYSF to entry number
- 16.6.2.5 New Calculation for FULL_SCALE
- 16.6.2.7 New Meaning of CTO(N)
- 16.6.3.5 New Calculation for FULL_SCALE
- 16.6.3.7 New Meaning of CSO(N)
- 16.6.4.2 New Calculation for FULL_SCALE
- 16.6.5.2 New Calculation for FULL_SCALE
- 16.7ff Handling of actions in the past, considering of VTN, VSN and SYSF for calculations, use of RDT_T_FS1 and RDT_S_FS1
- 16.8.6.7 Use of NMB_T_TAR and NMB_S_TAR
- 16.10 New registers for RAM initialization, NMB_T_TAR and NMB_S_TAR
- 16.11.ff Notes to specify write abilities added. Influence of SYSF, new FST and FSS bits in NUTC/NUSC registers, new DCGI bit in DPLL_IRQ_NOTIFY register; new interrupt line connections; DPLL_RAM_INI register
- 16.12ff Notes to specify write abilities added
- 16.13.4 NMB_T_TAR explained
- 16.13.8 NMB_S_TAR explained
- 16.13.16 Sign extension
- 16.13.17 Sign extension

- 16.14.1ff SYSF influence explained
- 18.5.2 Changed DPLL Interrupt ordering
-
- reworked MSC connection multiplexer structure together with controlling registers
- added forth set for MSC connections
- reworded old sets for MSC connections
- replace MSCxINCONy registers by MSCSETmCONn registers
- add registers MSCxINL/HCON registers
- removed second PSI5 connection register
- add GTM to Port Mapping for BGA-292
- add TIM0 inputs comming from ERU in SCU
- add TIM input connections for BGS-292
- add section for GTM to SENT connections
- add six additional triggers for CAN / TTCAN
- remove GTM to PSI5 trigger 1
- correct the address at the register image for register ADCTRIG0OUT1
- removed function for P32.1 (TOUT37 and TIN37)
- changes access limits for debug register from word to byte limitation

Changes from version 1.0 to 1.1

- add ATOM1 for ADC0 / 1 / 2 Trigger 0
- add ATOM0 for ADC0 / 1 / 2 Trigger 1
- replace ATOM5 with ATOM 3 for ADC5 / 6 / 7 Trigger 0/1
- skip ADC8 triggers
- shift ADC7 triggers to one group for ADC5 / 6 / 7 Triggers
- replace some TOM2 triggers with TOM0 triggers for ADC5 / 6 / 7 Trigger 0 / 1
- removed registers ADCTRIG0OUT1 and ADCTRIG1OUT1
- removed ATOM4 from MSC Set 4
- add register PSI5SOUTSEL
- removed DSADC inputs for TIM1 and TIM2 channels 6 and 7
- add connections from the ADC modules to GTM (end of conversion infromation)
- add debug improvements for TBU debugging

Changes from version 1.1 to 1.2

- change offset address of register DPLL_RAM_INI in the register image from $283BC_H$ to $281FC_H$
- add debug improvements for TBU debugging
- bring back triggers for ADC 8
-
- 2.1.2 Restricted TOM/ATOM trigger lines to a certian length
- 2.3.1 Changed number of ARU data destinations
- 2.3.2 Introduced formula to determine the device dependent roundtrip time

- 2.6.1 Specified register behaviour of GTM_halt more precisely
- 2.9.1 ision ID updated
- 2.9.7 Note about protection included
- 3.6.1 Changed register bit field mode
- 3.6.11 Register bit 0 name corrected
- 3.6.12 Note about protection included
- 4.5.1 Reset value corrected
- 4.5.5 Note about protection included
- 5.1 Fixed specification error, FIFO RAM not initialized with zeros after reset
- 5.5.12 Note cleared automatically included
- 9.1 Specified behaviour of TBU_UPx signals more precisely
- 10ff Clarified indices descriptions of registers and bit fields
- 11.2.2 Added note for signed compare of ACT_TB
- 11.8.4 Changed naming ans description of bit field ACT_TB
- 11.8.27 note about write protection included
- 12.3.2.3.3 Specified behaviour of WR_REQ bit more precisely
- 12.3.4.1ff Specified ATOM SOMS mode more precisely
- 12.6.12 Note about write prtection included
- 13.1.1 Added hint for MCS RAM addresses and changed MCS block diagram
- 13.3.3 Note cleared by CPU included
- 13.4.6 Reset value corrected
- 13.4.9 Note protection included
- 13.4.11 Reset value corrected
- 13.4.11 Note reset values dependencies included
- 14.4.14 Note cleared by MCS channel included
- 16.5.10.1 typo corrected: APS pointer
- 16.7 number of actions calculated per increment in worst case and typical
- 16.5.10.1 typo corrected: APS pointer
- 16.7.1ff calculation of fractional part changed;decision of calculation case is dependent on the relation between q and m
- 16.7.7ff chapter ordering swapped with 16.7.8
- 16.8.4.2ff more detailed description
- 16.8.6.3ff direction change description changed
- 16.8.6.7 changed schedule of RAM update, PSTC and PSSC first value, SGE effect
- 16.10 introduced addresses for shadow registers, changed RAM addresses for calculated target pulse numbers
- 16.11.1 description of change between normal and emergency mode
- 16.11.2 write protection explained, more detailed description of SYN_NT/SYN_NS
- 16.11.12 explained differences for direction change in normal mode (SMC=0) and for SMC=1
- 16.11.13 explained direction change process
- 16.11.19 Note protection and cleared automatically included
- 16.11.24 more detailed explanation of address pointer value extension

- 16.11.33 New Register
- 16.11.34 New Register
- 16.11.35 New Register
- 16.11.36 New Register
- 16.12.2 explanation DLA value for low resolution
- 16.13.4 Removed NMB_T_TAR register
- 16.13.8 Removed NMB_S_TAR register
- 16.13.10 explanation TOV value for low resolution
- 16.13.11 explanation TOV_S value for low resolution
- 16.13.16 New RAM storage address
- 16.13.17 New RAM storage address
- 16.13.18 New RAM storage address
- 16.13.19 New RAM storage address
- 16.13.45 mode limited
- 16.13.46 mode limited
- 16.15.1ff start address of RAM2 changed
- SPE: Note about protection included
- 18.5.1ff Register bit mode changed to R
- 18.5.1ff Register bit mode changed to R
- 19.7.4 Note about protection included
- 21.3 Changed reference to address map
-
- 2.2.1 updated list of register which return AEI status of illegal write access
- 2.3.3 (wrong) ARU round trip time calculation removed
- 12.6.6 Note about protection included
- 12.6.8 Note about protection included
- 8.1.1 Added clock source MUX to FXU
- 8.8.ff Added clock selection bit to register CMU_CLK_5_CTRL
- 13.1.1 Updated figure in Architecture section
- 13.3.3 RAM ECC Error disables MCS channel and raises ERR bit
- 13.3.5ff Bit9 naming corrected
- 13.4.12ff Bit9 naming corrected
- 14.1 Reformulated MCFG Spec to be more generic and device independent
- 14.2.1 Reformulated MCFG_CTRL register to be more generic and device independent
- 16.5.10.2 explanation of RAM init procedure
- 16.6.2 explanation of the use of filter values
- 16.7.1ff precise case conditions
- 16.7.5.6ff precise case conditions
- 16.7.8.2ff precise case conditions
- 16.8.5 correct PSTC/PSSC calculation
- 16.11.2 precise SMC bit meaning
- 16.11.23 correct copy/paste error for INC_CNT2

- 18.2.3ff number of submodules (TIM, MCS, TOM and ATOM) described generic with “[i]”
- 18.3 Interrupt signals for submodules TIM, MCS, TOM and ATOM described generic with “[i]”
-
- 2.2.1 updated list of register which return AEI status of illegal write access
- 2.3.1ff Table of ARU sources corrected
- 8.5 Added clock selection bit to description
- 8.8.4ff Added clock selection bit to register CMU_CLK_5_CTRL
- 10.7 Corrected link to sub section in overview table
- 11.8.7 Description of bit field FUPD_CTRL
- 12.3.2.2.1 Condition of bit SLA added
- 12.3.2.3 Condition of bit SLA added
- 12.3.2.4 Description of new mode bit SLA
- 12.3.3.5 Bit 16 is not used instead of reserved
- 12.3.4.9 Bit 16 is not used instead of reserved
- 12.6.2 Description of new mode bit SLA added
- 13.1.1 Added ECC Error handling to specification
- 13.3ff Clarified some minor parts of the description
- 13.3.3 Clarified the behaviour of the ERR bit in STA register
- 16.6.2.7 Changed CTO/CTON behaviour in case of negative CDT_TX(_nom) values
- 16.6.3.7 Changed CSO/CSON behaviour in case of negative CDT_SX(_nom) values
- 16.6.4.4 Specified setting of CDT_TX(_nom) in case of negative values
- 16.6.5.4 Specified setting of CDT_SX(_nom) in case of negative values
- 16.7.6.1 Changed calculation of TSAC when action in far future (normal mode)
- 16.7.8.1 Changed calculation of TSAC when action in far future (emergency mode)
- 16.8.3.6 Removed deletion of FF’s in case of new trigger/state event
- 16.8.6.3ff Specify that nmb_t/s_tar_new values replaces nmb_t/s_tar values in case of direction change
- 16.10 reconfiguration of some table elements for better reading
- 16.11.6 Introduced RAM2_ERR status flag, active when access to not configured memory space happened
- 20.4 MON_ACTIVITY_1 register introduced
- 20.7 MON_ACTIVITY_1 register introduced
- 20.8.3 MON_ACTIVITY_1 register introduced
-
- update connection to QSPI
- update bit description for OTSC1.MOE
- remove CPU access to RAM from MCS trigger set TS16_MCA
- correct number of words for DPLL1B RAM in table GTM memory addresses
- add note to warn fro unexpected triggers
- remove bit discriptions in register ODA as explained in seperate table

Changes from version 1.2 to 1.3

- shift ERAY input from TIM channels 0 to channels 7
- update TIM input mapping for TC26x and QFP176
- add note for clock speeds in debug modes
- add information for BGA 416 and BGA 516
- update DSADC to GTM connections
  - add TIM0 inputs
  - move SCU inputs for TIM0 from 1110_B to 1100_B
  - add register DSADCINSEL0
- increase number of bit fields in register DSADCINSELx to 8 for all versions
- add DSADC inputs to all channels of TIM 1 and 2
- shift some DSADC TIM inputs in TIM mapping
-
- 2.1.2 trigger chain length description modified
- 2.3.1 Explain ARU round trip time more precise
- 2.5 ff Typos
- 2.6.1 Typo
- 2.9.9 Register structure updated; introducedBit field SYNC_INPUT_REG
- 9.1 Removed TBU_TS0 indexing (x)
- 10.1 Removed specific channel number of eight
- 10.1 Removed TBU_TS0 indexing (z)
- 10.2.2 Corrected sentence
- 10.2.2.2.1 Corrected naming of filter mode
- 10.2.2.3.1 Corrected naming of filter mode
- 10.3.1 Corrected timeout calculation formula
- 10.4.2.5 Removed specific channel number of eight
- 10.6 Removed specific channel number of eight
- 10.7 Removed specific channel number of eight
- 10.8.1-13 Removed specific channel number of eight
- 10.8.14 Inserted note on register bit width dependency
- 12.3.2.4 bit ACB10 description
- 12.6.12 bit 1 TRG CCU1TC description
- 16.5.3 declaration of limits for SUB_INC1,2 clocks
- 16.8.3 after eq. 16.25b, 16.26b: explanation of SUB_INC1,2 frequency doubling possibilities
- 16.8.6.3 explanation of “make calculation”steps 3, after 5 : nmb_t replaced by nmb_t_tarin emergency step 2: explanation added at the end of chapter: some corrections
- 16.8.6.4 some corrections like 16.8.3.8 at end
- 16.10 explanation of TBU_TS_x and INC_CNT1,2 RAM Region 2 end depends on device chosen
- 16.11.1 Bits 24:11 explained more detailed

- 16.11.3 Bits 3,4: explained more detailed, correction
- 16.11.24,25 heading correction, Bits 5:0 explanation
- 18.3 in table GTM_DPLL_xxx description corrected
- 18.5.1 bit 24 and 25 description corrected
- 18.5.12 description corrected
- 20.8.3 MON_ACTIVITY_1 register at address 0x08
- 2.1.3 new functionality GTM signal multiplexing added
- 2.2.1 CMU_CLK_CTRL, CMU_FXCLK_CTRL, TIM[i]_CH[x]_GPR1 included
- DPLL_PSA, DPLL_DLA, DPLL_NA, DPLL_DTA removed
- 2.5 ff new error interrupt
- 2.8 new address map due to new register
- 2.9.1 bit field YEAR replaced by STEP
- 2.9.9 NOTE text improved
- 2.9.12 new error interrupt
- 2.9.13 new register GTM_TIM[i]_AUX_IN_SRC
- BRC new error interrupt
- 5.4 new error interrupt
- 5.5.14 new error interrupt
- 8.5 selection of clocks for fxclk
- 8.7 new CMU_FXCLK_CTRL
- 8.8.1 clarifying disable/enable functionality
- 8.8.5 no exception for CMU_CLK5_CTRL
- 8.8.9 selection of clocks for fxclk
- 10.1.1 Block diagram updated due to new functionality INPSRC, EXTCAPSRC
- 10.1.2 new functionality INPSRC selection added
- 10.1.3 new functionality EXTCAPSRC selection added
- 10.3 TDU Block diagram and description updated due to new functionality of edge selection
- 10.4.1 TIM channel block diagram and description updated due to new functionality (ECNT increased to16 bit, ECNT can be captured to GPRx_REG, External_capture)
- 10.4.2ff New functionality External_capture, EGPRx_SEL added to existing TIM modes
- 10.4.2.6 New TIM mode TGPS added
- 10.7 Configuration registers updated due to new added functions
- 10.8.1-2 New bitfields added to support new functionality
- 10.8.5 Register removed , rearranged to TDUV, TDUC register
- 10.8.15-20 Register description for new functions added
- 11.4 TOM_CH2 special mode hint added
- 11.8.17 CLK_SRC_SR bits: description improved
- RST_CCU0 bit: note added
- SPEM bit: note added
- CLK_SRC_SR bits:description improved
- 12.3.2.2.1ff table design corrected

- 12.3.2.2.1ff TRIGOUT bit: added
- CLK_SRC_SR bits: NOTE added
- ACBO bits: NOTE added
- 13.1.1 Clarified usage of write accesses to MCS registers in the case of multiple source. Usage of accessing common trigger register is clarified.
- 13.4.11 Added Error interrupt register MCS[i]_CH[x]_EIRQ_EN
- 13.4.13-14 Added Note for writing common trigger bits via AEI
- 15.1.1 figure updated, description of new DIR selection added
- 15.4.1 TSEL bit: TIM0_IN6 feature added
- LSEL bit: new configuration bit
- 16.6.2ff TRIGGER time stamp resolution for filter values considered
- 16.6.3ff STATE time stamp resolution for filter values considered
- 16.7ff up to 32 actions served for device 4
- 16.10 additional registers and address map changed
- 16.11.2 some control bits added
- 16.11.6 control register for 8 additional actions
- 16.11.78 control bits for 8 additional actions
- 16.11.20-21 additional EIRQ enable register
- 16.11.30-35 status register with changed address and omitting CTON/CSON
- up to 32 ID_PMTR register changed SHADOW register bits
- 16.12.1-4 extension to serve 32 actions
- 16.13.38-39 centralization for TRIGGER and STATE calculation
- 16.15ff additional register address range for changed and additional registers to serve up to 32 actions
- 17.2.2 figure updated
- 17.2.4new chapter for SPE revolution detection
- 17.3 new interrupt SPE_RCMP
- 17.4 new register added
- 17.5.5-6 new register
- 17.5.7 additional IRQ
- 17.5.8 additional IRQ
- 17.5.9 additional IRQ
- 17.5.11 new register
- 18.3 new GTM Error Interrupt
- 18.4 new BRC, FIFO[i]_CH[x], TIM[i]_CH[x], MCS[i]_CH[x], SPE[i], CMP, DPLL, GTM Error Interrupt register
- 18.5.13-18 description of new Error Interrupt Register
- 19.5 new error interrupt
- 19.6 new error interrupt
- 19.7.6 description of new Error Interrupt Register
- 20.5 Note concerning ARU roundtrip time measurement by MCS added
- 10.1.3 EXTCAP_SRC: enhanced functionality description

- 10.4.1 new functionality: TIM input signal value available via ECNT[0] if channel is disabled
- 10.4.2 ff EXT_CAP_EN: enhanced functionality description. Added to each TIM channel descrition of external capture behaviour.
  TGPS mode: enhanced functionality description. new functionality: in TGPS mode GPR1 operates as a shadow register for CNTS
- 10.8.7 Register description updated due to added TGPS functionality
- 2.2.1 List of registers and address ranges which return AEI status “10” corrected
- 3.3.1 Note for bit 12 (RREQ) and bit 13 (WREQ) of register ARU_ACCESS added
- 10.8.19 Note added to ECNT register (behaviour of ECNT if channel gets disabled)
- 14ff layout option changed to layout configuration
- 16.4ff clear index 9
- 16.4.2 no hex for width
- 16.5.5 IP like formulation of clock frequency requirements
- 16.5.6 Remove uncleared abbiation “CDG”
- 16.6.2 Reduction of CTON, CTO function to just CTO flag
- 16.6.3 Reduction of CSON, CSO function to just CSO flag
- 16.11.30 Clarification os SYS/SYT flags, because not influenced for TOR/SOR states
- 18.5.14ff correct naming IRQ to EIRQ
- 19.1.1 include CMP_EIRQ
- 19.3 include CMP_EIRQ_EN
- 19.5 include CMP_EIRQ
- changed reset value for TOM and ATOM CTRL registers SL bits from 0 to 1
-
- changed reset value for TOM and ATOM CTRL registers OL bits from 1 to 0
- update information about accress protection

Changes from version 1.3 to 1.4

- correct typo in ADCx Timer Trigger tables so that if match with the register description
- update GTM connections to ports for TC26x
  - add TOM1_12 and ATOM0_4 for P10.0
  - add TOM1_6 and ATOM1_6 for P10.4
  - add TOM1_8 and ATOM0_0 for P10.7
  - add TOM1_13 and ATOM0_5 for P10.8
  - add TIM2_2, TOM1_4 and ATOM3_4 for P14.10
  - add TOM1_0 and ATOM3_0 for P14.7
  - add TIM2_3 and TOM1_2 for P14.8
  - add TIM2_2 and TOM1_3 for P14.9
  - add TIM0_3 and TOM0_3 for P20.1
  - add TIM0_3 and TOM1_8 for P21.0
  - add TIM0_4 and TOM1_9 for P21.1

  - add TOM1_2 and ATOM1_2 for P23.5
- update GTM connections to ports for TC29x
  - move timer mapping for P00.13 to P00.15
  - move timer mapping for P00.15 to P00.13
  - update timer mapping for P01.0
  - move timer mapping for P01.09 to P01.1
  - move timer mapping for P01.13 to P01.10
  - move timer mapping for P01.15 to P01.11
  - move timer mapping for P01.08 to P01.12
  - move timer mapping for P01.11 to P01.13
  - move timer mapping for P01.02 to P01.15
  - move timer mapping for P01.01 to P01.2
  - add P01.3 to timer mapping
  - move timer mapping for P01.12 to P01.8
  - move timer mapping for P01.10 to P01.9
  - replace for P02.0 TOM0_12 by TOM0_8 and TOM1_12 by TOM1_8
  - move timer mapping for P02.14 to P02.13
  - move timer mapping for P02.15 to P02.14
  - move timer mapping for P02.13 to P02.15
  - move timer mapping for P10.13 to P10.11
  - move timer mapping for P10.15 to P10.12
  - move timer mapping for P10.12 to P10.13
  - move timer mapping for P10.11 to P10.14
  - move timer mapping for P10.14 to P10.15
  - move timer mapping for P14.15 to P13.14
  - move timer mapping for P14.11 to P13.09
  - move timer mapping for P13.09 to P14.11
  - move timer mapping for P13.12 to P14.12
  - move timer mapping for P13.11 to P14.13
  - move timer mapping for P13.10 to P14.14
  - move timer mapping for P13.14 to P14.15
  - add P26.0 to timer mapping
  - removed P34.0
  - 11.2.1 bit field name CLK_SRC_STAT replaced
  - 11.8.1 bit field name CLK_SRC_STAT replaced
  - 12.6.1 bit field name CLK_SRC_STAT replaced
  - 13.2.2.10 reference to ACB replaced by reference to MHB
  - 16.13.7 more precisely explanation of THMI
  - 16.13.8 more precisely explanation of THMA
  - 16.13.9 more precisely explanation of THVAL
  - 17.5.6 note releated to SPEi_RCMP interrupt added
  - remove GTM to QSPI connections
  - change encoding for TS16_DRA1A/1BC/2 DPLLRAM Access Address table

– updated register names for ATOMi_CHx_CTRL, TS_T, TS_T_OLD, PSTM, PSTM_OLD, PSSM, and PSSM_OLD for header generation

Changes from version 1.4 to 1.5

- removed second vadc_G6ARBCNT inputs for TIM1 at possition 1100
- update end addresses for the DPLL RAMs in the RAM address table
- removed TIM2_5 connetion to P34.5
- 2.3.3 round trip time advice
- 2.5 correct register name from (...CEI1 to ...CEI5) to (...CEI0 to ...CEI4)
- 2.5.4 exception advice
- 5.1 Explanation of flushing the FIFO after write accress to START_ADDR or END_ADDR register
- 5.2.2 Further explanation of ring buffer mode
- 5.5.2ff Note added for further explanation
- 5.5.4ff Note added for further explanation
- 8.3 more precisely explanation of unsing clocks
- 10.1.2 more precisely explanation of F_in(x)
- 10.4.2.5 removed wrong explanation that channels 1 to m-1 have to be disabled
- 10.4.2.6 corrected TGPS mode explanation (counting is done via selected CMU clock)
- 11.1 new indices definition
- 11.3.6 additional one shot mode handling hint
- 12.3.3.4 additional one shot mode handling hint
- 12.6.1 UPEN_CTRL0 Note deleted
- 16.10.5.1ff address relation and names in EXT register region and RAM2 precised
- 16.6.2ff signal names changed
- 16.7 operation times precised for new version
- 16.8.3.4 description of sub_inc generation conditions
- 16.11.2 relation of CMU_CLKo to system clock
- 16.11.3 - 6,8 activity of the enable bits only for DEN=1, reset of SWON_x for DEN=0
- 17.5.4 additional note to SPE_OUT_CTRL
- 182.5ff more precisely explanation of interrupt bundling
- correct typos

Changes from version 1.5 to 1.6

- removed bit OTSC1.MCE as this bit is not required for a correct trace
- correct typos
- replace connections for DSADC1 with DSADC3 for TC26x and TC24x
- removed GxARBCNT for x>3 of TC26x and TC24x
- changed P01.8 TIN158 / TOUT158 to TIN162 / TOUT162
- add ADC output trigger 4 for TC24x
- remove connections to and from P10.12

- remove connections to and from P13.8
- remove connections to and from P15.9
- added QFP-144 pinning for TC24x
- remove P00.5 for QFP-80
- remove P00.9 for QFP-100
- and hint for DPLL RAM 1a accress errors of TC26x
- added DSADC and ADC connections for TC29x
- add missing bit field for ADC 3 to registers ADCTRIG0OUT0 and ADCTRIG1OUT0 for TC24x
- 2.5 more detailed description of IRQ_NOTIFY
- 2.9.13 bit 0 formula corrected
- 5.5.3 end replaced by start
- 5.5.4 upper replaced by lower
- 5.5.6 EMPTY and FULL description corrected
- 10.2.3 more detailed information about filter reconfiguration
- 10.5 more detailed information about MAP interface
- 10.8.1ff more detailed information about TIM MODE reconfiguration and GELx_SEL
- 10.8.6 additional information about GPR0
- 10.8.7 additional information about GPR1
- 10.8.9 additional information about CNTS
- 10.8.20 additional information about input selection by EXT_CAP_SRC
- 11.3 more detailed specification behavior in case of reset of CN0 by CCU0 compare and trigger
- 12.3.2.3 additional information about compare strategy; figure and description above added
- 12.3.3ff more detailed specification of behavior in case of reset of CN0 by CCU0 compare and by trigger
- 12.3.3.4 figure description corrected
- 12.3.3.5 more detailed information about CLK_SRC_SR and RST_CCU0 in SOMP mode
- 12.6.2 additional / corrected notes for bit SL
- 13.4.1 added missing Note for MEM_ERR_IRQ bit
- 14.1ff new chapter for memory layout configurations and for memory layoutr parameters
- 16ff all equations numbering transformed from 16.xxx to DPLL-xxx

Changes from version 1.6 to 1.7

- add register MSC0INEXTLCON for TC24x
- removed PSI5 and PSI5-S connections for TC24x
- make some minor correct in the pinning list for TC24x QFP100

Changes from version 1.7 to 1.8

- add register MSC0INEXTLCON for TC26x
- update to Bosch specification version 1.5.5.1:
- 2.2.1 Additional information about status ‘10’
- 2.4.1 precising the number of generated clocks
- 2.5.1ff corrected signal nmae as same in figure
- 2.9.1 Additional information about bits and values
- 4.5.3 precising information about DID
- 5.5.1 precising information about WULOCK
- 8.3.6 precising the number of generated clocks
- 8.8.1 removed note: Any disabling to EN_ECLKz will be reset internal counters for external clocks
- 10.1.1 replaced GPRz by GPR0 and GPR1
- 10.1.2 state bit VAL_x(1) and MODE_x(1) introduced in diagram and textual description
- 10.1.3.1 precising enable external capture functionality
- 10.3.1 replaced GPRz by GPR0 and GPR1; Extended description of ACB(2:0) bit behavior in case of a timeout event
- 10.4.1 replaced GPRz by GPR0 and GPR1
- 10.4.2 replaced GPRxOFL by GPROFL
- 10.4.2.1 Extended description of CNTS register update
- 10.4.2.3 replaced GPRzOFL by GPROFL
- 10.6 replaced GPRz by GPR0 and GPR1
- 10.6 replaced GPRzOF by GPROFL
- 10.8.2. replaced GPRz by GPR0 and GPR1
- 10.8.10-12 replaced GPRzOFL by GPROFL
- 10.8.15 Description of VAL_0 and MODE_0 enhanced
- 10.8.16 replaced GPRzOFL by GPROFL
- 10.8.20 bit width of EXT_CAP_SRC corrected; new values added
- 11.3.6.1 precising of one shot mode handling
- 11.3.7.1 precising of pulse count modulation mode
- 12.3.2.2 precising description of serve last compare strategy
- 12.3.3.4. precising of one shot mode handling
- 12.6.9 additioanl note for RST_CCU0
- 13.3.3 precising usage of instruction in conjunction with STA
- 16.8.6.7 replaced invalid by inactive
- 16.11 precising section headline and content
- 16.11ff replaced lower case letters in bit fields by upper case letters; added missing prefix DPLL_ to all registers or momory labels
- 16.11.1 precising bit fields 15:11 and 24:16
- 16.11.7 replaced bit field 23:0 by 31:0; additional note for limitations
- 16.11.14 precising NUTE and WNUT definitions

- 16.11.17ff replaced lost by loss
- 16.11.30 precising SOR, MS, TOR,LOCK2, LOCK1 definition
- 16.11.37ff replaced section 16.12ff by 16.11.37-40

Changes from version 1.8 to 1.9

- correct error in BGA-416 TOUT numbering for 10.13 and 10.11
- connection shown in figures and register for SET5 and SET6 to MSC2 was corrected
- update describtion of bit field OCS.SUS
- update description of (A)TOM SOMP Mode
- clearify reset behavior of debug registers
- correct error for 2.11; it is connected to TIM4_4 not to TIM4_7
-

26 Capture/Compare Unit 6 (CCU6)

The CCU6 is a high-resolution 16-bit capture and compare unit with application specific modes, mainly for AC drive control. Special operating modes support the control of Brushless DC-motors using Hall sensors or Back-EMF detection. Furthermore, block commutation and control mechanisms for multi-phase machines are supported.
It also supports inputs to start several timers synchronously, an important feature in devices with several CCU6 kernels.

This chapter is structured as follows:

- Introduction (see **Section 26.1**)
  including register overview (see **Section 26.1.3**)
- Operating T12 (see **Section 26.2**)
  including T12-related registers (see **Section 26.2.8**)
  and capture/compare control registers (see **Section 26.2.9**)
- Operating T13 (see **Section 26.3**)
  including T13-related registers (see **Section 26.3.6**)
- Synchronous start feature (see **Section 26.4**)
- Trap handling (see **Section 26.5**)
- Multi-Channel mode (see **Section 26.6**)
- Hall sensor mode (see **Section 26.7**)
- Modulation control registers (see **Section 26.8**)
- Interrupt handling (see **Section 26.9**)
  including interrupt registers (see **Section 26.9.2**)
- General module operation (see **Section 26.10**)
  including general registers (see **Section 26.10.5**)
  and BPI registers (see **Section 26.10.6**)
- Module implementation (see **Section 26.11**)

26.1 Introduction

The CCU6 unit is made up of a Timer T12 Block with three capture/compare channels and a Timer T13 Block with one compare channel. The T12 channels can independently generate PWM signals or accept capture triggers, or they can jointly generate control signal patterns to drive AC-motors or inverters.

A rich set of status bits, synchronized updating of parameter values via shadow registers, and flexible generation of interrupt request signals provide means for efficient software-control.

Note: The capture/compare module itself is named CCU6 (capture/compare unit 6).
A capture/compare channel inside this module is named CC6x.

26.1.1 Feature Set Overview

This section gives an overview over the different building blocks and their main features.

Timer 12 Block Features

- Three capture/compare channels, each channel can be used either as capture or as compare channel
- Generation of a three-phase PWM supported (six outputs, individual signals for high-side and low-side switches)
- 16-bit resolution, maximum count frequency = peripheral clock
- Dead-time control for each channel to avoid short-circuits in the power stage
- Concurrent update of T12 registers
- Center-aligned and edge-aligned PWM can be generated
- Single-shot mode supported
- Start can be controlled by external events
- Capability of counting external events
- Many interrupt request sources
- Hysteresis-like control mode

Timer 13 Block Features

- One independent compare channel with one output
- 16-bit resolution, maximum count frequency = peripheral clock
- Concurrent update of T13 registers
- Can be synchronized to T12
- Interrupt generation at period-match and compare-match
- Single-shot mode supported
- Start can be controlled by external events
- Capability of counting external events

Additional Specific Functions

- Block commutation for Brushless DC-drives implemented
- Position detection via Hall-sensor pattern
- Noise filter supported for position input signals
- Automatic rotational speed measurement and commutation control for block commutation
- Integrated error handling
- Fast emergency stop without CPU load via external signal ($\overline{\text{CTRAP}}$)
- Control modes for multi-channel AC-drives
- Output levels can be selected and adapted to the power stage

26.1.2 Block Diagram

The Timer T12 can operate in capture and/or compare mode for its three channels. The modes can also be combined (e.g. a channel operates in compare mode, whereas another channel operates in capture mode). The Timer T13 can operate in compare mode only. The multi-channel control unit generates output patterns which can be modulated by T12 and/or T13. The modulation sources can be selected and combined for the signal modulation.

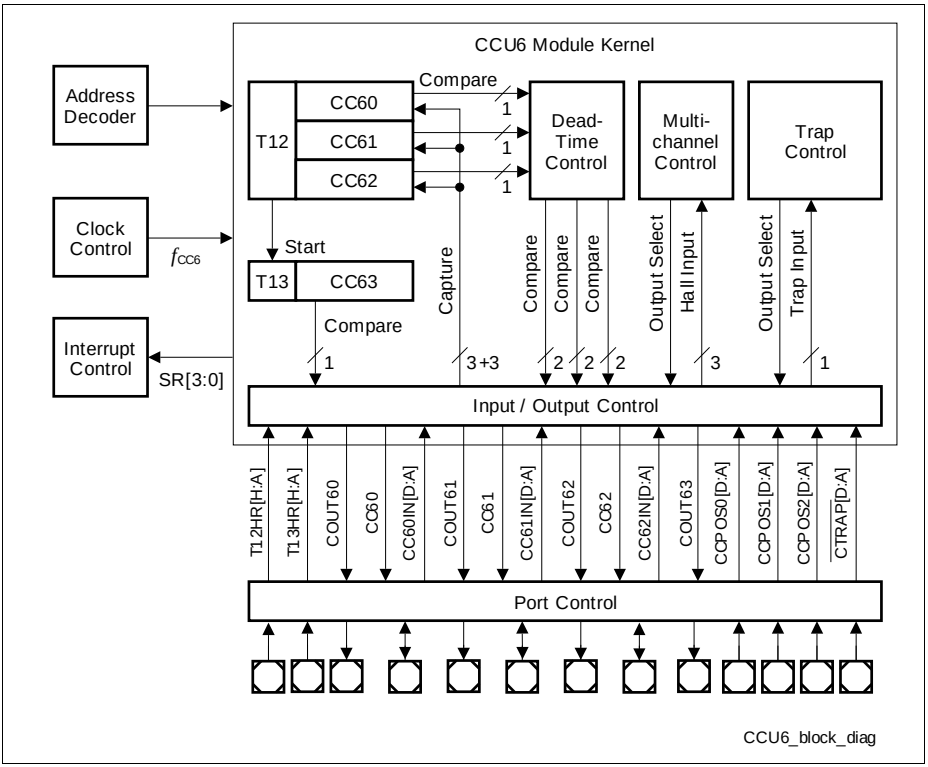

Figure 26-1 CCU6 Block Diagram

26.1.3 CCU6 Kernel Registers

For the generation of the overall register table, the prefix “CCU6x_” has to be added to the register names in this table to identify the registers of different CCU6 kernels that are implemented. In this naming convention, x indicates the kernel number.

Table 26-1 shows all registers required for programming of a CCU6. It summarizes the CCU6 kernel registers and defines their offset addresses. BPI registers are listed separately in **Table 26-14**, and Module Output Select registers are listed in **Table 26-16**.

The CCU6 module has no destructive register read mechanisms.

CCU6 Kernel Register Overview

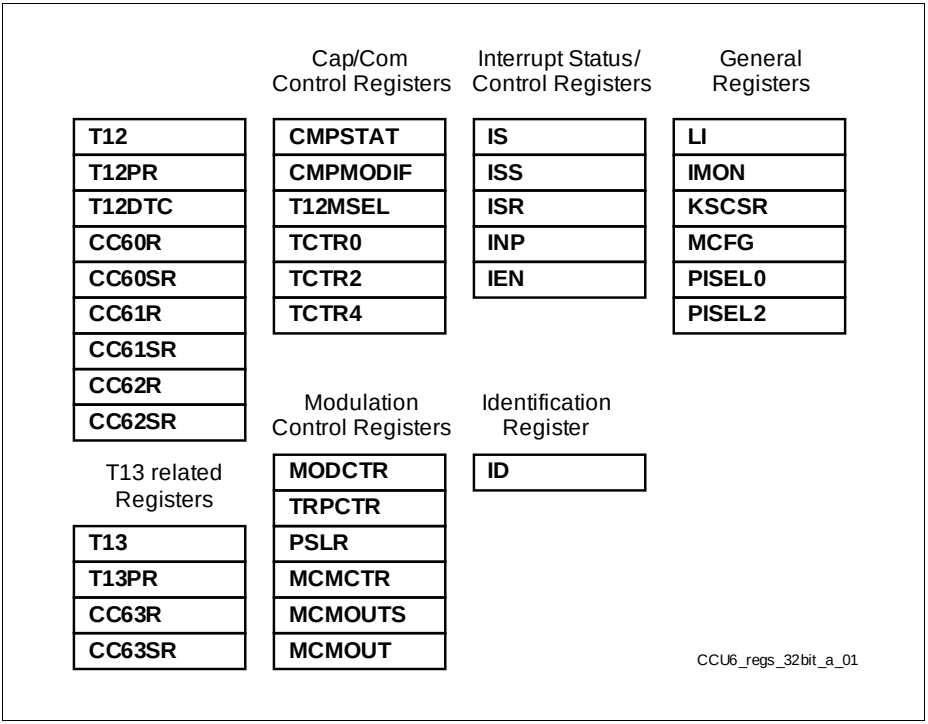

Figure 26-2 CCU6 Registers

Note: In the case of a write access to addresses inside the address range (that is covered by the same chip select signal), but that are not the addresses explicitly mentioned for the module, the write access is not taken into account for the

module. The same principle is valid for read accesses. In case of a read access to another address, the module does not react.

*Note: The exact register address is given by the relative address of the register (given in **Table 26-1**) plus the kernel base address (given in **Table 26-15**) of the kernel.*

26.2 Operating Timer T12

The timer T12 block is the main unit to generate the 3-phase PWM signals. A 16-bit counter is connected to 3 channel registers via comparators, that generate a signal when the counter contents match one of the channel register contents. A variety of control functions facilitate the adaptation of the T12 structure to different application needs.
Besides the 3-phase PWM generation, the T12 block offers options for individual compare and capture functions, as well as dead-time control and hysteresis-like compare mode.

This section provides information about:

- T12 overview (see **Section 26.2.1**)
- Counting scheme (see **Section 26.2.2**)
- Compare modes (see **Section 26.2.3**)
- Compare mode output path (see **Section 26.2.4**)
- Capture modes (see **Section 26.2.5**)
- Shadow transfer (see **Section 26.2.6**)
- T12 operating mode selection (see **Section 26.2.7**)
- T12 register description (see **Section 26.2.8**)

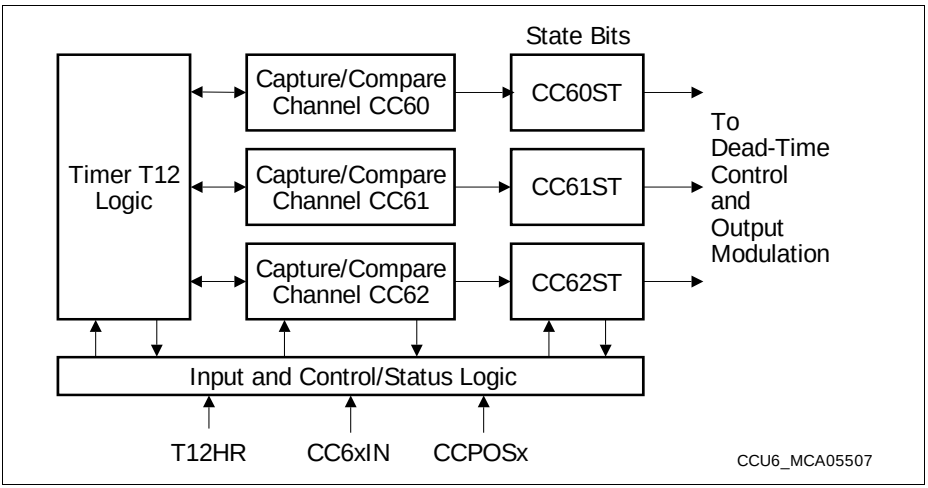

Figure 26-3 Overview Diagram of the Timer T12 Block

26.2.1 T12 Overview

Figure 26-4 shows a detailed block diagram of Timer T12. The functions of the timer T12 block are controlled by bits in registers **TCTR0**, **TCTR2**, and **PISEL0**.

Timer T12 receives its input clock (f_{T12}) from the module clock f_{CC6} via a programmable prescaler and an optional 1/256 divider or from an input signal T12HR. These options are controlled via bit fields T12CLK and T12PRE (see **Table 26-2**). T12 can count up or down, depending on the selected operation mode. A direction flag, CDIR, indicates the current counting direction.

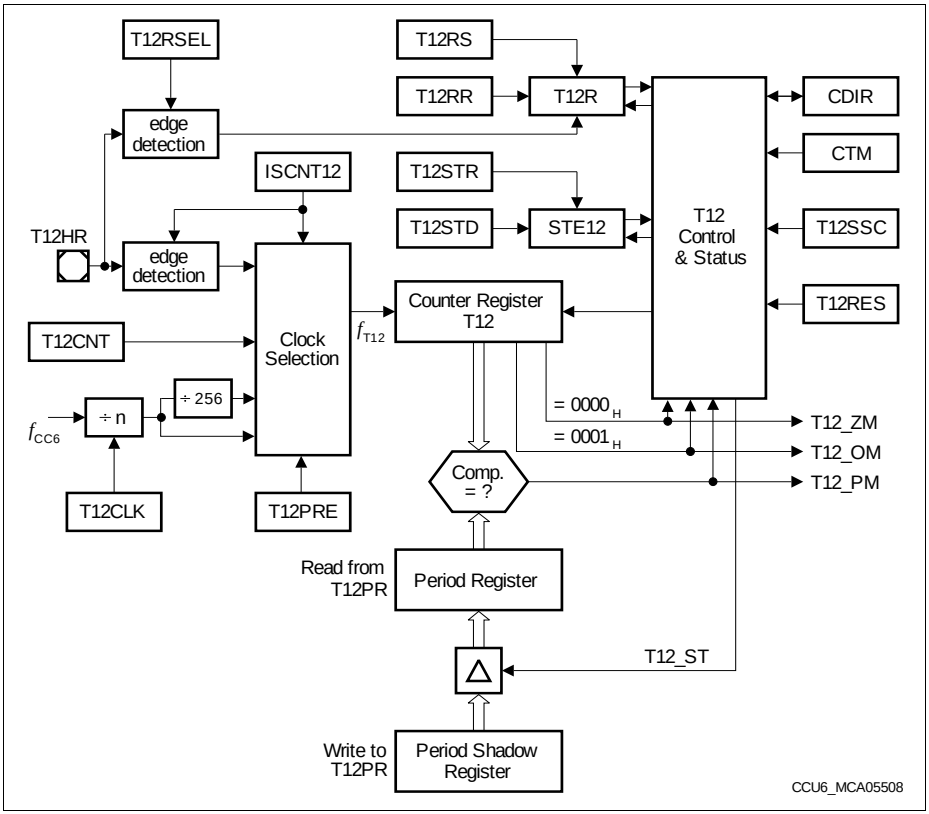

Figure 26-4 Timer T12 Logic and Period Comparators

Via a comparator, the T12 counter register **T12** is connected to a Period Register **T12PR**. This register determines the maximum count value for T12.

In Edge-Aligned mode, T12 is cleared to 0000_H after it has reached the period value defined by T12PR. In Center-Aligned mode, the count direction of T12 is set from ‘up’ to

‘down’ after it has reached the period value (please note that in this mode, T12 exceeds the period value by one before counting down). In both cases, signal T12_PM (T12 Period Match) is generated. The Period Register receives a new period value from its Shadow Period Register.
A read access to T12PR delivers the current period value at the comparator, whereas a write access targets the Shadow Period Register to prepare another period value. The transfer of a new period value from the Shadow Period Register into the Period Register (see **Section 26.2.6**) is controlled via the ‘T12 Shadow Transfer’ control signal, T12_ST. The generation of this signal depends on the operating mode and on the shadow transfer enable bit STE12. Providing a shadow register for the period value as well as for other values related to the generation of the PWM signal allows a concurrent update by software for all relevant parameters.
Two further signals indicate whether the counter contents are equal to 0000_H (T12_ZM = zero match) or 0001_H (T12_OM = one match). These signals control the counting and switching behavior of T12.

The basic operating mode of T12, either Edge-Aligned mode (**Figure 26-5**) or Center-Aligned mode (**Figure 26-6**), is selected via bit CTM. A Single-Shot control bit, T12SSC, enables an automatic stop of the timer when the current counting period is finished (see **Figure 26-7** and **Figure 26-8**).

The start or stop of T12 is controlled by the Run bit T12R that can be modified by bits in register **TCTR4**. The run bit can be set/cleared by software via the associated set/clear bits T12RS or T12RR, it can be set by a selectable edge of the input signal T12HR (**TCTR2**.T12RSEL), or it is cleared by hardware according to preselected conditions.
The timer T12 run bit T12R must not be set while the applied T12 period value is zero.
Timer T12 can be cleared via control bit T12RES. Setting this write-only bit does only clear the timer contents, but has no further effects, for example, it does not stop the timer.

The generation of the T12 shadow transfer control signal, T12_ST, is enabled via bit STE12. This bit can be set or reset by software indirectly through its associated set/clear control bits T12STR and T12STD.
While Timer T12 is running, write accesses to the count register T12 are not taken into account. If T12 is stopped and the Dead-Time counters are 0, write actions to register T12 are immediately taken into account.

26.2.2 T12 Counting Scheme

This section describes the clocking and counting capabilities of T12.

26.2.2.1 Clock Selection

In **Timer Mode** (**PISEL2**.ISCNT12 = 00_B), the input clock f_{T12} of Timer T12 is derived from the internal module clock f_{CC6} through a programmable prescaler and an optional 1/256 divider. The resulting prescaler factors are listed in **Table 26-2**. The prescaler of T12 is cleared while T12 is not running (**TCTR0**.T12R = 0) to ensure reproducible timings and delays.

Table 26-2 Timer T12 Input Frequency Options

T12CLK	Resulting Input Clock f_{T12} Prescaler Off (T12PRE = 0)	Resulting Input Clock f_{T12} Prescaler On (T12PRE = 1)
000_B	f_{CC6}	f_{CC6} / 256
001_B	f_{CC6} / 2	f_{CC6} / 512
010_B	f_{CC6} / 4	f_{CC6} / 1024
011_B	f_{CC6} / 8	f_{CC6} / 2048
100_B	f_{CC6} / 16	f_{CC6} / 4096
101_B	f_{CC6} / 32	f_{CC6} / 8192
110_B	f_{CC6} / 64	f_{CC6} / 16384
111_B	f_{CC6} / 128	f_{CC6} / 32768

In **Counter Mode**, timer T12 counts one step:

- If a 1 is written to **TCTR4**.T12CNT and **PISEL2**.ISCNT12 = 01_B
- If a rising edge of input signal T12HR is detected and **PISEL2**.ISCNT12 = 10_B
- If a falling edge of input signal T12HR is detected and **PISEL2**.ISCNT12 = 11_B

26.2.2.2 Edge-Aligned / Center-Aligned Mode

In **Edge-Aligned Mode** (CTM = 0), timer T12 is always counting upwards (CDIR = 0). When reaching the value given by the period register (period-match T12_PM), the value of T12 is cleared with the next counting step (saw tooth shape).

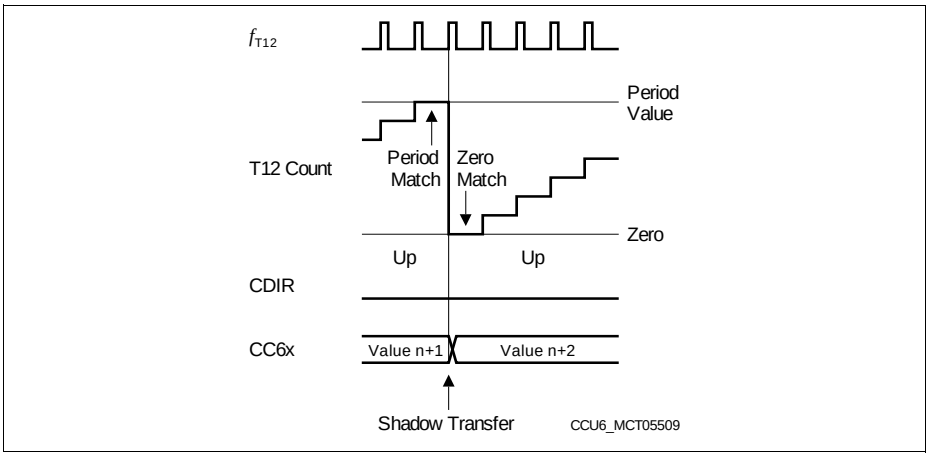

Figure 26-5 T12 Operation in Edge-Aligned Mode

As a result, in Edge-Aligned mode, the timer period is given by:

$T12_{PER}$ = <Period-Value> + 1; in T12 clocks (f_{T12}) (26.1)

In **Center-Aligned Mode** (CTM = 1), timer T12 is counting upwards or downwards (triangular shape). When reaching the value given by the period register (period-match T12_PM) while counting upwards (CDIR = 0), the counting direction control bit CDIR is changed to downwards (CDIR = 1) with the next counting step.
When reaching the value 0001_H (one-match T12_OM) while counting downwards, the counting direction control bit CDIR is changed to upwards with the next counting step.

As a result, in Center.Aligned mode, the timer period is given by:

$T12_{PER}$ = (<Period-Value> + 1) x 2; in T12 clocks (f_{T12}) (26.2)

- With the next clock event of f_{T12} the count direction is set to counting up (CDIR = 0) when the counter reaches 0001_H while counting down.
- With the next clock event of f_{T12} the count direction is set to counting down (CDIR = 1) when the Period-Match is detected while counting up.
- With the next clock event of f_{T12} the counter counts up while CDIR = 0 and it counts down while CDIR = 1.

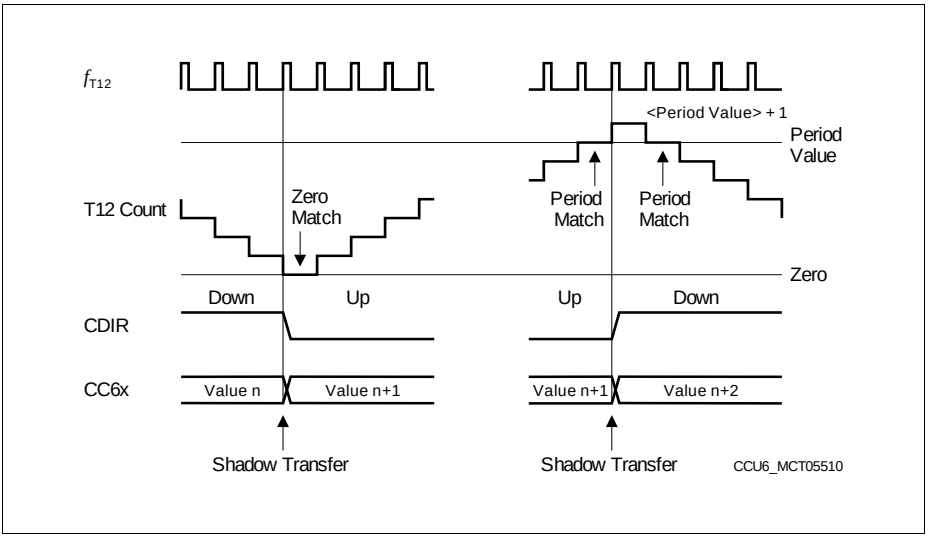

Figure 26-6 T12 Operation in Center-Aligned Mode

*Note: Bit CDIR changes with the next timer clock event after the one-match or the period-match. Therefore, the timer continues counting in the previous direction for one cycle before actually changing its direction (see **Figure 26-6**).*

26.2.2.3 Single-Shot Mode

In Single-Shot Mode, the timer run bit T12R is cleared by hardware. If bit T12SSC = 1, the timer T12 will stop when the current timer period is finished.

In Edge-Aligned mode, T12R is cleared when the timer becomes zero after having reached the period value (see **Figure 26-7**).

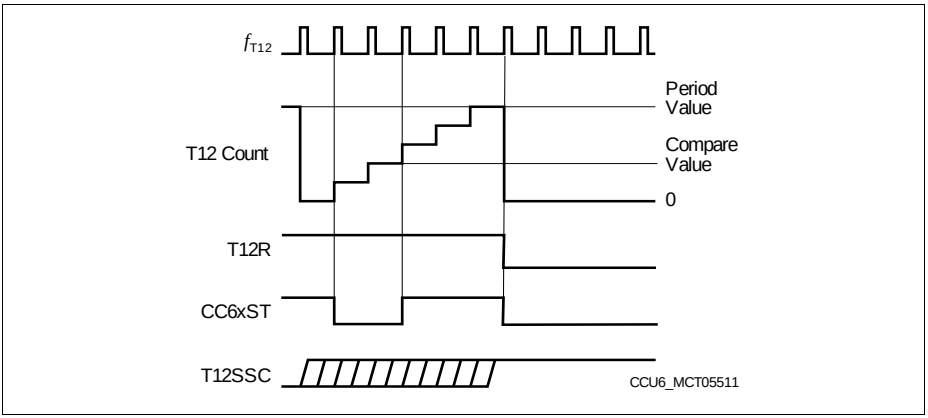

Figure 26-7 Single-Shot Operation in Edge-Aligned Mode

In Center-Aligned mode, the period is finished when the timer has counted down to zero (one clock cycle after the one-match while counting down, see **Figure 26-8**).

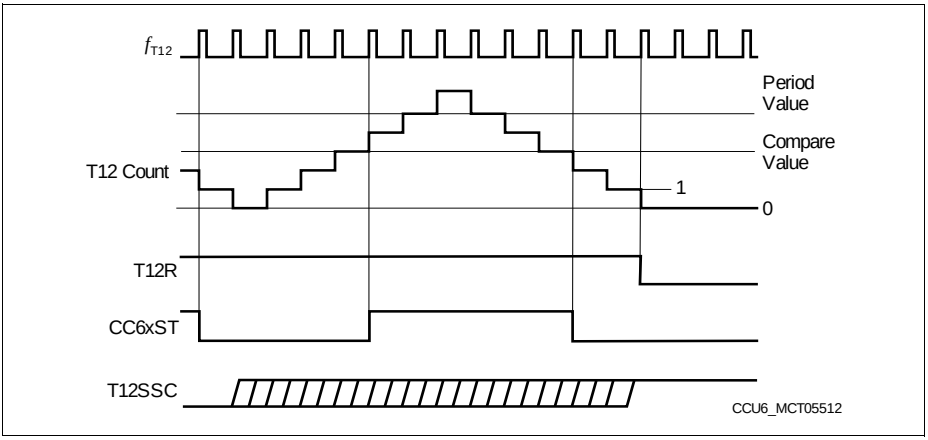

Figure 26-8 Single-Shot Operation in Center-Aligned Mode

26.2.3 T12 Compare Mode

Associated with Timer T12 are three individual capture/compare channels, that can perform compare or capture operations with regard to the contents of the T12 counter. The capture functions are explained in **Section 26.2.5**.

26.2.3.1 Compare Channels

In Compare Mode (see **Figure 26-9**), the three individual compare channels CC60 CC61, and CC62 can generate a three-phase PWM pattern.

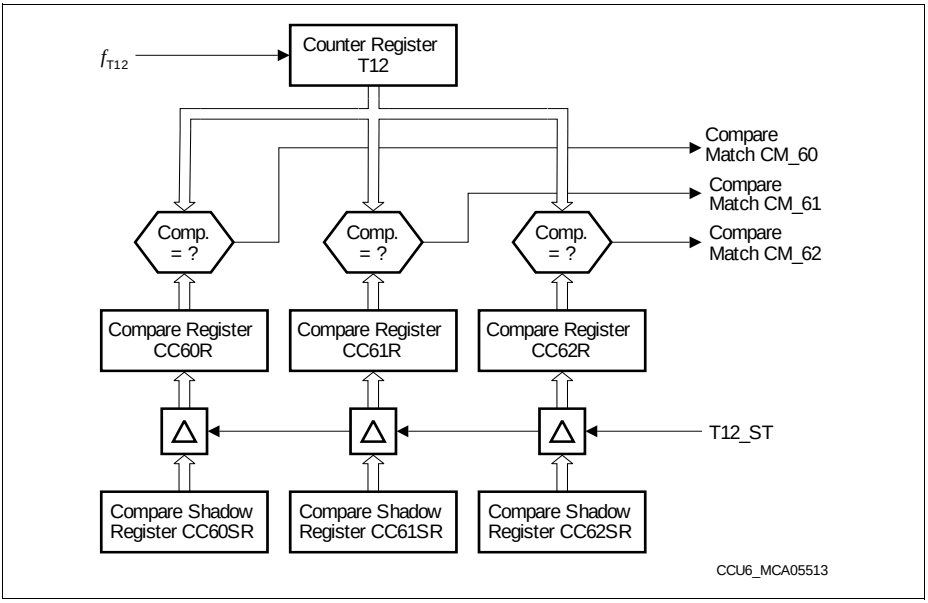

Figure 26-9 T12 Channel Comparators

Each compare channel is connected to the T12 counter register via its individual equal-to comparator, generating a match signal when the contents of the counter matches the contents of the associated compare register. Each channel consists of the comparator and a double register structure - the actual compare register CC6xR, feeding the comparator, and an associated shadow register CC6xSR, that is preloaded by software and transferred into the compare register when signal T12 shadow transfer, T12_ST, gets active. Providing a shadow register for the compare value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters of a three-phase PWM.

26.2.3.2 Channel State Bits

Associated with each (compare) channel is a State Bit, **CMPSTAT**.CC6xST, holding the status of the compare (or capture) operation (see **Figure 26-10**). In compare mode, the State Bits are modified according to a set of switching rules, depending on the current status of timer T12.

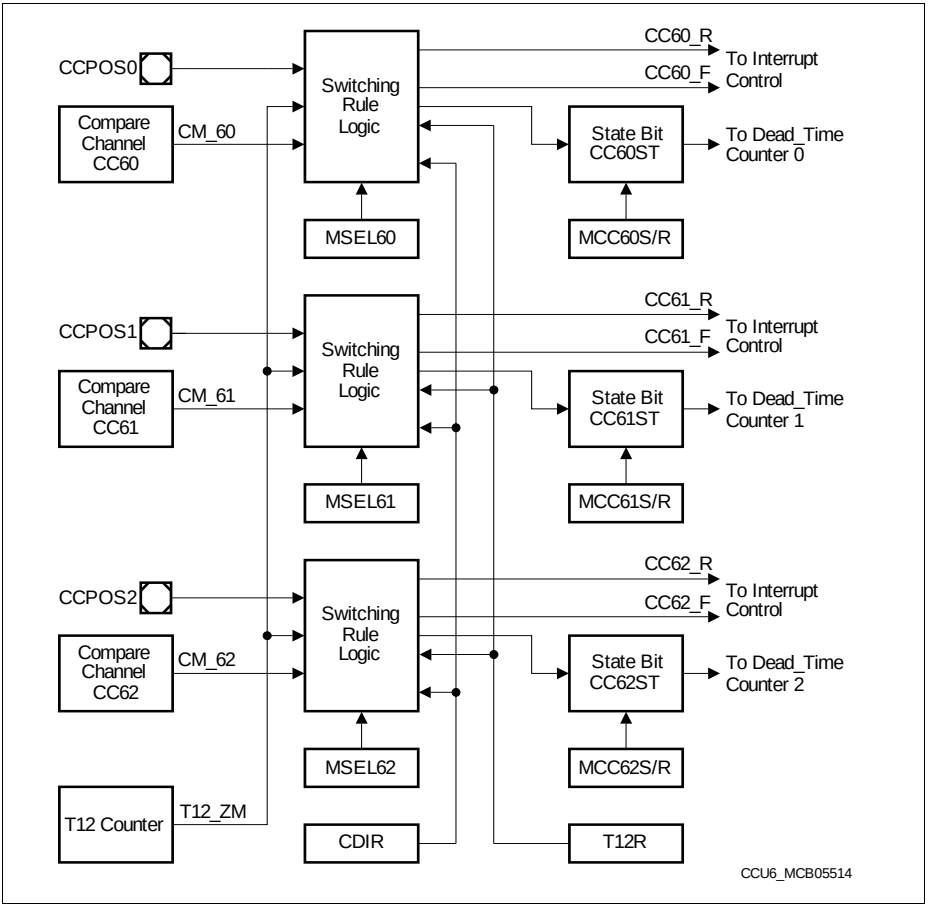

Figure 26-10 Compare State Bits for Compare Mode

The inputs to the switching rule logic for the CC6xST bits are the timer direction (CDIR), the timer run bit (T12R), the timer T12 zero-match signal (T12_ZM), and the actual individual compare-match signals CM_6x as well as the mode control bits, **T12MSEL**.MSEL6x.

In addition, each state bit can be set or cleared by software via the appropriate set and reset bits in register **CMPMODIF**, MCC6xS and MCC6xR. The input signals CCPOSx are used in hysteresis-like compare mode, whereas in normal compare mode, these inputs are ignored.

Note: In Hall Sensor, single shot or capture modes, additional/different rules are taken into account (see related sections).

A compare interrupt event CC6x_R is signaled when a compare match is detected while counting upwards, whereas the compare interrupt event CC6x_F is signaled when a compare match is detected while counting down. The actual setting of a State Bit has no influence on the interrupt generation in compare mode.

A modification of a State Bit CC6xST by the switching rule logic due to a compare action is only possible while Timer T12 is running (T12R = 1). If this is the case, the following switching rules apply for setting and clearing the State Bits in Compare Mode (illustrated in **Figure 26-11** and **Figure 26-12**):

A State Bit **CC6xST is set** to 1:

- with the next T12 clock (f_{T12}) after a compare-match when T12 is counting up (i.e., when the counter is incremented above the compare value);
- with the next T12 clock (f_{T12}) after a zero-match AND a parallel compare-match when T12 is counting up.

A State Bit **CC6xST is cleared** to 0:

- with the next T12 clock (f_{T12}) after a compare-match when T12 is counting down (i.e., when the counter is decremented below the compare value in center-aligned mode);
- with the next T12 clock (f_{T12}) after a zero-match AND NO parallel compare-match when T12 is counting up.

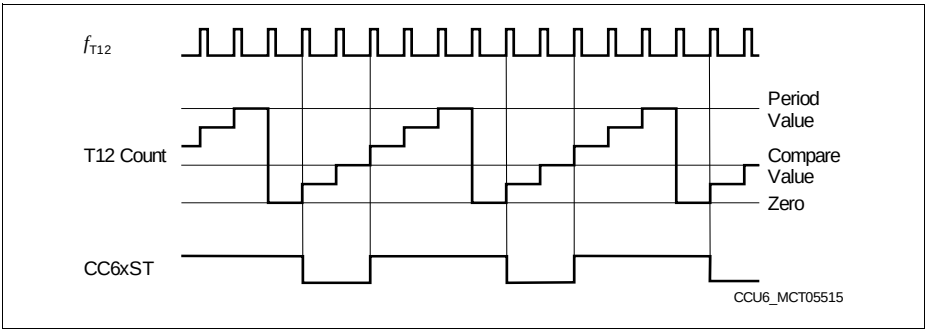

Figure 26-11 Compare Operation, Edge-Aligned Mode

Figure 26-13 illustrates some more examples for compare waveforms. It is important to note that in these examples, it is assumed that some of the compare values are changed

while the timer is running. This change is performed via a software preload of the Shadow Register, CC6xSR. The value is transferred to the actual Compare Register CC6xR with the T12 Shadow Transfer signal, T12_ST, that is assumed to be enabled.

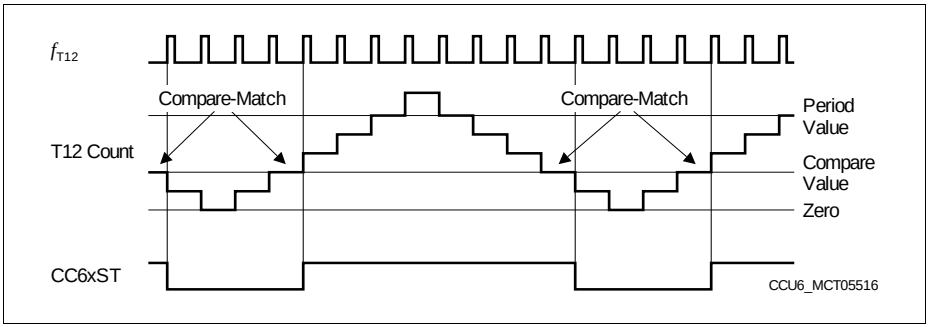

Figure 26-12 Compare Operation, Center-Aligned Mode

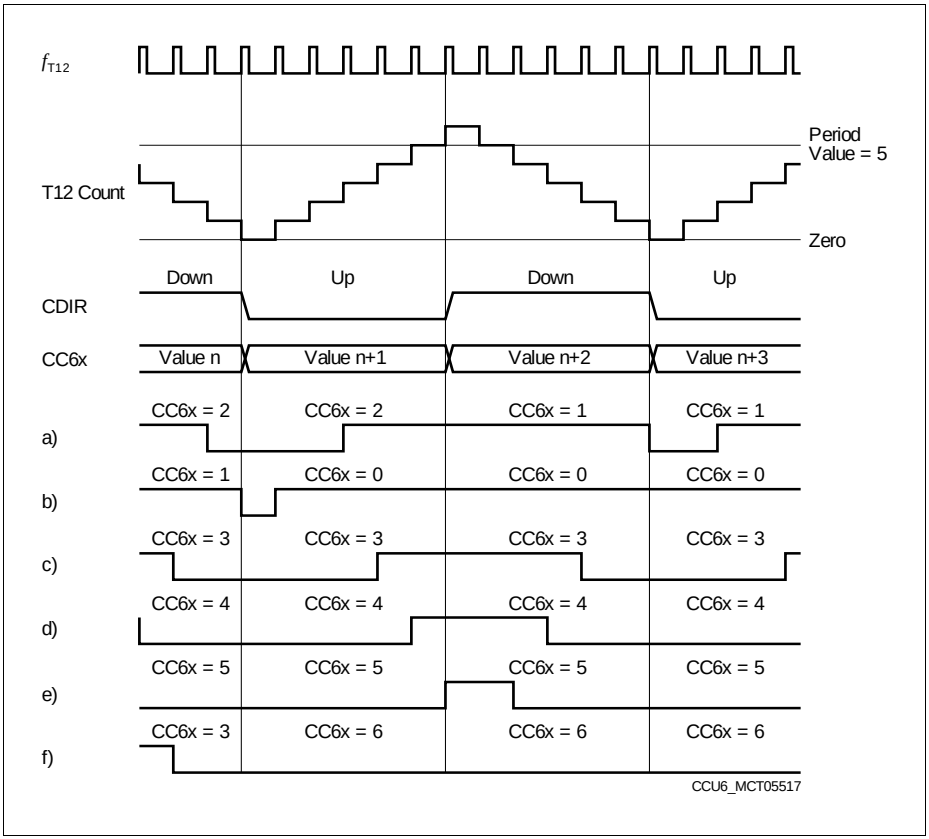

Figure 26-13 Compare Waveform Examples

Example b) illustrates the transition to a duty cycle of 100%. First, a compare value of 0001_H is used, then changed to 0000_H. Please note that a low pulse with the length of one T12 clock is still produced in the cycle where the new value 0000_H is in effect; this pulse originates from the previous value 0001_H. In the following timer cycles, the State Bit CC6xST remains at 1, producing a 100% duty cycle signal. In this case, the compare rule ‘zero-match AND compare-match’ is in effect.

Example f) shows the transition to a duty cycle of 0%. The new compare value is set to <Period-Value> + 1, and the State Bit CC6ST remains cleared.

Figure 26-14 illustrates an example for the waveforms of all three channels. With the appropriate dead-time control and output modulation, a very efficient 3-phase PWM signal can be generated.

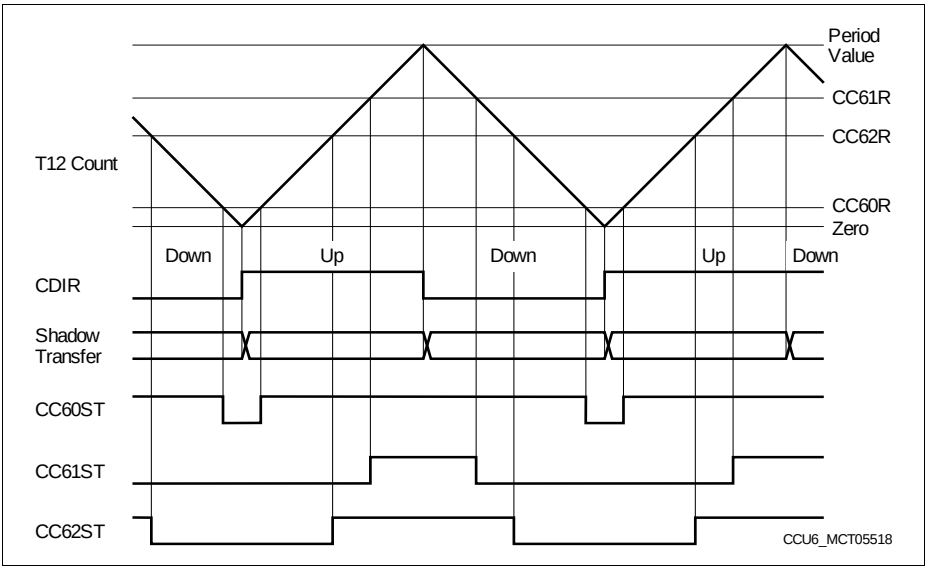

Figure 26-14 Three-Channel Compare Waveforms

26.2.3.3 Hysteresis-Like Control Mode

The hysteresis-like control mode (**T12MSEL**.MSEL6x = 1001_B) offers the possibility to switch off the PWM output if the input CCPOSx becomes 0 by clearing the State Bit CC6xST. This can be used as a simple motor control feature by using a comparator indicating, e.g., overcurrent. While CCPOSx = 0, the PWM outputs of the corresponding channel are driving their passive levels, because the setting of bit CC6xST is only possible while CCPOSx = 1.
As long as input CCPOSx is 0, the corresponding State Bit is held 0. When CCPOSx is at high level, the outputs can be in active state and are determined by bit CC6xST (see **Figure 26-10** for the state bit logic and **Figure 26-15** for the output paths).
The CCPOSx inputs are evaluated with f_{CC6}.

This mode can be used to introduce a timing-related behavior to a hysteresis controller. A standard hysteresis controller detects if a value exceeds a limit and switches its output according to the compare result. Depending on the operating conditions, the switching frequency and the duty cycle are not fixed, but change permanently.

If (outer) time-related control loops based on a hysteresis controller in an inner loop should be implemented, the outer loops show a better behavior if they are synchronized to the inner loops. Therefore, the hysteresis-like mode can be used, that combines timer-related switching with a hysteresis controller behavior. For example, in this mode, an output can be switched on according to a fixed time base, but it is switched off as soon as a falling edge is detected at input CCPOSx.

This mode can also be used for standard PWM with overcurrent protection. As long as there is no low level signal at pin CCPOSx, the output signals are generated in the normal manner as described in the previous sections. Only if input CCPOSx shows a low level, e.g. due to the detection of overcurrent, the outputs are shut off to avoid harmful stress to the system.

26.2.4 Compare Mode Output Path

Figure 26-15 gives an overview on the signal path from a channel State Bit to its output pin in its simplest form. As illustrated, a user has a variety of controls to determine the desired output signal switching behavior in relation to the current state of the State Bit, CC6xST. Please refer to **Section 26.2.4.3** for details on the output modulation.

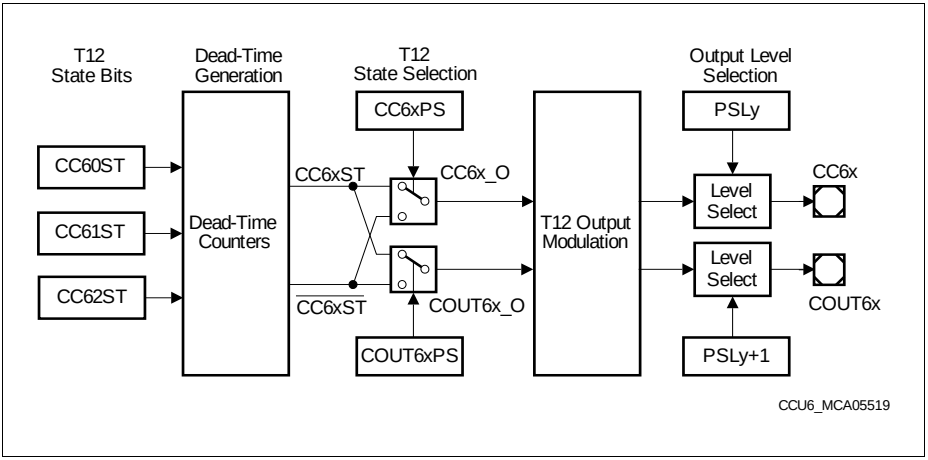

Figure 26-15 Compare Mode Simplified Output Path Diagram

The output path is based on signals that are defined as active or passive. The terms active and passive are not related to output levels, but to internal actions. This mainly applies for the modulation, where T12 and T13 signals are combined with the multi-channel signals and the trap function. The Output level Selection allows the user to define the output level at the output pin for the passive state (inverted level for the active state). It is recommended to configure this block in a way that an external power switch is switched off while the CCU6 delivers an output signal in the passive state.

26.2.4.1 Dead-Time Generation

The generation of (complementary) signals for the high-side and the low-side switches of one power inverter phase is based on the same compare channel. For example, if the high-side switch should be active while the T12 counter value is above the compare value (State Bit = 1), then the low-side switch should be active while the counter value is below the compare value (State Bit = 0).

In most cases, the switching behavior of the connected power switches is not symmetrical concerning the switch-on and switch-off times. A general problem arises if the time for switch-on is smaller than the time for switch-off of the power device. In this case, a short-circuit can occur in the inverter bridge leg, which may damage the complete system. In order to solve this problem by HW, this capture/compare unit

contains a programmable Dead-Time Generation Block, that delays the passive to active edge of the switching signals by a programmable time (the active to passive edge is not delayed).

The Dead-Time Generation Block, illustrated in **Figure 26-16**, is built in a similar way for all three channels of T12. It is controlled by bits in register **T12DTC**. Any change of a CC6xST State Bit activates the corresponding Dead-Time Counter, that is clocked with the same input clock as T12 (f_{T12}). The length of the dead-time can be programmed by bit field DTM. This value is identical for all three channels. Writing **TCTR4**.DTRES = 1 sets all dead-times to passive.

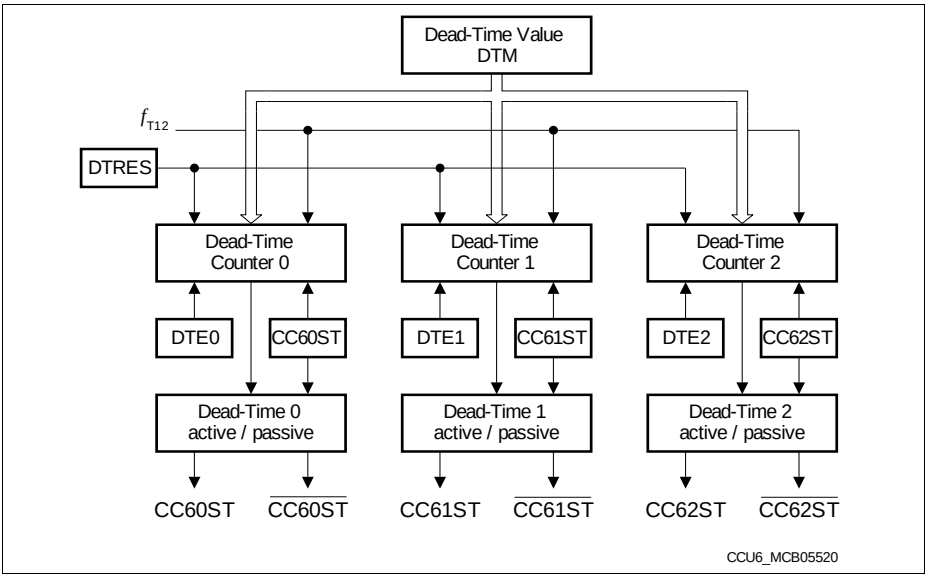

Figure 26-16 Dead-Time Generation Block Diagram

Each of the three dead-time counters has its individual dead-time enable bit, DTEx. An enabled dead-time counter generates a dead-time delaying the passive-to-active edge of the channel output signal. The change in a State Bit CC6xST is not taken into account while the dead-time generation of this channel is currently in progress (active). This avoids an unintentional additional dead-time if a State Bit CC6xST changes too early.
A disabled dead-time counter is always considered as passive and does not delay any edge of CC6xST.
Based on the State Bits CC6xST, the Dead-Time Generation Block outputs a direct signal CC6xST and an inverted signal $\overline{CC6xST}$ for each compare channel, each masked with the effect of the related Dead-Time Counters (waveforms illustrated in **Figure 26-17**).

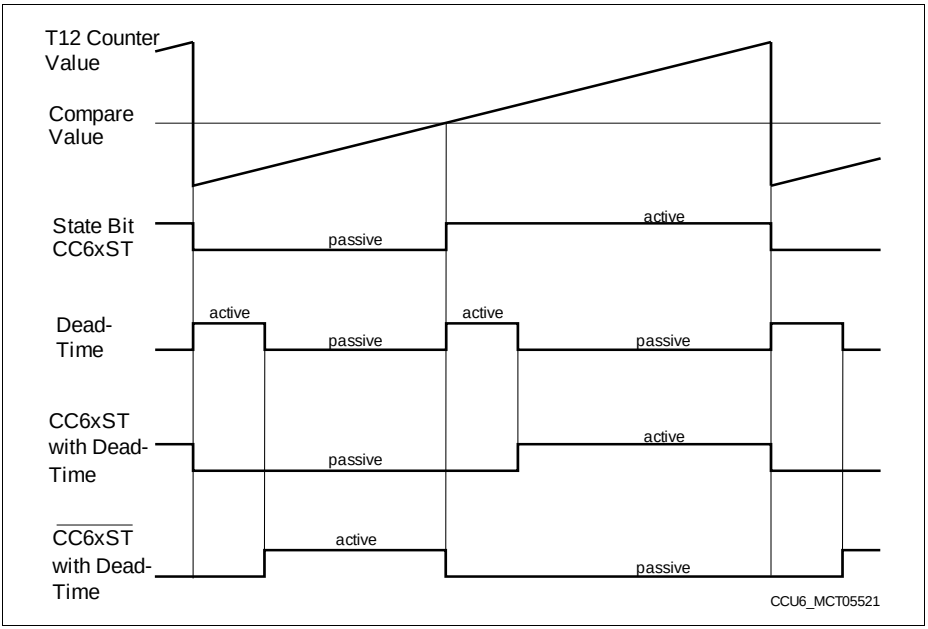

Figure 26-17 Dead-Time Generation Waveforms

26.2.4.2 State Selection

To support a wide range of power switches and drivers, the state selection offers the flexibility to define when an output can be active and can be modulated, especially useful for **complementary or multi-phase PWM** signals.

The state selection is based on the signals CC6xST and $\overline{\text{CC6xST}}$ delivered by the dead-time generator (see **Figure 26-15**). Both signals are never active at the same time, but can be passive at the same time. This happens during the dead-time of each compare channel after a change of the corresponding State Bit CC6xST.

The user can select independently for each output signal CC6xO and COUT6xO if it should be active before or after the compare value has been reached (see register **CMPSTAT**). With this selection, the active (conducting) phases of complementary power switches in a power inverter bridge leg can be positioned with respect to the compare value (e.g. signal CC6xO can be active before, whereas COUT6xO can be active after the compare value is reached). Like this, the output modulation, the trap logic and the output level selection can be programmed independently for each output signal, although two output signals are referring to the same compare channel.

26.2.4.3 Output Modulation and Level Selection

The last block of the data path is the Output Modulation block. Here, all the modulation sources and the trap functionality are combined and control the actual level of the output pins (controlled by the modulation enable bits T1xMODENy and MCMEN in register **MODCTR**). The following signal sources can be combined here **for each T12 output signal** (see **Figure 26-18** for compare channel CC60):

- A **T12 related compare signal** CC6x_O (for outputs CC6x) or COUT6x_O (for outputs COUT6x) delivered by the T12 block (state selection with dead-time) with an individual enable bit T12MODENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)
- The **T13 related compare signal** CC63_O delivered by the T13 state selection with an individual enable bit T13MODENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)
- A **multi-channel output signal** MCMPy (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x) with a common enable bit MCMEN
- The **trap state** TRPS with an individual enable bit TRPENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)

If one of the modulation input signals CC6x_O/COUT6x_O, CC63_O, or MCMPy of an output modulation block is enabled and is at passive state, the modulated is also in passive state, regardless of the state of the other signals that are enabled. Only if all enabled signals are in active state the modulated output shows an active state. If no modulation input is enabled, the output is in passive state.
If the Trap State is active (TRPS = 1), then the outputs that are enabled for the trap signal (by TRPENy = 1) are set to the passive state.

The output of each of the modulation control blocks is connected to a level select block that is configured by register **PSLR**. It offers the option to determine the actual output level of a pin, depending on the state of the output line (decoupling of active/passive state and output polarity) as specified by the Passive State Select bit PSLy. If the modulated output signal is in the passive state, the level specified directly by PSLy is output. If it is in the active state, the inverted level of PSLy is output. This allows the user to adapt the polarity of an active output signal to the connected circuitry.

The PSLy bits have shadow registers to allow for updates without undesired pulses on the output lines. The bits related to CC6x and COUT6x (x = 0, 1, 2) are updated with the T12 shadow transfer signal (T12_ST). A read action returns the actually used values, whereas a write action targets the shadow bits. Providing a shadow register for the PSL value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

Figure 26-18 shows the output modulation structure for compare channel CC60 (output signals CC60 and COUT60). A similar structure is implemented for the other two compare channels CC61 and CC62.

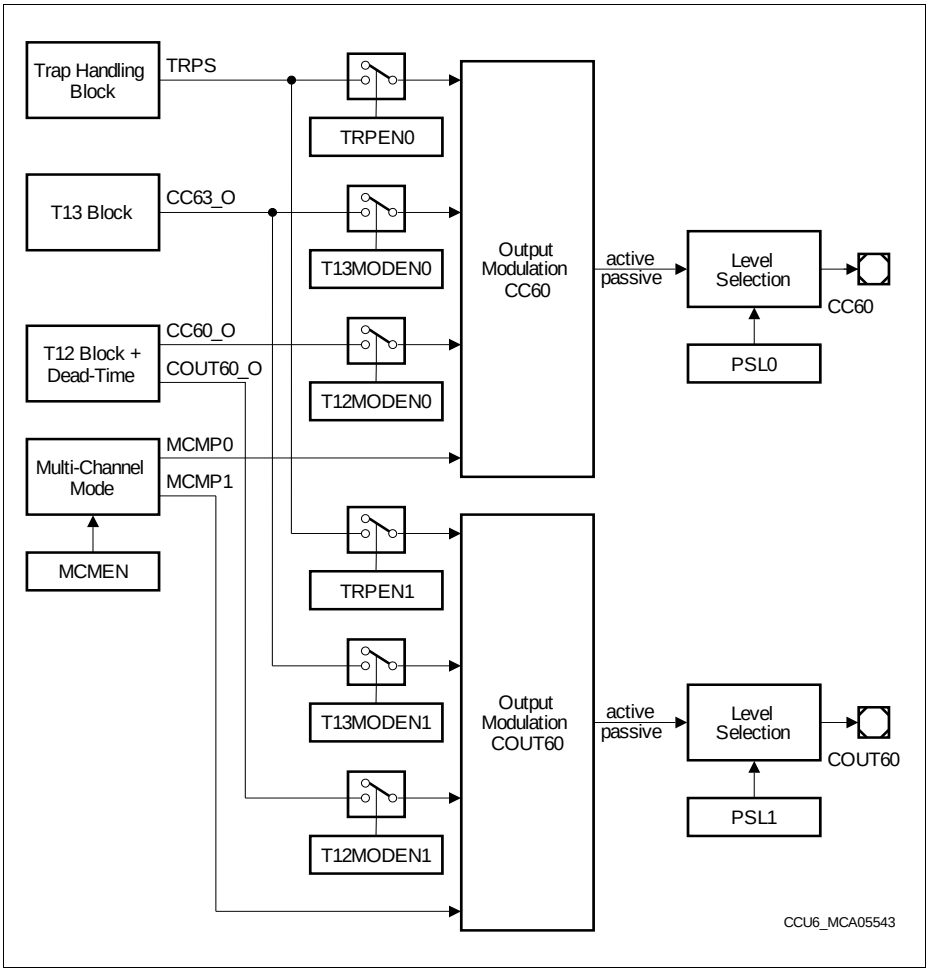

Figure 26-18 Output Modulation for Compare Channel CC60

26.2.5 T12 Capture Modes

Each of the three channels of the T12 Block can also be used to capture T12 time information in response to an external signal CC6xIN.
In capture mode, the interrupt event CC6x_R is detected when a rising edge is detected at the input CC6xIN, whereas the interrupt event CC6x_F is detected when a falling edge is detected.

There are a number of different modes for capture operation. In all modes, both of the registers of a channel are used. The selection of the capture modes is done via the **T12MSEL**.MSEL6x bit fields and can be selected individually for each of the channels.

Table 26-3 Capture Modes Overview

MSEL6x	Mode	Signal	Active Edge	CC6nSR Stored in	T12 Stored in
0100_B	1	CC6xIN	Rising	–	CC6xR
		CC6xIN	Falling	–	CC6xSR
0101_B	2	CC6xIN	Rising	CC6xR	CC6xSR
0110_B	3	CC6xIN	Falling	CC6xR	CC6xSR
0111_B	4	CC6xIN	Any	CC6xR	CC6xSR

Figure 26-19 illustrates **Capture Mode 1**. When a rising edge (0-to-1 transition) is detected at the corresponding input signal CC6xIN, the current contents of Timer T12 are captured into register CC6xR. When a falling edge (1-to-0 transition) is detected at the input signal CC6xIN, the contents of Timer T12 are captured into register CC6xSR.

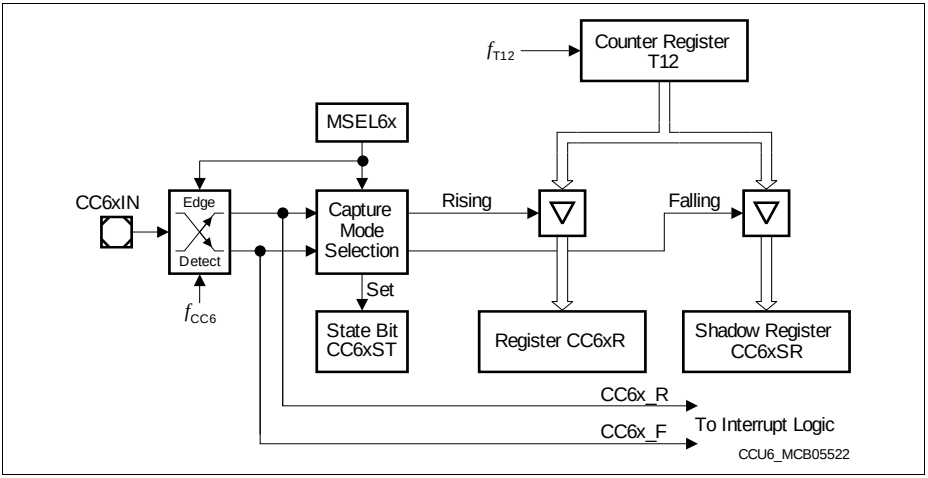

Figure 26-19 Capture Mode 1 Block Diagram

Capture Modes 2, 3 and 4 are shown in **Figure 26-20**. They differ only in the active edge causing the capture operation. In each of the three modes, when the selected edge is detected at the corresponding input signal CC6xIN, the current contents of the shadow register CC6xSR are transferred into register CC6xR, and the current Timer T12 contents are captured in register CC6xSR (simultaneous transfer). The active edge is a rising edge of CC6xIN for Capture Mode 2, a falling edge for Mode 3, and both, a rising or a falling edge for Capture Mode 4, as shown in **Table 26-3**. These capture modes are very useful in cases where there is little time between two consecutive edges of the input signal.

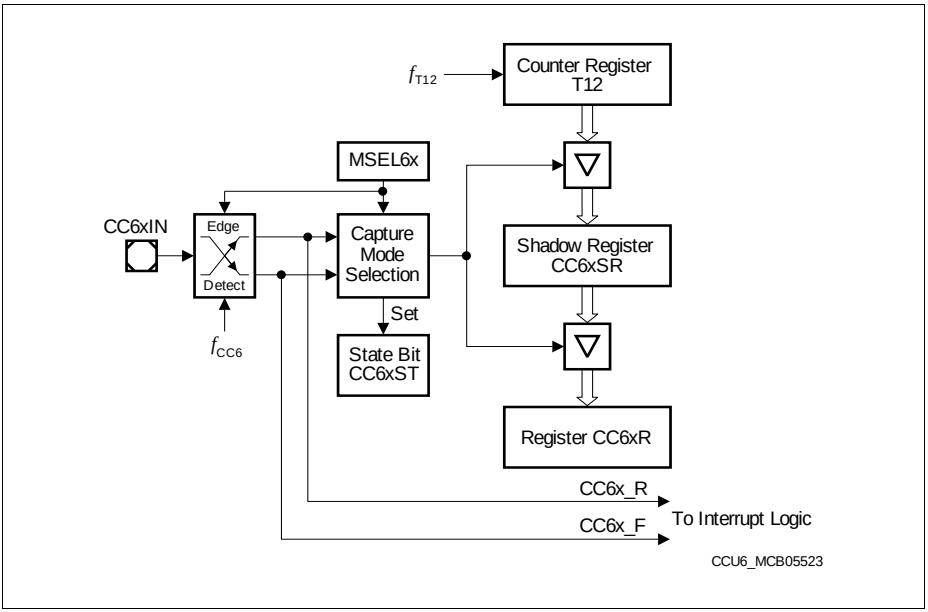

Figure 26-20 Capture Modes 2, 3 and 4 Block Diagram

Five further capture modes are called **Multi-Input Capture Modes**, as they use two different external inputs, signal CC6xIN and signal CCPOSx.

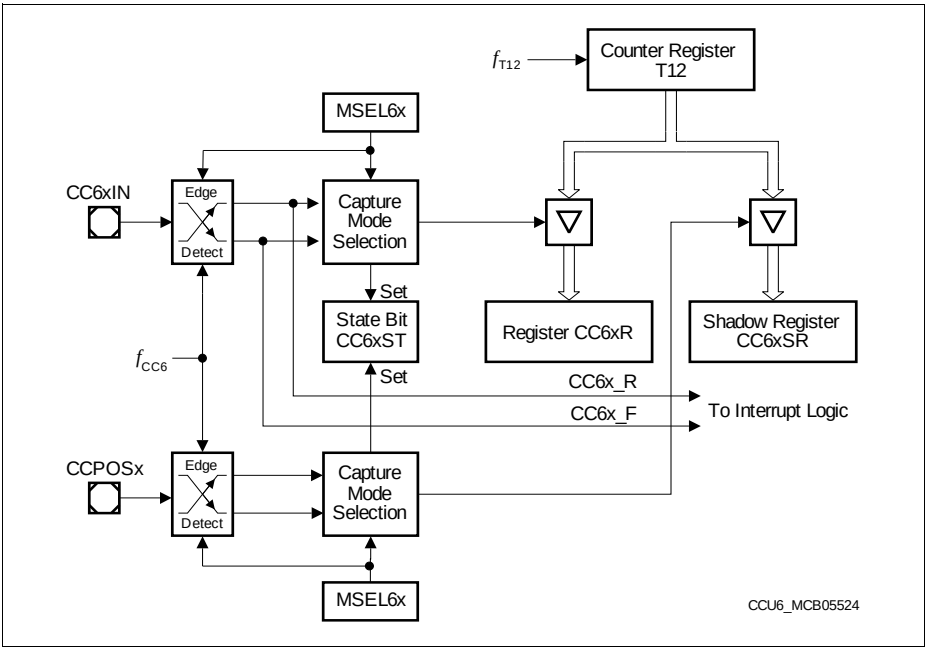

Figure 26-21 Multi-Input Capture Modes Block Diagram

In each of these modes, the current T12 contents are captured in register CC6xR in response to a selected event at signal CC6xIN, and in register CC6xSR in response to a selected event at signal CCPOSx. The possible events can be opposite input transitions, or the same transitions, or any transition at the two inputs. The different options are detailed in **Table 26-4**.

In each of the various capture modes, the Channel State Bit, CC6xST, is set to 1 when the selected capture trigger event at signal CC6xIN or CCPOSx has occurred. The State Bit is not cleared by hardware, but can be cleared by software.

In addition, appropriate signal lines to the interrupt logic are activated, that can generate an interrupt request to the CPU. Regardless of the selected active edge, all edges detected at signal CC6xIN can lead to the activation of the appropriate interrupt request line (see also **Section 26.9**).

Table 26-4 Multi-Input Capture Modes Overview

MSEL6x	Mode	Signal	Active Edge	T12 Stored in
1010_B	5	CC6xIN	Rising	CC6xR
		CCPOSx	Falling	CC6xSR
1011_B	6	CC6xIN	Falling	CC6xR
		CCPOSx	Rising	CC6xSR
1100_B	7	CC6xIN	Rising	CC6xR
		CCPOSx	Rising	CC6xSR
1101_B	8	CC6xIN	Falling	CC6xR
		CCPOSx	Falling	CC6xSR
1110_B	9	CC6xIN	Any	CC6xR
		CCPOSx	Any	CC6xSR
1111_B	–	reserved (no capture or compare action)		

26.2.6 T12 Shadow Register Transfer

A special shadow transfer signal (T12_ST) can be generated to facilitate updating the period and compare values of the compare channels CC60, CC61, and CC62 synchronously to the operation of T12. Providing a shadow register for values defining one PWM period facilitates a concurrent update by software for all relevant parameters. The next PWM period can run with a new set of parameters. The generation of this signal is requested by software via bit **TCTR0**.STE12 (set by writing 1 to the write-only bit **TCTR4**.T12STR, cleared by writing 1 to the write-only bit **TCTR4**.T12STD).

Figure 26-22 shows the shadow register structure and the shadow transfer signals, as well as on the read/write accessibility of the various registers.

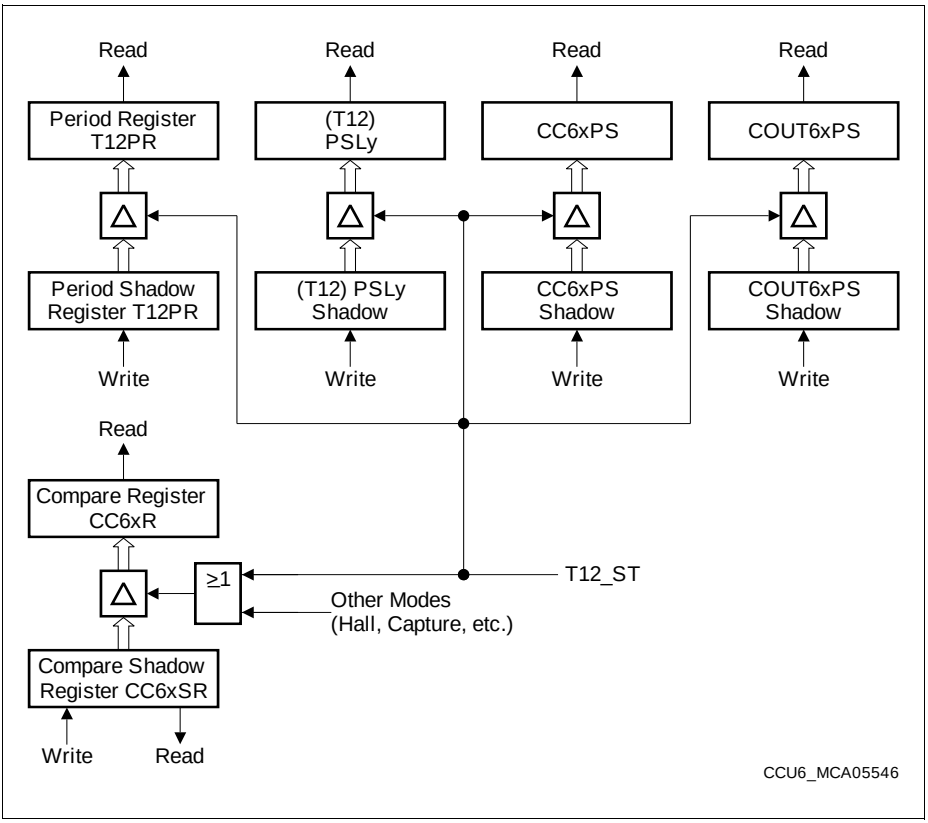

Figure 26-22 T12 Shadow Register Overview

A T12 shadow register transfer takes place (T12_ST active):

- while timer T12 is not running (T12R = 0), or
- STE12 = 1 and a Period-Match is detected while counting up, or
- STE12 = 1 and a One-Match is detected while counting down

When signal T12_ST is active, a shadow register transfer is triggered with the next cycle of the T12 clock. Bit STE12 is automatically cleared with the shadow register transfer.

26.2.7 Timer T12 Operating Mode Selection

The operating mode for the T12 channels are defined by the bit fields **T12MSEL**.MSEL6x.

Table 26-5 T12 Capture/Compare Modes Overview

MSEL6x	Selected Operating Mode
0000_B, 1111_B	Capture/Compare modes switched off
0001_B, 0010_B, 0011_B	Compare mode, see **Section 26.2.3** same behavior for all three codings
$01XX_B$	Double-Register Capture modes, see **Section 26.2.5**
1000_B	Hall Sensor Mode, see **Section 26.7** In order to properly enable this mode, all three MSEL6x fields have to be programmed to Hall Sensor mode.
1001_B	Hysteresis-like compare mode, see **Section 26.2.3.3**
1010_B 1011_B, 1100_B, 1101_B 1110_B	Multi-Input Capture modes, see **Section 26.2.5**

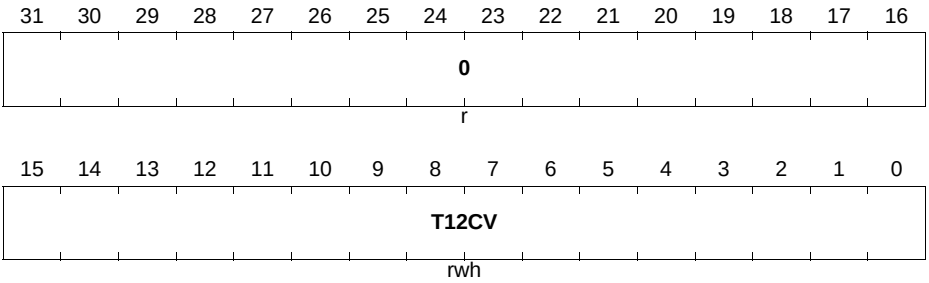
The clocking and counting scheme of the timers are controlled by the timer control registers **TCTR0** and **TCTR2**. Specific actions are triggered by write operations to register **TCTR4**.

26.2.8 T12 related Registers

26.2.8.1 T12 Counter Register

Register T12 represents the counting value of timer T12. It can only be written while the timer T12 is stopped. Write actions while T12 is running are not taken into account. Register T12 can always be read by SW.
In edge-aligned mode, T12 only counts up, whereas in center-aligned mode, T12 can count up and down.

T12
Timer T12 Counter Register **(20_H)** **Reset Value: 0000 0000_H**



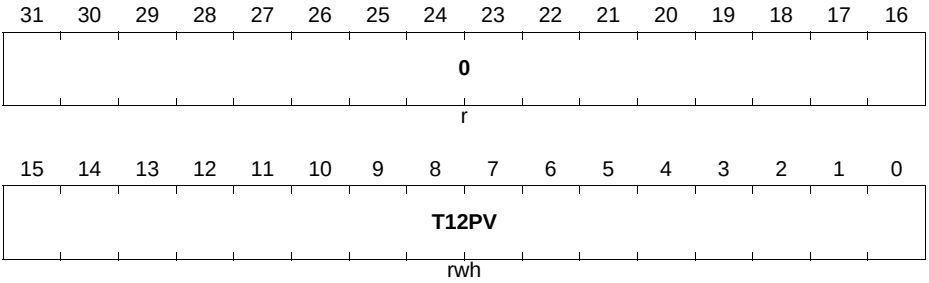
Field	Bits	Type	Description
T12CV	[15:0]	rwh	**Timer 12 Counter Value** This register represents the 16-bit counter value of Timer12.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

Note: While timer T12 is stopped, the internal clock divider is reset in order to ensure reproducible timings and delays.

26.2.8.2 Period Register

Register T12PR contains the period value for timer T12. The period value is compared to the actual counter value of T12 and the resulting counter actions depend on the defined counting rules. This register has a shadow register and the shadow transfer is controlled by bit STE12. A read action by SW delivers the value that is currently used for the compare action, whereas the write action targets a shadow register. The shadow register structure allows a concurrent update of all T12-related values.

T12PR
Timer 12 Period Register **(24_H)** **Reset Value: 0000 0000_H**

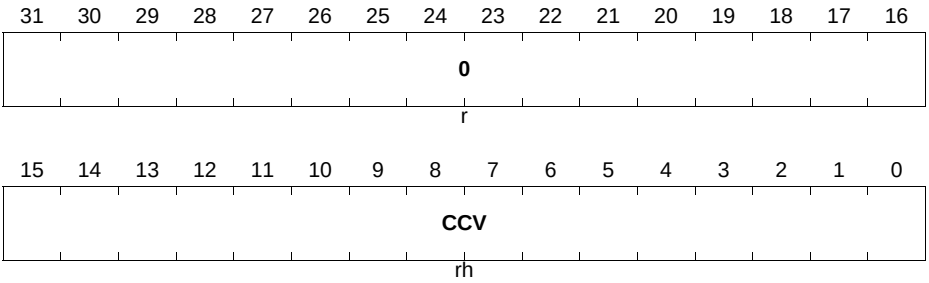


Field	Bits	Type	Description
T12PV	[15:0]	rwh	**T12 Period Value** The value T12PV defines the counter value for T12 leading to a period-match. When reaching this value, the timerT12 is set to zero (edge-aligned mode) or changes its count direction to down counting (center-aligned mode).
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.2.8.3 Capture/Compare Registers

In compare mode, the registers CC6xR (x = 0 - 2) are the actual compare registers for T12. The values stored in CC6xR are compared (all three channels in parallel) to the counter value of T12. In capture mode, the current value of the T12 counter register is captured by registers CC6xR if the corresponding capture event is detected.

CC6xR (x = 0-2)
Capture/Compare Register for Channel CC6x
(30_H + 4*x) **Reset Value: 0000 0000_H**

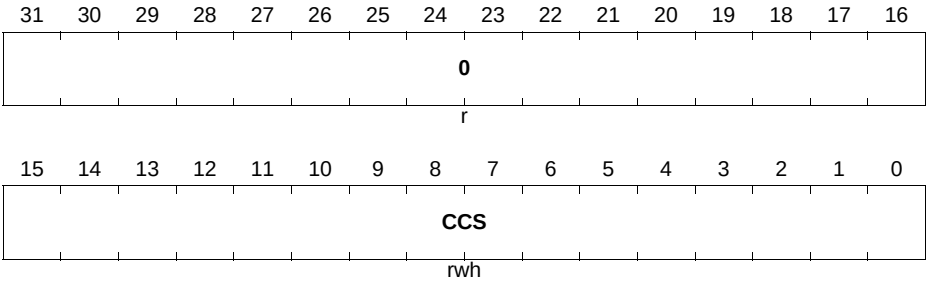


Field	Bits	Type	Description
CCV	[15:0]	rh	**Capture/Compare Value** In compare mode, the bit fields CCV contain the values, that are compared to the T12 counter value. In capture mode, the captured value of T12 can be read from these registers.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.2.8.4 Capture/Compare Shadow Registers

The registers CC6xR can only be read by SW, the modification of the value is done by a shadow register transfer from register CC6xSR. The corresponding shadow registers CC6xSR can be read and written by SW. In capture mode, the value of the T12 counter register can also be captured by registers CC6xSR if the selected capture event is detected (depending on the selected capture mode).

CC6xSR (x=0-2)
Capture/Compare Shadow Reg. for Channel CC6x
(40_H+4*x) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CCS	[15:0]	rwh	**Shadow Register for Channel x Capture/Compare Value** In compare mode, the bit fields contents of CCS are transferred to the bit fields CCV for the corresponding channel during a shadow transfer. In capture mode, the captured value of T12 can be read from these registers.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

Note: The shadow registers can also be written by SW in capture mode. In this case, the HW capture event wins over the SW write if both happen in the same cycle (the SW write is discarded).

26.2.8.5 Dead-time Control Register

Register T12DTC controls the dead-time generation for the timer T12 compare channels. Each channel can be independently enabled/disabled for dead-time generation. If enabled, the transition from passive state to active state is delayed by the value defined by bit field DTM.
The dead time counters are clocked with the same frequency as T12.
This structure allows symmetrical dead-time generation in center-aligned and in edge-aligned PWM mode. A duty cycle of 50% leads to CC6x, COUT6x switched on for: 0.5 * period - dead time.

Note: The dead-time counters are not reset by bit T12RES, but by bit DTRES.

T12DTC
Dead-Time Control Register for Timer12

(28_H) **Reset Value: 0000 0000$_H$**

Field	Bits	Type	Description
DTM	[7:0]	rw	**Dead-Time** Bit field DTM determines the programmable delay between switching from the passive state to the active state of the selected outputs. The switching from the active state to the passive state is not delayed.
DTE2, DTE1, DTE0	10, 9, 8	rw	**Dead Time Enable Bits** Bits DTE0..DTE2 enable and disable the dead time generation for each compare channel (0, 1, 2) of timer T12. 0_B Dead-Time Counter x is disabled. The corresponding outputs switch from the passive state to the active state (according to the actual compare status) without any delay. 1_B Dead-Time Counter x is enabled. The corresponding outputs switch from the passive state to the active state (according to the compare status) with the delay programmed in bit field DTM.
DTR2, DTR1, DTR0	14, 13, 12	rh	**Dead Time Run Indication Bits** Bits DTR0..DTR2 indicate the status of the dead time generation for each compare channel (0, 1, 2) of timer T12. 0_B Dead-Time Counter x is currently in the passive state. 1_B Dead-Time Counter x is currently in the active state.
0	11, [31:15]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.2.9 Capture/Compare Control Registers

26.2.9.1 Channel State Bits

The Compare State Register CMPSTAT contains status bits monitoring the current capture and compare state and control bits defining the active/passive state of the compare channels.

CMPSTAT
Compare State Register **(60_H)** **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CC60ST, CC61ST, CC62ST, CC63ST [1]	0, 1, 2, 6	rh	**Capture/Compare State Bits** Bits CC6xST monitor the state of the capture/compare channels. Bits CC6xST (x = 0, 1, 2) are related to T12, bit CC63ST is related to T13. 0_B In compare mode, the timer count is less than the compare value. In capture mode, the selected edge has not yet been detected since the bit has been cleared by SW the last time. 1_B In compare mode, the counter value is greater than or equal to the compare value. In capture mode, the selected edge has been detected.
CCPOS60, CCPOS61, CCPOS62	3, 4, 5	rh	**Sampled Hall Pattern Bits** Bits CCPOS6x (x = 0, 1, 2) are indicating the value of the input Hall pattern that has been compared to the current and expected value. The value is sampled when the event HCRDY (Hall Compare Ready) occurs. 0_B The input CCPOSx has been sampled as 0. 1_B The input CCPOSx has been sampled as 1.
CC60PS, CC61PS, CC62PS, COUT60PS, COUT61PS, COUT62PS, COUT63PS [2]	8, 10, 12, 9, 11, 13, 14	rwh	**Passive State Select for Compare Outputs** Bits CC6xPS, COUT6xPS select the state of the corresponding compare channel, that is considered to be the passive state. During the passive state, the passive level (defined in register PSLR) is driven by the output pin. Bits CC6xPS, COUT6xPS (x = 0, 1, 2) are related to T12, bit CC63PS is related to T13. 0_B The corresponding compare signal is in passive state while CC6xST is 0. 1_B The corresponding compare signal is in passive state while CC6xST is 1. In capture mode, these bits are not used.

Field	Bits	Type	Description
T13IM 3)	15	rwh	**T13 Inverted Modulation** Bit T13IM inverts the T13 signal for the modulation of the CC6x and COUT6x (x = 0, 1, 2) signals. 0_B T13 output CC63_O is equal to CC63ST. 1_B T13 output CC63_O is equal to $\overline{CC63ST}$.
0	7, [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

1) These bits are set and cleared according to the T12, T13 switching rules

2) These bits have shadow bits and are updated in parallel to the capture/compare registers of T12, T13 respectively. A read action targets the actually used values, whereas a write action targets the shadow bits.

3) This bit has a shadow bit and is updated in parallel to the compare and period registers of T13. A read action targets the actually used values, whereas a write action targets the shadow bit.

The Compare Status Modification Register CMPMODIF provides software-control (independent set and clear conditions) for the channel state bits CC6xST. This feature enables the user to individually change the status of the output lines by software, for example when the corresponding compare timer is stopped.

CMPMODIF
Compare State Modification Register

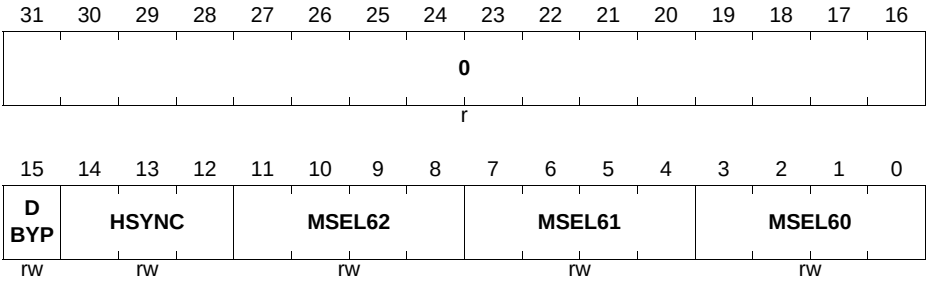
Field	Bits	Type	Description
MCC60S, MCC61S, MCC62S, MCC63S, MCC60R, MCC61R, MCC62R, MCC63R	0, 1, 2, 6, 8, 9, 10, 14	w	**Capture/Compare Status Modification Bits** These bits are used to bits to set (MCC6xS) or to clear (MCC6xR) the corresponding bits CC6xST by SW. This feature allows the user to individually change the status of the output lines by SW, e.g. when the corresponding compare timer is stopped. This allows a bit manipulation of CC6xST-bits by a single data write action. The following functionality of a write access to bits concerning the same capture/compare state bit is provided: [MCC6xR, MCC6xS] = 00_B Bit CC6xST is not changed. 01_B Bit CC6xST is set. 10_B Bit CC6xST is cleared. 11_B reserved
0	[5:3], 7, [13:11], [31:15]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.2.9.2 T12 Mode Control Register

Register T12MSEL contains control bits to select the capture/compare functionality of the three channels of Timer T12.

T12MSEL
T12 Mode Select Register **(68_H)** **Reset Value: 0000 0000$_H$**



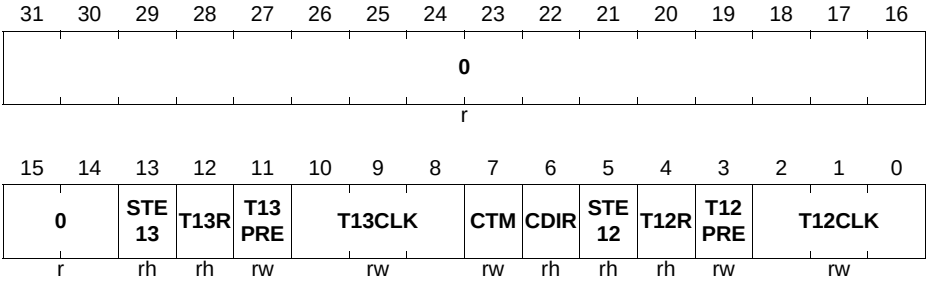
Field	Bits	Type	Description
MSEL60, MSEL61, MSEL62	[3:0], [7:4], [11:8]	rw	**Capture/Compare Mode Selection** These bit fields select the operating mode of the three T12 capture/compare channels. Each channel (x = 0, 1, 2) can be programmed individually for one of these modes (except for Hall Sensor Mode). Coding see **Table 26-5**.
HSYNC	[14:12]	rw	**Hall Synchronization** Bit field HSYNC defines the source for the sampling of the Hall input pattern and the comparison to the current and the expected Hall pattern bit fields. Coding see **Table 26-11**.
DBYP	15	rw	**Delay Bypass** DBYP controls whether the source signal for the sampling of the Hall input pattern (selected by HSYNC) is delayed by the Dead-Time Counter 0. 0_B The bypass is not active. Dead-Time Counter 0 is generating a delay after the source signal becomes active. 1_B The bypass is active. Dead-Time Counter 0 is not used for a delay.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.2.9.3 Timer Control Registers

Register TCTR0 controls the basic functionality of both timers, T12 and T13.

Note: A write action to the bit fields T12CLK or T12PRE is only taken into account while the timer T12 is not running (T12R=0). A write action to the bit fields T13CLK or T13PRE is only taken into account while the timer T13 is not running (T13R=0).

TCTR0
Timer Control Register 0 **(70_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T12CLK	[2:0]	rw	**Timer T12 Input Clock Select** Selects the input clock for timer T12 that is derived from the peripheral clock according to the equation $f_{T12} = f_{CC6} / 2^{<T12CLK>}$. 000_B $f_{T12} = f_{CC6}$ 001_B $f_{T12} = f_{CC6} / 2$ 010_B $f_{T12} = f_{CC6} / 4$ 011_B $f_{T12} = f_{CC6} / 8$ 100_B $f_{T12} = f_{CC6} / 16$ 101_B $f_{T12} = f_{CC6} / 32$ 110_B $f_{T12} = f_{CC6} / 64$ 111_B $f_{T12} = f_{CC6} / 128$
T12PRE	3	rw	**Timer T12 Prescaler Bit** In order to support higher clock frequencies, an additional prescaler factor of 1/256 can be enabled for the prescaler for T12. 0_B The additional prescaler for T12 is disabled. 1_B The additional prescaler for T12 is enabled.

Field	Bits	Type	Description
T12R	4	rh	**Timer T12 Run Bit**[1)] T12R starts and stops timer T12. It is set/cleared by SW by setting bits T12RR or T12RS or it is cleared by HW according to the function defined by bit field T12SSC. 0_B Timer T12 is stopped. 1_B Timer T12 is running.
STE12	5	rh	**Timer T12 Shadow Transfer Enable** Bit STE12 enables or disables the shadow transfer of the T12 period value, the compare values and passive state select bits and levels from their shadow registers to the actual registers if a T12 shadow transfer event is detected. Bit STE12 is cleared by hardware after the shadow transfer. A T12 shadow transfer event is a period-match while counting up or a one-match while counting down. 0_B The shadow register transfer is disabled. 1_B The shadow register transfer is enabled.
CDIR	6	rh	**Count Direction of Timer T12** This bit is set/cleared according to the counting rules of T12. 0_B T12 counts up. 1_B T12 counts down.
CTM	7	rw	**T12 Operating Mode** 0_B Edge-aligned Mode: T12 always counts up and continues counting from zero after reaching the period value. 1_B Center-aligned Mode: T12 counts down after detecting a period-match and counts up after detecting a one-match.

Field	Bits	Type	Description
T13CLK	[10:8]	rw	**Timer T13 Input Clock Select** Selects the input clock for timer T13 that is derived from the peripheral clock according to the equation $f_{T13} = f_{CC6} / 2^{<T13CLK>}$. 000_B $f_{T13} = f_{CC6}$ 001_B $f_{T13} = f_{CC6} / 2$ 010_B $f_{T13} = f_{CC6} / 4$ 011_B $f_{T13} = f_{CC6} / 8$ 100_B $f_{T13} = f_{CC6} / 16$ 101_B $f_{T13} = f_{CC6} / 32$ 110_B $f_{T13} = f_{CC6} / 64$ 111_B $f_{T13} = f_{CC6} / 128$
T13PRE	11	rw	**Timer T13 Prescaler Bit** In order to support higher clock frequencies, an additional prescaler factor of 1/256 can be enabled for the prescaler for T13. 0_B The additional prescaler for T13 is disabled. 1_B The additional prescaler for T13 is enabled.
T13R	12	rh	**Timer T13 Run Bit**[2)] T13R starts and stops timer T13. It is set/cleared by SW by setting bits T13RR orT13RS or it is set/cleared by HW according to the function defined by bit fields T13SSC, T13TEC and T13TED. 0_B Timer T13 is stopped. 1_B Timer T13 is running.
STE13	13	rh	**Timer T13 Shadow Transfer Enable** Bit STE13 enables or disables the shadow transfer of the T13 period value, the compare value and passive state select bit and level from their shadow registers to the actual registers if a T13 shadow transfer event is detected. Bit STE13 is cleared by hardware after the shadow transfer. A T13 shadow transfer event is a period-match. 0_B The shadow register transfer is disabled. 1_B The shadow register transfer is enabled.
0	[31:14]	r	**Reserved;** Returns 0 if read; should be written with 0.

1) A concurrent set/clear action on T12R (from T12SSC, T12RR or T12RS) will have no effect. The bit T12R will remain unchanged.

2) A concurrent set/cleared action on T13R (from T13SSC, T13TEC, T13RR or T13RS) will have no effect. The bit T12R will remain unchanged.

Register TCTR2 controls the single-shot and the synchronization functionality of both timers T12 and T13. Both timers can run in single-shot mode. In this mode they stop their counting sequence automatically after one counting period with a count value of zero. The single-shot mode and the synchronization feature of T13 to T12 allow the generation of events with a programmable delay after well-defined PWM actions of T12.

Field	Bits	Type	Description
T12SSC	0	rw	**Timer T12 Single Shot Control** This bit controls the single shot-mode of T12. 0_B The single-shot mode is disabled, no HW action on T12R. 1_B The single shot mode is enabled, the bit T12R is cleared by HW if - T12 reaches its period value in edge-aligned mode - T12 reaches the value 1 while down counting in center-aligned mode. In parallel to the clear action of bit T12R, the bits CC6xST (x=0, 1, 2) are cleared.
T13SSC	1	rw	**Timer T13 Single Shot Control** This bit controls the single shot-mode of T13. 0_B No HW action on T13R 1_B The single-shot mode is enabled, the bit T13R is cleared by HW if T13 reaches its period value. In parallel to the clear action of bit T13R, the bit CC63ST is cleared.

Field	Bits	Type	Description
T13TEC	[4:2]	rw	**T13 Trigger Event Control** Bit field T13TEC selects the trigger event to start T13 (automatic set of T13R for synchronization to T12 compare signals) according to following combinations: 000_B no action 001_B set T13R on a T12 compare event on channel 0 010_B set T13R on a T12 compare event on channel 1 011_B set T13R on a T12 compare event on channel 2 100_B set T13R on any T12 compare event (ch. 0, 1, 2) 101_B set T13R upon a period-match of T12 110_B set T13R upon a zero-match of T12 (while counting up) 111_B set T13R on any edge of inputs CCPOSx
T13TED	[6:5]	rw	**Timer T13 Trigger Event Direction**[1)] Bit field T13TED delivers additional information to control the automatic set of bit T13R in the case that the trigger action defined by T13TEC is detected. 00_B reserved, no action 01_B while T12 is counting up 10_B while T12 is counting down 11_B independent on the count direction of T12
T12RSEL	[9:8]	rw	**Timer T12 External Run Selection** Bit field T12RSEL defines the event of signal T12HR that can set the run bit T12R by HW. 00_B The external setting of T12R is disabled. 01_B Bit T12R is set if a rising edge of signal T12HR is detected. 10_B Bit T12R is set if a falling edge of signal T12HR is detected. 11_B Bit T12R is set if an edge of signal T12HR is detected.

Field	Bits	Type	Description
T13RSEL	[11:10]	rw	**Timer T13 External Run Selection** Bit field T13RSEL defines the event of signal T13HR that can set the run bit T13R by HW. 00_B The external setting of T13R is disabled. 01_B Bit T13R is set if a rising edge of signal T13HR is detected. 10_B Bit T13R is set if a falling edge of signal T13HR is detected. 11_B Bit T13R is set if an edge of signal T13HR is detected.
0	7, [31:12]	r	**Reserved;** Returns 0 if read; should be written with 0;

1) Example:
If the timer T13 is intended to start at any compare event on T12 (T13TEC=100) the trigger event direction can be programmed to
- counting up >> a T12 channel 0, 1, 2 compare match triggers T13R only while T12 is counting up
- counting down >> a T12 channel 0, 1, 2 compare match triggers T13R only while T12 is counting down
- independent from bit CDIR >> each T12 channel 0, 1, 2 compare match triggers T13R

The timer count direction is taken from the value of bit CDIR. As a result, if T12 is running in edge-aligned mode (counting up only), T13 can only be started automatically if bit field T13TED=01 or 11.

Register TCTR4 provides software-control (independent set and clear conditions) for the run bits T12R and T13R. Furthermore, the timers can be reset (while running) and bits STE12 and STE13 can be controlled by software. Reading these bits always returns 0.

TCTR4

T12RS	1	w	**Timer T12 Run Set** Setting this bit sets the T12R bit. 0_B T12R is not influenced. 1_B T12R is set, T12 starts counting.
T12RES	2	w	**Timer T12 Reset** 0_B No effect on T12. 1_B The T12 counter register is cleared to zero. The switching of the output signals is according to the switching rules. Setting of T12RES has no impact on bit T12R.
DTRES	3	w	**Dead-Time Counter Reset** 0_B No effect on the dead-time counters. 1_B The three dead-time counter channels are cleared to zero.
T12CNT	5	w	**Timer T12 Count Event** 0_B No action 1_B If enabled (PISEL2), timer T12 counts one step.

Field	Bits	Type	Description
T12STR	6	w	**Timer T12 Shadow Transfer Request** 0_B No action 1_B STE12 is set, enabling the shadow transfer.
T12STD	7	w	**Timer T12 Shadow Transfer Disable** 0_B No action 1_B STE12 is cleared without triggering the shadow transfer.
T13RR	8	w	**Timer T13 Run Reset** Setting this bit clears the T13R bit. 0_B T13R is not influenced. 1_B T13R is cleared, T13 stops counting.
T13RS	9	w	**Timer T13 Run Set** Setting this bit sets the T13R bit. 0_B T13R is not influenced. 1_B T13R is set, T13 starts counting.
T13RES	10	w	**Timer T13 Reset** 0_B No effect on T13. 1_B The T13 counter register is cleared to zero. The switching of the output signals is according to the switching rules. Setting of T13RES has no impact on bit T13R.
T13CNT	13	w	**Timer T13 Count Event** 0_B No action 1_B If enabled (PISEL2), timer T13 counts one step.
T13STR	14	w	**Timer T13 Shadow Transfer Request** 0_B No action 1_B STE13 is set, enabling the shadow transfer.
T13STD	15	w	**Timer T13 Shadow Transfer Disable** 0_B No action 1_B STE13 is cleared without triggering the shadow transfer.
0	4, [12:11], [31:16]	r	**reserved;** returns 0 if read; should be written with 0;

Note: A simultaneous write of a 1 to bits that set and clear the same bit will trigger no action. The corresponding bit will remain unchanged.

26.3 Operating Timer T13

Timer T13 is implemented similarly to Timer T12, but only with one channel in compare mode. A 16-bit up-counter is connected to a channel register via a comparator, that generates a signal when the counter contents match the contents of the channel register. A variety of control functions facilitate the adaptation of the T13 structure to different application needs. In addition, T13 can be started synchronously to timer T12 events.

This section provides information about:

- T13 overview (see **Section 26.3.1**)
- Counting scheme (see **Section 26.3.2**)
- Compare mode (see **Section 26.3.3**)
- Compare output path (see **Section 26.3.4**)
- Shadow register transfer (see **Section 26.3.5**)
- T13 counter register description (see **Section 26.3.6**)

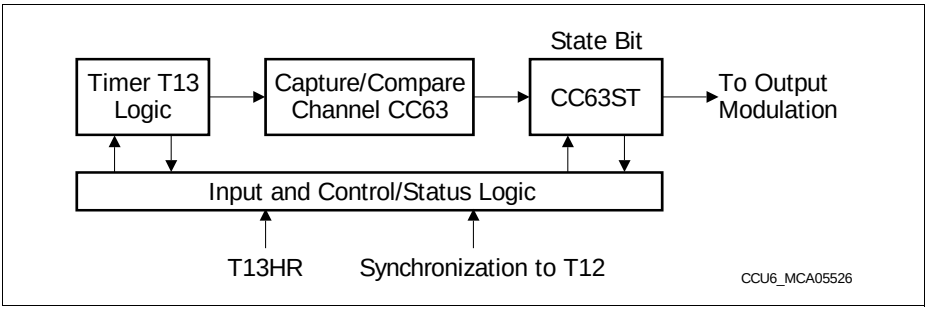

Figure 26-23 Overview Diagram of the Timer T13 Block

26.3.1 T13 Overview

Figure 26-24 shows a detailed block diagram of Timer T13. The functions of the timer T12 block are controlled by bits in registers **TCTR0**, **TCTR2**, and **PISEL2**.
Timer T13 receives its input clock, f_{T13}, from the module clock f_{CC6} via a programmable prescaler and an optional 1/256 divider or from an input signal T13HR. T13 can only count up (similar to the Edge-Aligned mode of T12).

Via a comparator, the timer T13 Counter Register **T13** is connected to the Period Register **T13PR**. This register determines the maximum count value for T13. When T13 reaches the period value, signal T13_PM (T13 Period Match) is generated and T13 is cleared to 0000_H with the next T13 clock edge. The Period Register receives a new period value from its Shadow Period Register, T13PS, that is loaded via software. The transfer of a new period value from the shadow register into T13PR is controlled via the 'T13 Shadow Transfer' control signal, T13_ST. The generation of this signal depends on the associated control bit STE13. Providing a shadow register for the period value as

well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters (refer to **Table 26.3.5**).
Another signal indicates whether the counter contents are equal to 0000_H (T13_ZM).

A Single-Shot control bit, T13SSC, enables an automatic stop of the timer when the current counting period is finished (see **Figure 26-26**).

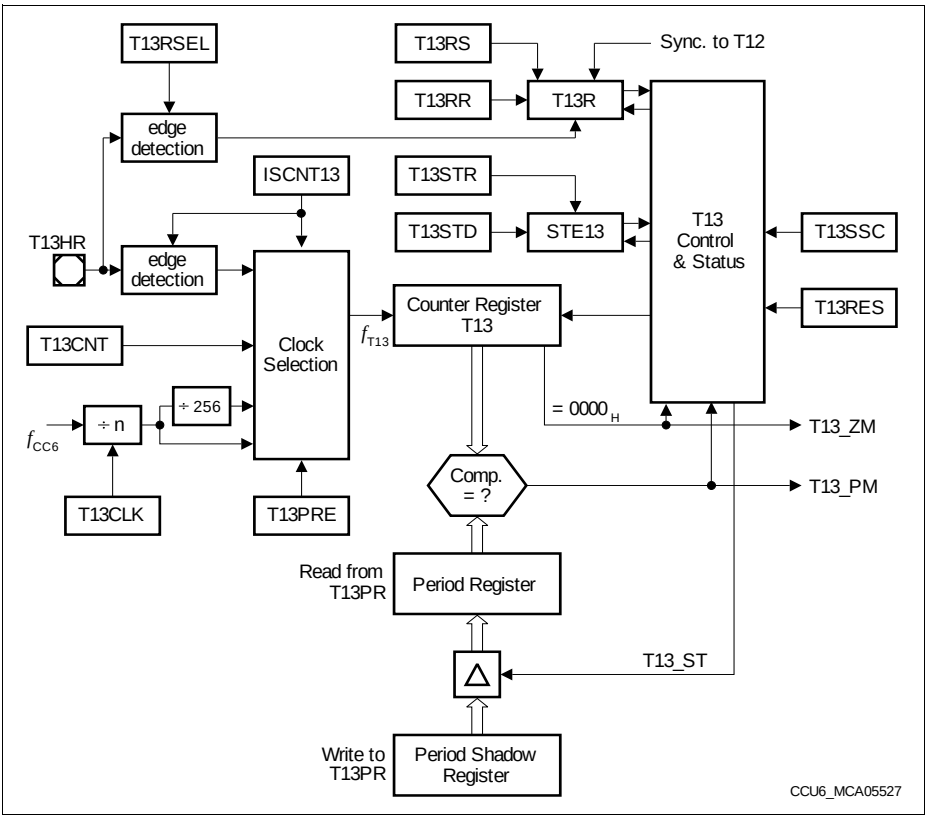

Figure 26-24 T13 Counter Logic and Period Comparators

The start or stop of T13 is controlled by the Run bit, T13R. This control bit can be set by software via the associated set/clear bits T13RS or T13RR in register **TCTR4**, or it is cleared by hardware according to preselected conditions (single-shot mode).
The timer T13 run bit T13R must not be set while the applied T13 period value is zero.
Bit T13R can be set automatically if an event of T12 is detected to synchronize T13 timings to T12 events, e.g. to generate a programmable delay via T13 after an edge of a T12 compare channel before triggering an AD conversion (T13 can trigger ADC

conversions).
Timer T13 can be cleared to 0000_H via control bit T13RES. Setting this write-only bit only clears the timer contents, but has no further effects, e.g., it does not stop the timer.

The generation of the T13 shadow transfer control signal, T13_ST, is enabled via bit STE13. This bit can be set or cleared by software indirectly through its associated set/reset control bits T13STR and T13STD.

Two bit fields, T13TEC and T13TED, control the synchronization of T13 to Timer T12 events. T13TEC selects the trigger event, while T13TED determines for which T12 count direction the trigger should be active.
While Timer T13 is running, write accesses to the count register T13 are not taken into account. If T13 is stopped, write actions to register T13 are immediately taken into account.

Note: The T13 Period Register and its associated shadow register are located at the same physical address. A write access to this address targets the Shadow Register, while a read access reads from the actual period register.

26.3.2 T13 Counting Scheme

This section describes the clocking and the counting capabilities of T13.

26.3.2.1 Clock Selection

In **Timer Mode** (**PISEL2**. ISCNT13 = 00_B), the input clock f_{T13} of Timer T13 is derived from the internal module clock f_{CC6} through a programmable prescaler and an optional 1/256 divider. The resulting prescaler factors are listed in **Table 26-6**. The prescaler of T13 is cleared while T13 is not running (**TCTR0**.T13R = 0) to ensure reproducible timings and delays.

Table 26-6 Timer T13 Input Clock Options

T13CLK	Resulting Input Clock f_{T13} Prescaler Off (T13PRE = 0)	Resulting Input Clock f_{T13} Prescaler On (T13PRE = 1)
000_B	f_{CC6}	f_{CC6} / 256
001_B	f_{CC6} / 2	f_{CC6} / 512
010_B	f_{CC6} / 4	f_{CC6} / 1024
011_B	f_{CC6} / 8	f_{CC6} / 2048
100_B	f_{CC6} / 16	f_{CC6} / 4096
101_B	f_{CC6} / 32	f_{CC6} / 8192
110_B	f_{CC6} / 64	f_{CC6} / 16384
111_B	f_{CC6} / 128	f_{CC6} / 32768

In **Counter Mode**, timer T13 counts one step:

- If a 1 is written to **TCTR4**.T13CNT and **PISEL2**.ISCNT13 = 01_B
- If a rising edge of input signal T13HR is detected and **PISEL2**.ISCNT13 = 10_B
- If a falling edge of input signal T13HR is detected and **PISEL2**.ISCNT13 = 11_B

26.3.2.2 T13 Counting

The period of the timer is determined by the value in the period Register T13PR according to the following formula:

$T13_{PER}$ = <Period-Value> + 1; in T13 clocks (f_{T13}) (26.3)

Timer T13 can only count up, comparable to the Edge-Aligned mode of T12. This leads to very simple ‘counting rule’ for the T13 counter:

- The counter is cleared with the next T13 clock edge if a Period-Match is detected. The counting direction is always upwards.

The behavior of T13 is illustrated in **Figure 26-25**.

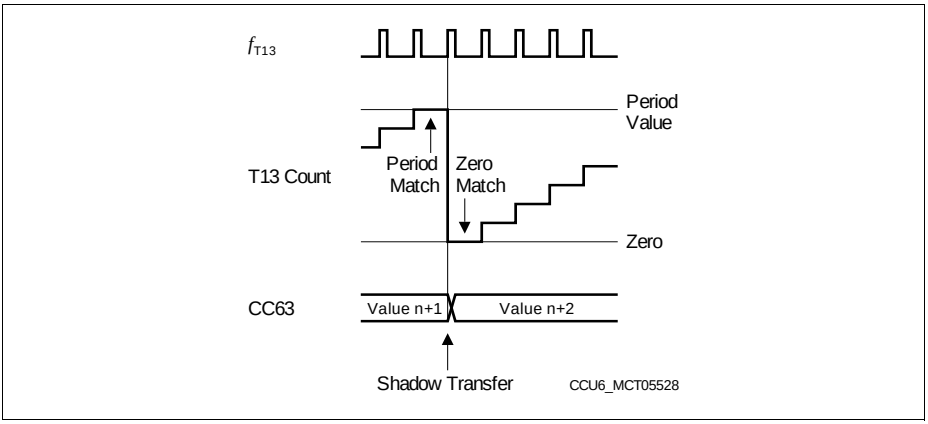

Figure 26-25 T13 Counting Sequence

26.3.2.3 Single-Shot Mode

In Single-Shot Mode, the timer run bit T13R is cleared by hardware. If bit T13SSC = 1, the timer T13 will stop when the current timer period is finished.

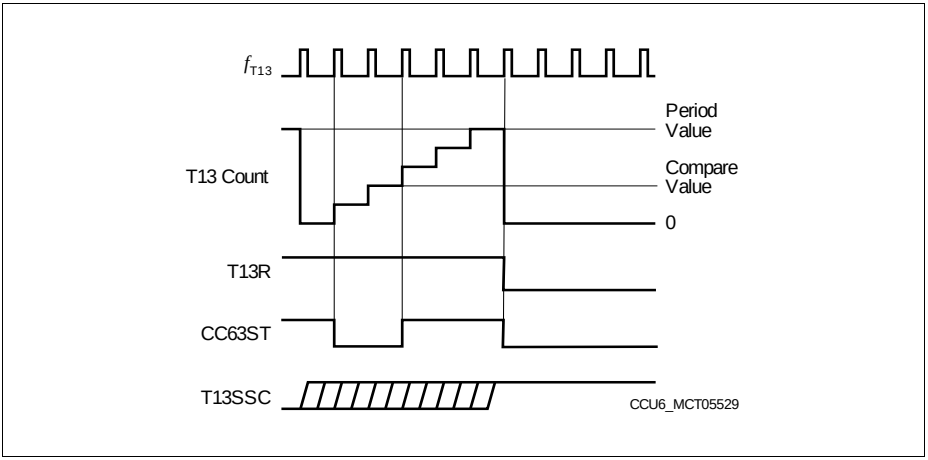

Figure 26-26 Single-Shot Operation of Timer T13

26.3.2.4 Synchronization to T12

Timer T13 can be synchronized to a T12 event. Bit fields T13TEC and T13TED select the event that is used to start Timer T13. The selected event sets bit T13R via HW, and T13 starts counting. Combined with the Single-Shot mode, this feature can be used to generate a programmable delay after a T12 event.

Figure 26-27 shows an example for the synchronization of T13 to a T12 event. Here, the selected event is a compare-match (compare value = 2) while counting up. The clocks of T12 and T13 can be different (other prescaler factor); the figure shows an example in which T13 is clocked with half the frequency of T12.

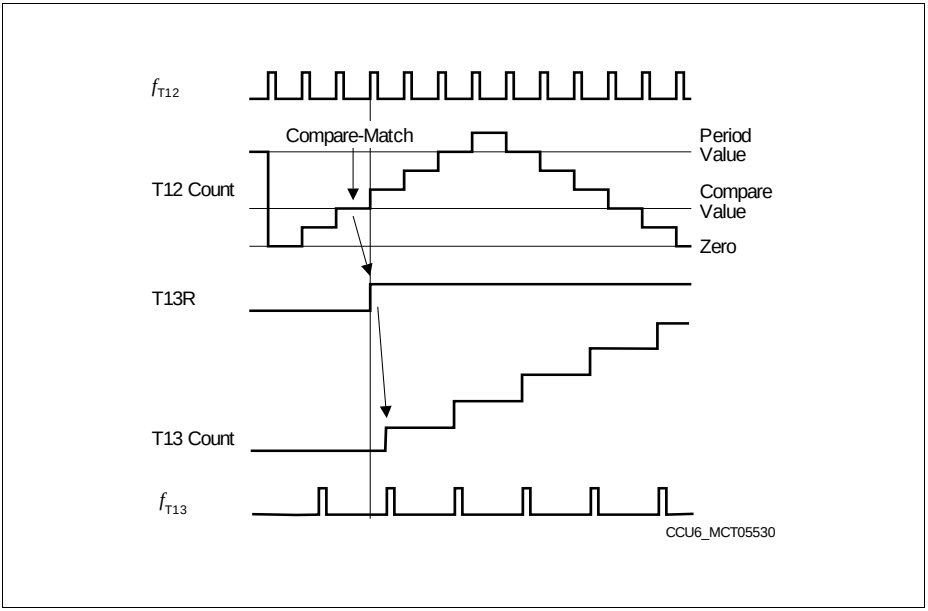

Figure 26-27 Synchronization of T13 to T12 Compare Match

Bit field T13TEC selects the trigger event to start T13 (automatic set of T13R for synchronization to T12 compare signals) according to the combinations shown in **Table 26-7**. Bit field T13TED additionally specifies for which count direction of T12 the selected trigger event should be regarded (see **Table 26-8**).

Table 26-7 T12 Trigger Event Selection

T13TEC	Selected Event
000_B	None
001_B	T12 Compare Event on Channel 0 (CM_CC60)
010_B	T12 Compare Event on Channel 1 (CM_CC61)
011_B	T12 Compare Event on Channel 2 (CM_CC62)
100_B	T12 Compare Event on any Channel (0, 1, 2)
101_B	T12 Period-Match (T12_PM)
110_B	T12 Zero-Match while counting up (T12_ZM and CDIR = 0)
111_B	Any Hall State Change

Table 26-8 T12 Trigger Event Additional Specifier

T13TED	Selected Event Specifier
00_B	Reserved, no action
01_B	Selected event is active while T12 is counting up (CDIR = 0)
10_B	Selected event is active while T12 is counting down (CDIR = 1)
11_B	Selected event is active independently of the count direction of T12

26.3.3 T13 Compare Mode

Associated with Timer T13 is one compare channel, that can perform compare operations with regard to the contents of the T13 counter.

Figure 26-23 gives an overview on the T13 channel in Compare Mode. The channel is connected to the T13 counter register via an equal-to comparator, generating a compare match signal when the contents of the counter matches the contents of the compare register.

The channel consists of the comparator and a double register structure - the actual compare register, **CC63R**, feeding the comparator, and an associated shadow register, **CC63SR**, that is preloaded by software and transferred into the compare register when signal T13 shadow transfer, T13_ST, gets active. Providing a shadow register for the compare value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

Associated with the channel is a State Bit, **CMPSTAT**.CC63ST, holding the status of the compare operation. **Figure 26-28** gives an overview on the logic for the State Bit.

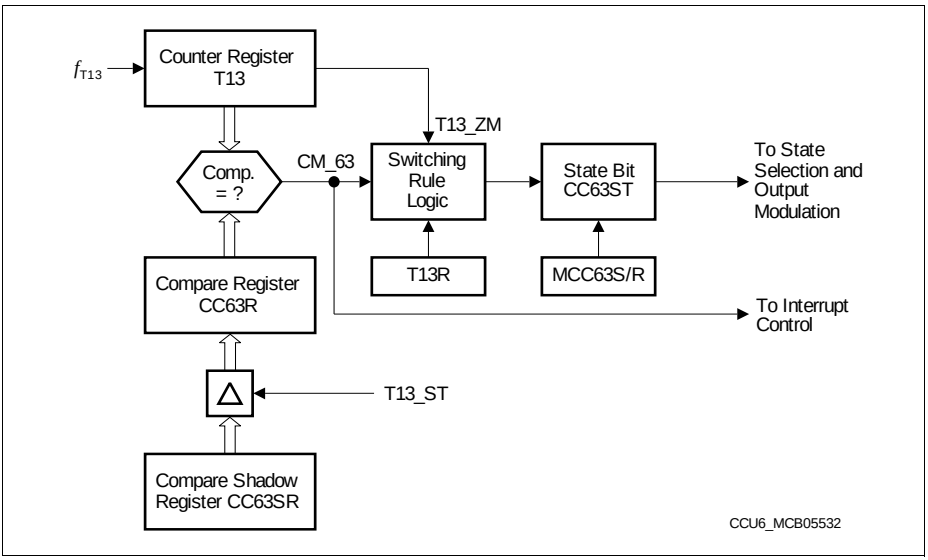

Figure 26-28 T13 State Bit Block Diagram

A compare interrupt event CM_63 is signaled when a compare match is detected. The actual setting of a State Bit has no influence on the interrupt generation.

The inputs to the switching rule logic for the CC63ST bit are the timer run bit (T13R), the timer zero-match signal (T13_ZM), and the actual individual compare-match signal CM_63. In addition, the state bit can be set or cleared by software via bits MCC63S and

MCC63R in register **CMPMODIF**.
A modification of the State Bit CC63ST by hardware is only possible while Timer T13 is running (T13R = 1). If this is the case, the following switching rules apply for setting and resetting the State Bit in Compare Mode:

State Bit **CC63ST is set** to 1

- with the next T13 clock (f_{T13}) after a compare-match (T13 is always counting up) (i.e., when the counter is incremented above the compare value);
- with the next T13 clock (f_{T13}) after a zero-match AND a parallel compare-match.

State Bit **CC63ST is cleared** to 0

- with the next T13 clock (f_{T13}) after a zero-match AND NO parallel compare-match.

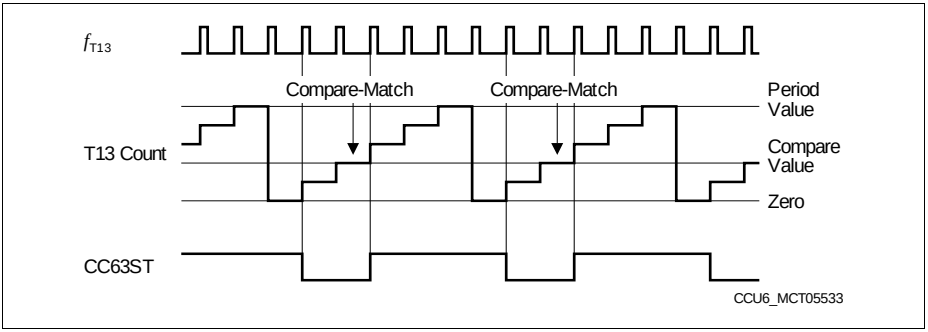

Figure 26-29 T13 Compare Operation

26.3.4 Compare Mode Output Path

Figure 26-30 gives an overview on the signal path from the channel State Bit CC63ST to its output pin COUT63. As illustrated, a user can determine the desired output behavior in relation to the current state of CC63ST. Please refer to **Section 26.2.4.3** for detailed information on the output modulation for T12 signals.

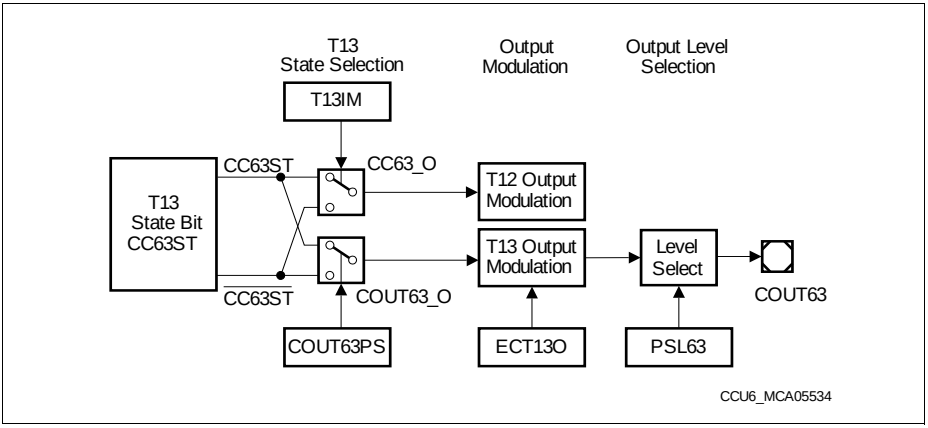

Figure 26-30 Channel 63 Output Path

The output line COUT63_O can generate a T13 PWM at the output pin COUT63. The signal CC63_O can be used to modulate the T12-related output signals with a T13 PWM. In order to decouple COUT63 from the internal modulation, the compare state leading to an active signal can be selected independently by bits T13IM and COUT63PS.

The last block of the data path is the Output Modulation block. Here, the modulation source T13 and the trap functionality are combined and control the actual level of the output pin COUT63 (see **Figure 26-31**):

- The **T13 related compare signal** COUT63_O delivered by the T13 state selection with the enable bit **MODCTR**.ECT13O
- The **trap state** TRPS with an individual enable bit **TRPCTR**.TRPEN13

If the modulation input signal COUT63_O is enabled (ECT13O = 1) and is at passive state, the modulated is also in passive state. If the modulation input is not enabled, the output is in passive state.
If the Trap State is active (TRPS = 1), then the output enabled for the trap signal (by TRPEN13 = 1) is set to the passive state.

The output of the modulation control block is connected to a level select block. It offers the option to determine the actual output level of a pin, depending on the state of the output line (decoupling of active/passive state and output polarity) as specified by the Passive State Select bit **PSLR**.PSL63. If the modulated output signal is in the passive

state, the level specified directly by PSL63 is output. If it is in the active state, the inverted level of PSL63 is output. This allows the user to adapt the polarity of an active output signal to the connected circuitry.

The PSL63 bit has a shadow register to allow for updates with the T13 shadow transfer signal (T13_ST) without undesired pulses on the output lines. A read action returns the actually used value, whereas a write action targets the shadow bit. Providing a shadow register for the PSL value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

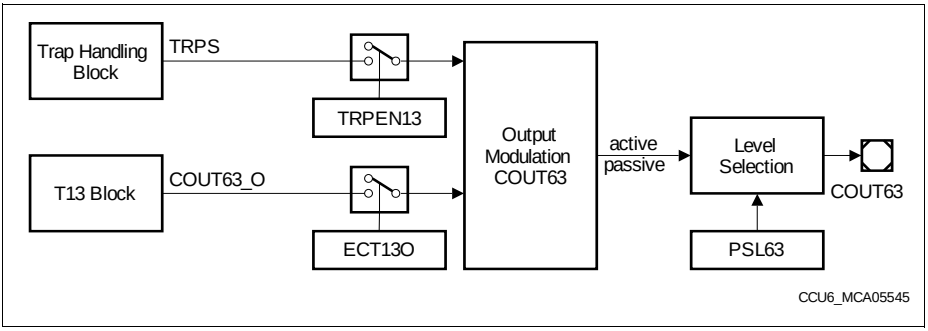

Figure 26-31 T13 Output Modulation

26.3.5 T13 Shadow Register Transfer

A special shadow transfer signal (T13_ST) can be generated to facilitate updating the period and compare values of the compare channel CC63 synchronously to the operation of T13. Providing a shadow register for values defining one PWM period facilitates a concurrent update by software for all relevant parameters. The next PWM period can run with a new set of parameters. The generation of this signal is requested by software via bit **TCTR0**.STE13 (set by writing 1 to the write-only bit **TCTR4**.T13STR, cleared by writing 1 to the write-only bit **TCTR4**.T13STD).
When signal T13_ST is active, a shadow register transfer is triggered with the next cycle of the T13 clock. Bit STE13 is automatically cleared with the shadow register transfer.
A T13 shadow register transfer takes place (T13_ST active):

- while timer T13 is not running (T13R = 0), or
- STE13 = 1 and a Period-Match is detected while T13R = 1

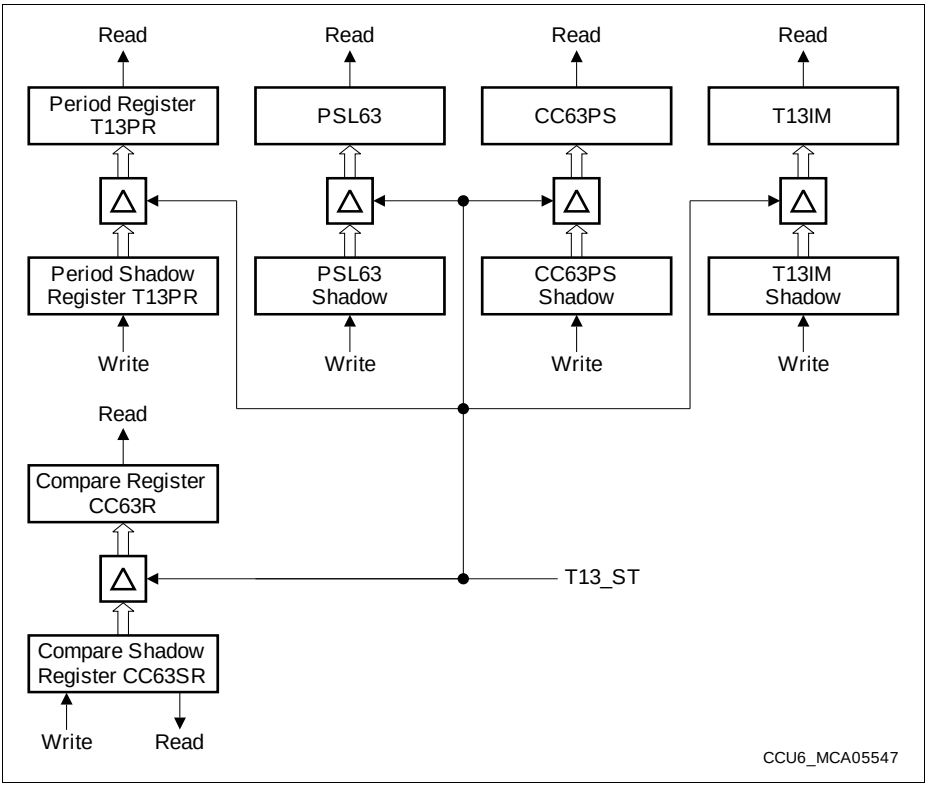

Figure 26-32 T13 Shadow Register Overview

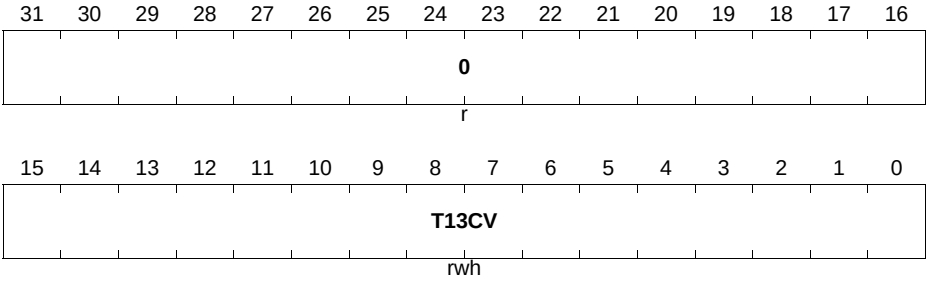
26.3.6 T13 related Registers

26.3.6.1 T13 Counter Register

The generation of the patterns for a single channel pulse width modulation (PWM) is based on timer T13. The registers related to timer T13 can be concurrently updated (with well-defined conditions) in order to ensure consistency of the PWM signal. T13 can be synchronized to several timer T12 events.
Timer T13 only supports compare mode on its compare channel CC63.
Register T13 represents the counting value of timer T13. It can only be written while the timer T13 is stopped. Write actions while T13 is running are not taken into account. Register T13 can always be read by SW.
Timer T13 only supports edge-aligned mode (counting up).

T13
Timer T13 Counter Register **(50_H)** **Reset Value: 0000 0000_H**



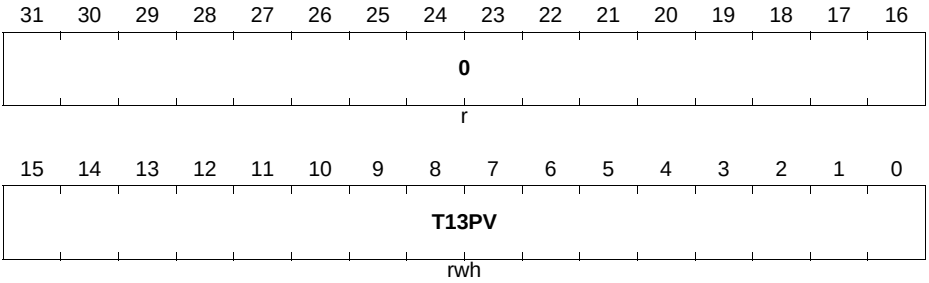
Field	Bits	Type	Description
T13CV	[15:0]	rwh	**Timer 13 Counter Value** This register represents the 16-bit counter value of Timer13.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

Note: While timer T13 is stopped, the internal clock divider is reset in order to ensure reproducible timings and delays.

26.3.6.2 Period Register

Register T13PR contains the period value for timer T13. The period value is compared to the actual counter value of T13 and the resulting counter actions depend on the defined counting rules. This register has a shadow register and the shadow transfer is controlled by bit STE13. A read action by SW delivers the value currently used for the compare action, whereas the write action targets a shadow register. The shadow register structure allows a concurrent update of all T13-related values.

T13PR
Timer 13 Period Register **(54_H)** **Reset Value: 0000 0000_H**

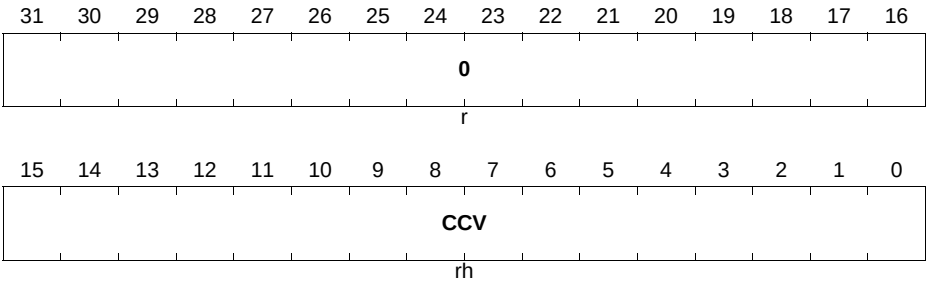


Field	Bits	Type	Description
T13PV	[15:0]	rwh	**T13 Period Value** The value T13PV defines the counter value for T13 leading to a period-match. When reaching this value, the timer T13 is set to zero.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.3.6.3 Compare Register

Registers CC63R is the actual compare register for T13. The values stored in CC63R is compared to the counter value of T13. The State Bit CC63ST is located in register **CMPSTAT**.

CC63R
Compare Register for T13 **(58_H)** **Reset Value: 0000 0000$_H$**



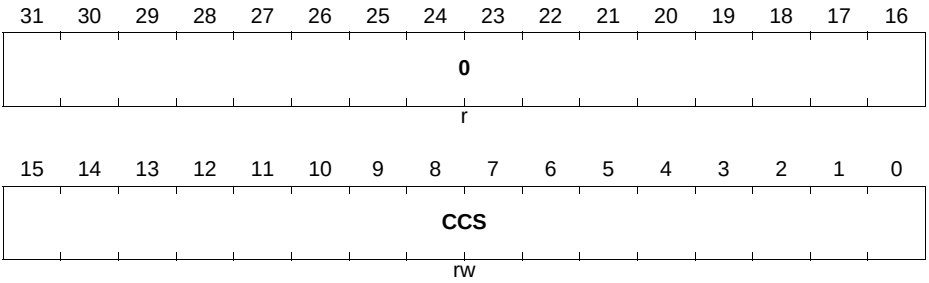
Field	Bits	Type	Description
CCV	[15:0]	rh	**Channel CC63 Compare Value** The bit field CCV contains the value, that is compared to the T13 counter value.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.3.6.4 Compare Shadow Register

The register CC63R can only be read by SW, the modification of the value is done by a shadow register transfer from register CC63SR. The corresponding shadow register CC63SR can be read and written by SW.

CC63SR
Compare Shadow Register for T13

($5C_H$) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CCS	[15:0]	rw	**Shadow Register for Channel CC63 Compare Value** The bit field contents of CCS is transferred to the bit field CCV during a shadow transfer.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.4 Synchronous Start Feature

The T12 and T13 timers can be started synchronously through the T12HR and T13HR inputs of all CCU6x kernels.

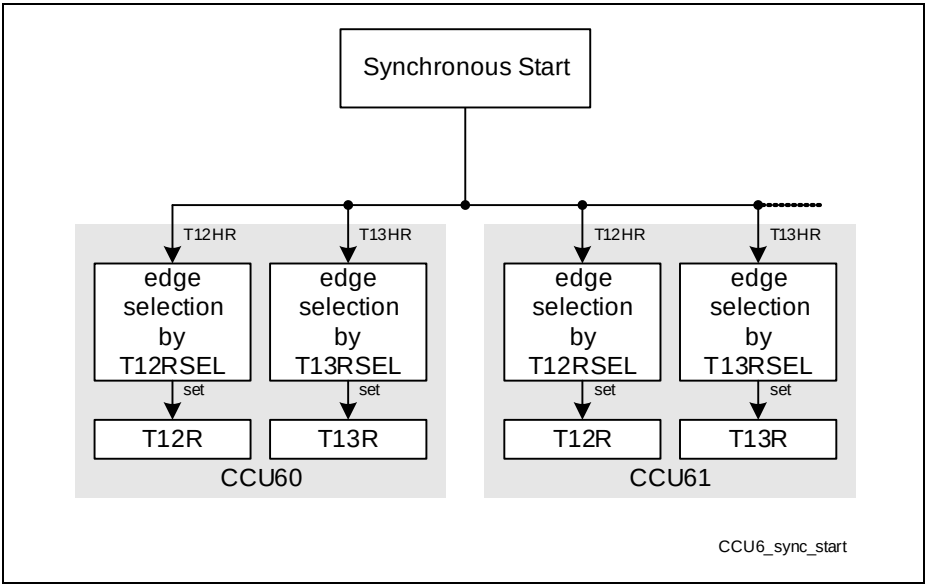


Figure 26-33 Synchronization Concept

26.5 Trap Handling

The trap functionality permits the PWM outputs to react on the state of the input signal CTRAP. This functionality can be used to switch off the power devices if the trap input becomes active (e.g. to perform an emergency stop). The trap handling and the effect on the output modulation are controlled by the bits in the trap control register **TRPCTR**. The trap flags TRPF and TRPS are located in register **IS** and can be set/cleared by SW by writing to registers **ISS** and **ISR**.
Figure 26-34 gives an overview on the trap function.

The Trap Flag TRPF monitors the trap input and initiates the entry into the Trap State. The Trap State Bit TRPS determines the effect on the outputs and controls the exit of the Trap State.
When a trap condition is detected ($\overline{\text{CTRAP}}$ = 0) and the input is enabled (TRPPEN = 1), both, the Trap Flag TRPF and the Trap State Bit TRPS, are set to 1 (trap state active). The output of the Trap State Bit TRPS leads to the Output Modulation Blocks (for T12 and for T13) and can there deactivate the outputs (set them to the passive state). Individual enable control bits for each of the six T12-related outputs and the T13-related output facilitate a flexible adaptation to the application needs.

There are a number of different ways to exit the Trap State. This offers SW the option to select the best operation for the application. Exiting the Trap State can be done either immediately when the trap condition is removed ($\overline{\text{CTRAP}}$ = 1 or TRPPEN = 0), or under software control, or synchronously to the PWM generated by either Timer T12 or Timer T13.

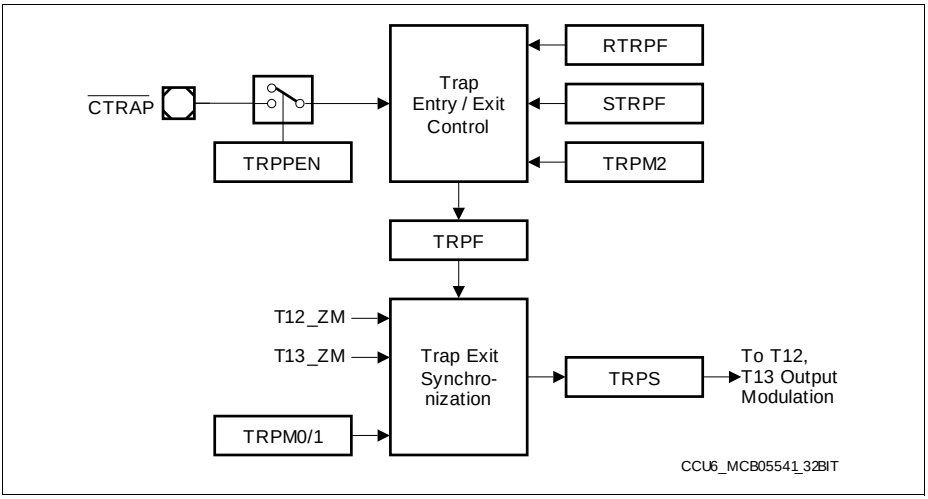

Figure 26-34 Trap Logic Block Diagram

Clearing of TRPF is controlled by the mode control bit TRPM2. If TRPM2 = 0, TRPF is automatically cleared by HW when $\overline{\text{CTRAP}}$ returns to the inactive level ($\overline{\text{CTRAP}}$ = 1) or if the trap input is disabled (TRPPEN = 0). When TRPM2 = 1, TRPF must be reset by SW after $\overline{\text{CTRAP}}$ has become inactive.

Clearing of TRPS is controlled by the mode control bits TRPM1 and TRPM0 (located in the Trap Control Register TRPCTR). A reset of TRPS terminates the Trap State and returns to normal operation. There are three options selected by TRPM1 and TRPM0. One is that the Trap State is left immediately when the Trap Flag TRPF is cleared, without any synchronization to timers T12 or T13. The other two options facilitate the synchronization of the termination of the Trap State to the count periods of either Timer T12 or Timer T13. **Figure 26-35** gives an overview on the associated operation.

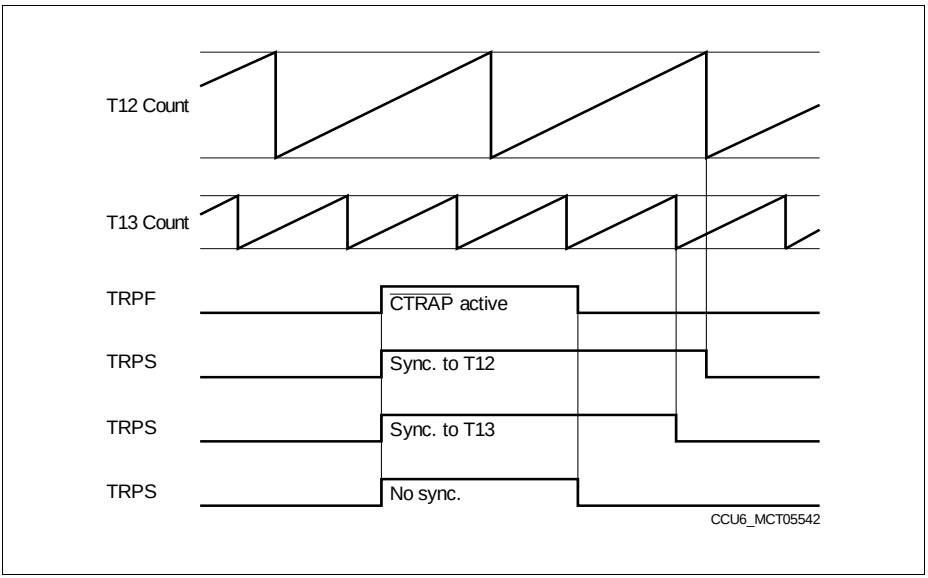

Figure 26-35 Trap State Synchronization (with TRPM2 = 0)

26.6 Multi-Channel Mode

The Multi-Channel mode offers the possibility to modulate all six T12-related output signals with one instruction. The bits in bit field **MCMOUT**.MCMP are used to specify the outputs that may become active. If Multi-Channel mode is enabled (bit **MODCTR**.MCMEN = 1), only those outputs may become active, that have a 1 at the corresponding bit position in bit field MCMP.
This bit field has its own shadow bit field **MCMOUTS**.MCMPS, that can be written by software. The transfer of the new value in MCMPS to the bit field MCMP can be triggered by, and synchronized to, T12 or T13 events. This structure permits the software to write the new value, that is then taken into account by the hardware at a well-defined moment and synchronized to a PWM signal. This avoids unintended pulses due to unsynchronized modulation sources.

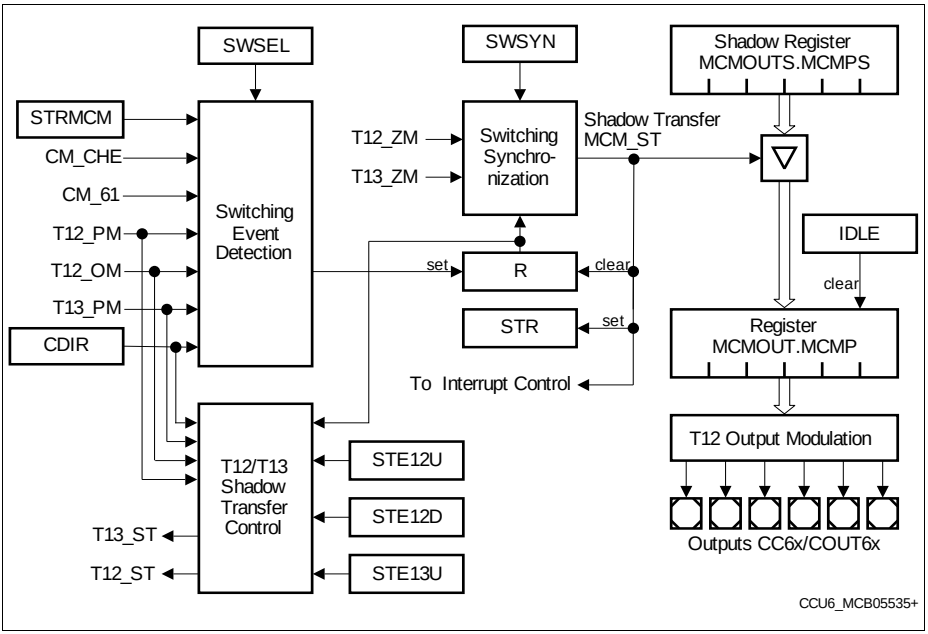

Figure 26-36 Multi-Channel Mode Block Diagram

Figure 26-36 shows the functional blocks for the Multi-Channel operation, controlled by bit fields in register **MCMCTR**. The event that triggers the update of bit field MCMP is chosen by SWSEL. In order to synchronize the update of MCMP to a PWM generated by T12 or T13, bit field SWSYN allows the selection of the synchronization event leading to the transfer from MCMPS to MCMP. Due to this structure, an update takes place with a new PWM period. A reminder flag R is set when the selected switching event occurs

(the event is not necessarily synchronous to the modulating PWM), and is cleared when the transfer takes place. This flag can be monitored by software to check for the status of this logic block. If the shadow transfer from MCMPS to MCMP takes place, bit **IS**.STR becomes set and an interrupt can be generated.
In addition to the Multi-Channel shadow transfer event MCM_ST, the shadow transfers for T12 (T12_ST) and T13 (T13_ST) can be generated to allow concurrent updates of applied duty cycles for T12 and/or T13 modulation and Multi-Channel patterns.

If it is explicitly desired, the update takes place immediately with the occurrence of the selected event when the direct synchronization mode is selected. The update can also be requested by software by writing to bit field MCMPS with the shadow transfer request bit STRMCM = 1. The option to trigger an update by SW is possible for all settings of SWSEL.
By using the direct mode and bit STRMCM = 1, the update takes place completely under software control.

Table 26-9 Multi-Channel Mode Switching Event Selection

SWSEL	Selected Event (see register MCMCTR)
000_B	No automatic event detection
001_B	Correct Hall Event (CM_CHE) detected at input signals CCPOSx without additional delay
010_B	T13 Period-Match (T13_PM)
011_B	T12 One-Match while counting down (T12_OM and CDIR = 1)
100_B	T12 Compare Channel 1 Event while counting up (CM_61 and CDIR = 0) to support the phase delay function by CC61 for block commutation mode.
101_B	T12 Period-Match while counting up (T12_PM and CDIR = 0)
110_B, 111_B	Reserved, no action

Table 26-10 Multi-Channel Mode Switching Synchronization

SWSYN	Synchronization Event (see register MCMCTR)
00_B	Direct Mode: the trigger event directly causes the shadow transfer
01_B	T13 Zero-Match (T13_ZM), the MCM shadow transfer is synchronized to a T13 PWM
10_B	T12 Zero-Match (T12_ZM), the MCM shadow transfer is synchronized to a T12 PWM
11_B	Reserved, no action

26.7 Hall Sensor Mode

For Brushless DC-Motors in block commutation mode, the Multi-Channel Mode has been introduced to provide efficient means for switching pattern generation. These patterns need to be output in relation to the angular position of the motor. For this, usually Hall sensors or Back-EMF sensing are used to determine the angular rotor position. The CCU6 provides three inputs, CCPOS0, CCPOS1, and CCPOS2, that can be used as inputs for the Hall sensors or the Back-EMF detection signals.

There is a strong correlation between the motor position and the output modulation pattern. When a certain position of the motor has been reached, indicated by the sampled Hall sensor inputs (the Hall pattern), the next, pre-determined Multi-Channel Modulation pattern has to be output. Because of different machine types, the modulation pattern for driving the motor can vary. Therefore, it is wishful to have a wide flexibility in defining the correlation between the Hall pattern and the corresponding Modulation pattern. Furthermore, a hardware mechanism significantly reduces the CPU for block-commutation.

The CCU6 offers the flexibility by having a register containing the currently assumed Hall pattern (CURH), the next expected Hall pattern (EXPH) and the corresponding output pattern (MCMP). A new Modulation pattern is output when the sampled Hall inputs match the expected ones (EXPH). To detect the next rotation phase (segment for block commutation), the CCU6 monitors the Hall inputs for changes. When the next expected Hall pattern is detected, the next corresponding Modulation pattern is output.

To increase for noise immunity (to a certain extend), the CCU6 offers the possibility to introduce a sampling delay for the Hall inputs. Some changes of the Hall inputs are not leading to the expected Hall pattern, because they are only short spikes due to noise. The Hall pattern compare logic compares the Hall inputs to the next expected pattern and also to the currently assumed pattern to filter out spikes.

For the Hall and Modulation output patterns, a double-register structure is implemented. While register **MCMOUT** holds the actually used values, its shadow register **MCMOUTS** can be loaded by software from a pre-defined table, holding the appropriate Hall and Modulation patterns for the given motor control.
A transfer from the shadow register into register MCMOUT can take place when a correct Hall pattern change is detected. Software can then load the next values into register MCMOUTS. It is also possible by software to force a transfer from MCMOUTS into MCMOUT.

Note: The Hall input signals CCPOSx and the CURH and EXPH bit fields are arranged in the following order:
CCPOS0 corresponds to CURH.0 (LSB) and EXPH.0 (LSB)
CCPOS1 corresponds to CURH.1 and EXPH.1
CCPOS2 corresponds to CURH.2 (MSB) and EXPH.2 (MSB)

26.7.1 Hall Pattern Evaluation

The Hall sensor inputs CCPOSx can be permanently monitored via an edge detection block (with the module clock f_{CC6}). In order to suppress spikes on the Hall inputs due to noise in rugged inverter environment, two optional noise filtering methods are supported by the Hall logic (both methods can be combined).

- Noise filtering with delay:
  For this function, the mode control bit fields MSEL6x for all T12 compare channels must be programmed to 1000_B and DBYP = 0. The selected event triggers Dead-Time Counter 0 to generate a programmable delay (defined by bit field DTM). When the delay has elapsed, the evaluation signal HCRDY becomes activated.
  Output modulation with T12 PWM signals is not possible in this mode.
- Noise filtering by synchronization to PWM:
  The Hall inputs are not permanently monitored by the edge detection block, but samples are taken only at defined points in time during a PWM period. This can be used to sample the Hall inputs when the switching noise (due to PWM) does not disturb the Hall input signals.

If neither the delay function of Dead-Time Counter 0 is not used for the Hall pattern evaluation nor the Hall mode for Brushless DC-Drive control is enabled, the timer T12 block is available for PWM generation and output modulation.

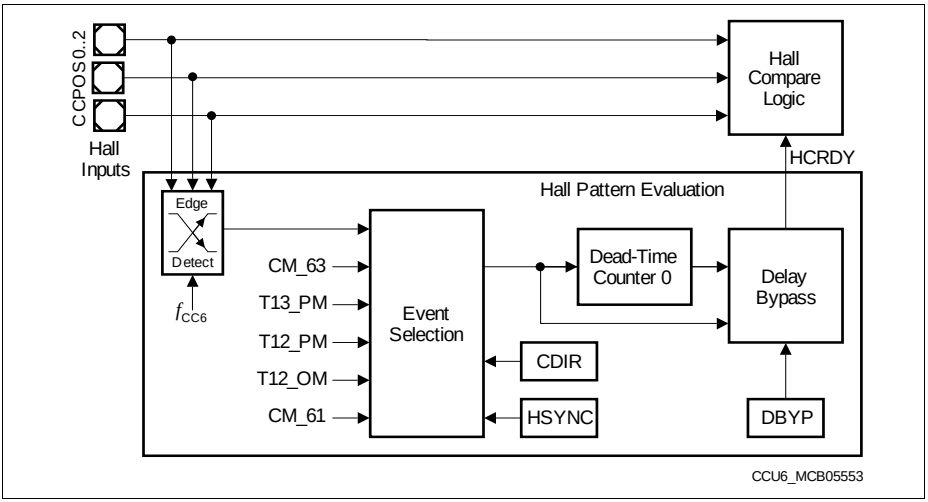

Figure 26-37 Hall Pattern Evaluation

If the evaluation signal HCRDY (Hall Compare Ready, see **Figure 26-38**) becomes activated, the Hall inputs are sampled and the Hall compare logic starts the evaluation of the Hall inputs.

Figure 26-37 illustrates the events for Hall pattern evaluation and the noise filter logic, Table 26-11 summarizes the selectable trigger input signals.

Table 26-11 Hall Sensor Mode Trigger Event Selection

HSYNC	Selected Event (see register T12MSEL)
000_B	Any edge at any of the inputs CCPOSx, independent from any PWM signal (permanent check).
001_B	A T13 Compare-Match (CM_63).
010_B	A T13 Period-Match (T13_PM).
011_B	Hall sampling triggered by HW sources is switched off.
100_B	A T12 Period-Match while counting up (T12_PM and CDIR = 0).
101_B	A T12 One-Match while counting down (T12_OM and CDIR = 1).
110_B	A T12 Compare-Match of compare channel CC61 while counting up (CM_61 and CDIR = 0).
111_B	A T12 Compare-Match of compare channel CC61 while counting down (CM_61 and CDIR = 1).

26.7.2 Hall Pattern Compare Logic

Figure 26-38 gives an overview on the double-register structure and the pattern compare logic. Software writes the next modulation pattern (MCMPS) and the corresponding current (CURHS) and expected (EXPHS) Hall patterns into the shadow register MCMOUTS. Register MCMOUT holds the actually used values CURH and EXPH. The modulation pattern MCMP is provided to the T12 Output Modulation block. The current (CURH) and expected (EXPH) Hall patterns are compared to the sampled Hall sensor inputs (visible in register **CMPSTAT**). Sampling of the inputs and the evaluation of the comparator outputs is triggered by the evaluation signal HCRDY (Hall Compare Ready), that is detailed in the next section.

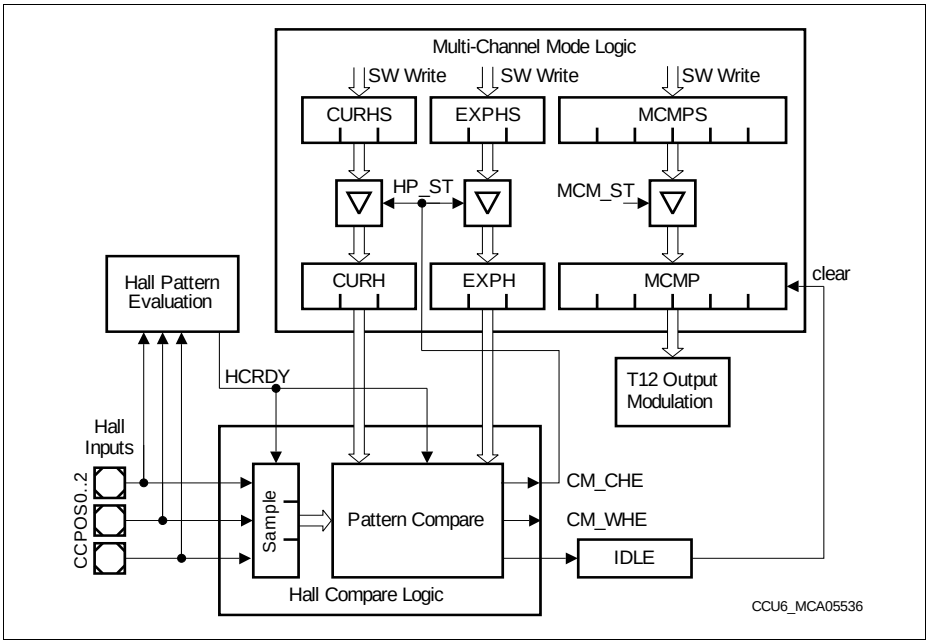

Figure 26-38 Hall Pattern Compare Logic

- If the sampled Hall pattern matches the value programmed in CURH, the detected transition was a spike (no Hall event) and no further actions are necessary.
- If the sampled Hall pattern matches the value programmed in EXPH, the detected transition was the expected event (correct Hall event CM_CHE) and the MCMP value has to change.
- If the sampled Hall pattern matches neither CURH nor EXPH, the transition was due to a major error (wrong Hall event CM_CWE) and can lead to an emergency shut down (IDLE).

At every correct Hall event (CM_CHE), the next Hall patterns are transferred from the shadow register MCMOUTS into MCMOUT (Hall pattern shadow transfer HP_ST), and a new Hall pattern with its corresponding output pattern can be loaded (e.g. from a predefined table in memory) by software into MCMOUTS. For the Modulation patterns, signal MCM_ST is used to trigger the transfer.
Loading this shadow register can also be done by writing MCMOUTS.STRHP = 1 (for EXPH and CURH) or MCMOUTS.STRMCMP = 1 (for MCMP).

26.7.3 Hall Mode Flags

Depending on the Hall pattern compare operation, a number of flags are set in order to indicate the status of the module and to trigger further actions and interrupt requests.

Flag **IS**.CHE (Correct Hall Event) is set by signal CM_CHE when the sampled Hall pattern matches the expected one (EXPH). This flag can also be set by SW by setting bit **ISS**.SCHE = 1. If enabled by bit **IEN**.ENCHE = 1, the set signal for CHE can also generate an interrupt request to the CPU. Bit field **INP**.INPCHE defines which service request output becomes activated in case of an interrupt request.To clear flag CHE, SW needs to write **ISR**.RCHE = 1.
Flag IS.WHE indicates a Wrong Hall Event. Its handling for flag setting and resetting as well as interrupt request generation are similar to the mechanism for flag CHE.
The implementation of flag STR is done in the same way as for CHE and WHE. This flag is set by HW by the shadow transfer signal MCM_ST (see also **Figure 26-36**).

Please note that for flags CHE, WHE, and STR, the interrupt request generation is triggered by the set signal for the flag. That means, a request can be generated even if the flag is already set. There is no need to clear the flag in order to enable further interrupt requests.

The implementation for the IDLE flag is different. It is set by HW through signal CM_WHE if enabled by bit ENIDLE. Software can also set the flag via bit SIDLE. As long as bit IDLE is set, the modulation pattern field MCMP is cleared to force the outputs to the passive state. Flag IDLE must be cleared by software by writing RIDLE = 1 in order to return to normal operation. To fully restart from IDLE mode, the transfer requests for the bit fields in register MCMOUTS to register MCMOUT have to be initiated by software via bits STRMCM and STRHP in register MCMOUTS. In this way, the release from IDLE mode is under software control, but can be performed synchronously to the PWM signal.

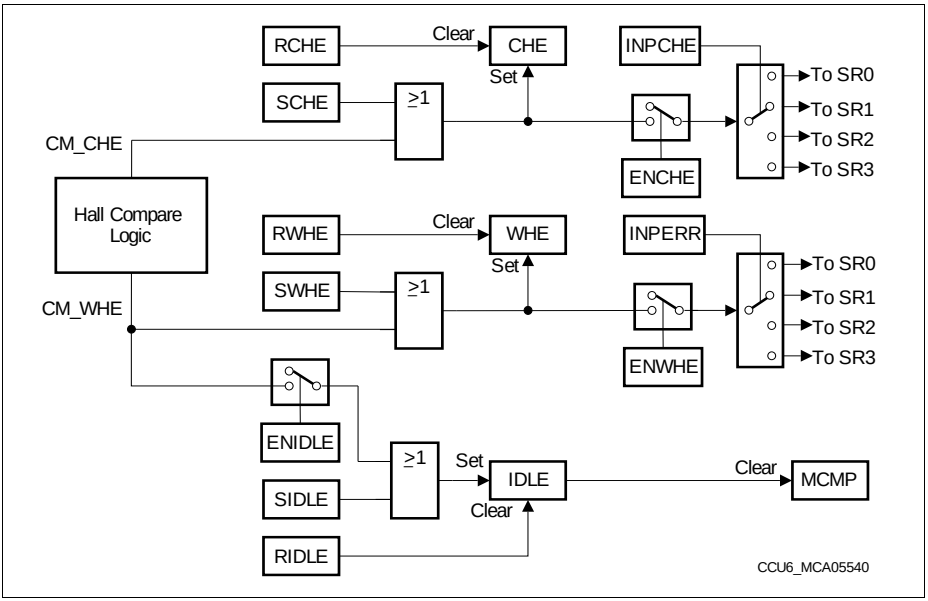

Figure 26-39 Hall Mode Flags

26.7.4 Hall Mode for Brushless DC-Motor Control

The CCU6 provides a mode for the Timer T12 Block especially targeted for convenient control of block commutation patterns for Brushless DC-Motors. This mode is selected by setting all **T12MSEL**.MSEL6x bit fields of the three T12 Channels to 1000_B.
In this mode, illustrated in **Figure 26-40**, channel CC60 is placed in capture mode to measure the time elapsed between the last two correct Hall events, channel CC61 in compare mode to provide a programmable phase delay between the Hall event and the application of a new PWM output pattern, and channel CC62 also in compare mode as first time-out criterion. A second time-out criterion can be built by the T12 period match event.

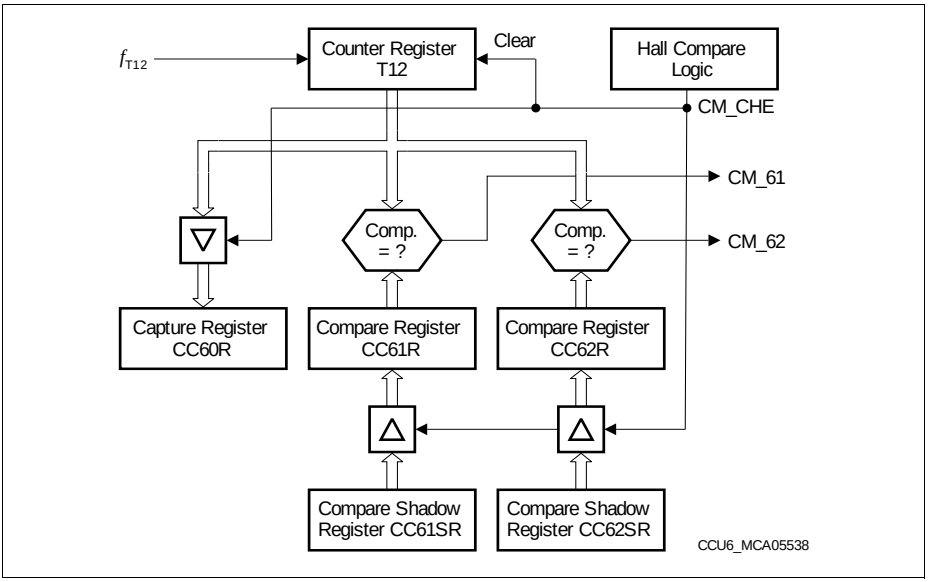

Figure 26-40 T12 Block in Hall Sensor Mode

The signal CM_CHE from the Hall compare logic is used to transfer the new compare values from the shadow registers CC6xSR into the actual compare registers CC6xR, performs the shadow transfer for the T12 period register, to capture the current T12 contents into register CC60R, and to clear T12.

Note: In this mode, the shadow transfer signal T12_ST is not generated. Not all shadow bits, such as the PSLy bits, will be transferred to their main registers. To program the main registers, SW needs to write to these registers while Timer T12 is stopped. In this case, a SW write actualizes both registers.

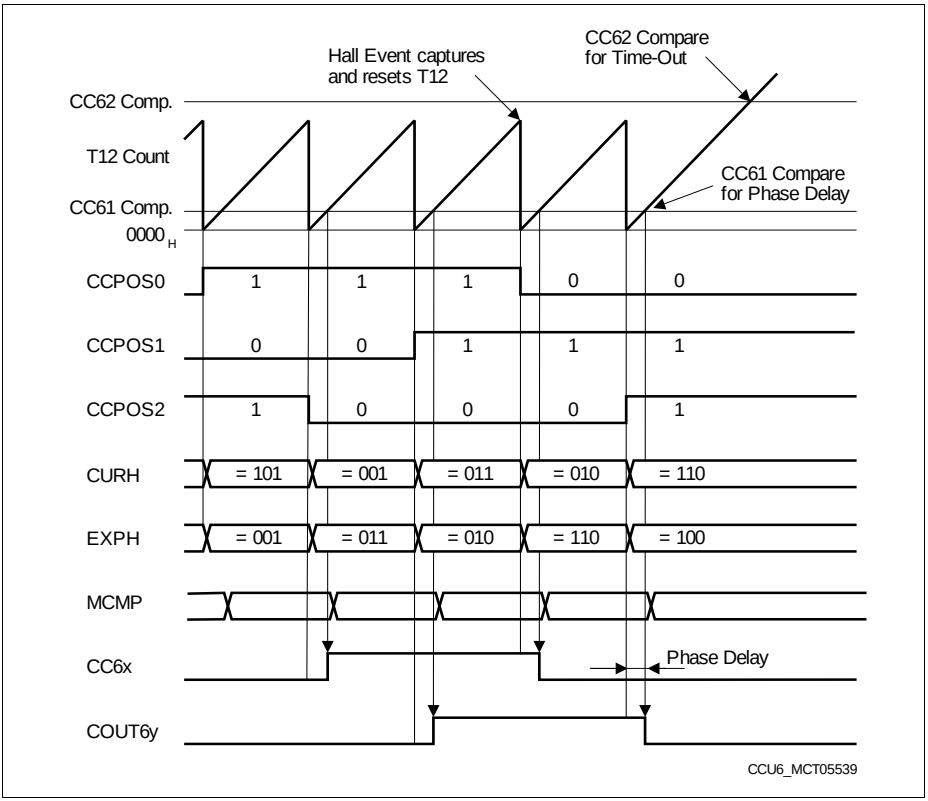

Figure 26-41 Brushless DC-Motor Control Example (all MSEL6x = 1000_B)

After the detection of an expected Hall pattern (CM_CHE active), the T12 count value is captured into channel CC60 (representing the actual rotor speed by measuring the elapsed time between the last two correct Hall events), and T12 is reset. When the timer reaches the compare value in channel CC61, the next multi-channel state is switched by triggering the shadow transfer of bit field MCMP (if enabled in bit field **SWEN**). This trigger event can be combined with the synchronization of the next multi-channel state to the PWM source (to avoid spikes on the output lines, see **Section 26.6**). This compare function of channel CC61 can be used as a phase delay from the position sensor input signals to the switching of the output signals, that is necessary if a sensorless back-EMF technique or Hall sensors are used. The compare value in channel CC62 can be used as a time-out trigger (interrupt), indicating that the actual motor speed is far below the desired destination value. An abnormal load change can be detected with this feature and PWM generation can be disabled.

26.8 Modulation Control Registers

26.8.1 Modulation Control

This register contains bits enabling the modulation of the corresponding output signal by PWM pattern generated by the timers T12 and T13. Furthermore, the multi-channel mode can be enabled as additional modulation source for the output signals.

MODCTR
Modulation Control Register **(80_H)** **Reset Value: $0000\ 0000_H$**

MCMEN	7	rw	**Multi-Channel Mode Enable** 0_B The modulation of the corresponding output signal by a multi-channel pattern according to bit field MCMOUT is disabled. 1_B The modulation of the corresponding output signal by a multi-channel pattern according to bit field MCMOUT is enabled.
T13MODEN	[13:8]	rw	**T13 Modulation Enable** These bits enable the modulation of the corresponding output signal by the PWM pattern CC63_O generated by timer T13. T13MODEN0 = MODCTR.8 for output CC60 T13MODEN1 = MODCTR.9 for output COUT60 T13MODEN2 = MODCTR.10 for output CC61 T13MODEN3 = MODCTR.11 for output COUT61 T13MODEN4 = MODCTR.12 for output CC62 T13MODEN5 = MODCTR.13 for output COUT62 0_B The modulation of the corresponding output signal by a T13 PWM pattern is disabled. 1_B The modulation of the corresponding output signal by a T13 PWM pattern is enabled.

Field	Bits	Type	Description
ECT13O	15	rw	**Enable Compare Timer T13 Output** 0_B The output COUT63 is in the passive state. 1_B The output COUT63 is enabled for the PWM signal generated by T13.
0	6, 14, [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.8.2 Trap Control Register

The register TRPCTR controls the trap functionality. It contains independent enable bits for each output signal and control bits to select the behavior in case of a trap condition. The trap condition is a low level on the $\overline{\text{CTRAP}}$ input pin, that is monitored (inverted level) by bit IS.TRPF. While TRPF=1 (trap input active), the trap state bit IS.TRPS is set to 1.

TRPCTR
Trap Control Register **(84_H)** **Reset Value: 0000 0000$_H$**

TRPPEN	TRPEN13	TRPEN						0					TRPM2	TRPM1	TRPM0
rw	rw	rw						r					rw	rw	rw

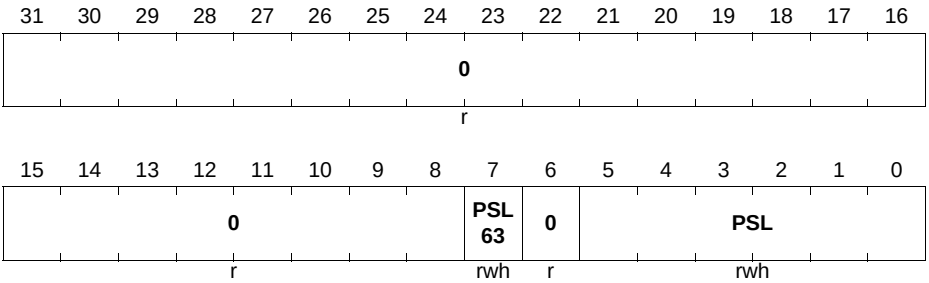
Field	Bits	Type	Description
TRPM1, TRPM0	1, 0	rw	**Trap Mode Control Bits 1, 0** These two bits define the behavior of the selected outputs when leaving the trap state after the trap condition has become inactive again. A synchronization to the timer driving the PWM pattern avoids unintended pulses when leaving the trap state. The combination [TRPM1, TRPM0] leads to: 00_B The trap state is left (return to normal operation) after TRPF has become 0 again when a zero-match of T12 (while counting up) is detected (synchronization to T12). 01_B The trap state is left (return to normal operation) after TRPF has become 0 again when a zero-match of T13 is detected (synchronization to T13). 10_B reserved 11_B The trap state is left (return to normal operation) immediately after TRPF has become 0 again without any synchronization to T12 or T13.
TRPM2	2	rw	**Trap Mode Control Bit 2** This bit defines how the trap flag TRPF can be cleared after the trap input condition ($\overline{\text{CTRAP}}$ = 0 and TRPPEN = 1) is no longer valid (either by $\overline{\text{CTRAP}}$ = 1 or by TRPPEN = 0). 0_B Automatic Mode: Bit TRPF is cleared by HW if the trap input condition is no longer valid. 1_B Manual Mode: Bit TRPF stays 0 after the trap input condition is no longer valid. It has to be cleared by SW by writing ISR.RTRPF = 1.

Field	Bits	Type	Description
TRPEN	[13:8]	rw	**Trap Enable Control** Setting a bit enables the trap functionality for the following corresponding output signals: TRPEN0 = TRPCTR.8 for output CC60 TRPEN1 = TRPCTR.9 for output COUT60 TRPEN2 = TRPCTR.10 for output CC61 TRPEN3 = TRPCTR.11 for output COUT61 TRPEN4 = TRPCTR.12 for output CC62 TRPEN5 = TRPCTR.13 for output COUT62 0_B The trap functionality of the corresponding output signal is disabled. The output state is independent from bit IS.TRPS. 1_B The trap functionality of the corresponding output signal is enabled. The output state is set to the passive while IS.TRPS=1.
TRPEN13	14	rw	**Trap Enable Control for Timer T13** 0_B The trap functionality for output COUT63 is disabled. The output state is independent from bit IS.TRPS. 1_B The trap functionality for output COUT63 is enabled. The output state is set to the passive while IS.TRPS=1.
TRPPEN	15	rw	**Trap Pin Enable** This bit enables the input (pin) function for the trap generation. An interrupt can only be generated if a falling edge is detected at pin $\overline{\text{CTRAP}}$ while TRPPEN = 1. 0_B The CCU6 trap functionality based on the input $\overline{\text{CTRAP}}$ is disabled. A CCU6 trap can only be generated by SW by setting bit TRPF. 1_B The CCU6 trap functionality based on the input $\overline{\text{CTRAP}}$ is enabled. A CCU6 trap can be generated by SW by setting bit TRPF or by $\overline{\text{CTRAP}}$=0.
0	[7:3], [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.8.3 Passive State Level Register

Register PSLR defines the passive state level of the PWM outputs of the module. The passive state level is the value that is driven during the passive state of the output. During the active state, the corresponding output pin drives the active state level, that is the inverted passive state level. The passive state level permits to adapt the driven output levels to the driver polarity (inverted, not inverted) of the connected power stage. The bits in this register have shadow bit fields to permit a concurrent update of all PWM-related parameters (bit field PSL is updated with T12_ST, whereas PSL63 is updated with T13_ST). The actually used values can be read (attribute “rh”), whereas the shadow bits can only be written (attribute “w”).

PSLR
Passive State Level Register **(88_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
PSL	[5:0]	rwh	**Compare Outputs Passive State Level** These bits define the passive level driven by the module outputs during the passive state. PSL0 = PSLR.0 for output CC60 PSL1 = PSLR.1 for output COUT60 PSL2 = PSLR.2 for output CC61 PSL3 = PSLR.3 for output COUT61 PSL4 = PSLR.4 for output CC62 PSL5 = PSLR.5 for output COUT62 0_B The passive level is 0. 1_B The passive level is 1.
PSL63	7	rwh	**Passive State Level of Output COUT63** This bit defines the passive level driven by the module output COUT63 during the passive state. 0_B The passive level is 0. 1_B The passive level is 1.
0	6, [31:8]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.8.4 Multi-Channel Mode Registers

Register MCMCTR contains control bits for the multi-channel functionality.

MCMCTR
Multi-Channel Mode Control Register

Field	Bits	Type	Description
SWSEL	[2:0]	rw	**Switching Selection** Bit field SWSEL selects one of the following trigger request sources (next multi-channel event) for the shadow transfer MCM_ST from MCMPS to MCMP. The trigger request is stored in the reminder flag R until the shadow transfer is done and flag R is cleared automatically with the shadow transfer. The shadow transfer takes place synchronously with an event selected in bit field SWSYN. 000_B No trigger request will be generated 001_B Correct Hall pattern detected (CM_CHE) 010_B T13 period-match detected (while counting up) 011_B T12 one-match (while counting down) 100_B T12 channel 1 compare-match detected (phase delay function) 101_B T12 period match detected (while counting up) 110_B reserved, no trigger request will be generated 111_B reserved, no trigger request will be generated
SWSYN	[5:4]	rw	**Switching Synchronization** Bit field SWSYN defines the synchronization mechanism of the shadow transfer event MCM_ST if it has been requested before (flag R set by an event selected by SWSEL) and if MCMEN = 1. This feature permits the synchronization of the outputs to the PWM source, that is used for modulation (T12 or T13). 00_B Direct; the trigger event immediately leads to the shadow transfer 01_B A T13 zero-match triggers the shadow transfer 10_B A T12 zero-match (while counting up) triggers the shadow transfer 11_B reserved; no action
STE12U	8	rw	**Shadow Transfer Enable for T12 Upcounting** This bit enables the shadow transfer T12_ST if flag MCMOUT.R is set or becomes set while a T12 period match is detected while counting up. 0_B No action 1_B The T12_ST shadow transfer mechanism is enabled if MCMEN = 1.

Field	Bits	Type	Description
STE12D	9	rw	**Shadow Transfer Enable for T12 Downcounting** This bit enables the shadow transfer T12_ST if flag MCMOUT.R is set or becomes set while a T12 one match is detected while counting down. 0_B No action 1_B The T12_ST shadow transfer mechanism is enabled if MCMEN = 1.
STE13U	10	rw	**Shadow Transfer Enable for T13 Upcounting** This bit enables the shadow transfer T13_ST if flag MCMOUT.R is set or becomes set while a T13 period match is detected. 0_B No action 1_B The T13_ST shadow transfer mechanism is enabled if MCMEN = 1.
0	3, [7:6], [31:11]	r	**Reserved;** Returns 0 if read; should be written with 0.

Register MCMOUTS contains bits used as pattern input for the multi-channel mode and the Hall mode. This register is a shadow register (that can be read and written) for register MCMOUT, indicating the currently active signals.

MCMOUTS
Multi-Channel Mode Output Shadow Register

($8C_H$) **Reset Value: $0000\ 0000_H$**

w	r	rw			rw			w	r	rw					

Field	Bits	Type	Description
MCMPS	[5:0]	rw	**Multi-Channel PWM Pattern Shadow** Bit field MCMPS is the shadow bit field for bit field MCMP. The multi-channel shadow transfer is triggered by MCM_ST according to the transfer conditions defined by register MCMCTR.
STRMCM	7	w	**Shadow Transfer Request for MCMPS** Writing STRMCM = 1 leads to an immediate activation of MCM_ST to update bit field MCMP by the value of MCMPS. When read, this bit always delivers 0. 0_B No action. 1_B Bit field MCMP is updated.
EXPHS	[10:8]	rw	**Expected Hall Pattern Shadow** Bit field EXPHS is the shadow bit field for bit field EXPH. The shadow transfer takes place when a correct Hall event is detected (CM_CHE).
CURHS	[13:11]	rw	**Current Hall Pattern Shadow** Bit field CURHS is the shadow bit field for bit field CURH. The shadow transfer takes place when a correct Hall event is detected (CM_CHE).

Field	Bits	Type	Description
STRHP	15	w	**Shadow Transfer Request for the Hall Pattern** Writing STRHP = 1 leads to an immediate activation of HP_ST to update bit fields EXPH and CURH by EXPHS and CURHS. When read, this bit always delivers 0. 0_B No action. 1_B Bit fields EXPH and CURH are updated.
0	6, 14, [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

MCMOUT
Multi-Channel Mode Output Register

(90_H) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		**CURH**			**EXPH**			**0**	**R**	**MCMP**					
r		rh			rh			r	rh	rh					

Field	Bits	Type	Description
MCMP	[5:0]	rh	**Multi-Channel PWM Pattern** Bit field MCMP defines the output pattern for the multi-channel mode. If this mode is enabled by MODCTR.MCMEN = 1, the output state of all T12 related PWM outputs can be modified. This bit field is 0 while IS.IDLE = 1. MCMP0 = MCMOUT.0 for output CC60 MCMP1 = MCMOUT.1 for output COUT60 MCMP2 = MCMOUT.2 for output CC61 MCMP3 = MCMOUT.3 for output COUT61 MCMP4 = MCMOUT.4 for output CC62 MCMP5 = MCMOUT.5 for output COUT62 0_B The output is set to the passive state. A PWM generated by T12 or T13 are not taken into account. 1_B The output can be in the active state, depending on the enabled PWM modulation signals generated by T12, T13 and the trap state.
R	6	rh	**Reminder Flag** This flag indicates that the shadow transfer from MCMPS to MCMP has been requested by the selected trigger source. It is cleared when the shadow transfer takes place or while MCMEN=0. 0_B A shadow transfer MCM_ST is not requested. 1_B A shadow transfer MCM_ST is requested, but has not yet been executed, because the selected synchronization condition has not yet occurred.
EXPH	[10:8]	rh	**Expected Hall Pattern** Bit field EXPH is updated by a shadow transfer HP_ST from bit field EXPHS. If HCRDY = 1, EXPH is compared to the sampled CCPOSx inputs in order to detect the occurrence of the next desired (=expected) hall pattern or a wrong pattern. If the sampled hall pattern at the hall input pins is equal to bit field EXPH, a correct Hall event has been detected (CM_CHE).

Field	Bits	Type	Description
CURH	[13:11]	rh	**Current Hall Pattern** Bit field CURH is updated by a shadow transfer HP_ST from bit field CURHS. If HCRDY = 1, CURH is compared to the sampled CCPOSx inputs in order to detect a spike. If the sampled Hall pattern at the Hall input pins is equal to bit field CURH, no Hall event has been detected. If the sampled Hall input pattern is neither equal to CURH nor equal to EXPH, the Hall event was not the desired one and may be due to a fatal error (e.g. blocked rotor, etc.). In this case, a wrong Hall event has been detected (CM_WHE).
0	7, [31:14]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.9 Interrupt Handling

This section describes the interrupt handling of the CCU6 module.

26.9.1 Interrupt Structure

The HW interrupt event or the SW setting of the corresponding interrupt set bit (in register ISS) sets the event indication flags (in register IS) and can trigger the interrupt generation. The interrupt pulse is generated independently from the interrupt status flag in register IS (it is not necessary to clear the related status bit to be able to generate another interrupt). The interrupt flag can be cleared by SW by writing to the corresponding bit in register ISR.

If enabled by the related interrupt enable bit in register IEN, an interrupt pulse can be generated on one of the four service request outputs (SR0 to SR3) of the module. If more than one interrupt source is connected to the same interrupt node pointer (in register INP), the requests are logically OR-combined to one common service request output (see **Figure 26-42**).

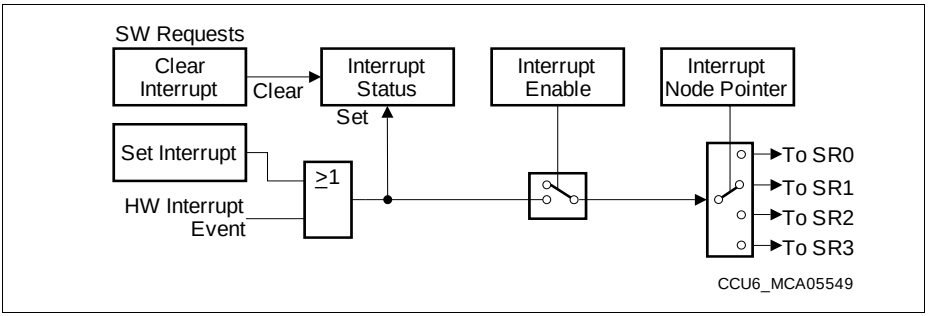

Figure 26-42 General Interrupt Structure

The available interrupt events in the CCU6 are shown in **Figure 26-43**.

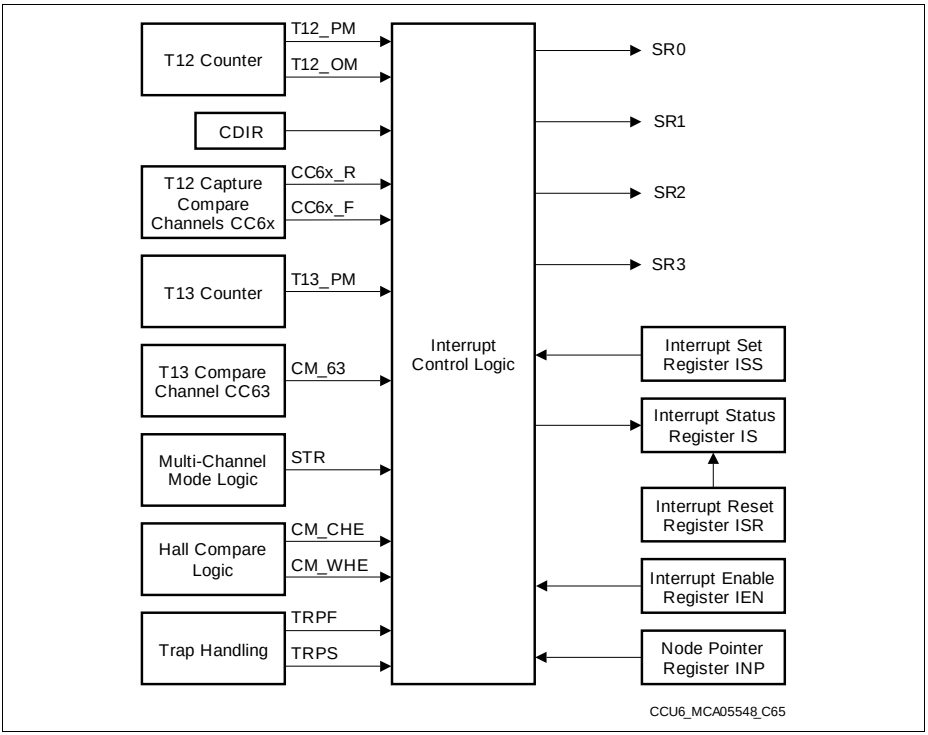

Figure 26-43 Interrupt Sources and Events

26.9.2 Interrupt Registers

26.9.2.1 Interrupt Status Register

Register IS contains the individual interrupt request bits. This register can only be read, write actions have no impact on the contents of this register. The SW can set or clear the bits individually by writing to the registers ISS (to set the bits) or to register ISR (to clear the bits).

The interrupt generation is independent from the value of the bits in register IS, e.g. the interrupt will be generated (if enabled) even if the corresponding bit is already set. The trigger for an interrupt generation is the detection of a set condition (by HW or SW) for the corresponding bit in register IS.

In compare mode (and hall mode), the timer-related interrupts are only generated while the timer is running (T1xR=1). In capture mode, the capture interrupts are also generated while the timer T12 is stopped.

Note: Not all bits in register IS can generate an interrupt. Other status bits have been added, that have a similar structure for their set and clear actions. It is recommended that SW checks the interrupt bits bit-wisely (instead of common OR over the bits).

IS
Interrupt Status Register **($A0_H$)** **Reset Value: $0000\ 0000_H$**

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
ICC60R, ICC61R, ICC62R	0, 2, 4	rh	**Capture, Compare-Match Rising Edge Flag** This bit indicates that event CC6x_R has been detected. This event occurs in compare mode when a compare-match is detected while T12 is counting up (CM_6x and CDIR = 0) and in capture mode when a rising edge is detected at the related input CC6xIN. 0_B The event has not yet been detected. 1_B The event has been detected.
ICC60F, ICC61F, ICC62F	1, 3, 5	rh	**Capture, Compare-Match Falling Edge Flag** This bit indicates that event CC6x_F has been detected. This event occurs in compare mode when a compare-match is detected while T12 is counting down (CM_6x and CDIR = 1) and in capture mode when a falling edge is detected at the related input CC6xIN. 0_B The event has not yet been detected. 1_B The event has been detected.
T12OM	6	rh	**Timer T12 One-Match Flag** This bit indicates that a timer T12 one-match while counting down (T12_OM and CDIR = 1) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
T12PM	7	rh	**Timer T12 Period-Match Flag** This bit indicates that a timer T12 period-match while counting up (T12_PM and CDIR = 0) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
T13CM	8	rh	**Timer T13 Compare-Match Flag** This bit indicates that a timer T13 compare-match (CM_63) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
T13PM	9	rh	**Timer T13 Period-Match Flag** This bit indicates that a timer T13 period-match (T13_PM) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.

Field	Bits	Type	Description
TRPF	10	rh	**Trap Flag** This bit indicates if a trap condition (input $\overline{\text{CTRAP}}$ = 0 or by SW) is / has been detected. If TRPM2= 0, it becomes cleared automatically if $\overline{\text{CTRAP}}$ = 1 or TRPPEN = 0, whereas if TRPM2 = 1, it has to be cleared by writing RTRPF = 1. 0_B The trap condition has not been detected. 1_B The trap condition is / has been detected.
TRPS	11	rh	**Trap State**[1)] This bit indicates the actual trap state. It is set if TRPF = 1 and becomes cleared according to the mode selected in register TRPCTR. 0_B The trap state is not active. 1_B The trap state is active.
CHE	12	rh	**Correct Hall Event** This bit indicates that a correct Hall event (CM_CHE) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
WHE	13	rh	**Wrong Hall Event** This bit indicates that a wrong Hall event (CM_WHE) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
IDLE	14	rh	**IDLE State** If enabled by ENIDLE = 1, this bit is set together with bit WHE and it has to be cleared by SW. 0_B No action. 1_B Bit field MCMP is cleared, the selected outputs are set to passive state.
STR	15	rh	**Multi-Channel Mode Shadow Transfer Request** This bit indicates that a shadow transfer from MCMPS to MCMP (MCM_ST) has taken place. 0_B The event has not yet been detected. 1_B The event has been detected.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

1) During the trap state, the selected outputs are set to the passive state. The logic level driven during the passive state is defined by the corresponding bit in register PSLR. Bits TRPS=1 and TRPF=0 can occur if the trap condition is no longer active but the selected synchronization has not yet taken place.

26.9.2.2 Interrupt Status Set Register

Register ISS contains individual interrupt request set bits to generate a CCU6 interrupt request by software. Writing a 1 sets the bit(s) in register IS at the corresponding bit position(s) and can generate an interrupt event (if available and enabled).
All bit positions read as 0.

The service request output that will be activated is selected by bit field INPCC6x.
ENCC60F, ENCC61F, ENCC62F	1, 3, 5	rw	**Capture, Compare-Match Falling Edge Interrupt Enable for Channel CC6x** 0_B No interrupt will be generated if the set condition for bit CC6xF in register IS occurs. 1_B An interrupt will be generated if the set condition for bit CC6xF in register IS occurs. The service request output that will be activated is selected by bit field INPCC6x.

Field	Bits	Type	Description
ENT12OM	6	rw	**Enable Interrupt for T12 One-Match** 0_B No interrupt will be generated if the set condition for bit T12OM in register IS occurs. 1_B An interrupt will be generated if the set condition for bit T12OM in register IS occurs. The service request output that will be activated is selected by bit field INPT12.
ENT12PM	7	rw	**Enable Interrupt for T12 Period-Match** 0_B No interrupt will be generated if the set condition for bit T12PM in register IS occurs. 1_B An interrupt will be generated if the set condition for bit T12PM in register IS occurs. The service request output that will be activated is selected by bit field INPT12.
ENT13CM	8	rw	**Enable Interrupt for T13 Compare-Match** 0_B No interrupt will be generated if the set condition for bit T13CM in register IS occurs. 1_B An interrupt will be generated if the set condition for bit T13CM in register IS occurs. The service request output that will be activated is selected by bit field INPT13.
ENT13PM	9	rw	**Enable Interrupt for T13 Period-Match** 0_B No interrupt will be generated if the set condition for bit T13PM in register IS occurs. 1_B An interrupt will be generated if the set condition for bit T13PM in register IS occurs. The service request output that will be activated is selected by bit field INPT13.
ENTRPF	10	rw	**Enable Interrupt for Trap Flag** 0_B No interrupt will be generated if the set condition for bit TRPF in register IS occurs. 1_B An interrupt will be generated if the set condition for bit TRPF in register IS occurs. The service request output that will be activated is selected by bit field INPERR.

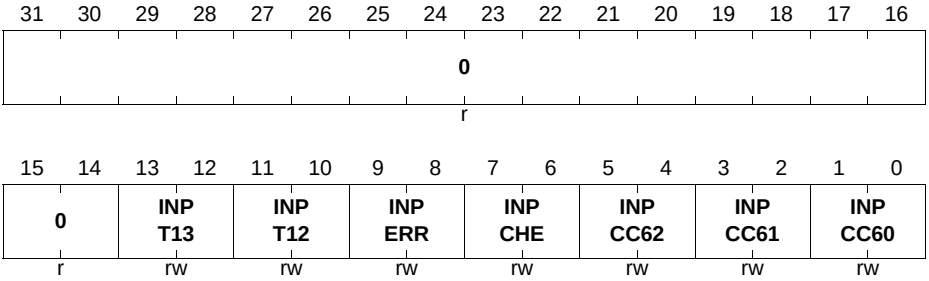
Field	Bits	Type	Description
ENCHE	12	rw	**Enable Interrupt for Correct Hall Event** 0_B No interrupt will be generated if the set condition for bit CHE in register IS occurs. 1_B An interrupt will be generated if the set condition for bit CHE in register IS occurs. The service request output that will be activated is selected by bit field INPCHE.
ENWHE	13	rw	**Enable Interrupt for Wrong Hall Event** 0_B No interrupt will be generated if the set condition for bit WHE in register IS occurs. 1_B An interrupt will be generated if the set condition for bit WHE in register IS occurs. The service request output that will be activated is selected by bit field INPERR.
ENIDLE	14	rw	**Enable Idle** This bit enables the automatic entering of the idle state (bit IDLE will be set) after a wrong hall event has been detected (bit WHE is set). During the idle state, the bit field MCMP is automatically cleared. 0_B The bit IDLE is not automatically set when a wrong hall event is detected. 1_B The bit IDLE is automatically set when a wrong hall event is detected.
ENSTR	15	rw	**Enable Multi-Channel Mode Shadow Transfer Interrupt** 0_B No interrupt will be generated if the set condition for bit STR in register IS occurs. 1_B An interrupt will be generated if the set condition for bit STR in register IS occurs. The service request output that will be activated is selected by bit field INPCHE.
0	11, [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.9.2.5 Interrupt Node Pointer Register

Register INP contains the interrupt node pointers allowing a flexible interrupt handling. These bit fields define which service request output will be activated if the corresponding interrupt event occurs and the interrupt generation for this event is enabled.

INP

Interrupt Node Pointer Register **(AC_H)** **Reset Value: 0000 3940$_H$**



Field	Bits	Type	Description
INPCC60, INPCC61, INPCC62	[1:0], [3:2], [5:4]	rw	**Interrupt Node Pointer for Channel CC6x Interrupts** This bit field defines the service request output activated due to a set condition for bit CC6xR (if enabled by bit ENCC6xR) or for bit CC6xF (if enabled by bit ENCC6xF). 00_B Service request output SR0 is selected. 01_B Service request output SR1 is selected. 10_B Service request output SR2 is selected. 11_B Service request output SR3 is selected.
INPCHE	[7:6]	rw	**Interrupt Node Pointer for the CHE Interrupt** This bit field defines the service request output activated due to a set condition for bit CHE (if enabled by bit ENCHE) of for bit STR (if enabled by bit ENSTR). Coding see INPCC6x.
INPERR	[9:8]	rw	**Interrupt Node Pointer for Error Interrupts** This bit field defines the service request output activated due to a set condition for bit TRPF (if enabled by bit ENTRPF) or for bit WHE (if enabled by bit ENWHE). Coding see INPCC6x.
INPT12	[11:10]	rw	**Interrupt Node Pointer for Timer12 Interrupts** This bit field defines the service request output activated due to a set condition for bit T12OM (if enabled by bit ENT12OM) or for bit T12PM (if enabled by bit ENT12PM). Coding see INPCC6x.

Field	Bits	Type	Description
INPT13	[13:12]	rw	**Interrupt Node Pointer for Timer13 Interrupt** This bit field defines the service request output activated due to a set condition for bit T13CM (if enabled by bit ENT13CM) or for bit T13PM (if enabled by bit ENT13PM). Coding see INPCC6x.
0	[31:14]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.10 General Module Operation

This section provides information about the:

- Input Selection (see **Section 26.10.1**)
- Input Monitoring (see **Section 26.10.2**)
- OCDS Suspend Functionality (see **Section 26.10.3**)
- OCDS Trigger Bus (OTGB) Interface (see **Section 26.10.4**)
- General Register Description (see **Section 26.10.5**)
- BPI Register Description (see **Section 26.10.6**)

26.10.1 Input Selection

Each CCU6 input signal can be selected from a vector of four or eight possible inputs by programming the port input select registers **PISEL0** and **PISEL2**. This permits to adapt the pin functionality of the device to the application requirements.
The output pins for the module output signals are chosen in the ports.

Naming convention:
The input vector CC60IN[D:A] for input signal CC60IN is composed of the signals CC60INA to CC60IND.

Note: All functional inputs of the CCU6 are synchronized to f_{CC6} before they affect the module internal logic. The resulting delay of $2/f_{CC6}$ and for asynchronous signals an additional uncertainty of $1/f_{CC6}$ have to be taken into account for precise timing calculation. An edge of an input signal can only be correctly detected if the high phase and the low phase of the input signal are both longer than $1/f_{CC6}$.

26.10.2 Input Monitoring

A selected event which occurs at each CCU6 input signal can be monitored through **IMON**.x. Every input signal can be included for the detection of a lost bit event (**IMON**.LBE) if enabled through its individual lost indicator enable bits (**LI**.yEN). The lost bit event occurs if a selected event occurs again with the previous event captured (IMON.x remains set) and its lost indicator is enabled for at least one of the monitored input signals. The lost bit event can be enabled (**LI**.LBEEN) for an interrupt to be generated at one of the SRx line, selected through **LI**.INPLBE. The LBE output signal of the kernel can be connected to a capture input to indicate when does the lost bit event happens.

The lost bit event can be used as a kind of interrupt or event watchdog to monitor if an action related to an event has been processed before a second event of the same type occurs. Like this, if a certain event is treated by an interrupt that should be monitored, the related indication flag has to be cleared by SW. If the SW has not yet cleared the flag and the event occurs again, the event is considered as being lost and another interrupt can be generated to inform the system about the loss. This can be also used to indicate that input events occur too often and the main task has not enough time to treat them.

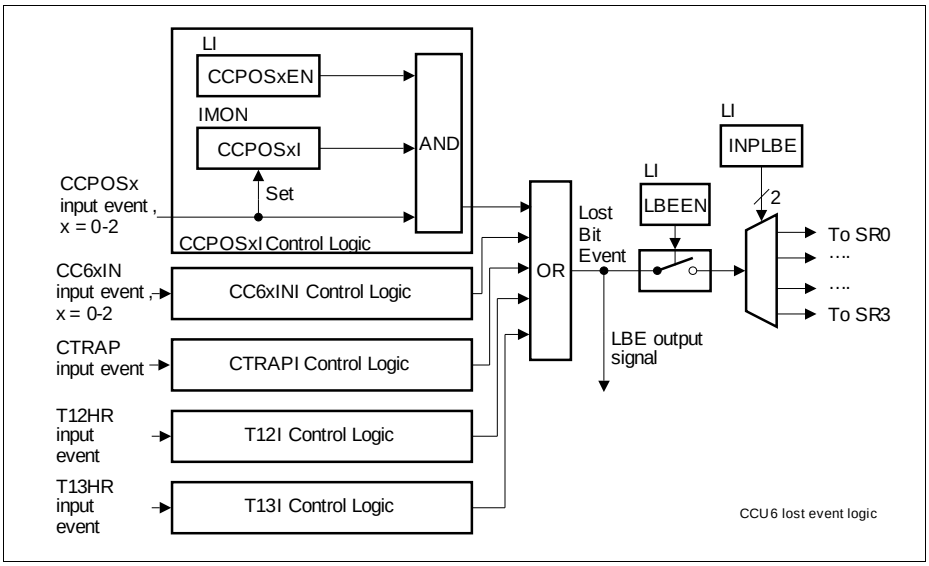


Figure 26-44 Lost Event Logic

26.10.3 OCDS Suspend

The behavior of CCU6 upon an OCDS suspend request is controlled by the **OCS** register. CCU6 supports both Hard Suspend Mode and Soft Suspend Mode.

Hard Suspend Mode

In Hard Suspend Mode the CCU6 kernel clock is switched off immediately. Reading and writing of registers is possible but will enable the kernel clock for a few cycles.

Attention: Register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a CCU6 kernel reset might not be sufficient to bring the system into a defined state.

Soft Suspend Mode

In Soft Suspend Mode CCU6 may finalize specific actions before it enters the suspended state with **OCS**.SUSSTA set. This can be advantageous for applications (e.g. motor control) where critical system states could occur if the kernel clock would be switched off immediately upon an OCDS suspend request.

Soft Suspend mode does not influence the kernel clock. Reading and writing of registers is possible without the side effects that may occur when reading/writing registers in Hard Suspend Mode.

For CCU6, two basic soft suspend options (**Stop Mode 0**, **Stop Mode 1**) are available, selected via bit field **OCS**.SUS.

In addition, the internal functional blocks (T12, T13, Hall logic, Trap logic) may individually be programmed via their Sensitivity Bits in register **KSCSR** to accept or ignore a suspend request. If the request sensitivity is disabled, the block continues normal operation. If the request sensitivity is enabled, the block operates as specified for the selected stop mode. The mapping of the CCU6 functional blocks to their Sensitivity Bits is shown in **Table 26-12**.

Stop Mode 0

In Stop Mode 0, if selected to be stopped, the Hall and Trap logic stops immediately, while Timer T12 and/or T13 continues normal operation (if running) until it reaches the end of the PWM period; then it stops (same stop condition as in single shot mode). When Timer T12 stops, the capture inputs CC6xIN are frozen.

Stop Mode 1

In Stop Mode 1, if selected to be stopped, the internal functional blocks (T12, T13, Hall logic, Trap logic) will stop immediately upon a suspend request.

If the sensitivity bits for Timer T12 or T13 are set, the corresponding output lines enabled for the trap condition are set to their passive values (similar to a trap condition).

Table 26-12 summarizes the reaction of the CCU6 functional blocks to OCDS suspend requests.

Table 26-12 CCU6 Functional Blocks

Block	Reaction to OCDS Suspend Request	Sensitivity Bit
0	**Timer T12:** if bit SB0 = 1_B, - in **Stop Mode 0** Timer T12 continues (if running) until the end of the PWM period. Then it stops and the CCxIN input stages are frozen. - in **Stop Mode 1** Timer T12 stops immediately and the CC6xIN input stages are frozen. Output lines CC6x, COUT6x with enabled trap functionality are set to their passive states.	KSCSR.SB0
1	**Timer T13:** if bit SB1 = 1_B, - in **Stop Mode 0** Timer T13 continues (if running) until the end of the PWM period. Then it stops. - in **Stop Mode 1** Timer T13 stops immediately. If trap functionality for COUT63 is enabled, it is set to the passive state.	KSCSR.SB1
2	**Hall Logic:** if bit SB2 = 1_B, the hall logic is stopped immediately and the CCPOSx input stages are frozen (same behavior for Stop Mode 0 and 1).	KSCSR.SB2
3	**Trap Logic:** if bit SB3 = 1_B, the trap logic is stopped immediately and the CTRAP input stage is frozen (same behavior for Stop Mode 0 and 1).	KSCSR.SB3

26.10.4 OCDS Trigger Bus (OTGB) Interface

The CCU6 kernel provides a set of 16 internal status signals that are combined to a Trigger Set. The CCU6 Trigger Set is shown in **Table 26-13**. It is output on OTGB0 or OTGB1 controlled by the **OCS** register.

Table 26-13 TS16_CCU6 Trigger Set CCU6

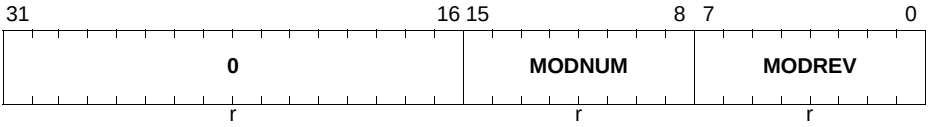
Bits	Name	Description
0	T12pre	T12 prescaler output
1	T13pre	T13 prescaler output
2	T12_cm0	T12 compare match channel 0
3	T12_cm1	T12 compare match channel 1
4	T12_cm2	T12 compare match channel 2
5	T12_pm	T12 period match
6	T12_om	T12 one match
7	T12_cdir	T12 count direction
8	T12_zm	T12 zero match
9	T13_cm	T13 compare match
10	T13_pm	T13 period match
11	T13_zm	T13 zero match
12	mcm_st	MCM shadow transfer
13	che	Correct Hall event
14	whe	Wrong Hall event
15	trpf	Trap flag

26.10.5 General Registers

26.10.5.1 ID Register

The CCU6 Module Identification Register ID contains read-only information about the module identification number and its revision.

ID
Module Identification Register **(08_H)** **Reset Value: 0000 54XX$_H$**

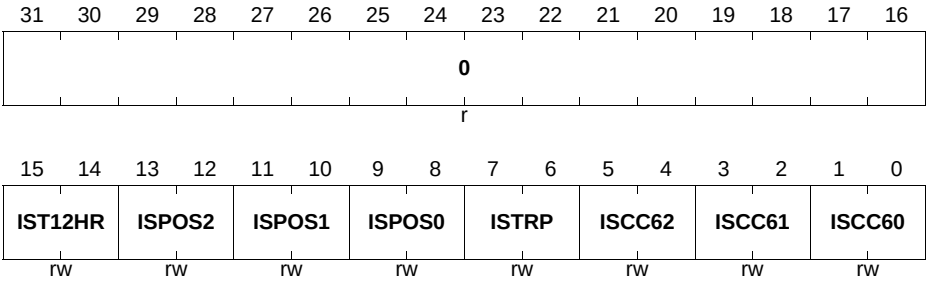


Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01_H (first revision), 02_H, 03_H, ... up to FF_H.
MODNUM	[15:8]	r	**Module Number Value** This bit field defines the module identification number for the CCU6: 54_H
0	[31:16]	r	**Reserved** Read as 0.

26.10.5.2 Port Input Select Registers

Registers PISEL0 and PISEL2 contain bit fields selecting the actual input signal for the module inputs.

PISEL0
Port Input Select Register 0 (10_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
ISCC60	[1:0]	rw	**Input Select for CC60** This bit field defines the input signal used as CC60 capture input. 00_B The signal CC60INA is selected. 01_B The signal CC60INB is selected. 10_B The signal CC60INC is selected. 11_B The signal CC60IND is selected.
ISCC61	[3:2]	rw	**Input Select for CC61** This bit field defines the input signal used as CC61 capture input. 00_B The signal CC61INA is selected. 01_B The signal CC61INB is selected. 10_B The signal CC61INC is selected. 11_B The signal CC61IND is selected.
ISCC62	[5:4]	rw	**Input Select for CC62** This bit field defines the input signal used as CC62 capture input. 00_B The signal CC62INA is selected. 01_B The signal CC62INB is selected. 10_B The signal CC62INC is selected. 11_B The signal CC62IND is selected.

Field	Bits	Type	Description
ISTRP	[7:6]	rw	**Input Select for CTRAP** This bit field defines the input signal used as CTRAP input. 00_B The signal CTRAPA is selected. 01_B The signal CTRAPB is selected. 10_B The signal CTRAPC is selected. 11_B The signal CTRAPD is selected.
ISPOS0	[9:8]	rw	**Input Select for CCPOS0** This bit field defines the input signal used as CCPOS0 input. 00_B The signal CCPOS0A is selected. 01_B The signal CCPOS0B is selected. 10_B The signal CCPOS0C is selected. 11_B The signal CCPOS0D is selected.
ISPOS1	[11:10]	rw	**Input Select for CCPOS1** This bit field defines the input signal used as CCPOS1 input. 00_B The signal CCPOS1A is selected. 01_B The signal CCPOS1B is selected. 10_B The signal CCPOS1C is selected. 11_B The signal CCPOS1D is selected.
ISPOS2	[13:12]	rw	**Input Select for CCPOS2** This bit field defines the input signal used as CCPOS2 input. 00_B The signal CCPOS2A is selected. 01_B The signal CCPOS2B is selected. 10_B The signal CCPOS2C is selected. 11_B The signal CCPOS2D is selected.

Field	Bits	Type	Description
IST12HR	[15:14]	rw	**Input Select for T12HR** This bit field defines the input signal used as T12HR input. 00_B Either signal T12HRA (if T12EXT = 0) or T12HRE (if T12EXT = 1) is selected. 01_B Either signal T12HRB (if T12EXT = 0) or T12HRF (if T12EXT = 1) is selected. 10_B Either signal T12HRC (if T12EXT = 0) or T12HRG (if T12EXT = 1) is selected. 11_B Either signal T12HRD (if T12EXT = 0) or T12HRH (if T12EXT = 1) is selected.
0	[31:16]	r	**Reserved** Returns 0 if read, should be written with 0.

PISEL2

Port Input Select Register 2 **(14_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0								**T13 EXT**	**T12 EXT**	**ISCNT13**		**ISCNT12**		**IST13HR**	
r								rw	rw	rw		rw		rw	

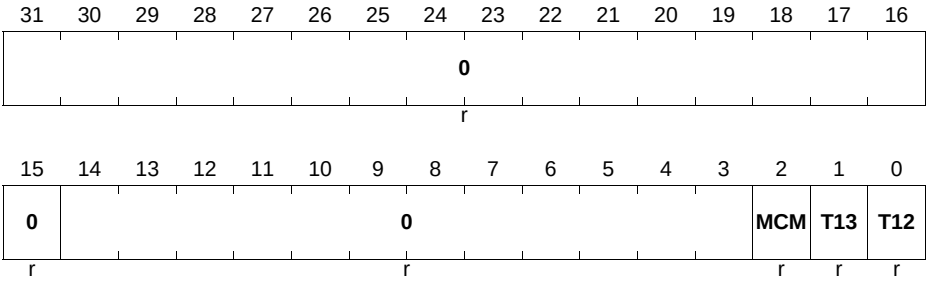
Field	Bits	Type	Description
IST13HR	[1:0]	rw	**Input Select for T13HR** This bit field defines the input signal used as T13HR input. 00_B Either signal T13HRA (if T13EXT = 0) or T13HRE (if T13EXT = 1) is selected. 01_B Either signal T13HRB (if T13EXT = 0) or T13HRF (if T13EXT = 1) is selected. 10_B Either signal T13HRC (if T13EXT = 0) or T13HRG (if T13EXT = 1) is selected. 11_B Either signal T13HRD (if T13EXT = 0) or T13HRH (if T13EXT = 1) is selected.
ISCNT12	[3:2]	rw	**Input Select for T12 Counting Input** This bit field defines the input event leading to a counting action of T12. 00_B The T12 prescaler generates the counting events. Bit TCTR4.T12CNT is not taken into account. 01_B Bit TCTR4.T12CNT written with 1 is a counting event. The T12 prescaler is not taken into account. 10_B The timer T12 is counting each rising edge detected in the selected T12HR signal. 11_B The timer T12 is counting each falling edge detected in the selected T12HR signal.
ISCNT13	[5:4]	rw	**Input Select for T13 Counting Input** This bit field defines the input event leading to a counting action of T13. 00_B The T13 prescaler generates the counting events. Bit TCTR4.T13CNT is not taken into account. 01_B Bit TCTR4.T13CNT written with 1 is a counting event. The T13 prescaler is not taken into account. 10_B The timer T13 is counting each rising edge detected in the selected T13HR signal. 11_B The timer T13 is counting each falling edge detected in the selected T13HR signal.
T12EXT	6	rw	**Extension for T12HR Inputs** This bit extends the 2-bit field IST12HR. 0_B One of the signals T12HR[D:A] is selected. 1_B One of the signals T12HR[H:E] is selected.

Field	Bits	Type	Description
T13EXT	7	rw	**Extension for T13HR Inputs** This bit extends the 2-bit field IST13HR. 0_B One of the signals T13HR[D:A] is selected. 1_B One of the signals T13HR[H:E] is selected.
0	[31:8]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.10.5.3 Module Configuration Register

The module configuration register contains bits describing the functionality that is available in the CCU6 module.

MCFG
Module Configuration Register (04_H) Reset Value: 0000 0007$_H$



Field	Bits	Type	Description
T12	0	r	**T12 Available** This bit indicates if the T12 block is available. 0_B The T12 block is not available. A write access to T12PR is ignored. 1_B The T12 block is available. A write access to T12PR is executed.
T13	1	r	**T13 Available** This bit indicates if the T13 block is available. 0_B The T13 block is not available. A write access to T13PR is ignored. 1_B The T13 block is available. A write access to T13PR is executed.
MCM	2	r	**Multi-Channel Mode Available** This bit indicates if the multi-channel mode functionality is available. 0_B The multi-channel mode functionality is not available. A write access to MCMOUTS is ignored. 1_B The multi-channel mode functionality is available. A write access to MCMOUTS is executed.
0	[31:3]	r	**Reserved;** read as 0; should be written with 0.

26.10.5.4 Input Monitoring Register

The input monitoring register monitors the occurrence of a selected event for the input signals. If a hardware event triggers the setting of bit IMON.x and the same bit is written with 1 via software at the same time, then the corresponding bit is cleared (software overrules hardware). The lost bit event is indicated if an event is detected again at one or more input signals with its lost indicator enabled.

Note: The register is only applicable in capture modes if the edges are selected through T12MSEL.MSEL6x.

IMON
Input Monitoring Register **(98_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						T13HRI	T12HRI	CTRAPI	CC62INI	CC61INI	CC60INI	CCPOS2I	CCPOS1I	CCPOS0I	LBE
r						rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
LBE	0	rwh	**Lost Bit Event** This bit determines if a lost bit event has occurred. A lost bit event occurs when a selected event occurs again with the previous event captured (IMON.x remains set) and its lost indicator is enabled, for at least one of the monitored input signals. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B The lost bit event has not occurred. 1_B The lost bit event has occurred.
CCPOSxI (x = 0 -2)	x + 1	rwh	**Event indication for input signal CCPOSx** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B A selected event has not occurred. 1_B Edge detection indicates a selected event has occurred. *Note: The dedicated edge is indicated for a selected event if Hysteretic-like Control or Capture modes are initialized in T12MSEL.MSEL6x. If these modes are not selected, then all edges will be indicated as an event for the inputs.*
CC6xINI (x = 0 -2)	x + 4	rwh	**Event indication for input signal CC6xIN** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B A selected event has not occurred. 1_B Edge detection indicates a selected event has occurred.
CTRAPI	7	rwh	**Event indication for input signal CTRAP** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B An event has not occurred. 1_B Edge detection indicates an event has occurred.

Field	Bits	Type	Description
T12HRI	8	rwh	**Event indication for input signal T12HR** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B An event has not occurred. 1_B Edge detection indicates an event has occurred.
T13HRI	9	rwh	**Event indication for input signal T13HR** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B An event has not occurred. 1_B Edge detection indicates an event has occurred.
0	[31:10]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.10.5.5 Lost Indicator Register

The lost indicator register has the lost indicator enable bits for its detected event at the input signals. The lost bit event can then be enabled as an output signal through one of the service request lines.

LI
Lost Indicator Register **($9C_H$)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw		rw	r			rw	rw	rw	rw	rw	rw	rw	rw	rw	r

Field	Bits	Type	Description
CCPOSxEN (x = 0 -2)	x + 1	rw	**Lost Indicator Enable for input signal CCPOSx** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
CC6xINEN (x = 0 -2)	x + 4	rw	**Lost Indicator Enable for input signal CC6xIN** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.

Field	Bits	Type	Description
CTRAPEN	7	rw	**Lost Indicator Enable for input signal CTRAP** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
T12HREN	8	rw	**Lost Indicator Enable for input signal T12HR** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
T13HREN	9	rw	**Lost Indicator Enable for input signal T13HR** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
LBEEN	13	rw	**Interrupt Enable for Lost Bit Event** This bit determines if a SRx line is activated if lost bit event is detected. 0_B Lost bit event is disabled for the activation of a SRx line. 1_B Lost bit event is enabled for the activation of a SRx line.
INPLBE	[15:14]	rw	**Interrupt Node Pointer for lost bit event** This bit field defines which service request output line is selected to output an lost event alert for an enabled lost bit event. 00_B Service request output SR0 is selected. 01_B Service request output SR1 is selected. 10_B Service request output SR2 is selected. 11_B Service request output SR3 is selected.
0	0, [12:10], [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.10.5.6 Kernel State Control Sensitivity Register

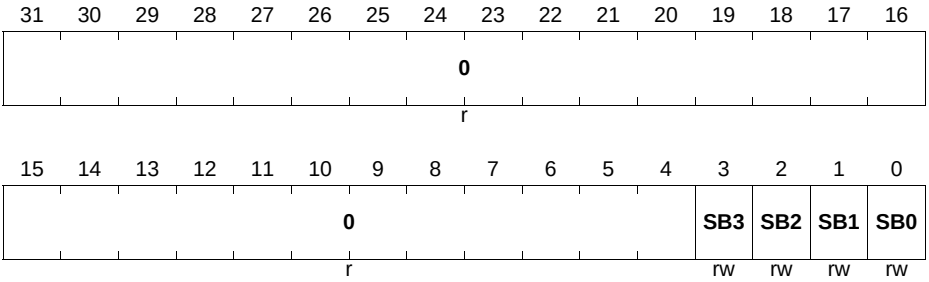
The kernel state control sensitivity register bits define which internal block is affected by Stop Modes 0 and 1, as described in section **Soft Suspend Mode**.

The Kernel State Control Sensitivity Register (KSCSR) is cleared by Debug Reset.

The register can only be written while the OCDS is enabled (OCDS enable = ´1´).

KSCSR
Kernel State Control Sensitivity Register

(1C$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SB0, **SB1,** **SB2,** **SB3**	0, 1, 2, 3	rw	**Sensitivity Block x** This bit defines if block x of the CCU6 kernel is sensitive to Stop Mode 0 or Stop Mode 1. The functional definition of the blocks is given in **Table 26-12**. 0_B Block x is not sensitive to Stop Mode 0 or Stop Mode 1. It continues normal operation without respecting the defined stop condition. 1_B Block x is sensitive to Stop Mode 0 or Stop Mode 1. It is respecting the defined stop condition.
0	[31:4]	r	**Reserved;** Returns 0 if read; should be written with 0.

26.10.6 BPI Registers

This section describes the registers of the BPI (Bus Peripheral Interface). **Figure 26-45** shows all registers associated with the BPI for one CCU6 kernel.

BPI Registers Overview

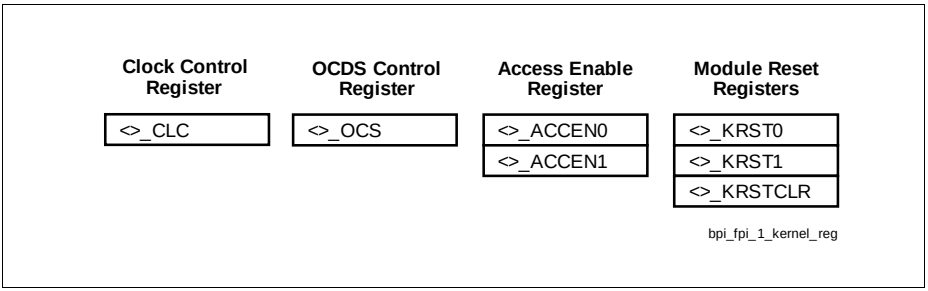


Figure 26-45 BPI Registers

Table 26-14 gives an overview of the BPI registers, including their access modes and reset class.

Table 26-14 Registers Overview - BPI Registers

Register Short Name	Description	Offset Addr.	Access Mode		Reset	Page Num.
			Read	Write		
CLC	Clock Control Register	00_H	U, SV	SV, E, P	Application Reset	26-130
-	Kernel Registers	-	-	-	-	-
OCS	OCDS Control and Status Register	$E8_H$	U, SV	SV, P	Debug Reset	26-131
KRSTCLR	Reset Status Clear Register	EC_H	U, SV	SV, E, P	Application Reset	26-137
KRST1	Reset Control Register 1	$F0_H$	U, SV	SV, E, P	Application Reset	26-136
KRST0	Reset Control Register 0	$F4_H$	U, SV	SV, E, P	Application Reset	26-135

Table 26-14 Registers Overview - BPI Registers

Register Short Name	Description	Offset Addr.	Access Mode		Reset	Page Num.
			Read	Write		
ACCEN1	Access Enable Register 1	$F8_H$	U, SV	SV, SE	Application Reset	26-134
ACCEN0	Access Enable Register 0	FC_H	U, SV	SV, SE	Application Reset	26-133

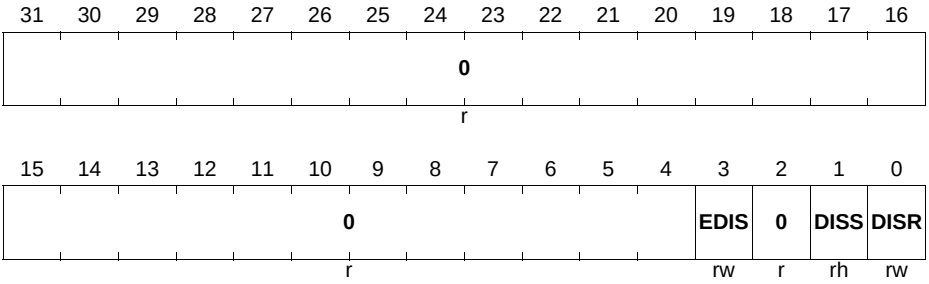
Note: Register bits marked “r” in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

26.10.6.1 System Registers

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI for the CCU6. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{CCU6} module clock signal and Sleep Mode for the module.

CLC
Clock Control Register (00_H) Reset Value: $0000\ 0003_H$



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B Module disable is not requested. 1_B Module disable is requested.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module. 0_B Module is enabled. 1_B Module is disabled.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode. 0_B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode. 1_B Sleep Mode request is disregarded: Sleep Mode cannot be entered upon a request.

Field	Bits	Type	Description
0	[31:16], [15:4], 2	r	**Reserved** Read as 0; should be written with 0.

Note: Upon an accepted Sleep Mode request (with EDIS = '1'), or upon a disable request (DISR = '1'), the CCU6 kernel clock is switched off immediately. Therefore, software should ensure that the system controlled by the CCU6 kernel has reached a safe state before triggering a Sleep Mode or module disable request.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective.

Write access is 32 bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status Register ($E8_H$) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r												w	rw	rw	

Field	Bits	Type	Description
TGS	[1:0]	rw	**Trigger Set for OTGB0/1** 0_H No Trigger Set output 1_H Trigger Set TS16_CCU6 (**Table 26-13**) **others**, reserved
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1

Field	Bits	Type	Description
TG_P	3	w	**TGS, TGB Write Protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. 2_H Soft suspend, Stop Mode 0 3_H Soft suspend, Stop Mode 1 **others**, reserved Effects of soft suspend options on CCU6 Functional Blocks are described in section **Soft Suspend Mode**
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:4], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register 0 (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ..., EN31 -> TAG ID 011111_B.

1) The BPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

ACCEN0
Access Enable Register 0 **(FC_H)** **Reset Value: FFFF FFFF$_H$**

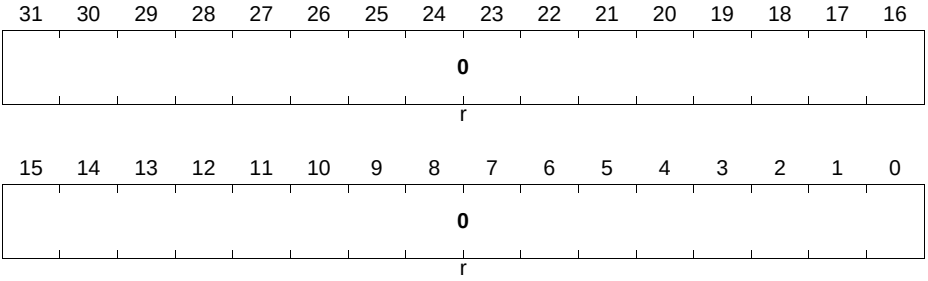
Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register 1 (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ..., EN31 -> TAG ID 111111_B.

ACCEN1
Access Enable Register 1 **($F8_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

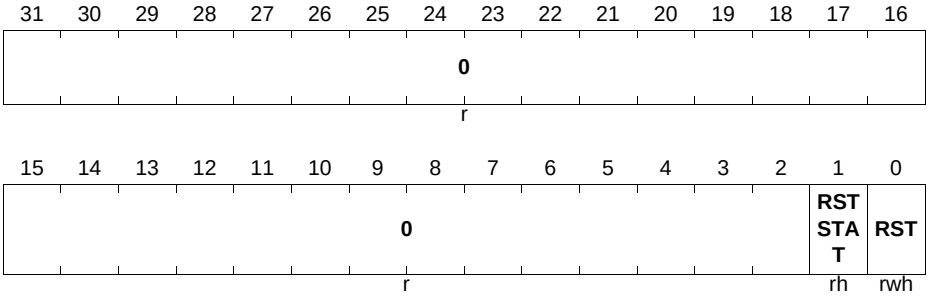
The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers related to the module kernel. The RST bit will be re-set (cleared to ‘0’) by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI in the same clock cycle the RST bit is re-set by the BPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the CLR bit in the related KRSTCLR register.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge

*Note: A kernel reset, initiated via registers KRST0/KRST1, does not affect the port logic. Because register **PSLR** is set to its default value, the passive level 0 is selected for the outputs CC60..CC62 and COUT60..COUT63 upon a kernel reset. Therefore, software must ensure appropriate levels for the external system at the port pins in case they are different from the default values selected via PSLR.*

KRST0
Kernel Reset Register 0 **($F4_H$)** **Reset Value: 0000 0000$_H$**

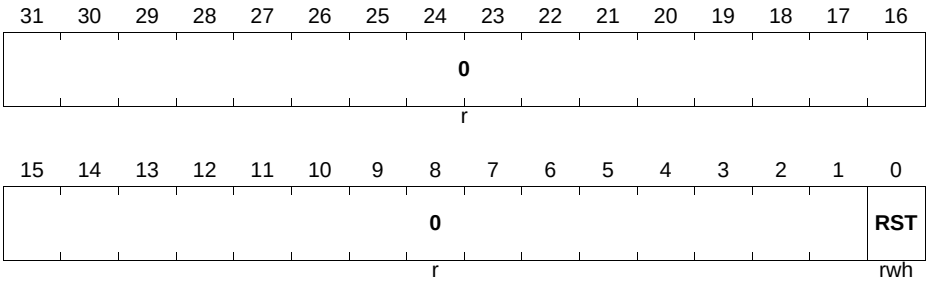


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI after the kernel reset was executed.
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers (KRSTx1.RST and KRSTx0.RST) related to the module kernel that should be reset. The RST bit will be re-set (cleared to ‘0’) by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($F0_H$)** **Reset Value: 0000 0000$_H$**



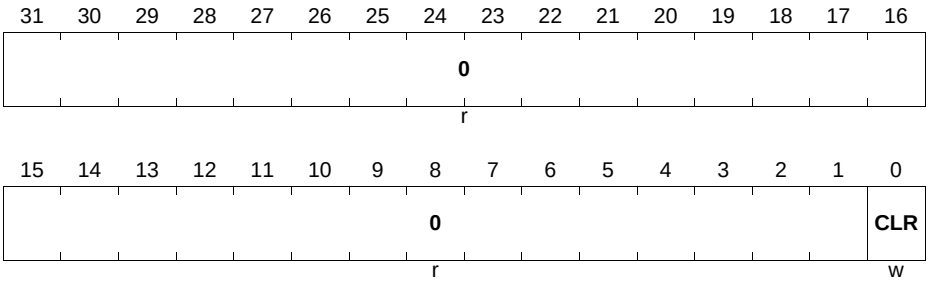
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear Register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (EC_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

26.11 Implementation

This chapter describes the implementation of the CCU6 module in the TC27x device.

- Address map (see **Section 26.11.1**)
- Module output select (see **Section 26.11.2**)
- Synchronous start (see **Section 26.11.3**)
- Digital Connections (see **Section 26.11.4**)

26.11.1 Address Map

There are two CCU6 kernels in the TC27x, namely CCU60 and CCU61. The CCU6061 module consists of CCU60 and CCU61 kernels .

Table 26-15 Registers Address Space

Module	Base Address	End Address	Note
CCU60	$F000\ 2A00_H$	$F000\ 2AFF_H$	CCU6061 module includes CCU60 and CCU61 kernels
CCU61	$F000\ 2B00_H$	$F000\ 2BFF_H$	CCU6061 module includes CCU60 and CCU61 kernels

Table 26-16 Registers Overview - CCU6 Module Registers

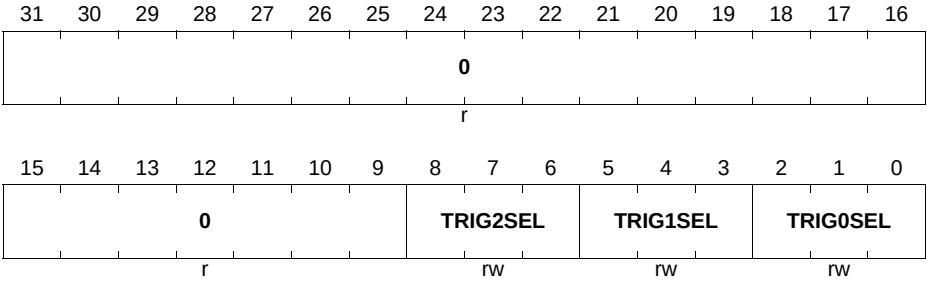
Register Short Name	Register Long Name	Offset Addr.	Access Mode		Reset	Page Num.
			Read	Write		
CCU6061 Module Registers (only available in the address range of CCU60)						
CCU60_MOSEL	CCU60 Module Output Select Register	$0C_H$	U, SV	U, SV, P	Application Reset	26-139

26.11.1.1 Module Registers

Module Output Select Register

MOSEL contains bit fields to select the output signal from module CCU6061 for the trigger signals to the A/D converters in the VADC module.

CCU60_MOSEL
CCU60 Module Output Select Register($0C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TRIG0SEL	[2:0]	rw	**Output Trigger Select for CCU6061 TRIG0** This bit field defines the output signal from the CCU6061 module used as the trigger signal to the VADC inputs. 000_B The signal CCU60_COUT63 is selected. 001_B The signal CCU61_COUT63 is selected. 010_B The signal CCU60_CC60 is selected. 011_B The signal CCU61_CC60 is selected. 100_B The signal CCU60_SR1 is selected. 101_B The signal CCU61_SR1 is selected. 110_B The signal CCU60_SR3 is selected. 111_B The signal CCU61_SR3 is selected.
TRIG1SEL	[5:3]	rw	**Output Trigger Select for CCU6061 TRIG1** This bit field defines the output signal from the CCU6061 module used as the trigger signal to the VADC inputs. 000_B The signal CCU60_COUT63 is selected. 001_B The signal CCU61_COUT63 is selected. 010_B The signal CCU60_CC61 is selected. 011_B The signal CCU61_CC61 is selected. 100_B The signal CCU60_SR1 is selected. 101_B The signal CCU61_SR1 is selected. 110_B The signal CCU60_SR3 is selected. 111_B The signal CCU61_SR3 is selected.
TRIG2SEL	[8:6]	rw	**Output Trigger Select for CCU6061 TRIG2** This bit field defines the output signal from the CCU6061 module used as the trigger signal to the VADC inputs. 000_B The signal CCU60_COUT63 is selected. 001_B The signal CCU61_COUT63 is selected. 010_B The signal CCU60_CC62 is selected. 011_B The signal CCU61_CC62 is selected. 100_B The signal CCU60_SR1 is selected. 101_B The signal CCU61_SR1 is selected. 110_B The signal CCU60_SR3 is selected. 111_B The signal CCU61_SR3 is selected.
0	[31:9]	r	**Reserved** Returns 0 if read, should be written with 0.

*Note: CCU60_MOSEL is located in the address space of kernel CCU60. Therefore, when a reset of kernel CCU60 is triggered via registers CCU60_**KRST0** and CCU60_**KRST1**, register CCU60_MOSEL is also reset.*

*CCU60_MOSEL is **not** reset when a reset of kernel CCU61 is triggered via registers CCU61_KRST0 and CCU61_KRST1.*
*Because CCU60_MOSEL controls both signals from kernel CCU60 and CCU61, the output signals TRIG0..2 will be set to their inactive levels during **any** kernel reset of CCU60 as well as of CCU61 (see also **Figure 26-46**).*
Depending on the application, it may make sense to always reset both kernels in this case.

26.11.2 Module Output Select

For CCU6061 module, there are 3 trigger signals which are selectable from the output signals of the CCU60 and CCU61 kernels.

Each of the trigger signals (TRIG0, TRIG1, TRIG2) of the module is routed to each converter of the VADC module, as follows:

- TRIG0 of CCU6061 is routed to inputs BGREQGTC and GxREQGTC, x = 0..7
- TRIG1 of CCU6061 is routed to inputs BGREQGTD and GxREQGTD, x = 0..7
- TRIG2 of CCU6061 is routed to inputs BGREQGTE and GxREQGTE, x = 0..7

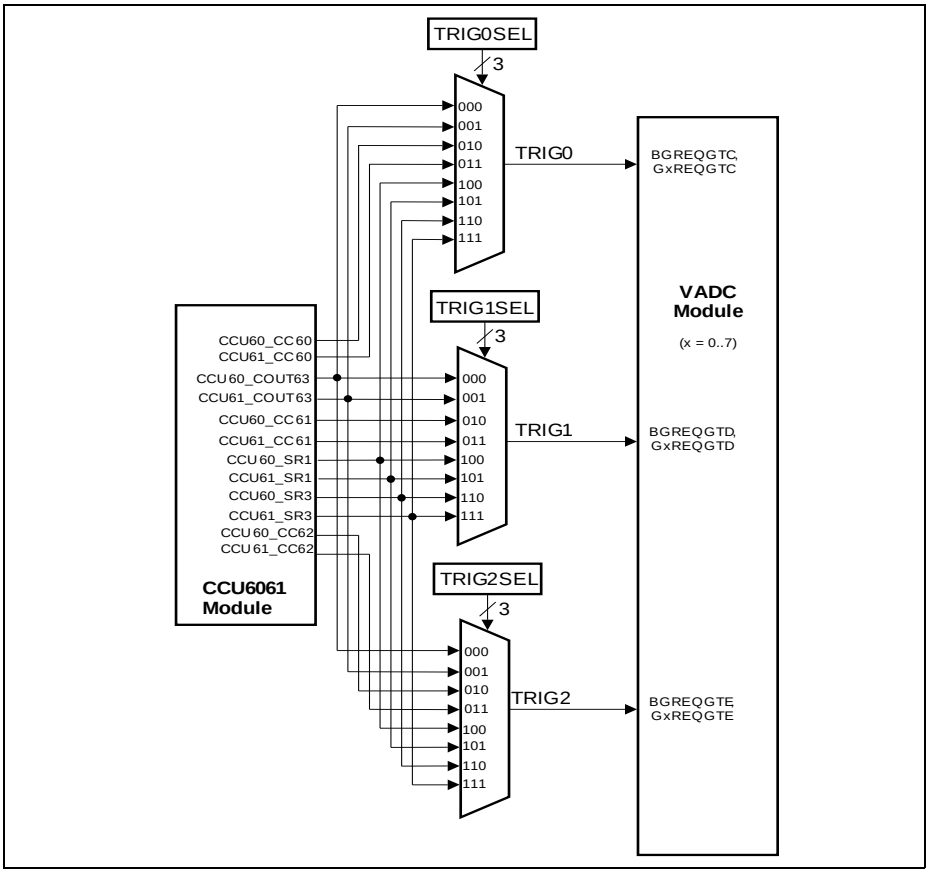


Figure 26-46 Output select trigger TC27x

26.11.3 Synchronous Start

Synchronous start of the capture/compare timers is supported by control bit SYSCON.CCTRIG0 in the SCU module. Bit SYSCON.CCTRIG0 is connected to the T12HR and T13HR inputs of the CCU60 and CCU61 kernels.

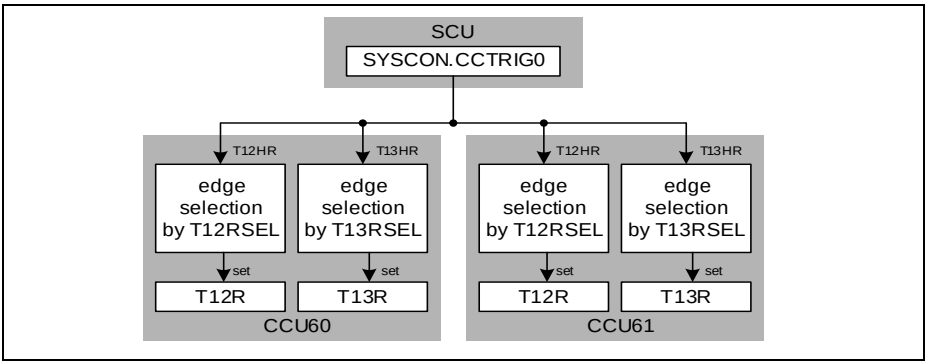

Figure 26-47 Synchronization Concept in TC27x

26.11.4 Digital Connections

The following tables show the digital connections of the CCU6x module with other modules or pins in the TC27x device.
Each input signal can be selected among 4 or 8 possible input lines, e.g. the input vector for input signal CC60IN is composed of CC60IN[D:A], whereas the input vectors for T12HR and T13HR are composed of T12HR[H:A] and T13HR[H:A]. The following sections refer to the interface signals.

The CCU6x module is clocked with the SPB_Bus clock, so $f_{CC6} = f_{SPB}$.

Note: All functional inputs of the CCU6 are synchronized to f_{CC6} before they can affect the module internal logic. The resulting delay of $2/f_{CC6}$ and an uncertainty of $1/f_{CC6}$ have to be taken into account for precise timing calculation.
An edge of an input signal can only be correctly detected if both, the high phase and the low phase of the input signal are each longer than $1/f_{CC6}$.

26.11.4.1 Connections of CCU60

This table describes the module interconnections of CCU60.

27 General Purpose Timer Unit (GPT12)

The General Purpose Timer Unit blocks GPT1 and GPT2 have very flexible multifunctional timer structures which may be used for timing, event counting, pulse width measurement, pulse generation, frequency multiplication, and other purposes.

They incorporate five 16-bit timers that are grouped into the two timer blocks GPT1 and GPT2. Each timer in each block may operate independently in a number of different modes such as Gated Timer or Counter Mode, or may be concatenated with another timer of the same block.

Each block has alternate input/output functions and specific interrupts (service requests) associated with it. Input signals can be selected from several sources by register PISEL.

The GPT12 module is clocked with clock f_{GPT}.

Block GPT1 contains three timers/counters: The core timer T3 and the two auxiliary timers T2 and T4. The maximum resolution is $f_{GPT}/4$. The auxiliary timers of GPT1 may optionally be configured as reload or capture registers for the core timer. These registers are listed in **Section 27.1.6.1**.

The following list summarizes the supported features:

- $f_{GPT}/4$ maximum resolution
- 3 independent timers/counters
- Timers/counters can be concatenated
- 4 operating modes:
  - Timer Mode
  - Gated Timer Mode
  - Counter Mode
  - Incremental Interface Mode
- Reload and Capture functionality
- Separate interrupts

Block GPT2 contains two timers/counters: The core timer T6 and the auxiliary timer T5. The maximum resolution is $f_{GPT}/2$. An additional Capture/Reload register (CAPREL) supports capture and reload operation with extended functionality. These registers are listed in **Section 27.2.7.1**.

The following list summarizes the supported features:

- $f_{GPT}/2$ maximum resolution
- 2 independent timers/counters
- Timers/counters can be concatenated
- 3 operating modes:
  - Timer Mode
  - Gated Timer Mode
  - Counter Mode
- Extended capture/reload functions via 16-bit capture/reload register CAPREL
- Separate interrupts

27.1 Timer Block GPT1

All three timers of block GPT1 (T2, T3, T4) can run in one of 4 basic modes: Timer Mode, Gated Timer Mode, Counter Mode, or Incremental Interface Mode. All timers can count up or down. Each timer of GPT1 is controlled by a separate control register TxCON.

Each timer has an input pin TxIN (alternate pin function) associated with it, which serves as the gate control in Gated Timer Mode, or as the count input in Counter Mode. The count direction (up/down) may be programmed via software or may be dynamically altered by a signal at the External Up/Down control input TxEUD (alternate pin function). An overflow/underflow of core timer T3 is indicated by the Output Toggle Latch T3OTL, whose state may be output on the associated pin T3OUT (alternate pin function). The auxiliary timers T2 and T4 may additionally be concatenated with the core timer T3 (through T3OTL) or may be used as capture or reload registers for the core timer T3.

The current contents of each timer can be read or modified by the CPU by accessing the corresponding timer count registers T2, T3, or T4. When any of the timer registers is written to by the CPU in the state immediately preceding a timer increment, decrement, reload, or capture operation, the CPU write operation has priority in order to guarantee correct results.

The interrupt requests of GPT1 are signalled on service request lines SR0, SR1, and SR2.

The input and output lines of GPT1 are connected to pins. The control registers for the port functions are located in the respective port modules.

*Note: The timing requirements for external input signals can be found in **Section 27.1.5**, **Section 27.5.2** summarizes the module interface signals, including pins and interrupt request signals.*

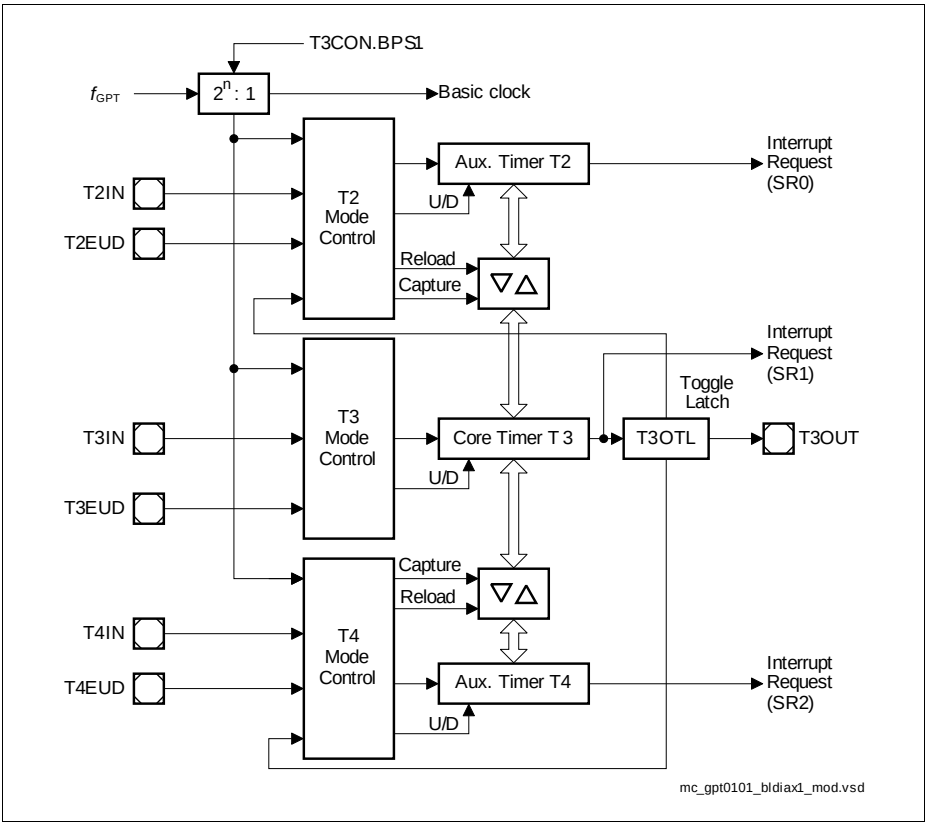

Figure 27-1 GPT1 Block Diagram

27.1.1 GPT1 Core Timer T3 Control

The current contents of the core timer T3 are reflected by its count register T3. This register can also be written to by the CPU, for example, to set the initial start value.

The core timer T3 is configured and controlled via its control register T3CON.

Timer T3 Run Control

The core timer T3 can be started or stopped by software through bit T3R (Timer T3 Run Bit). This bit is relevant in all operating modes of T3. Setting bit T3R will start the timer, clearing bit T3R stops the timer.

In Gated Timer Mode, the timer will only run if T3R = 1 and the gate is active (high or low, as programmed).

Note: When bit T2RC or T4RC in timer control register T2CON or T4CON is set, bit T3R will also control (start and stop) the auxiliary timer(s) T2 and/or T4.

Count Direction Control

The count direction of the GPT1 timers (core timer and auxiliary timers) can be controlled either by software or by the external input pin TxEUD (Timer Tx External Up/Down Control Input). These options are selected by bits TxUD and TxUDE in the respective control register TxCON. When the up/down control is provided by software (bit TxUDE = 0), the count direction can be altered by setting or clearing bit TxUD. When bit TxUDE = 1, pin TxEUD is selected to be the controlling source of the count direction. However, bit TxUD can still be used to reverse the actual count direction, as shown in **Table 27-6**. The count direction can be changed regardless of whether or not the timer is running.

Note: When pin TxEUD is used as external count direction control input, it must be configured as input.

Timer T3 Output Toggle Latch

The overflow/underflow signal of timer T3 is connected to a block named ‘Toggle Latch’, shown in the Timer Mode diagrams. **Figure 27-2** illustrates the details of this block. An overflow or underflow of T3 will clock two latches: The first latch represents bit T3OTL in control register T3CON. The second latch is an internal latch toggled by T3OTL’s output. Both latch outputs are connected to the input control blocks of the auxiliary timers T2 and T4. The output level of the shadow latch will match the output level of T3OTL, but is delayed by one clock cycle. When the T3OTL value changes, this will result in a temporarily different output level from T3OTL and the shadow latch, which can trigger the selected count event in T2 and/or T4.

When software writes to T3OTL, both latches are set or cleared simultaneously. In this case, both signals to the auxiliary timers carry the same level and no edge will be detected. Bit T3OE (overflow/underflow output enable) in register T3CON enables the state of T3OTL to be monitored via an external pin T3OUT. When T3OTL is linked to an external port pin (must be configured as output), T3OUT can be used to control external HW. If T3OE = 1, pin T3OUT outputs the state of T3OTL. If T3OE = 0, pin T3OUT outputs a high level (as long as the T3OUT alternate function is selected for the port pin).

The trigger signals can serve as an input for the counter function or as a trigger source for the reload function of the auxiliary timers T2 and T4.

As can be seen from **Figure 27-2**, when latch T3OTL is modified by software to determine the state of the output line, also the internal shadow latch is set or cleared accordingly. Therefore, no trigger condition is detected by T2/T4 in this case.

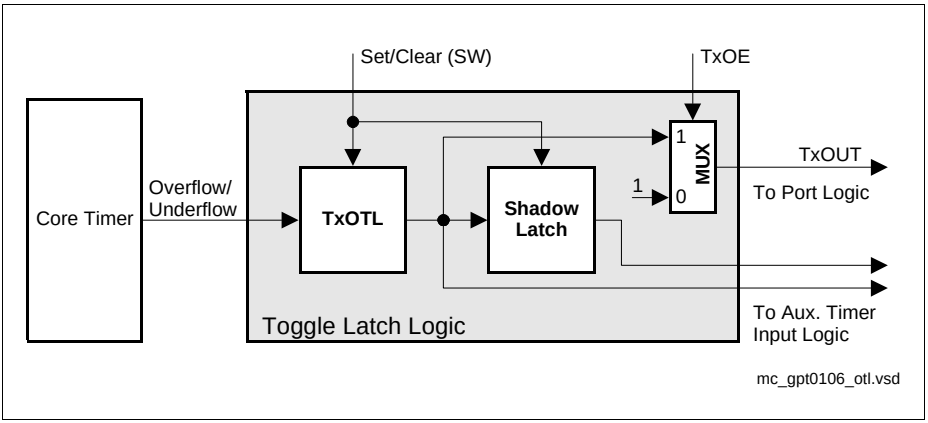

Figure 27-2 Block Diagram of the Toggle Latch Logic of Core Timer T3 (x = 3)

27.1.2 GPT1 Core Timer T3 Operating Modes

Timer T3 can operate in one of several modes.

Timer T3 in Timer Mode

Timer Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 000_B. In Timer Mode, T3 is clocked with the module's input clock f_{GPT} divided by two programmable prescalers controlled by bitfields BPS1 and T3I in register T3CON. Please see **Section 27.1.5** for details on the input clock options.

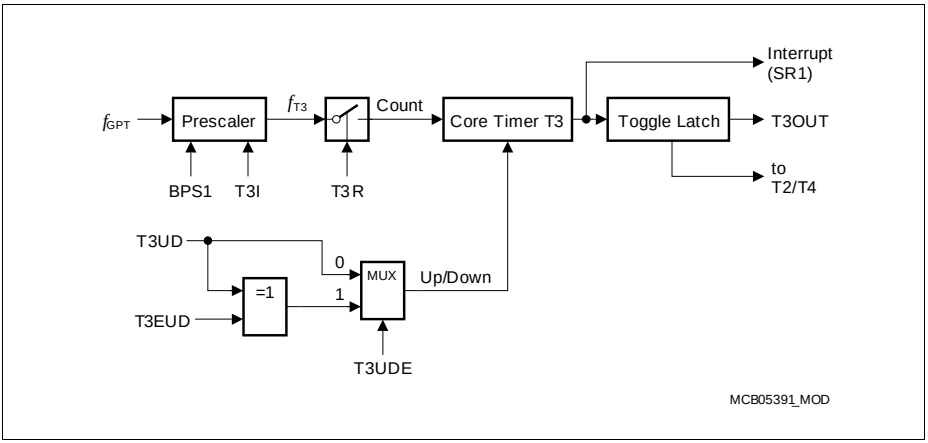

Figure 27-3 Block Diagram of Core Timer T3 in Timer Mode

Timer T3 in Gated Timer Mode

Gated Timer Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 010_B or 011_B. Bit T3M.0 (T3CON.3) selects the active level of the gate input. The same options for the input frequency are available in Gated Timer Mode as in Timer Mode (see **Section 27.1.5**). However, the input clock to the timer in this mode is gated by the external input pin T3IN (Timer T3 External Input).

To enable this operation, the associated pin T3IN must be configured as input.

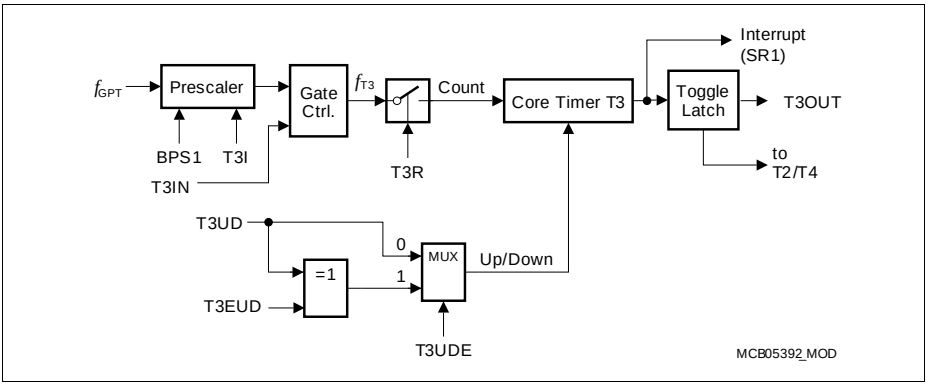

Figure 27-4 Block Diagram of Core Timer T3 in Gated Timer Mode

If T3M = 010_B, the timer is enabled when T3IN shows a low level. A high level at this line stops the timer. If T3M = 011_B, line T3IN must have a high level in order to enable the timer. Additionally, the timer can be turned on or off by software using bit T3R. The timer will only run if T3R is 1 and the gate is active. It will stop if either T3R is 0 or the gate is inactive.

Note: A transition of the gate signal at pin T3IN does not cause a service request via SR1.

Timer T3 in Counter Mode

Counter Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 001_B. In Counter Mode, timer T3 is clocked by a transition at the external input pin T3IN. The event causing an increment or decrement of the timer can be a positive, a negative, or both a positive and a negative transition at this line. Bitfield T3I in control register T3CON selects the triggering transition (see **Table 27-8**).

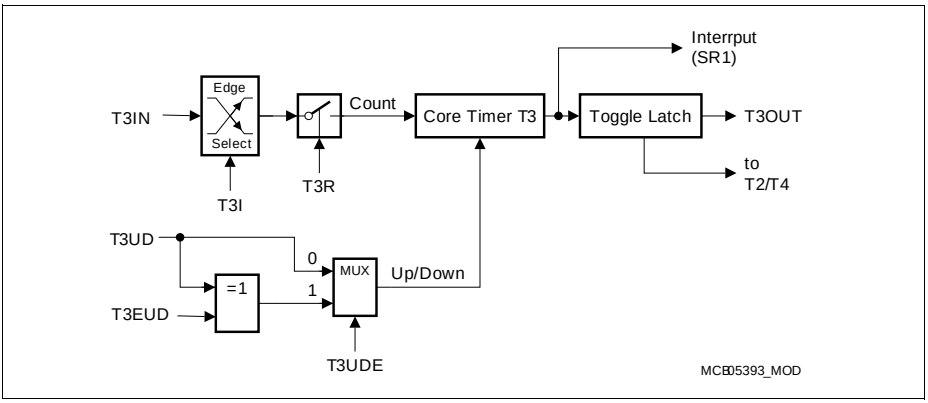

Figure 27-5 Block Diagram of Core Timer T3 in Counter Mode

For Counter Mode operation, pin T3IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T3IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 27.1.5**.

Timer T3 in Incremental Interface Mode

Incremental Interface Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 110_B or 111_B. In Incremental Interface Mode, the two inputs associated with core timer T3 (T3IN, T3EUD) are used to interface to an incremental encoder. T3 is clocked by each transition on one or both of the external input pins to provide 2-fold or 4-fold resolution of the encoder input.

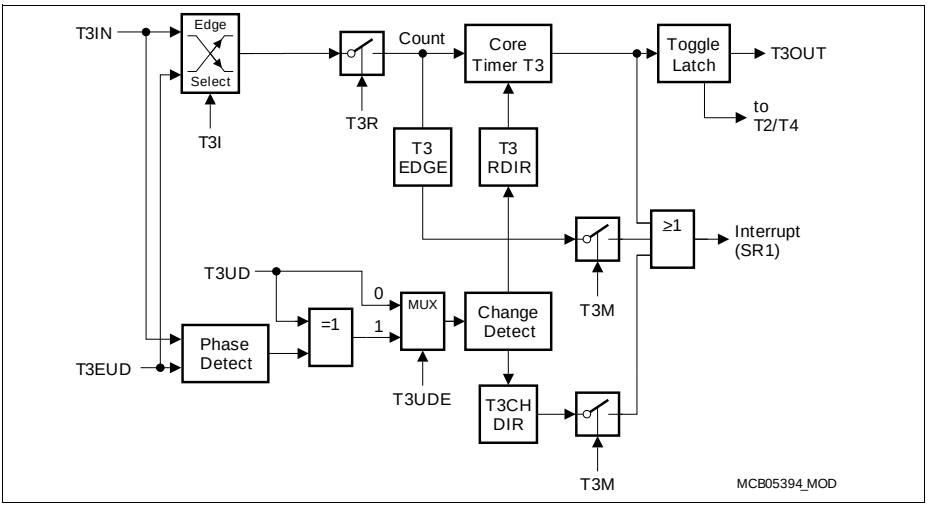

Figure 27-6 Block Diagram of Core Timer T3 in Incremental Interface Mode

Bitfield T3I in control register T3CON selects the triggering transitions (see **Table 27-10**). The sequence of the transitions of the two input signals is evaluated and generates count pulses as well as the direction signal. So T3 is modified automatically according to the speed and the direction of the incremental encoder and, therefore, its contents always represent the encoder's current position.

The service request generation can be selected: In Rotation Detection Mode (T3M = 110_B), a service request is generated each time the count direction of T3 changes. In Edge Detection Mode (T3M = 111_B), a service request is generated each time a count edge for T3 is detected. Count direction, changes in the count direction, and count requests are monitored by status bits T3RDIR, T3CHDIR, and T3EDGE in register T3CON.

The incremental encoder can be connected directly to the TC27x without external interface logic. In a standard system, however, comparators will be employed to convert the encoder's differential outputs (such as A, $\overline{A}$) to digital signals (such as A). This greatly increases noise immunity.

Note: The third encoder output T0, that indicates the mechanical zero position, may be connected to an external interrupt input and trigger a reset of timer T3.
*If input T4IN is available, T0 can be connected there and clear T3 automatically without requiring an interrupt (see bit CLRT3EN in register **T4CON**).*

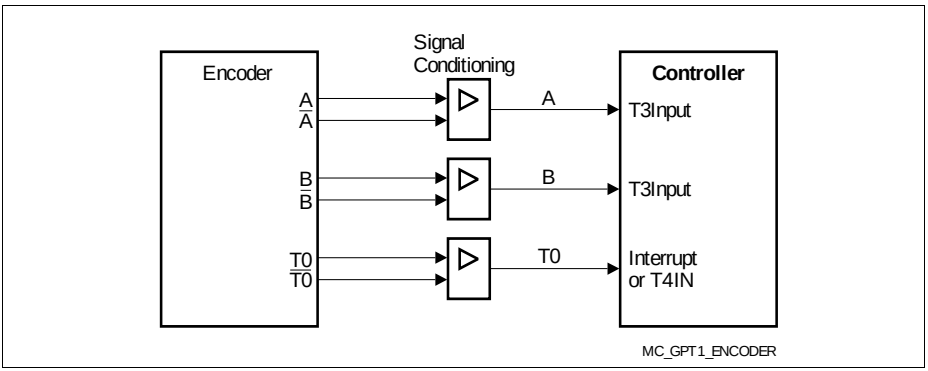

Figure 27-7 Connection of the Encoder to the TC27x

For Incremental Interface Mode operation, the following conditions must be met:

- Bitfield T3M must be 110_B or 111_B.
- Both pins T3IN and T3EUD must be configured as input.
- Pin T4IN must be configured as input, if used for T0.
- Bit T3UDE must be 1 to enable automatic external direction control.

The maximum count frequency allowed in Incremental Interface Mode depends on the selected prescaler value. To ensure that a transition of any input signal is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 27.1.5**.

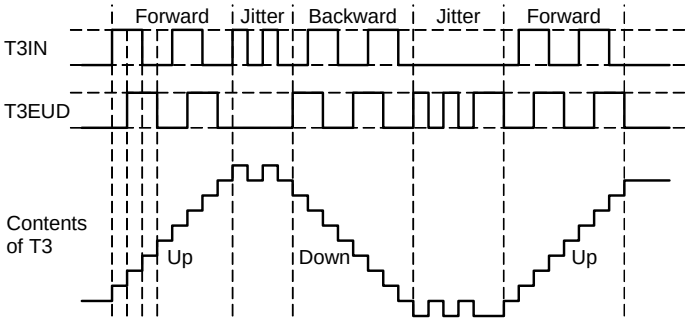
As in Incremental Interface Mode two input signals with a 90° phase shift are evaluated, their maximum input frequency can be half the maximum count frequency.

In Incremental Interface Mode, the count direction is automatically derived from the sequence in which the input signals change, which corresponds to the rotation direction of the connected sensor. **Table 27-1** summarizes the possible combinations.

Table 27-1 GPT1 Core Timer T3 (Incremental Interface Mode) Count Direction

Level on Respective other Input	T3IN Input		T3EUD Input	
	Rising ↑	**Falling ↓**	**Rising ↑**	**Falling ↓**
High	Down	Up	Up	Down
Low	Up	Down	Down	Up

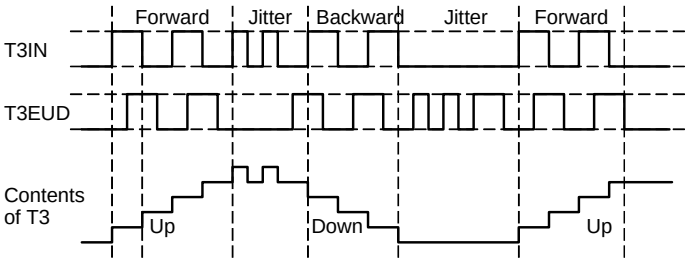
Figure 27-8 and **Figure 27-9** give examples of T3's operation, visualizing count signal generation and direction control. They also show how input jitter is compensated, which might occur if the sensor rests near to one of its switching points.



Note: This example shows the timer behaviour assuming that T3 counts upon any transition on any input (T3IN and T3EUD), i.e. T3I = 011_B.

MCT04373

Figure 27-8 Evaluation of Incremental Encoder Signals, 2 Count Inputs



Note: This example shows the timer behaviour assuming that T3 counts upon any transition on input T3IN, i.e. T3I = 001_B.

MCT04374

Figure 27-9 Evaluation of Incremental Encoder Signals, 1 Count Input

Note: Timer T3 operating in Incremental Interface Mode automatically provides information on the sensor's current position. Dynamic information (speed,

acceleration, deceleration) may be obtained by measuring the incoming signal periods (see ***"Combined Capture Modes" on Page 27-58****).*

27.1.3 GPT1 Auxiliary Timers T2/T4 Control

Auxiliary timers T2 and T4 have exactly the same functionality. They can be configured for Timer Mode, Gated Timer Mode, Counter Mode, or Incremental Interface Mode with the same options for the timer frequencies and the count signal as the core timer T3. In addition to these 4 counting modes, the auxiliary timers can be concatenated with the core timer, or they may be used as reload or capture registers in conjunction with the core timer. The start/stop function of the auxiliary timers can be remotely controlled by the T3 run control bit. Several timers may thus be controlled synchronously.

The current contents of an auxiliary timer are reflected by its count register T2 or T4, respectively. These registers can also be written to by the CPU, for example, to set the initial start value.

The individual configurations for timers T2 and T4 are determined by their control registers T2CON and T4CON, that are organized identically. Note that functions which are present in all 3 timers of block GPT1 are controlled in the same bit positions and in the same manner in each of the specific control registers.

Note: The auxiliary timers have no output toggle latch and no alternate output function.

Timer T2/T4 Run Control

Each of the auxiliary timers T2 and T4 can be started or stopped by software in two different ways:

- Through the associated timer run bit (T2R or T4R). In this case it is required that the respective control bit TxRC = 0.
- Through the core timer's run bit (T3R). In this case the respective remote control bit must be set (TxRC = 1).

The selected run bit is relevant in all operating modes of T2/T4. Setting the bit will start the timer, clearing the bit stops the timer.

In Gated Timer Mode, the timer will only run if the selected run bit is set and the gate is active (high or low, as programmed).

Note: If remote control is selected T3R will start/stop timer T3 and the selected auxiliary timer(s) synchronously.

Count Direction Control

The count direction of the GPT1 timers (core timer and auxiliary timers) is controlled in the same way, either by software or by the external input pin TxEUD. Please refer to the description in **Table 27-6**.

Note: When pin TxEUD is used as external count direction control input, it must be configured as input.

27.1.4 GPT1 Auxiliary Timers T2/T4 Operating Modes

The operation of the auxiliary timers in the basic operating modes is almost identical with the core timer's operation, with very few exceptions. Additionally, some combined operating modes can be selected.

Timers T2 and T4 in Timer Mode

Timer Mode for an auxiliary timer Tx is selected by setting its bitfield TxM in register TxCON to 000_B.

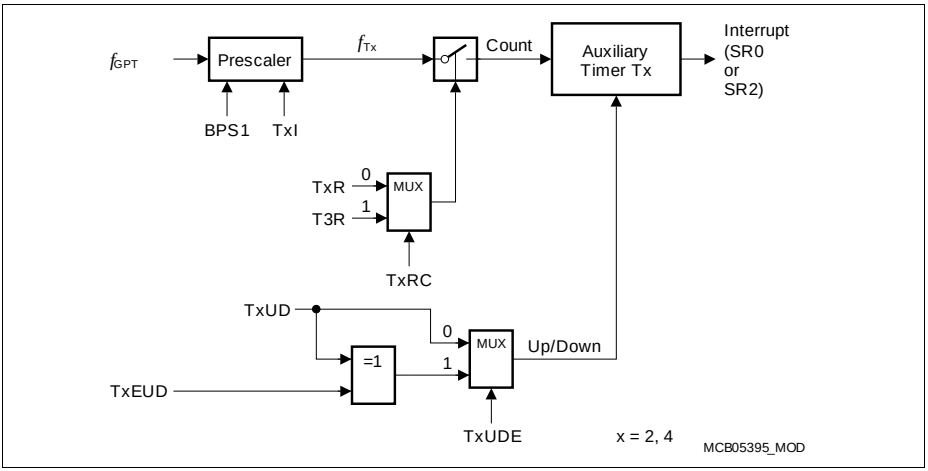


Figure 27-10 Block Diagram of an Auxiliary Timer in Timer Mode

Timers T2 and T4 in Gated Timer Mode

Gated Timer Mode for an auxiliary timer Tx is selected by setting bitfield TxM in register TxCON to 010_B or 011_B. Bit TxM.0 (TxCON.3) selects the active level of the gate input.

Note: A transition of the gate signal at TxIN does not cause a service request. Service requests of timer T2 are handled via SR0, and service requests of timer T4 are handled via SR2.

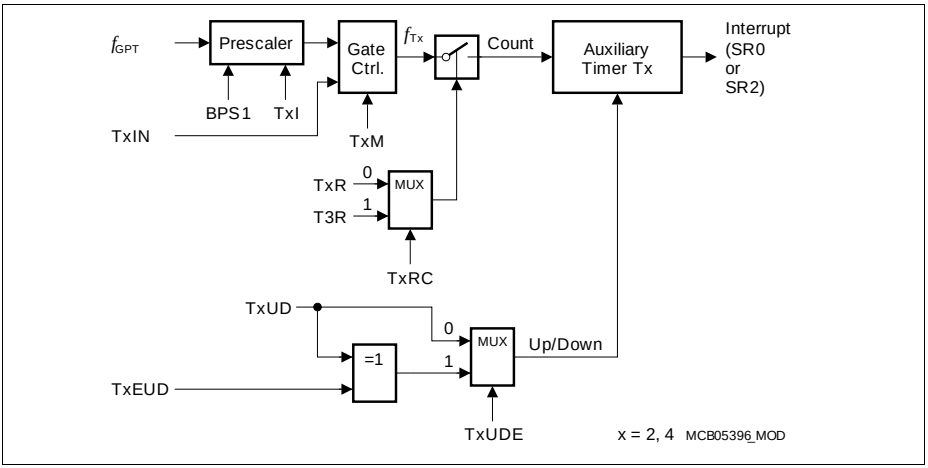

Figure 27-11 Block Diagram of an Auxiliary Timer in Gated Timer Mode

Note: There is no output toggle latch for T2 and T4.
Start/stop of an auxiliary timer can be controlled locally or remotely.

Timers T2 and T4 in Counter Mode

Counter Mode for an auxiliary timer Tx is selected by setting bitfield TxM in register TxCON to 001_B. In Counter Mode, an auxiliary timer can be clocked either by a transition at its external input line TxIN, or by a transition of timer T3's toggle latch T3OTL. The event causing an increment or decrement of a timer can be a positive, a negative, or both a positive and a negative transition at either the respective input pin or at the toggle latch. Bitfield TxI in control register TxCON selects the triggering transition (see **Table 27-9**).

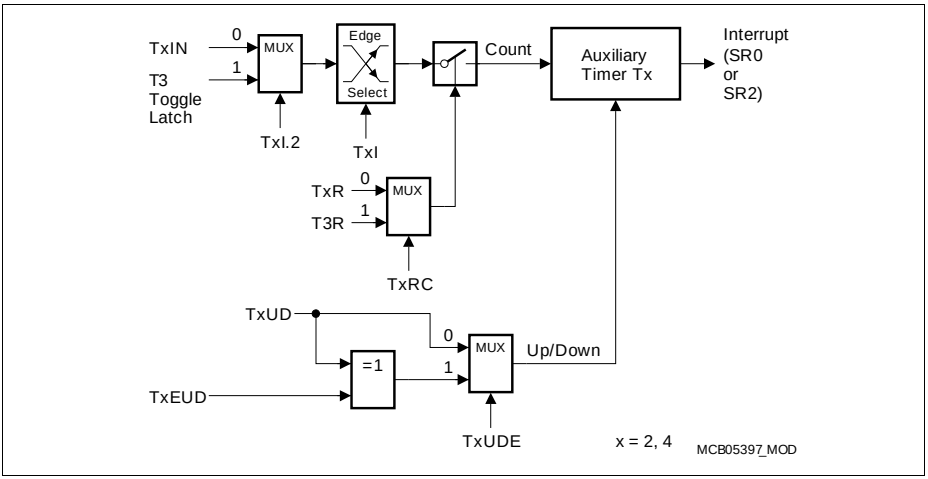

Figure 27-12 Block Diagram of an Auxiliary Timer in Counter Mode

Note: Only state transitions of T3OTL which are caused by the overflows/underflows of T3 will trigger the counter function of T2/T4. Modifications of T3OTL via software will NOT trigger the counter function of T2/T4.

For counter operation, pin TxIN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 27.1.5**.

Timer Concatenation

Using the toggle bit T3OTL as a clock source for an auxiliary timer in Counter Mode concatenates the core timer T3 with the respective auxiliary timer. This concatenation forms either a 32-bit or a 33-bit timer/counter, depending on which transition of T3OTL is selected to clock the auxiliary timer.

- **32-bit Timer/Counter:** If both a positive and a negative transition of T3OTL are used to clock the auxiliary timer, this timer is clocked on every overflow/underflow of the core timer T3. Thus, the two timers form a 32-bit timer.
- **33-bit Timer/Counter:** If either a positive or a negative transition of T3OTL is selected to clock the auxiliary timer, this timer is clocked on every second overflow/underflow of the core timer T3. This configuration forms a 33-bit timer (16-bit core timer + T3OTL + 16-bit auxiliary timer).
  As long as bit T3OTL is not modified by software, it represents the state of the internal toggle latch, and can be regarded as part of the 33-bit timer.

The count directions of the two concatenated timers are not required to be the same. This offers a wide variety of different configurations.

T3, which represents the low-order part of the concatenated timer, can operate in Timer Mode, Gated Timer Mode or Counter Mode in this case.

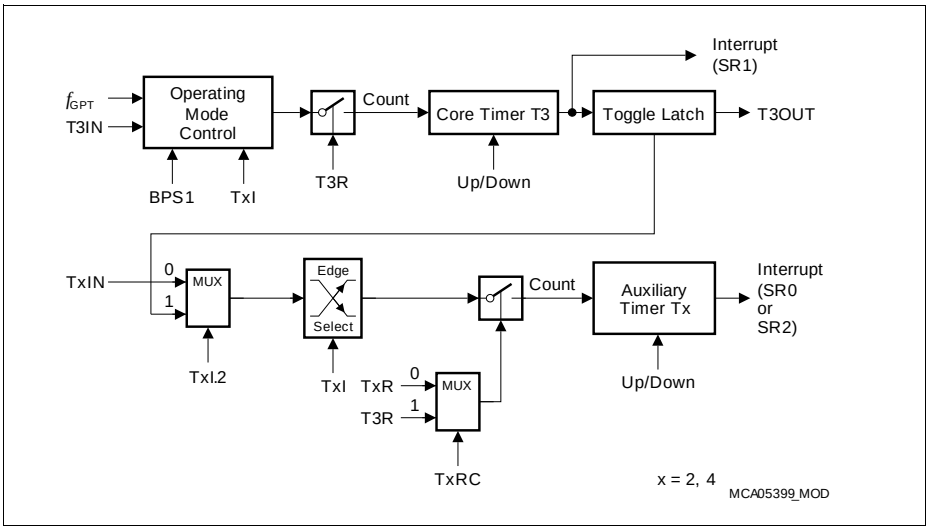

Figure 27-13 Concatenation of Core Timer T3 and an Auxiliary Timer

When reading the low and high parts of the concatenated timer, care must be taken to obtain consistent values in particular after a timer overflow/underflow (e.g. one part may already have considered an overflow, while the other has not).

Note: This is a general issue when reading multi-word results with consecutive instructions, and not necessarily unique to the GPT12 module architecture.

The following algorithm may be used to read concatenated GPT1 timers, represented by TIMER_HIGH (for auxiliary timer, here T2) and TIMER_LOW (for core timer T3). The high part is read twice, and reading of the low part is repeated if two different values were read for the high part:

- TIMER_HIGH_TMP = T2
- TIMER_LOW = T3
- Wait two basic clock cycles (to allow increment/decrement of auxiliary timer in case of core timer overflow/underflow) - see **Table 27-2**
- TIMER_HIGH = T2
- If TIMER_HIGH is not equal to TIMER_HIGH_TMP then TIMER_LOW = T3

After execution of this algorithm, TIMER_HIGH and TIMER_LOW represent a consistent time stamp of the concatenated timers.

The equivalent number of module clock cycles corresponding to two basic clock cycles is shown in **Table 27-2**.

Table 27-2 Number of Module Clock Cycles to Wait for Two Basic Clock Cycles

Block Prescaler	BPS1 = 01_B	BPS1 = 00_B	BPS1 = 11_B	BPS1 = 10_B
Number of Module clocks	8	16	32	64

In case the required timer resolution can be achieved with different combinations of the Block Prescaler BPS1 and the Individual Prescalers TxI (see **Table 27-7**), the variant with the smallest value for the Block Prescaler may be chosen to minimize the waiting time.

Timers T2 and T4 in Incremental Interface Mode

Incremental Interface Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 110_B or 111_B. In Incremental Interface Mode, the two inputs associated with an auxiliary timer Tx (TxIN, TxEUD) are used to interface to an incremental encoder. Tx is clocked by each transition on one or both of the external input pins to provide 2-fold or 4-fold resolution of the encoder input.

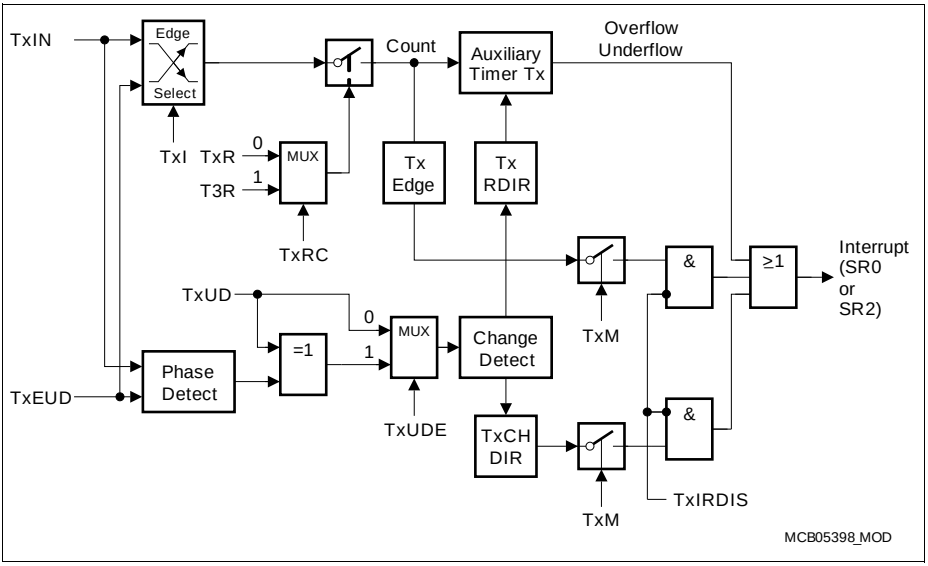

Figure 27-14 Block Diagram of an Auxiliary Timer in Incremental Interface Mode

The operation of the auxiliary timers T2 and T4 in Incremental Interface Mode and the interrupt generation are the same as described for the core timer T3. The descriptions, figures and tables apply accordingly.

Note: Timers T2 and T4 operating in Incremental Interface Mode automatically provide information on the sensor's current position. For dynamic information (speed, acceleration, deceleration) see ***"Combined Capture Modes" on Page 27-58****).*

Timers T2 and T4 in Reload Mode

Reload Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 100_B. In Reload Mode, the core timer T3 is reloaded with the contents of an auxiliary timer register, triggered by one of two different signals. The trigger signal is selected the same way as the clock source for Counter Mode (see **Table 27-9**), i.e. a transition of the auxiliary timer's input TxIN or the toggle latch T3OTL may trigger the reload.

Note: When programmed for Reload Mode, the respective auxiliary timer (T2 or T4) stops independently of its run flag T2R or T4R.
The timer input pin TxIN must be configured as input if it shall trigger a reload operation.

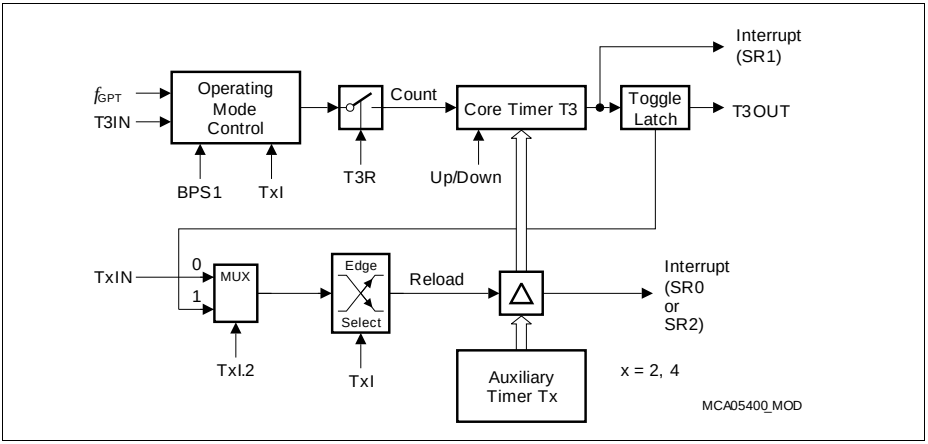

Figure 27-15 GPT1 Auxiliary Timer in Reload Mode

Upon a trigger signal, T3 is loaded with the contents of the respective timer register (T2 or T4) and the respective service request SR0 or SR2 is activated.

Note: When a T3OTL transition is selected for the trigger signal, service request SR1 will also become active, indicating T3's overflow or underflow. Modifications of T3OTL via software will NOT trigger the counter function of T2/T4.

To ensure that a transition of the reload input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in **Section 27.1.5**.

The Reload Mode triggered by the T3 toggle latch can be used in a number of different configurations. The following functions can be performed, depending on the selected active transition:

- If both a positive and a negative transition of T3OTL are selected to trigger a reload, the core timer will be reloaded with the contents of the auxiliary timer each time it overflows or underflows. This is the standard Reload Mode (reload on overflow/underflow).
- If either a positive or a negative transition of T3OTL is selected to trigger a reload, the core timer will be reloaded with the contents of the auxiliary timer on every second overflow or underflow.
- Using this “single-transition” mode for both auxiliary timers allows to perform very flexible Pulse Width Modulation (PWM). One of the auxiliary timers is programmed to reload the core timer on a positive transition of T3OTL, the other is programmed for a reload on a negative transition of T3OTL. With this combination the core timer is alternately reloaded from the two auxiliary timers.

Figure 27-16 shows an example for the generation of a PWM signal using the “single-transition” reload mechanism. T2 defines the high time of the PWM signal (reloaded on positive transitions) and T4 defines the low time of the PWM signal (reloaded on negative transitions). The PWM signal can be output on pin T3OUT if T3OE = 1. With this method, the high and low time of the PWM signal can be varied in a wide range.

Note: The output toggle latch T3OTL is accessible via software and may be changed, if required, to modify the PWM signal.
However, this will NOT trigger the reloading of T3.

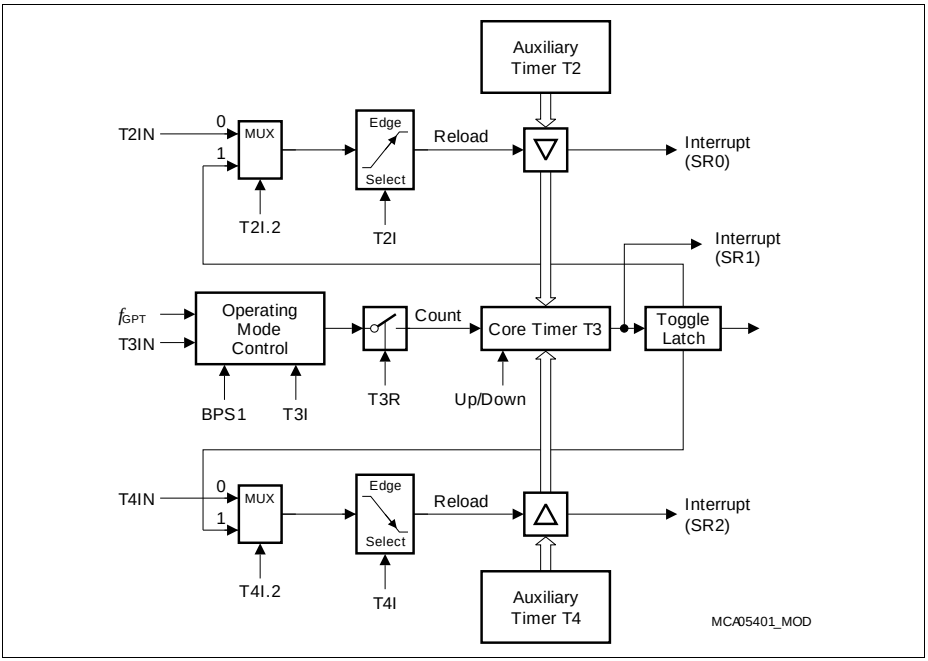

Figure 27-16 GPT1 Timer Reload Configuration for PWM Generation

Note: Although possible, selecting the same reload trigger event for both auxiliary timers should be avoided. In such a case, both reload registers would try to load the core timer at the same time. If this combination is selected, T2 is disregarded and the contents of T4 is reloaded.

The implementation of the GPT1 finite state machine may require special consideration in following cases.

In Case 1, when T2 or T4 are used to reload T3 on overflow/underflow, and T3 is read by software on the fly, the following unexpected values may be read from T3:

- When T3 is counting up, 0000_H or 0001_H may be read from T3 directly after an overflow, although the reload value in T2/T4 is higher (0001_H may be read in particular if BPS1 = 01_B and T3I = 000_B).
- When T3 is counting down, $FFFF_H$ or $FFFE_H$ may be read from T3 directly after an underflow, although the reload value in T2/T4 is lower ($FFFE_H$ may be read in particular if BPS1 = 01_B and T3I = 000_B).

Note: All timings derived from T3 in this configuration (e.g. distance between service requests, PWM waveform on T3OUT, etc.) are accurate except for the specific case described below.

Recommendation:

- When T3 counts up, and T3_value < reload value is read from T3, T3_value should be replaced with the reload value for further calculations.
- When T3 counts down, and T3_value > reload value is read from T3, T3_value should be replaced with the reload value for further calculations.

Alternatively, if the intention is to identify the overflow/underflow of T3, the T3 service request (SR1) may be used.

In Case 2, when T2 is used to reload T3 in the configuration with BPS1 = 01_B and T3I = 000_B (i.e. fastest configuration/highest resolution of T3), the reload of T3 is performed with a delay of one basic clock cycle.

Recommendation:

To compensate the delay and achieve correct timing,

- increment the reload value in T2 by 1 when T3 is configured to count up,
- decrement the reload value in T2 by 1 when T3 is configured to count down.

Alternatively, use T4 instead of T2 as reload register for T3. In this configuration the reload of T3 is not delayed, i.e. the effect described above does not occur with T4.

Timers T2 and T4 in Capture Mode

Capture Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 101_B. In Capture Mode, the contents of the core timer T3 are latched into an auxiliary timer register in response to a signal transition at the respective auxiliary timer's external input pin TxIN. The capture trigger signal can be a positive, a negative, or both a positive and a negative transition.

The two least significant bits of bitfield TxI select the active transition (see **Table 27-9**). Bit 2 of TxI is irrelevant for Capture Mode and must be cleared (TxI.2 = 0).

Note: When programmed for Capture Mode, the respective auxiliary timer (T2 or T4) stops independently of its run flag T2R or T4R.

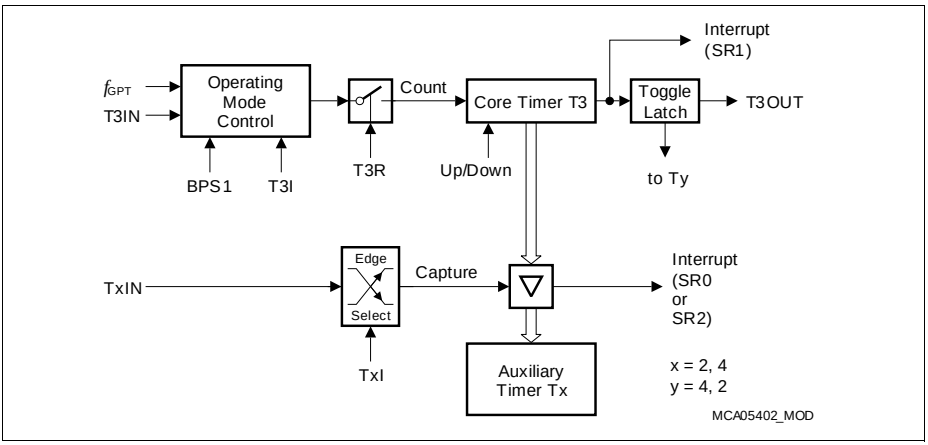

Figure 27-17 GPT1 Auxiliary Timer in Capture Mode

Upon a trigger (selected transition) at the corresponding input pin TxIN the contents of the core timer T3 are loaded into the auxiliary timer register Tx and the associated service request (SR0 or SR2) will be activated.

For Capture Mode operation, the respective timer input pin TxIN must be configured as input. To ensure that a transition of the capture input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in **Section 27.1.5**.

27.1.5 GPT1 Clock Signal Control

All actions within the timer block GPT1 are triggered by transitions of its basic clock. This basic clock is derived from the module clock f_{GPT} by a basic block prescaler, controlled by bitfield BPS1 in register T3CON (see **Figure 27-1**). The count clock can be generated in two different ways:

- **Internal count clock**, derived from GPT1's basic clock via a programmable prescaler, is used for (Gated) Timer Mode.
- **External count clock**, derived from the timer's input pin(s), is used for Counter Mode or Incremental Interface Mode.

For both ways, the basic clock determines the maximum count frequency and the timer's resolution:

Table 27-3 Basic Clock Selection for Block GPT1

Block Prescaler[1)]	BPS1 = 01_B	BPS1 = 00_B[2)]	BPS1 = 11_B	BPS1 = 10_B
Prescaling Factor for GPT1: F(BPS1)	F(BPS1) = 4	F(BPS1) = 8	F(BPS1) = 16	F(BPS1) = 32
Maximum External Count Frequency	$f_{GPT}/8$	$f_{GPT}/16$	$f_{GPT}/32$	$f_{GPT}/64$
Input Signal Stable Time	4 x t_{GPT}	8 x t_{GPT}	16 x t_{GPT}	32 x t_{GPT}

1) Please note the non-linear encoding of bitfield BPS1.

2) Default after reset.

Note: The GPT1 block uses a finite state machine to control the actions. Since multiple interactions are possible between the timers (T2, T3, T4), these elements are processed sequentially. However, all actions are normally completed within one basic clock cycle. The GPT1 state machine has 8 states (4 states when BPS1 = 01_B) and processes the timers in the order T3 - T2 (all actions except capture) - T4 - T2 (capture).

Note: When initializing the GPT1 block after reset, and the block prescaler BPS1 in register T3CON needs to be set to a value different from its default value (00_B), it must be initialized first before any mode involving external trigger signals is configured. These modes include counter, incremental interface, capture, and reload mode. Otherwise, unintended count/capture/reload events may occur during the first basic clock cycle.
In this case, or when changing BPS1 during operation of the GPT1 block, disable related interrupts before modification of BPS1, and afterwards clear the corresponding service request flags and re-initialize those registers (T2, T3, T4) that might be affected by a count/capture/reload event.

Internal Count Clock Generation

In Timer Mode and Gated Timer Mode, the count clock for each GPT1 timer is derived from the GPT1 basic clock by a programmable prescaler, controlled by bitfield TxI in the respective timer's control register TxCON.

The count frequency f_{Tx} for a timer Tx and its resolution r_{Tx} are scaled linearly with lower clock frequencies, as can be seen from the following formula:

$$f_{Tx} = \frac{f_{GPT}}{F(BPS1) \times 2^{<TxI>}} \qquad r_{Tx}[\mu s] = \frac{F(BPS1) \times 2^{<TxI>}}{f_{GPT}[MHz]} \tag{27.1}$$

The effective count frequency depends on the common module clock prescaler factor F(BPS1) as well as on the individual input prescaler factor $2^{<TxI>}$. **Table 27-7** summarizes the resulting overall divider factors for a GPT1 timer that result from these cascaded prescalers.

Table 27-4 lists GPT1 timer's parameters (such as count frequency, resolution, and period) resulting from the selected overall prescaler factor F(BPS1) x $2^{<TxI>}$ and the module clock f_{GPT}. Note that some numbers may be rounded.

Table 27-4 GPT1 Timer Parameters

Overall Prescaler Factor	Example 1: Module Clock f_{GPT} = 100 MHz			Example 2: Module Clock f_{GPT} = 66.5 MHz		
	Frequency	Resolution	Period	Frequency	Resolution	Period
4	25 MHz	40 ns	2.62 ms	16.625 MHz	60.2 ns	3.94 ms
8	12.5 MHz	80 ns	5.24 ms	8.313 MHz	120.3 ns	7.88 ms
16	6.25 MHz	160 ns	10.49 ms	4.156 MHz	240.6 ns	15.77 ms
32	3.125 MHz	320 ns	20.97 ms	2.078 MHz	481.2 ns	31.54 ms
64	1.563 MHz	640 ns	41.94 ms	1.039 MHz	962.4 ns	63.07 ms
128	781.25 kHz	1.28 µs	83.89 ms	519.53 kHz	1.924 µs	126.1 ms
256	390.6 kHz	2.56 µs	167.8 ms	259.77 kHz	3.850 µs	252.3 ms
512	195.3 kHz	5.12 µs	335.5 ms	129.88 kHz	7.699 µs	504.6 ms
1024	97.7 kHz	10.24 µs	671.1 ms	64.94 kHz	15.398 µs	1.009 s
2048	48.8 kHz	20.48 µs	1.342 s	32.47 kHz	30.797 µs	2.018 s
4096	24.4 kHz	40.96 µs	2.684 s	16.24 kHz	61.594 µs	4.037 s

External Count Clock Input

The external input signals of the GPT1 block are sampled with the GPT1 basic clock (see **Figure 27-1**). To ensure that a signal is recognized correctly, its current level (high or

low) must be held active for at least one complete sampling period, before changing. A signal transition is recognized if two subsequent samples of the input signal represent different levels. Therefore, a minimum of two basic clock periods is required for the sampling of an external input signal. Thus, the maximum frequency of an input signal must not be higher than half the basic clock.

Table 27-5 summarizes the resulting requirements for external GPT1 input signals.

Table 27-5 GPT1 External Input Signal Limits

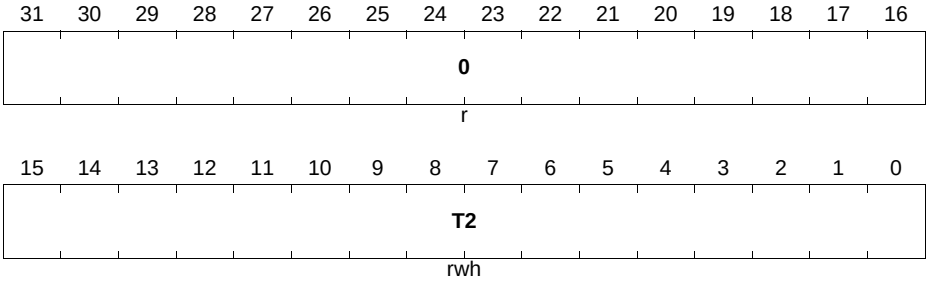
GPT1 Divider BPS1	Input Freq. Factor	Input Phase Duration	Example 1: Module Clock f_{GPT} = 100 MHz		Example 2: Module Clock f_{GPT} = 66.5 MHz	
			Max. Input Frequency	Min. Level Hold Time	Max. Input Frequency	Min. Level Hold Time
01_B	$f_{GPT}/8$	4 x t_{GPT}	12.5 MHz	40 ns	8.313 MHz	60.2 ns
00_B	$f_{GPT}/16$	8 x t_{GPT}	6.25 MHz	80 ns	4.156 MHz	120.3 ns
11_B	$f_{GPT}/32$	16 x t_{GPT}	3.125 MHz	160 ns	2.078 MHz	240.6 ns
10_B	$f_{GPT}/64$	32 x t_{GPT}	1.563 MHz	320 ns	1.039 MHz	481.2 ns

These limitations are valid for all external input signals to GPT1, including the external count signals in Counter Mode and Incremental Interface Mode, the gate input signals in Gated Timer Mode, and the external direction signals.

27.1.6 GPT1 Registers

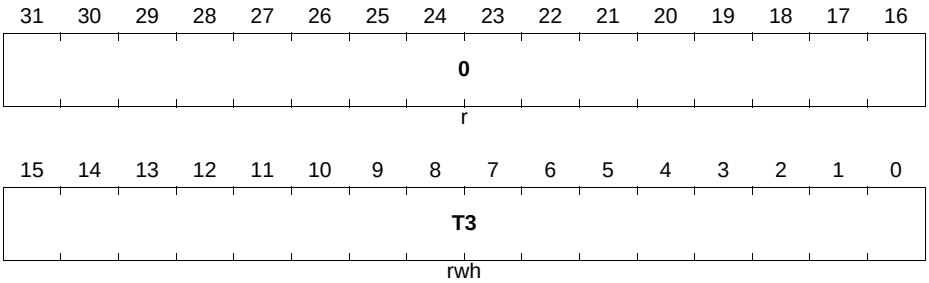
27.1.6.1 GPT1 Timer Registers

T2
Timer T2 Register **(34_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
T2	[15:0]	rwh	**Timer T2** Contains the current value of Timer T2.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

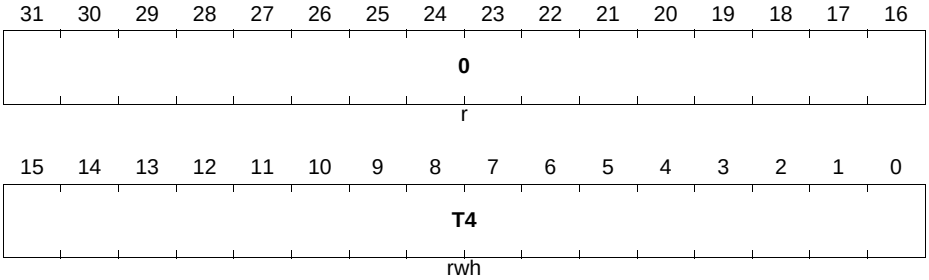
T3
Timer T3 Register **(38_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
T3	[15:0]	rwh	**Timer T3** Contains the current value of Timer T3.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

T4

Timer T4 Register **($3C_H$)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
T4	[15:0]	rwh	**Timer T4** Contains the current value of Timer T4.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

27.1.6.2 GPT1 Timer Control Registers

GPT1 Core Timer T3 Control Register

Encoding of GPT1 Input Edge Selection in Counter Mode

Table 27-8 GPT1 Core Timer T3 Input Edge Selection (Counter Mode)

TxI	Triggering Edge for Counter Increment/Decrement
000_B	None. Counter T3 is disabled
001_B	Positive transition (rising edge) on T3IN
010_B	Negative transition (falling edge) on T3IN
011_B	Any transition (rising or falling edge) on T3IN
$1XX_B$	Reserved. Do not use this combination

Table 27-9 GPT1 Auxiliary Timers T2/T4 Input Edge Selection

T2I/T4I	Triggering Edge for Counter Increment/Decrement, Capture[1] or Reload
$X00_B$	None. Counter Tx is disabled
001_B	Positive transition (rising edge) on TxIN
010_B	Negative transition (falling edge) on TxIN
011_B	Any transition (rising or falling edge) on TxIN
101_B	Positive transition (rising edge) of T3 toggle latch T3OTL[2]
110_B	Negative transition (falling edge) of T3 toggle latch T3OTL[2]
111_B	Any transition (rising or falling edge) of T3 toggle latch T3OTL[2]

1) For Capture Mode, only settings TxI = 0XX may be used.

2) Not for Capture Mode.

Encoding of Input Edge Selection in Incremental Interface Mode

Table 27-10 GPT1 Timer Tx Input Edge Selection (Incremental Interface Mode)

TxI	Triggering Edge for Counter Increment/Decrement
000_B	None. Counter Tx stops.
001_B	Any transition (rising or falling edge) on TxIN.
010_B	Any transition (rising or falling edge) on TxEUD.
011_B	Any transition (rising or falling edge) on any Tx input (TxIN or TxEUD).
$1XX_B$	Reserved. Do not use this combination.

27.2 Timer Block GPT2

Both timers of block GPT2 (T5, T6) can run in one of 3 basic modes: Timer Mode, Gated Timer Mode, or Counter Mode. All timers can count up or down. Each timer of GPT2 is controlled by a separate control register TxCON.

Each timer has an input pin TxIN (alternate pin function) associated with it, which serves as the gate control in Gated Timer Mode, or as the count input in Counter Mode. The count direction (up/down) may be programmed via software or may be dynamically altered by a signal at the External Up/Down control input TxEUD (alternate pin function). An overflow/underflow of core timer T6 is indicated by the Output Toggle Latch T6OTL, whose state may be output on the associated pin T6OUT (alternate pin function). The auxiliary timer T5 may additionally be concatenated with core timer T6 (through T6OTL).

The Capture/Reload register CAPREL can be used to capture the contents of timer T5, or to reload timer T6. A special mode facilitates the use of register CAPREL for both functions at the same time. This mode allows frequency multiplication. The capture function is triggered by the input pin CAPIN, or by GPT1 timer's T3 input lines T3IN and T3EUD. The reload function is triggered by an overflow or underflow of timer T6.

The current contents of each timer can be read or modified by the CPU by accessing the corresponding timer count registers T5 or T6. When any of the timer registers is written by the CPU in the state immediately preceding a timer increment, decrement, reload, or capture operation, the CPU write operation has priority in order to guarantee correct results.

The interrupt requests of GPT2 are signalled on service request lines SR3, SR4, and SR5.

The input and output lines of GPT2 are connected to pins. The control registers for the port functions are located in the respective port modules.

*Note: The timing requirements for external input signals can be found in **Section 27.2.6**, **Section 27.5.2** summarizes the module interface signals, including pins and interrupt request signals.*

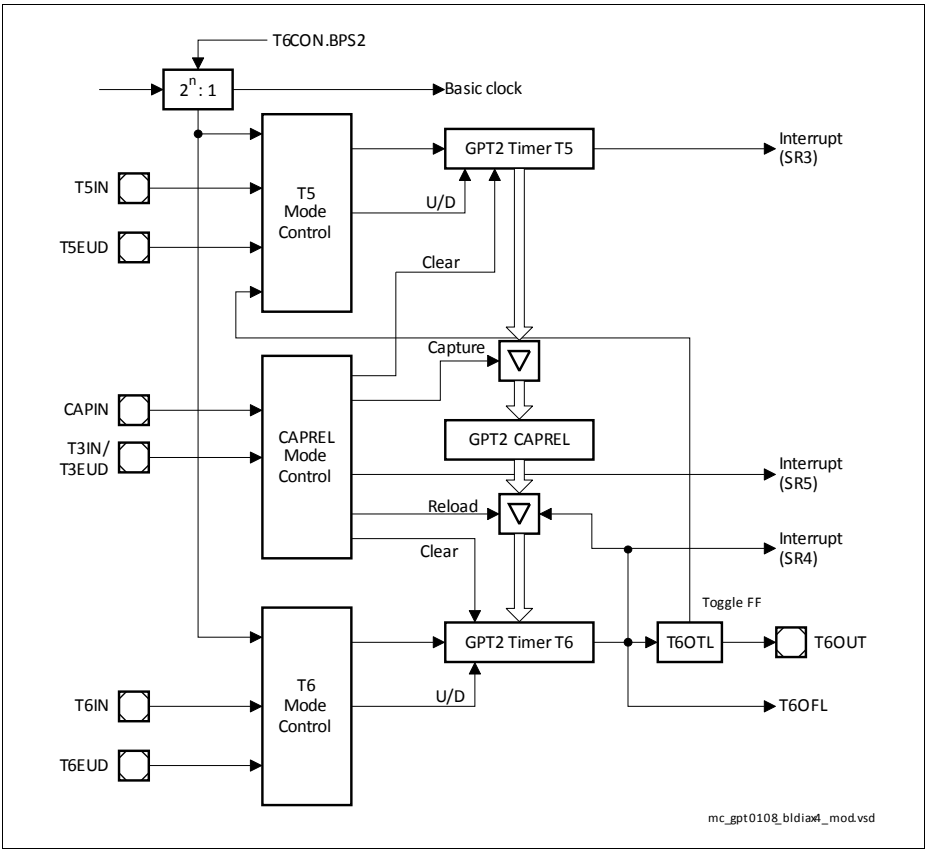

Figure 27-18 GPT2 Block Diagram

27.2.1 GPT2 Core Timer T6 Control

The current contents of the core timer T6 are reflected by its count register T6. This register can also be written to by the CPU, for example, to set the initial start value.

The core timer T6 is configured and controlled via its control register T6CON.

Timer T6 Run Control

The core timer T6 can be started or stopped by software through bit T6R (timer T6 run bit). This bit is relevant in all operating modes of T6. Setting bit T6R will start the timer, clearing bit T6R stops the timer.

In Gated Timer Mode, the timer will only run if T6R = 1 and the gate is active (high or low, as programmed).

Note: When bit T5RC in timer control register T5CON is set, bit T6R will also control (start and stop) the Auxiliary Timer T5.

Count Direction Control

The count direction of the GPT2 timers (core timer and auxiliary timer) can be controlled either by software or by the external input pin TxEUD (Timer Tx External Up/Down Control Input). These options are selected by bits TxUD and TxUDE in the respective control register TxCON. When the up/down control is provided by software (bit TxUDE = 0), the count direction can be altered by setting or clearing bit TxUD. When bit TxUDE = 1, pin TxEUD is selected to be the controlling source of the count direction. However, bit TxUD can still be used to reverse the actual count direction, as shown in **Table 27-15**. The count direction can be changed regardless of whether or not the timer is running.

Timer T6 Output Toggle Latch

The overflow/underflow signal of timer T6 is connected to a block named ‘Toggle Latch’, shown in the Timer Mode diagrams. **Figure 27-19** illustrates the details of this block. An overflow or underflow of T6 will clock two latches: The first latch represents bit T6OTL in control register T6CON. The second latch is an internal latch toggled by T6OTL’s output. Both latch outputs are connected to the input control block of the auxiliary timer T5. The output level of the shadow latch will match the output level of T6OTL, but is delayed by one clock cycle. When the T6OTL value changes, this will result in a temporarily different output level from T6OTL and the shadow latch, which can trigger the selected count event in T5.

When software writes to T6OTL, both latches are set or cleared simultaneously. In this case, both signals to the auxiliary timer carry the same level and no edge will be detected. Bit T6OE (overflow/underflow output enable) in register T6CON enables the state of T6OTL to be monitored via an external pin T6OUT. When T6OTL is linked to an external port pin (must be configured as output), T6OUT can be used to control external HW. If T6OE = 1, pin T6OUT outputs the state of T6OTL. If T6OE = 0, pin T6OUT outputs a high level (while it selects the timer output signal).

As can be seen from **Figure 27-19**, when latch T6OTL is modified by software to determine the state of the output line, also the internal shadow latch is set or cleared accordingly. Therefore, no trigger condition is detected by T5 in this case.

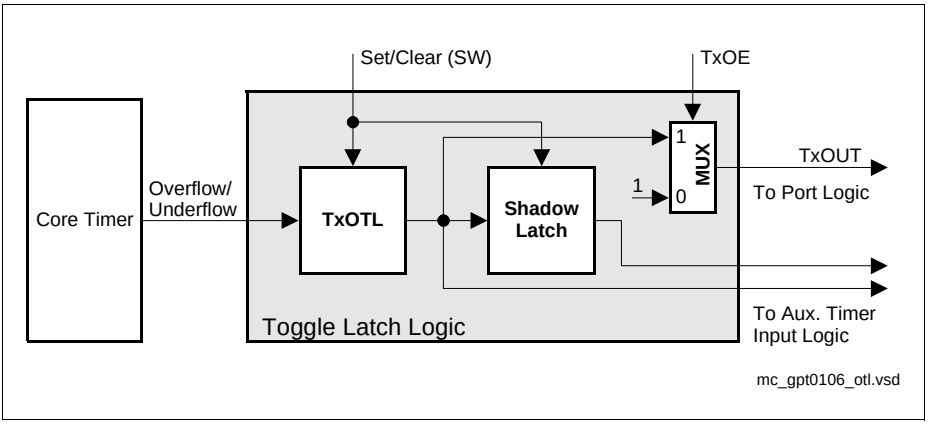

Figure 27-19 Block Diagram of the Toggle Latch Logic of Core Timer T6 (x = 6)

27.2.2 GPT2 Core Timer T6 Operating Modes

Timer T6 can operate in one of several modes.

Timer T6 in Timer Mode

Timer Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 000_B. In this mode, T6 is clocked with the module's input clock f_{GPT} divided by two programmable prescalers controlled by bitfields BPS2 and T6I in register T6CON. Please see **Section 27.2.6** for details on the input clock options.

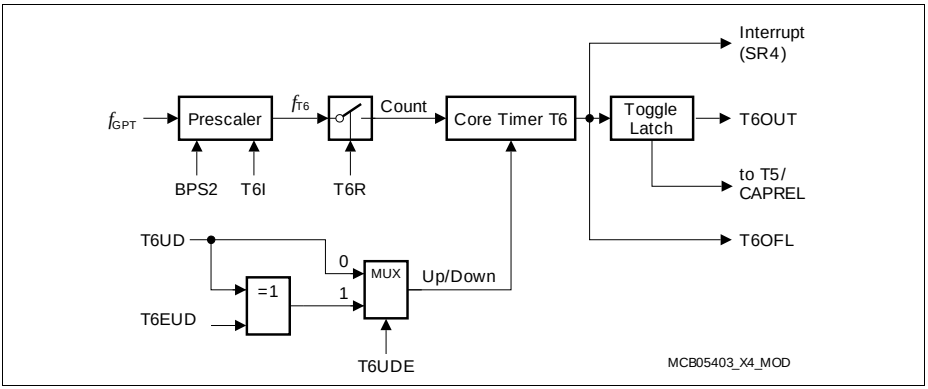

Figure 27-20 Block Diagram of Core Timer T6 in Timer Mode

Timer 6 in Gated Timer Mode

Gated Timer Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 010_B or 011_B. Bit T6M.0 (T6CON.3) selects the active level of the gate input. The same options for the input frequency are available in Gated Timer Mode as in Timer Mode (see **Section 27.2.6**). However, the input clock to the timer in this mode is gated by the external input pin T6IN (Timer T6 External Input).
To enable this operation, the associated pin T6IN must be configured as input.

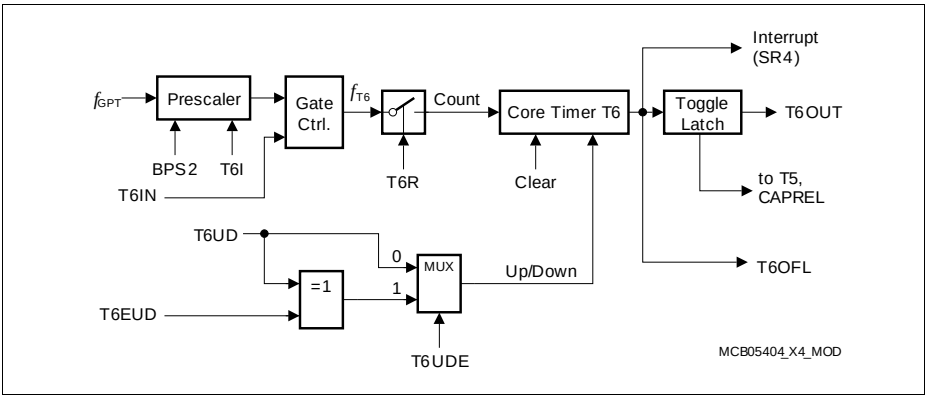

Figure 27-21 Block Diagram of Core Timer T6 in Gated Timer Mode

If T6M = 010_B, the timer is enabled when T6IN shows a low level. A high level at this line stops the timer. If T6M = 011_B, line T6IN must have a high level in order to enable the timer. Additionally, the timer can be turned on or off by software using bit T6R. The timer will only run if T6R is 1 and the gate is active. It will stop if either T6R is 0 or the gate is inactive.

Note: A transition of the gate signal at pin T6IN does not cause a service request.

Timer 6 in Counter Mode

Counter Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 001_B. In Counter Mode, timer T6 is clocked by a transition at the external input pin T6IN. The event causing an increment or decrement of the timer can be a positive, a negative, or both a positive and a negative transition at this line. Bitfield T6I in control register T6CON selects the triggering transition (see **Table 27-17**).

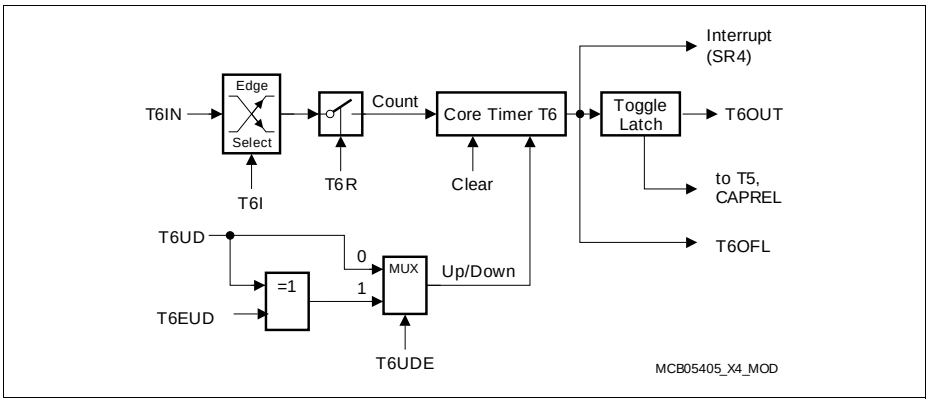

Figure 27-22 Block Diagram of Core Timer T6 in Counter Mode

For Counter Mode operation, pin T6IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T6IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 27.2.6**.

27.2.3 GPT2 Auxiliary Timer T5 Control

Auxiliary timer T5 can be configured for Timer Mode, Gated Timer Mode, or Counter Mode with the same options for the timer frequencies and the count signal as the core timer T6. In addition to these 3 counting modes, the auxiliary timer can be concatenated with the core timer. The contents of T5 may be captured to register CAPREL upon an external or an internal trigger. The start/stop function of the auxiliary timer can be remotely controlled by the T6 run control bit. Both timers may thus be controlled synchronously.

The current contents of the auxiliary timer are reflected by its count register T5. This register can also be written to by the CPU, for example, to set the initial start value.

The individual configurations for timer T5 are determined by its control register T5CON. Some bits in this register also control the function of the CAPREL register. Note that functions which are present in all timers of block GPT2 are controlled in the same bit positions and in the same manner in each of the specific control registers.

Note: The auxiliary timer has no output toggle latch and no alternate output function.

Timer T5 Run Control

The auxiliary timer T5 can be started or stopped by software in two different ways:

- Through the associated timer run bit (T5R). In this case it is required that the respective control bit T5RC = 0.
- Through the core timer's run bit (T6R). In this case the respective remote control bit must be set (T5RC = 1).

The selected run bit is relevant in all operating modes of T5. Setting the bit will start the timer, clearing the bit stops the timer.

In Gated Timer Mode, the timer will only run if the selected run bit is set and the gate is active (high or low, as programmed).

Note: If remote control is selected T6R will start/stop timer T6 and the auxiliary timer T5 synchronously.

27.2.4 GPT2 Auxiliary Timer T5 Operating Modes

The operation of the auxiliary timer in the basic operating modes is almost identical with the core timer's operation, with very few exceptions. Additionally, some combined operating modes can be selected.

Timer T5 in Timer Mode

Timer Mode for the auxiliary timer T5 is selected by setting its bitfield T5M in register T5CON to 000_B.

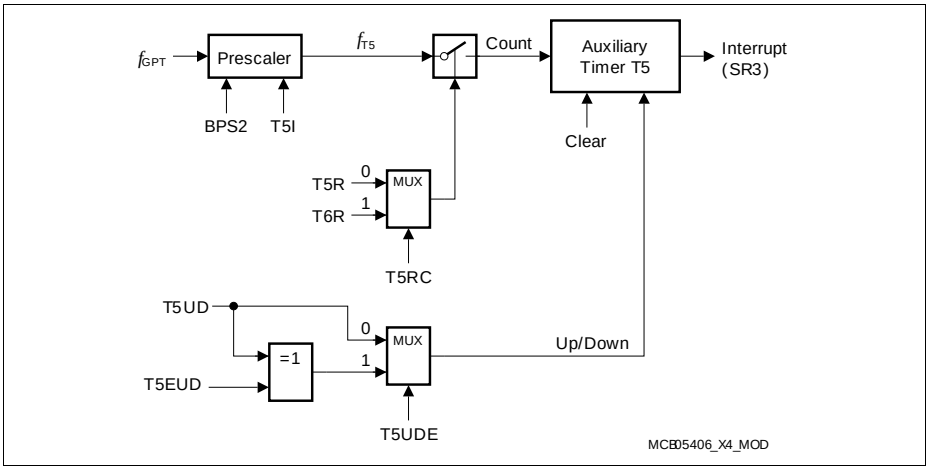

Figure 27-23 Block Diagram of Auxiliary Timer T5 in Timer Mode

Timer T5 in Gated Timer Mode

Gated Timer Mode for the auxiliary timer T5 is selected by setting bitfield T5M in register T5CON to 010_B or 011_B. Bit T5M.0 (T5CON.3) selects the active level of the gate input.

Note: A transition of the gate signal at line T5IN does not cause a service request.

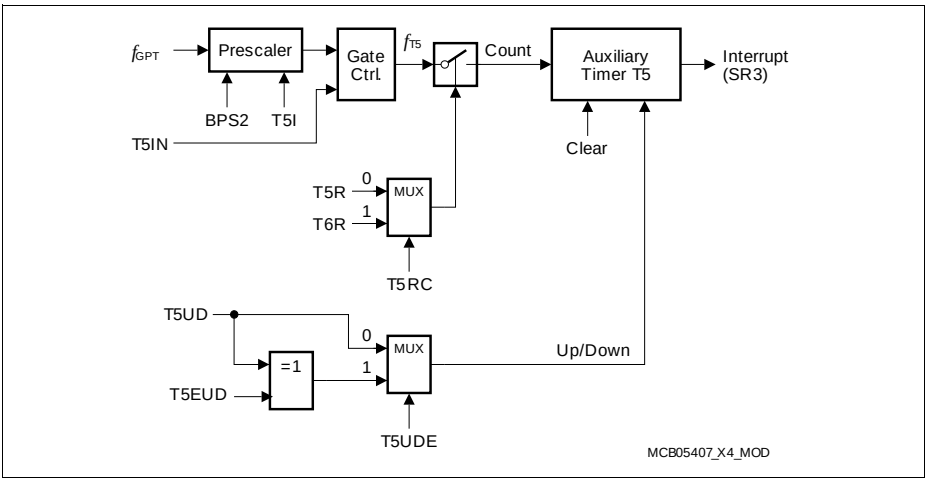

Figure 27-24 Block Diagram of Auxiliary Timer T5 in Gated Timer Mode

Note: There is no output toggle latch for T5.
Start/stop of the auxiliary timer can be controlled locally or remotely.

Timer T5 in Counter Mode

Counter Mode for auxiliary timer T5 is selected by setting bitfield T5M in register T5CON to 001_B. In Counter Mode, the auxiliary timer can be clocked either by a transition at its external input line T5IN, or by a transition of timer T6's toggle latch T6OTL. The event causing an increment or decrement of a timer can be a positive, a negative, or both a positive and a negative transition at either the respective input pin or at the toggle latch. Bitfield T5I in control register T5CON selects the triggering transition (see **Table 27-18**).

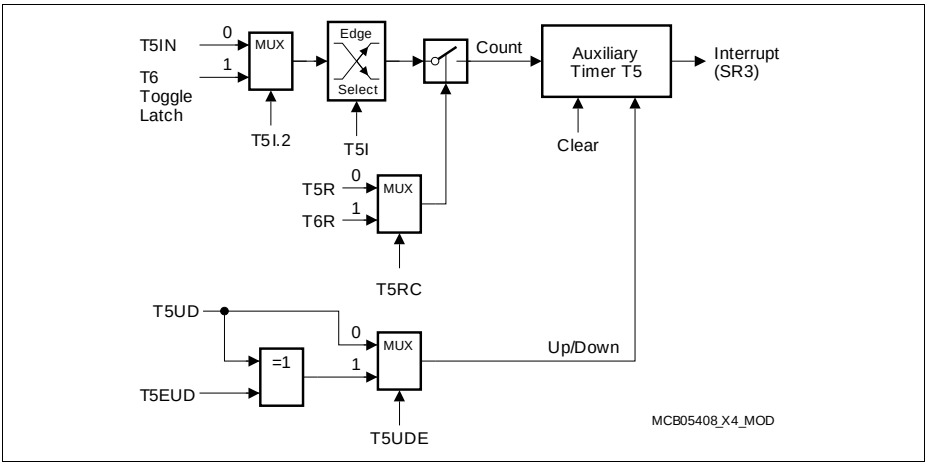

Figure 27-25 Block Diagram of Auxiliary Timer T5 in Counter Mode

Note: Only state transitions of T6OTL which are caused by the overflows/underflows of T6 will trigger the counter function of T5. Modifications of T6OTL via software will NOT trigger the counter function of T5.

For counter operation, pin T5IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T5IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 27.2.6**.

Timer Concatenation

Using the toggle bit T6OTL as a clock source for the auxiliary timer in Counter Mode concatenates the core timer T6 with the auxiliary timer T5. This concatenation forms either a 32-bit or a 33-bit timer/counter, depending on which transition of T6OTL is selected to clock the auxiliary timer.

- **32-bit Timer/Counter:** If both a positive and a negative transition of T6OTL are used to clock the auxiliary timer, this timer is clocked on every overflow/underflow of the core timer T6. Thus, the two timers form a 32-bit timer.
- **33-bit Timer/Counter:** If either a positive or a negative transition of T6OTL is selected to clock the auxiliary timer, this timer is clocked on every second overflow/underflow of the core timer T6. This configuration forms a 33-bit timer (16-bit core timer + T6OTL + 16-bit auxiliary timer).
  As long as bit T6OTL is not modified by software, it represents the state of the internal toggle latch, and can be regarded as part of the 33-bit timer.

The count directions of the two concatenated timers are not required to be the same. This offers a wide variety of different configurations.

T6, which represents the low-order part of the concatenated timer, can operate in Timer Mode, Gated Timer Mode or Counter Mode in this case.

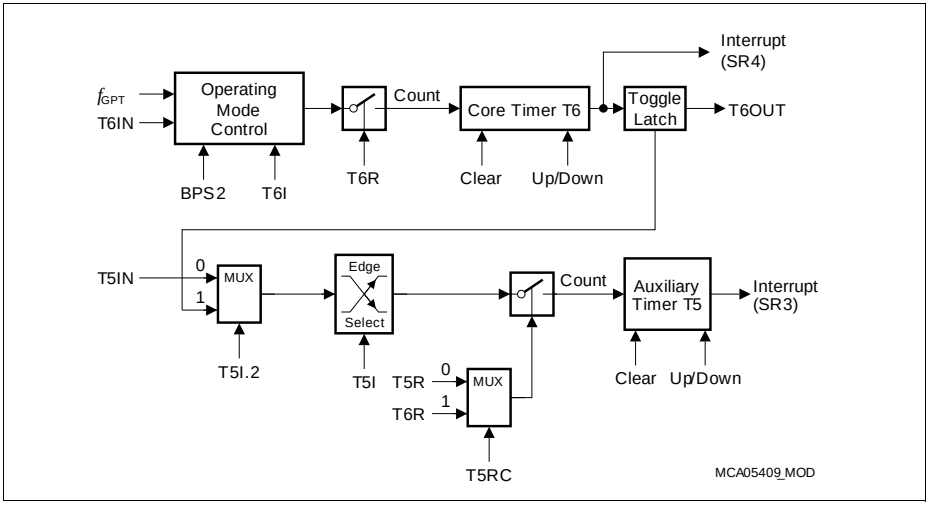

Figure 27-26 Concatenation of Core Timer T6 and Auxiliary Timer T5

When reading the low and high parts of the concatenated timer, care must be taken to obtain consistent values in particular after a timer overflow/underflow (e.g. one part may already have considered an overflow, while the other has not).

Note: This is a general issue when reading multi-word results with consecutive instructions, and not necessarily unique to the GPT12 module architecture.

The following algorithm may be used to read concatenated GPT2 timers, represented by TIMER_HIGH (for auxiliary timer T5) and TIMER_LOW (for core timer T6). The high part is read twice, and reading of the low part is repeated if two different values were read for the high part:

- TIMER_HIGH_TMP = T5
- TIMER_LOW = T6
- Wait two basic clock cycles (to allow increment/decrement of auxiliary timer in case of core timer overflow/underflow) - see **Table 27-11**
- TIMER_HIGH = T5
- If TIMER_HIGH is not equal to TIMER_HIGH_TMP then TIMER_LOW = T6

After execution of this algorithm, TIMER_HIGH and TIMER_LOW represent a consistent time stamp of the concatenated timers.

The equivalent number of module clock cycles corresponding to two basic clock cycles is shown in **Table 27-11**.

Table 27-11 Number of Module Clock Cycles to Wait for Two Basic Clock Cycles

Block Prescaler	BPS2 = 01_B	BPS2 = 00_B	BPS2 = 11_B	BPS2 = 10_B
Number of module clocks	4	8	16	32

In case the required timer resolution can be achieved with different combinations of the Block Prescaler BPS2 and the Individual Prescalers TxI (see **Table 27-16**), the variant with the smallest value for the Block Prescaler may be chosen to minimize the waiting time. E.g. in order to run T6 at f_{SYS}/512, select BPS2 = 00_B, T6I = 111_B, and insert 8 NOPs (or other instructions) to ensure the required waiting time before reading TIMER_HIGH the second time.

27.2.5 GPT2 Register CAPREL Operating Modes

The Capture/Reload register CAPREL can be used to capture the contents of timer T5, or to reload timer T6. A special mode facilitates the use of register CAPREL for both functions at the same time. This mode allows frequency multiplication. The capture function is triggered by the input pin CAPIN, by GPT1 timer's T3 input lines T3IN and T3EUD, or by read accesses to GPT1 timers. The reload function is triggered by an overflow or underflow of timer T6.

The capture trigger signal can also be used to clear the contents of timers T5 and T6 individually.

The functions of register CAPREL are controlled via several bit(field)s in the timer control registers T5CON and T6CON.

Capture/Reload Register CAPREL in Capture Mode

Capture Mode for register CAPREL is selected by setting bit T5SC in control register T5CON (set bitfield CI in register T5CON to a non-zero value to select a trigger signal). In Capture Mode, the contents of the auxiliary timer T5 are latched into register CAPREL in response to a signal transition at the selected external input pin(s). Bit CT3 selects the external input line CAPIN or the input lines T3IN and/or T3EUD of GPT1 timer T3 as the source for a capture trigger. Either a positive, a negative, or both a positive and a negative transition at line CAPIN can be selected to trigger the capture function, or transitions on input T3IN or input T3EUD or both inputs, T3IN and T3EUD. The active edge is controlled by bitfield CI in register T5CON. **Table 27-19** summarizes these options.

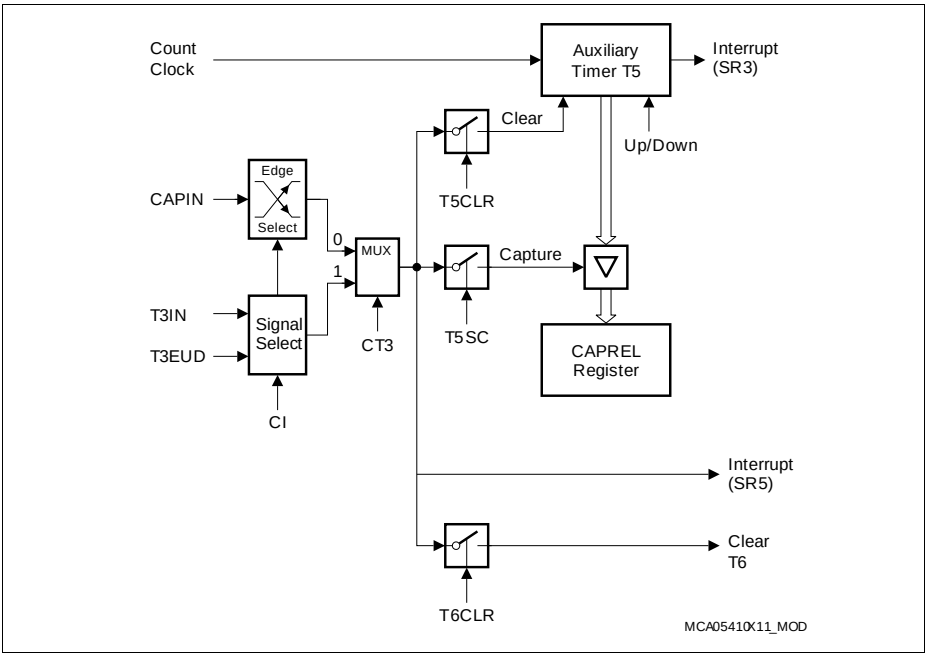

Figure 27-27 Capture/Reload Register CAPREL in Capture Mode

When a selected trigger is detected, the contents of the auxiliary timer T5 are latched into register CAPREL and the service request is activated. The same event can optionally clear timer T5 and/or timer T6. This option is enabled by bit T5CLR in register T5CON and bit T6CLR in register T6CON, respectively. If TxCLR = 0 the contents of timer Tx is not affected by a capture. If TxCLR = 1 timer Tx is cleared after the current timer T5 value has been latched into register CAPREL.

Note: Bit T5SC only controls whether or not a capture is performed. If T5SC is cleared the external input pin(s) can still be used to clear timer T5 and/or T6, or as external interrupt input(s). This interrupt is signalled by the CAPREL interrupt request SR5.

When capture triggers T3IN or T3EUD are enabled (CT3 = 1), register CAPREL captures the contents of T5 upon transitions of the selected input(s). These values can be used to measure T3's input signals. This is useful, for example, when T3 operates in Incremental Interface Mode, in order to derive dynamic information (speed, acceleration) from the input signals.

For Capture Mode operation, the selected pins CAPIN, T3IN, or T3EUD must be configured as input. To ensure that a transition of a trigger input signal applied to one of

these inputs is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in **Section 27.2.6**.

Capture/Reload Register CAPREL in Reload Mode

Reload Mode for register CAPREL is selected by setting bit T6SR in control register T6CON. In Reload Mode, the core timer T6 is reloaded with the contents of register CAPREL, triggered by an overflow or underflow of T6. This will not activate the service request SR5 associated with the CAPREL register. However, service request SR4 will be activated, indicating the overflow/underflow of T6.

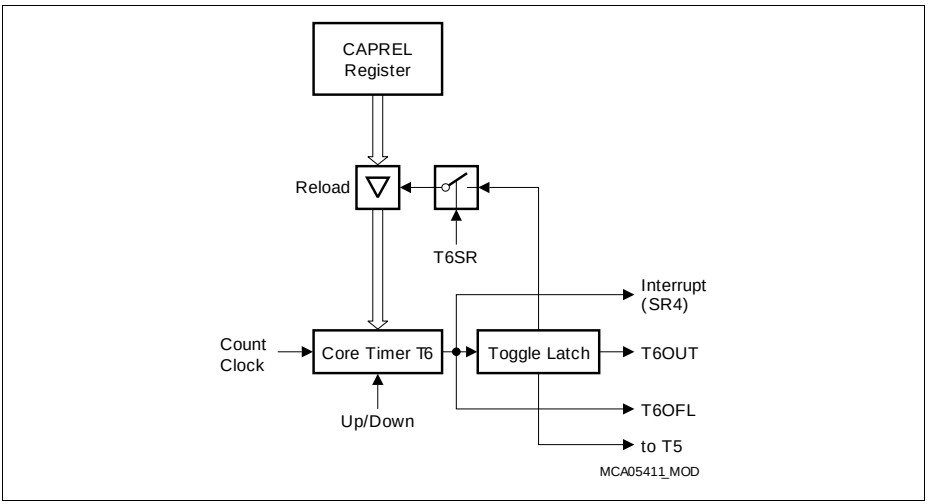

Figure 27-28 Capture/Reload Register CAPREL in Reload Mode

Capture/Reload Register CAPREL in Capture-And-Reload Mode

Since the reload function and the capture function of register CAPREL can be enabled individually by bits T5SC and T6SR, the two functions can be enabled simultaneously by setting both bits. This feature can be used to generate an output frequency that is a multiple of the input frequency.

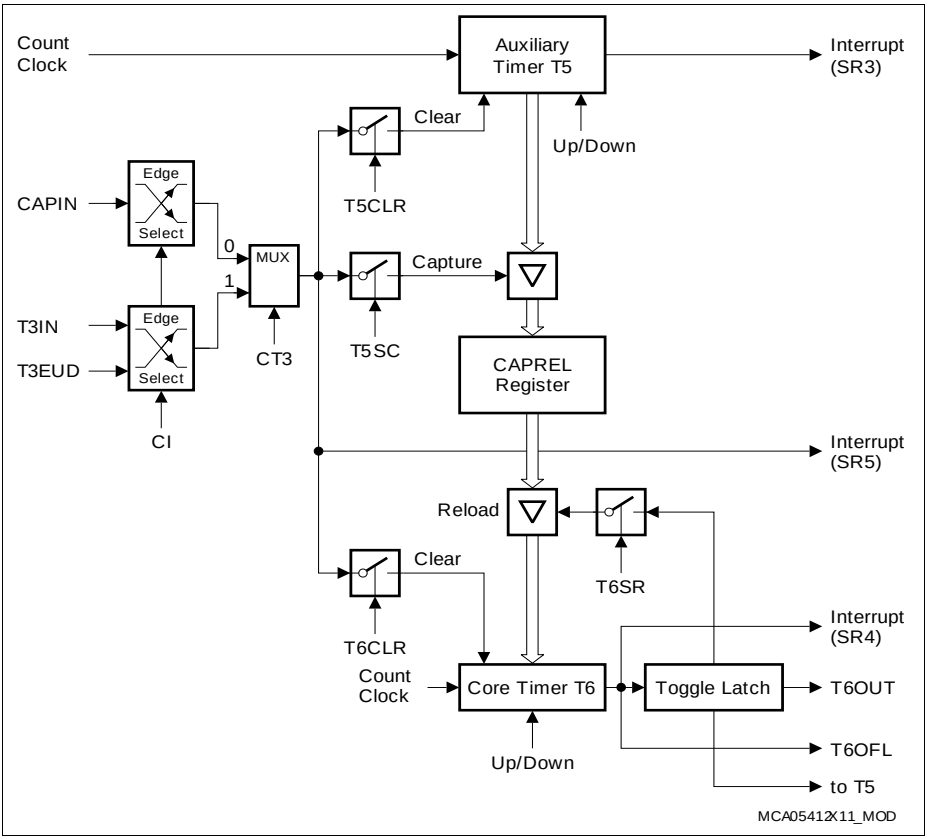

Figure 27-29 Capture/Reload Register CAPREL in Capture-And-Reload Mode

This combined mode can be used to detect consecutive external events which may occur aperiodically, but where a finer resolution, that means, more ‘ticks’ within the time between two external events is required.

For this purpose, the time between the external events is measured using timer T5 and the CAPREL register. Timer T5 runs in Timer Mode counting up with a frequency of e.g. $f_{GPT}/32$. The external events are applied e.g. to pin CAPIN (or other pins supporting

capture mode, see **Table 27-19**). When an external event occurs, the contents of timer T5 are latched into register CAPREL and timer T5 is cleared (T5CLR = 1). Thus, register CAPREL always contains the correct time between two events, measured in timer T5 increments. Timer T6, which runs in Timer Mode counting down with a frequency of e.g. $f_{GPT}/4$, uses the value in register CAPREL to perform a reload on underflow. This means, the value in register CAPREL represents the time between two underflows of timer T6, now measured in timer T6 increments. Since (in this example) timer T6 runs 8 times faster than timer T5, it will underflow 8 times within the time between two external events. Thus, the underflow signal of timer T6 generates 8 'ticks'. Upon each underflow, the interrupt request SR4 will be activated and bit T6OTL will be toggled. The state of T6OTL may be output on pin T6OUT. This signal on T6OUT has 8 times more transitions than the signal which is applied to the selected input (CAPIN in this example).

*Note: The underflow signal of Timer T6 can furthermore be used to clock functional units in other modules, e.g. one or more of the timers of the capture/compare units CCU6 (connections see **Section 27.5.2**). This gives the user the possibility to set compare events based on a finer resolution than that of the external events. This connection is accomplished via signal T6OFL.*

Capture Correction

A certain deviation of the output frequency is generated by the fact that timer T5 will count actual time units (e.g. T5 running at 1 MHz will count up to the value $64_H/100_D$ for a 10 kHz input signal), while T6OTL will only toggle upon an underflow of T6 (i.e. the transition from 0000_H to $FFFF_H$). In the above mentioned example, T6 would count down from 64_H, so the underflow would occur after 101 timing ticks of T6. The actual output frequency then is 79.2 kHz, instead of the expected 80 kHz.

This deviation can be compensated for by using T6 overflows. In this case, T5 counts down and T6 counts up. Upon a signal transition at the selected input pin(s), e.g. on CAPIN, the count value in T5 is captured into CAPREL and T5 is cleared to 0000_H. In its next clock cycle, T5 underflows to $FFFF_H$, and continues to count down with the following clocks. T6 is reloaded from CAPREL upon an overflow, and continues to count up with its following clock cycles (8 times faster in the above example). In this case, T5 and T6 count the same number of steps with their respective internal count frequency.

In the above example, T5 running at 1 MHz will count down to the value $FF9C_H/-100_D$ for a 10 kHz input signal applied e.g. at CAPIN, while T6 counts up from $FF9C_H$ through $FFFF_H$ to 0000_H. So the overflow occurs after 100 timing ticks of T6, and the actual output frequency at T6OUT then is the expected 80 kHz.

However, in this case CAPREL does not directly contain the time between two external events, but rather its 2's complement. Software will have to convert this value, if it is required for the operation.

Combined Capture Modes

For incremental interface applications in particular, several timer features can be combined to obtain dynamic information such as speed, acceleration, or deceleration. The current position itself can be obtained directly from the timer register (T2, T3, T4).

The time information to determine the dynamic parameters is generated by capturing the contents of the free-running timer T5 into register CAPREL. Two trigger sources for this event can be selected:

- Capture trigger on sensor signal transitions
- Capture trigger on position read operations

Capturing on sensor signal transitions is available for timer T3 inputs. This mode is selected by setting bit CT3 and selecting the intended signal(s) via bitfield CI in register T5CON. CAPREL then indicates the time between two selected transitions (measured in T5 counts).

Capturing on position read operations is available for timers T2, T3, and T4. This mode is selected by clearing bit CT3 and selecting the rising edge via bitfield CI in register T5CON. Bitfield ISCAPIN in register PISEL then selects either a read access from T3 or a read access from any of T2 or T3 or T4. CAPREL then indicates the time between two read accesses.

In general, GPT12 has no destructive read mechanisms, except for this special operation mode ‘capture on position read operations’, where register CAPREL is intentionally updated after a read of T3 or T2/T4 (and T5 or T6 are optionally cleared). In this case, also the associated service request flag in register SRC_GPT120CIRQ is set.

Note: If mode ‘capturing on position read operations’ is selected, and the corresponding timer (T3, or any of T2, T3, T4) is read by a debugger, a capture event may be triggered (T5 is captured into CAPREL, and T5 or T6 may optionally be cleared (if T5CLR = 1 or T6CLR = 1)).

These operating modes directly support the measurement of position and rotational speed. Acceleration and deceleration can then be determined by evaluating subsequent speed measurements.

27.2.6 GPT2 Clock Signal Control

All actions within the timer block GPT2 are triggered by transitions of its basic clock. This basic clock is derived from the module clock f_{GPT} by a basic block prescaler, controlled by bitfield BPS2 in register T6CON (see **Figure 27-18**). The count clock can be generated in two different ways:

- **Internal count clock**, derived from GPT2's basic clock via a programmable prescaler, is used for (Gated) Timer Mode.
- **External count clock**, derived from the timer's input pin(s), is used for Counter Mode.

For both ways, the basic clock determines the maximum count frequency and the timer's resolution:

Table 27-12 Basic Clock Selection for Block GPT2

Block Prescaler[1]	BPS2 = 01_B	BPS2 = 00_B[2]	BPS2 = 11_B	BPS2 = 10_B
Prescaling Factor for GPT2: F(BPS2)	F(BPS2) = 2	F(BPS2) = 4	F(BPS2) = 8	F(BPS2) = 16
Maximum External Count Frequency	$f_{GPT}/4$	$f_{GPT}/8$	$f_{GPT}/16$	$f_{GPT}/32$
Input Signal Stable Time	2 x t_{GPT}	4 x t_{GPT}	8 x t_{GPT}	16 x t_{GPT}

1) Please note the non-linear encoding of bitfield BPS2.

2) Default after reset.

Note: The GPT2 module uses a finite state machine to control the actions. Since multiple interactions are possible between the timers (T5, T6) and register CAPREL, these elements are processed sequentially. However, all actions are normally completed within one basic clock cycle. The GPT2 state machine has 4 states (2 states when BPS2 = 01_B) and processes T6 before T5.

Note: When initializing the GPT2 block after reset, and the block prescaler BPS2 in register T6CON needs to be set to a value different from its default value (00_B), it must be initialized first before any mode involving external trigger signals is configured. These modes include counter, capture, and reload mode. Otherwise, unintended count/capture/reload events may occur during the first basic clock cycle.
In this case, or when changing BPS2 during operation of the GPT2 block, disable related interrupts before modification of BPS2, and afterwards clear the corresponding service request flags and re-initialize those registers (T5, T6, CAPREL) that might be affected by a count/capture/reload event.

Internal Count Clock Generation

In Timer Mode and Gated Timer Mode, the count clock for each GPT2 timer is derived from the GPT2 basic clock by a programmable prescaler, controlled by bitfield TxI in the respective timer's control register TxCON.

The count frequency f_{Tx} for a timer Tx and its resolution r_{Tx} are scaled linearly with lower clock frequencies, as can be seen from the following formula:

$$f_{Tx} = \frac{f_{GPT}}{F(BPS2) \times 2^{<TxI>}} \qquad r_{Tx}[\mu s] = \frac{F(BPS2) \times 2^{<TxI>}}{f_{GPT}[MHz]} \tag{27.2}$$

The effective count frequency depends on the common module clock prescaler factor F(BPS2) as well as on the individual input prescaler factor $2^{<TxI>}$. **Table 27-16** summarizes the resulting overall divider factors for a GPT2 timer that result from these cascaded prescalers.

Table 27-13 lists GPT2 timer's parameters (such as count frequency, resolution, and period) resulting from the selected overall prescaler factor F(BPS2) x $2^{<TxI>}$ and the module clock f_{GPT}. Note that some numbers may be rounded.

Table 27-13 GPT2 Timer Parameters

Overall Prescaler Factor	Example 1: Module Clock f_{GPT} = 100 MHz			Example 2: Module Clock f_{GPT} = 66.5 MHz		
	Frequency	Resolution	Period	Frequency	Resolution	Period
2	50 MHz	20 ns	1.311 ms	33.25 MHz	30.1 ns	1.97 ms
4	25 MHz	40 ns	2.621 ms	16.625 MHz	60.2 ns	3.94 ms
8	12.5 MHz	80 ns	5.243 ms	8.313 MHz	120.3 ns	7.88 ms
16	6.25 MHz	160 ns	10.49 ms	4.156 MHz	240.6 ns	15.77 ms
32	3.125 MHz	320 ns	20.97 ms	2.078 MHz	481.2 ns	31.54 ms
64	1.563 MHz	640 ns	41.94 ms	1.039 MHz	962.4 ns	63.07 ms
128	781.25 kHz	1.28 µs	83.89 ms	519.53 kHz	1.924 µs	126.1 ms
256	390.6 kHz	2.56 µs	167.8 ms	259.77 kHz	3.850 µs	252.3 ms
512	195.3 kHz	5.12 µs	335.5 ms	129.88 kHz	7.699 µs	504.6 ms
1024	97.7 kHz	10.24 µs	671.1 ms	64.94 kHz	15.398 µs	1.009 s
2048	48.8 kHz	20.48 µs	1.342 s	32.47 kHz	30.797 µs	2.018 s

External Count Clock Input

The external input signals of the GPT2 block are sampled with the GPT2 basic clock (see **Figure 27-18**). To ensure that a signal is recognized correctly, its current level (high or

low) must be held active for at least one complete sampling period, before changing. A signal transition is recognized if two subsequent samples of the input signal represent different levels. Therefore, a minimum of two basic clock periods are required for the sampling of an external input signal. Thus, the maximum frequency of an input signal must not be higher than half the basic clock.

Table 27-14 summarizes the resulting requirements for external GPT2 input signals.

Table 27-14 GPT2 External Input Signal Limits

GPT2 Divider BPS2	Input Freq. Factor	Input Phase Duration	Example 1: Module Clock f_{GPT} = 100 MHz		Example 2: Module Clock f_{GPT} = 66.5 MHz	
			Max. Input Frequency	Min. Level Hold Time	Max. Input Frequency	Min. Level Hold Time
01_B	$f_{GPT}/4$	2 x t_{GPT}	25 MHz	20 ns	16.625 MHz	30.1 ns
00_B	$f_{GPT}/8$	4 x t_{GPT}	12.5 MHz	40 ns	8.313 MHz	60.2 ns
11_B	$f_{GPT}/16$	8 x t_{GPT}	6.25 MHz	80 ns	4.156 MHz	120.3 ns
10_B	$f_{GPT}/32$	16 x t_{GPT}	3.125 MHz	160 ns	2.078 MHz	240.6 ns

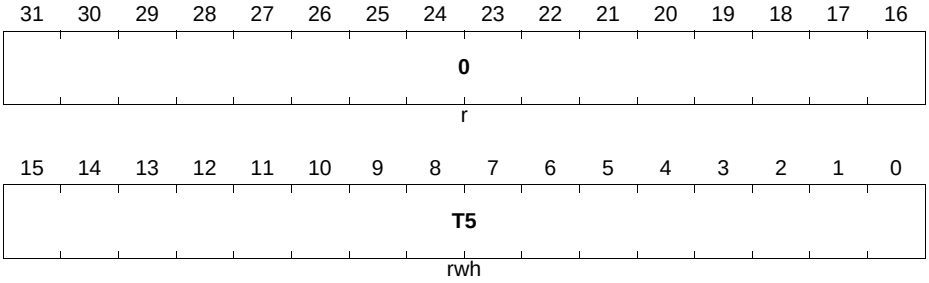
These limitations are valid for all external input signals to GPT2, including the external count signals in Counter Mode and the gate input signals in Gated Timer Mode.

27.2.7 GPT2 Registers

27.2.7.1 GPT2 Timer Registers

T5

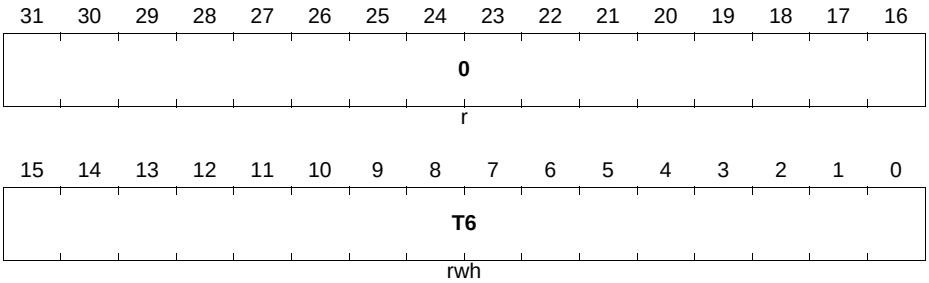
Timer T5 Register **(40_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
T5	[15:0]	rwh	**Timer T5** Contains the current value of Timer T5.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

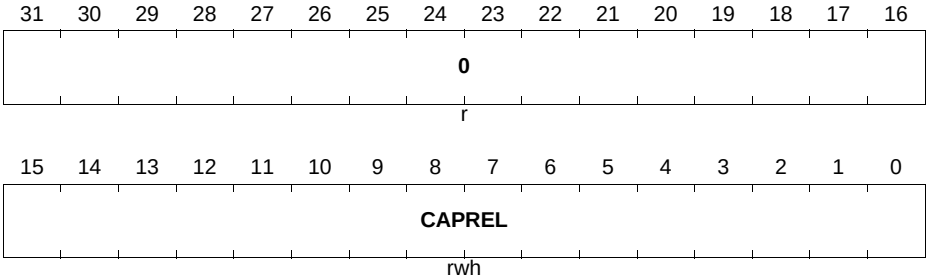
T6

Timer T6 Register **(44_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
T6	[15:0]	rwh	**Timer T6** Contains the current value of Timer T6.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

CAPREL
Capture and Reload Register **(30_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CAPREL	[15:0]	rwh	**Current reload value or Captured value**
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

27.2.7.2 GPT2 Timer Control Registers

T4	Timer T4 Register	$3C_H$	U, SV	U, SV, P	Application Reset	27-29
T5	Timer T5 Register	40_H	U, SV	U, SV, P	Application Reset	27-62
T6	Timer T6 Register	44_H	U, SV	U, SV, P	Application Reset	27-62

1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

27.4 General Module Operation

This section provides information about the:

- Input Selection (see **Section 27.4.1**)
- OCDS Suspend Functionality (see **Section 27.4.2**)
- Miscellaneous GPT12 Register Description (see **Section 27.4.3**)
- BPI Register Description (see **Section 27.4.4**)

27.4.1 Input Selection

Each GPT12 input signal can be selected from a vector of two or four possible inputs by programming the port input select register **PISEL**. This permits to adapt the pin functionality of the device to the application requirements.
The output pins for the module output signals are chosen in the ports.

Naming convention (example):
The input vector T3IN[D:A] for input signal T3IN is composed of the signals T3INA to T3IND.

*Note: All functional inputs of the GPT12 module are synchronized to the internal basic clock of the GPT1 and GPT2 block, respectively. An edge of an input signal can only be correctly recognized if the high phase and the low phase are longer than one basic clock period. See **Table 27-5** for GPT1 external input signal limits, and **Table 27-14** for GPT2 external input signal limits.*

27.4.2 OCDS Suspend

The behavior of GPT12 upon an OCDS suspend request is controlled by the **OCS** register. GPT12 supports only Hard Suspend Mode.

Hard Suspend Mode

In Hard Suspend Mode the GPT12 kernel clock is switched off immediately. Reading and writing of registers is possible but will enable the kernel clock for a few cycles.

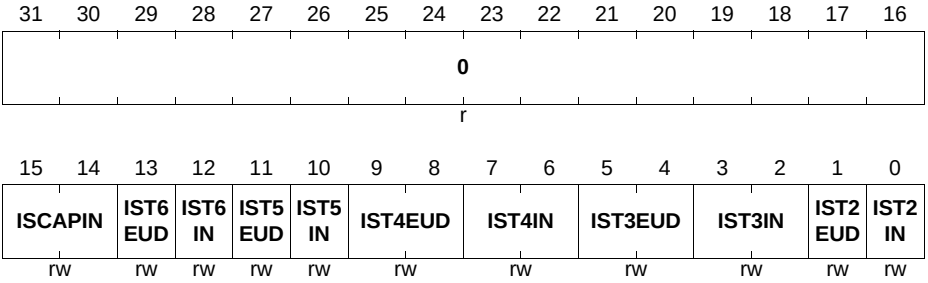
Attention: Register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a GPT12 kernel reset might not be sufficient to bring the system into a defined state.

27.4.3 Miscellaneous GPT12 Registers

27.4.3.1 Port Input Select Register

Register PISEL contains bit fields selecting the actual input signal for the module inputs.

PISEL
Port Input Select Register **(04_H)** **Reset Value: $0000\ 0000_H$**



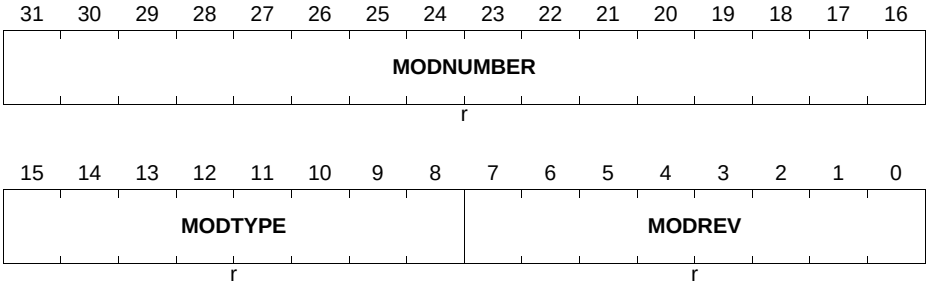
Field	Bits	Type	Description
IST2IN	0	rw	**Input Select for T2IN** 0_B Signal T2INA is selected 1_B Signal T2INB is selected
IST2EUD	1	rw	**Input Select for T2EUD** 0_B Signal T2EUDA is selected 1_B Signal T2EUDB is selected
IST3IN	[3:2]	rw	**Input Select for T3IN** 00_B Signal T3INA is selected 01_B Signal T3INB is selected 10_B Signal T3INC is selected 11_B Signal T3IND is selected
IST3EUD	[5:4]	rw	**Input Select for T3EUD** 00_B Signal T3EUDA is selected 01_B Signal T3EUDB is selected 10_B Signal T3EUDC is selected 11_B Signal T3EUDD is selected

Field	Bits	Type	Description
IST4IN	[7:6]	rw	**Input Select for T4IN** 00_B Signal T4INA is selected 01_B Signal T4INB is selected 10_B Signal T4INC is selected 11_B Signal T4IND is selected
IST4EUD	[9:8]	rw	**Input Select for T4EUD** 00_B Signal T4EUDA is selected 01_B Signal T4EUDB is selected 10_B Signal T4EUDC is selected 11_B Signal T4EUDD is selected
IST5IN	10	rw	**Input Select for T5IN** 0_B Signal T5INA is selected 1_B Signal T5INB is selected
IST5EUD	11	rw	**Input Select for T5EUD** 0_B Signal T5EUDA is selected 1_B Signal T5EUDB is selected
IST6IN	12	rw	**Input Select for T6IN** 0_B Signal T6INA is selected 1_B Signal T6INB is selected
IST6EUD	13	rw	**Input Select for T6EUD** 0_B Signal T6EUDA is selected 1_B Signal T6EUDB is selected
ISCAPIN	[15:14]	rw	**Input Select for CAPIN** 00_B Signal CAPINA is selected 01_B Signal CAPINB is selected 10_B Signal CAPINC (Read trigger from T3) is selected 11_B Signal CAPIND (Read trigger from T2 or T3 or T4) is selected
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

27.4.3.2 Identification Register

The GPT12 Module Identification Register ID contains read-only information about the module identification number and its revision.

ID
Identification Register **(08_H)** **Reset Value: 0068 C0XX$_H$**



Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field indicates the revision number of the TC27x module (01_H = first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field is $C0_H$. It defines a 32-bit module
MODNUMBER	[31:16]	r	**Module Number** This bit field defines the module identification number. For the GPT12 module the module identification number is 68_H.

27.4.4 BPI Registers

This section describes the registers of the BPI (Bus Peripheral Interface). **Figure 27-30** shows all registers associated with the BPI of a GPT12 module.

BPI Registers Overview

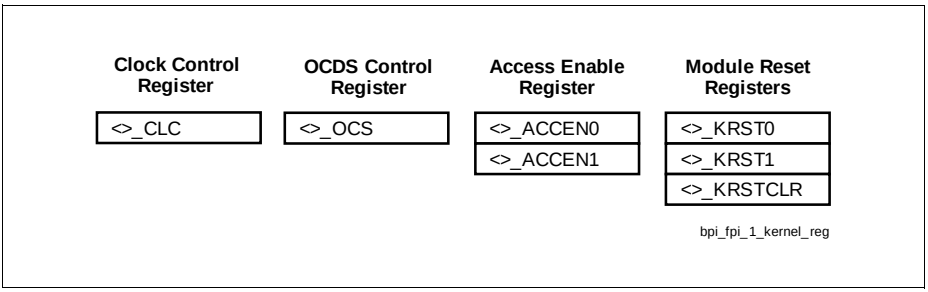


Figure 27-30 BPI Registers

Table 27-21 gives an overview of the BPI registers, including their access modes and reset class.

Table 27-21 Registers Overview - BPI Registers

Register Short Name	Description	Offset Addr.	Access Mode		Reset	Page Num.
			Read	Write		
CLC	Clock Control Register	00_H	U, SV	SV, E, P	Application Reset	27-78
-	Kernel Registers	-	-	-	-	-
OCS	OCDS Control and Status Register	$E8_H$	U, SV	SV, P	Debug Reset	27-79
KRSTCLR	Reset Status Clear Register	EC_H	U, SV	SV, E, P	Application Reset	27-84
KRST1	Reset Control Register 1	$F0_H$	U, SV	SV, E, P	Application Reset	27-83
KRST0	Reset Control Register 0	$F4_H$	U, SV	SV, E, P	Application Reset	27-82
ACCEN1	Access Enable Register 1	$F8_H$	U, SV	SV, SE	Application Reset	27-81
ACCEN0	Access Enable Register 0	FC_H	U, SV	SV, SE	Application Reset	27-80

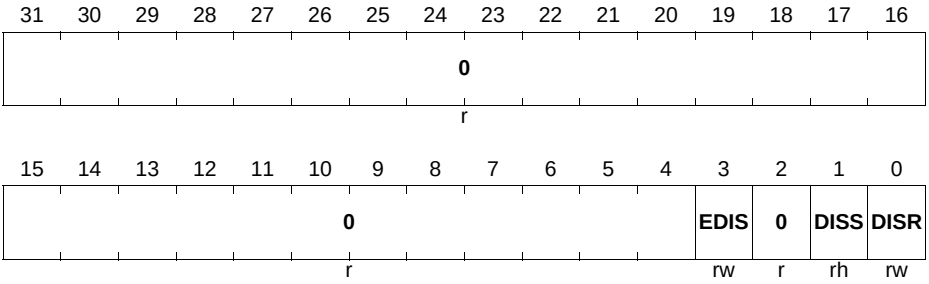
Note: Register bits marked “r” in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

27.4.4.1 System Registers

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI for the GPT12 module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{GPT} module clock signal and Sleep Mode for the module.

CLC
Clock Control Register (00_H) Reset Value: $0000\ 0003_H$



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B Module disable is not requested. 1_B Module disable is requested.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module. 0_B Module is enabled. 1_B Module is disabled.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode. 0_B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode. 1_B Sleep Mode request is disregarded: Sleep Mode cannot be entered upon a request.

Field	Bits	Type	Description
0	[31:16], [15:4], 2	r	**Reserved** Read as 0; should be written with 0.

Note: Upon an accepted Sleep Mode request (with EDIS = '1'), or upon a disable request (DISR = '1'), the GPT12 kernel clock is switched off immediately. Therefore, software should ensure that the system controlled by the GPT12 kernel has reached a safe state before triggering a Sleep Mode or module disable request.

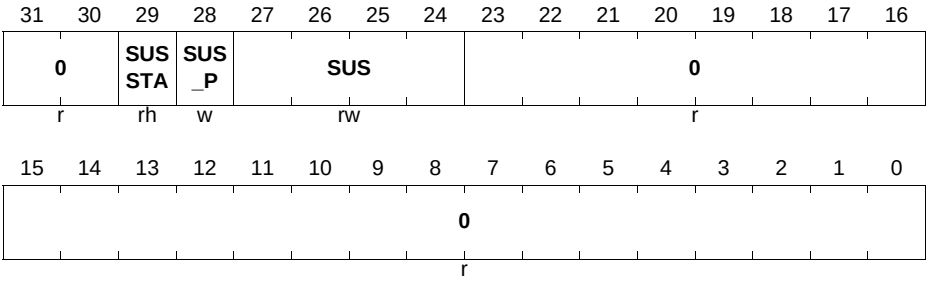
OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective.

Write access is 32 bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status Register ($E8_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.

Field	Bits	Type	Description
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register 0 (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

ACCEN0
Access Enable Register 0 **(FC_H)** **Reset Value: $FFFF\ FFFF_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EN31	**EN30**	**EN29**	**EN28**	**EN27**	**EN26**	**EN25**	**EN24**	**EN23**	**EN22**	**EN21**	**EN20**	**EN19**	**EN18**	**EN17**	**EN16**
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN15	**EN14**	**EN13**	**EN12**	**EN11**	**EN10**	**EN9**	**EN8**	**EN7**	**EN6**	**EN5**	**EN4**	**EN3**	**EN2**	**EN1**	**EN0**
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn **(n = 0-31)**	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

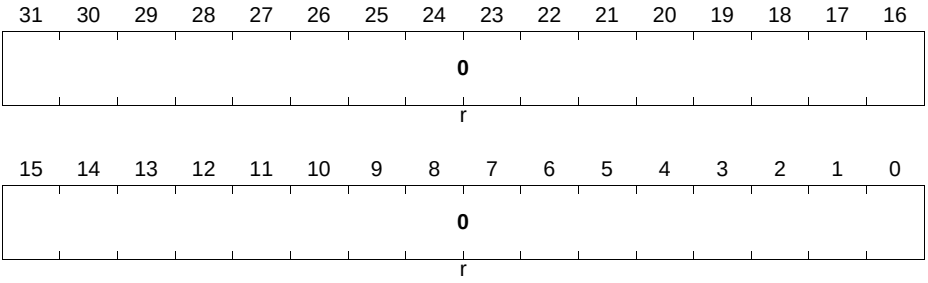
1) The BPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

Access Enable Register 1 (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ACCEN1
Access Enable Register 1 **($F8_H$)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

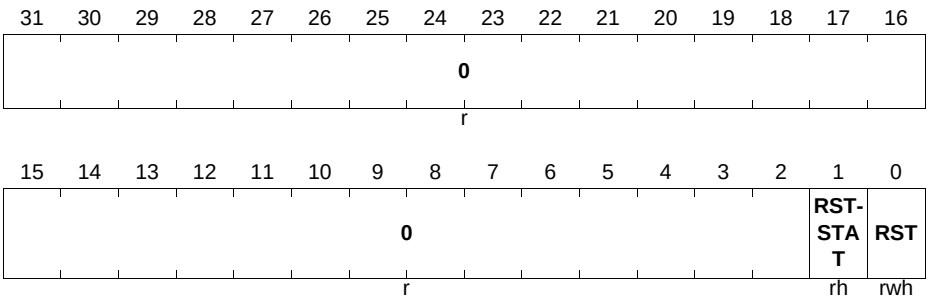
Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers. The RST bit will be re-set (cleared to ‘0’) by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI in the same clock cycle the RST bit is re-set by the BPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **($F4_H$)** **Reset Value: 0000 0000$_H$**

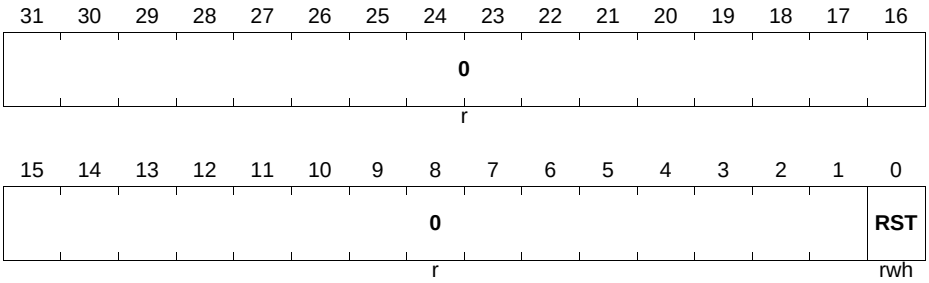


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI after the kernel reset was executed.
RSTSTAT	1	rw	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers. The RST bit will be re-set (cleared to ‘0’) by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($F0_H$)** **Reset Value: 0000 0000$_H$**



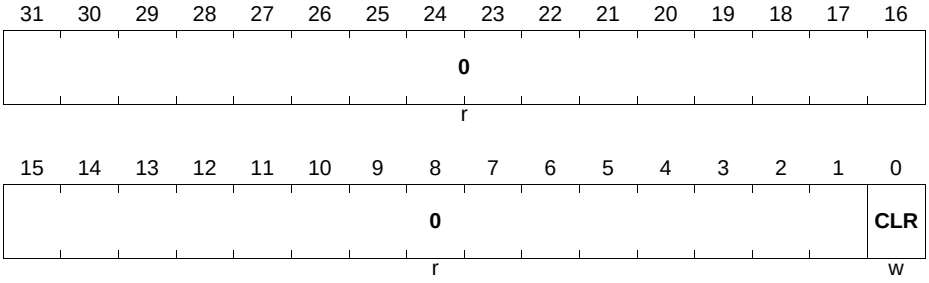
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear Register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (EC_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

27.5 Implementation of the GPT12 Module

This chapter describes the implementation of the GPT12 module in the TC27x device.

27.5.1 Address Map

There is one GPT12 kernel implemented in the TC27x, namely GPT120.

Table 27-22 Registers Address Space

Module	Base Address	End Address	Note
GPT120	F000 2E00$_H$	F000 2EFF$_H$	

27.5.2 Module Connections

The following table shows the digital connections of the GPT12 module with other modules or pins in the TC27x device.

The GPT12 module is clocked with the SPB_Bus clock, so $f_{GPT} = f_{SPB}$.

Table 27-23 GPT120 Digital Connections in TC27x

Signal	from/to Module	I/O to GPT120	Can be used to/as
T2INA	P00.7	I	count input signals for timer T2
T2INB	P33.7	I

28 Versatile Analog-to-Digital Converter (VADC)

The TC27x provides a series of analog input channels connected to a cluster of Analog/Digital Converters using the Successive Approximation Register (SAR) principle to convert analog input values (voltages) to discrete digital values.

The TC27x is based on individual SAR converters with dedicated Sample&Hold units.

The number of analog input channels and ADCs depends on the chosen product type (refer to **"Product-Specific Configuration" on Page 28-146**).

Each converter of the ADC cluster can operate independent of the others, controlled by a dedicated set of registers and triggered by a dedicated group request source. The results of each channel can be stored in a dedicated channel-specific result register or in a group-specific result register.

A background request source can access all analog input channels that are not assigned to any group request source. These conversions are executed with low priority. The background request source can, therefore, be regarded as an additional background converter.

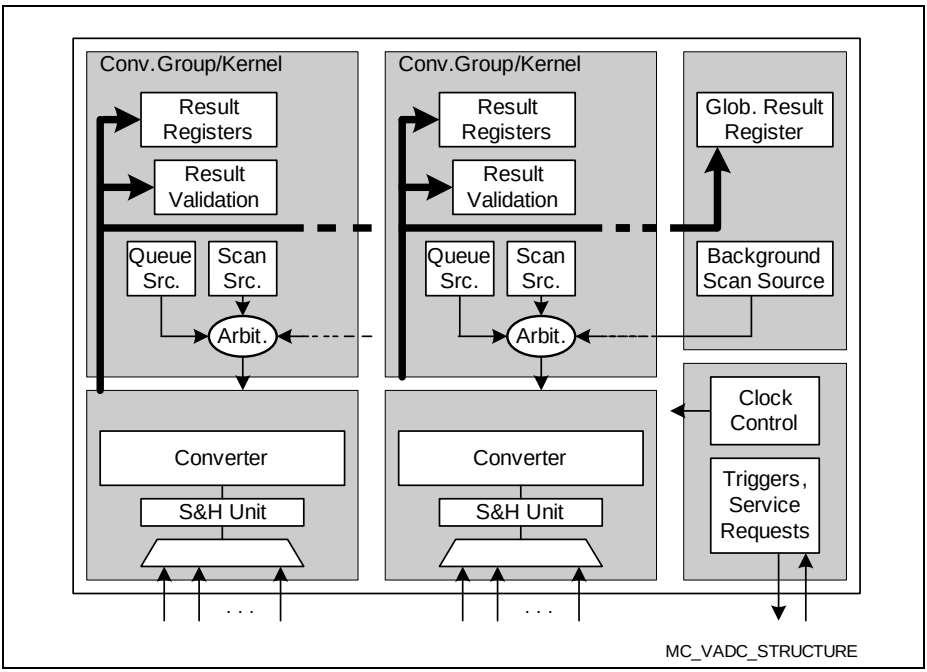

Figure 28-1 ADC Structure Overview

You will find the following major sections within this chapter:

Feature List

The following features describe the functionality of the ADC cluster:

- Nominal analog supply voltage 5.0 V, operation at 3.3 V with reduced performance
- Input voltage range from 0 V up to analog supply voltage
- Standard (V_{AREF}) and alternate (CH0) reference voltage source selectable for each channel to support ratiometric measurements and different signal scales
- Up to 8 independent converters with up to 8 analog input channels
- External analog multiplexer control, including adjusted sample time and scan support
- Conversion speed and sample time adjustable to adapt to sensors and reference
- Conversion time below 1 µs (depending on result width and sample time)
- Flexible source selection and arbitration
  - Programmable arbitrary conversion sequence (single or repeated)
  - Configurable auto scan conversion (single or repeated) on each converter
  - Configurable auto scan conversion (single or repeated) in the background (all converters)
  - Conversions triggered by software, timer events, or external events
  - Cancel-inject-restart mode for reduced conversion delay on priority channels
- Powerful result handling
  - Selectable result width of 8/10/12 bits
  - Fast Compare Mode
  - Independent result registers
  - Configurable limit checking against programmable border values
  - Data rate reduction through adding a selectable number of conversion results
  - FIR/IIR filter with selectable coefficients

- Flexible service request generation based on selectable events
- Built-in safety features
  - Configurable register access protection supports safety applications
  - Broken wire detection with programmable default levels
  - Multiplexer test mode to verify signal path integrity
- Support of suspend and power saving modes

Table 28-1 Abbreviations used in ADC chapter

Abbreviation	Meaning
ADC	Analog to Digital Converter
DMA	Direct Memory Access (controller)
DNL	Differential Non-Linearity (error)
INL	Integral Non-Linearity (error)
LSB_n	Least Significant Bit: finest granularity of the analog value in digital format, represented by one least significant bit of the conversion result with n bits resolution (measurement range divided in 2^n equally distributed steps)
SCU	System Control Unit of the device
TUE	Total Unadjusted Error

28.1 Introduction and Basic Structure

The Versatile Analog to Digital Converter module (VADC) of the TC27x comprises a set of converter blocks that can be operated either independently or via a common request source that emulates a background converter. Each converter block is equipped with a dedicated input multiplexer and dedicated request sources, which together build separate groups, each assigned to a kernel.

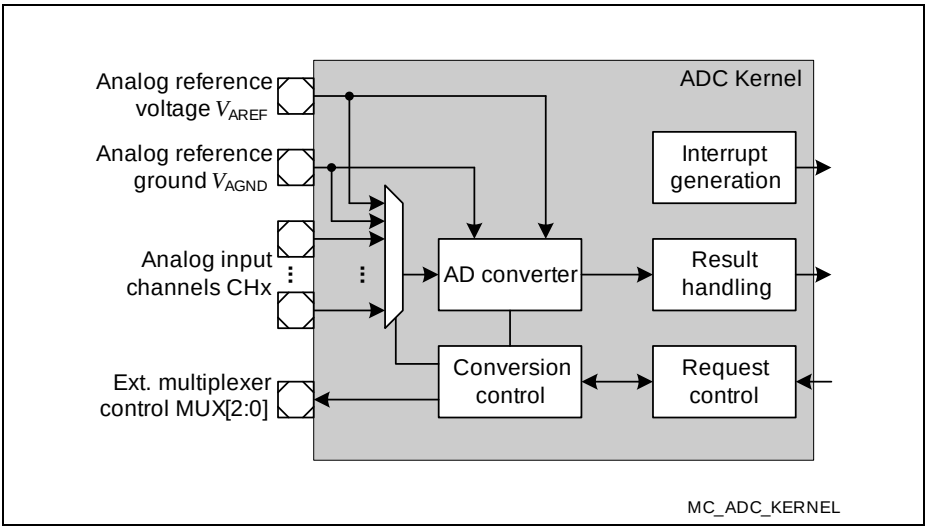

Figure 28-2 ADC Kernel Block Diagram

This basic structure supports application-oriented programming and operating while still providing general access to all resources. The almost identical converter groups allow a flexible assignment of functions to channels.

A set of functional units (described further down in this section) can be configured according to the requirements of a given application. These units build a path from the input signals to the digital results.

Each kernel provides a dedicated Sample&Hold unit connected to the input multiplexer.

The basic module clock f_{VADC} is connected to the system clock signal f_{SPB}.

Conversion Modes and Request Sources

Analog/Digital conversions can be requested by several request sources (2 group request sources and the background request source) and can be executed in several conversion modes. The request sources can be enabled concurrently with configurable priorities.

- **Fixed Channel Conversion (single or continuous)**
  A specific channel source requests conversions of one selectable channel (once or repeatedly)
- **Auto Scan Conversion (single or continuous)**
  A channel scan source (request source 1 or 2) requests auto scan conversions of a configurable linear sequence of all available channels (once or repeatedly)
- **Channel Sequence Conversion (single or continuous)**
  A queued source (request source 0) requests a sequence of conversions of up to 8 arbitrarily selectable channels (once or repeatedly)

The conversion modes can be used concurrently by the available request sources, i.e. conversions in different modes can be enabled at the same time. Each source can be enabled separately and can be triggered by external events, such as edges of PWM or timer signals, or pin transitions.

Request Source Control

Because all request sources can be enabled at the same time, an arbiter resolves concurrent conversion requests from different sources. Each source can be triggered by external signals, by on-chip signals, or by software.

Requests with higher priority can either cancel a running lower-priority conversion (cancel-inject-repeat mode) or be converted immediately after the currently running conversion (wait-for-start mode). If the target result register has not been read, a conversion can be deferred (wait-for-read mode).

Certain channels can also be synchronized with other ADC kernels, so several signals can be converted in parallel.

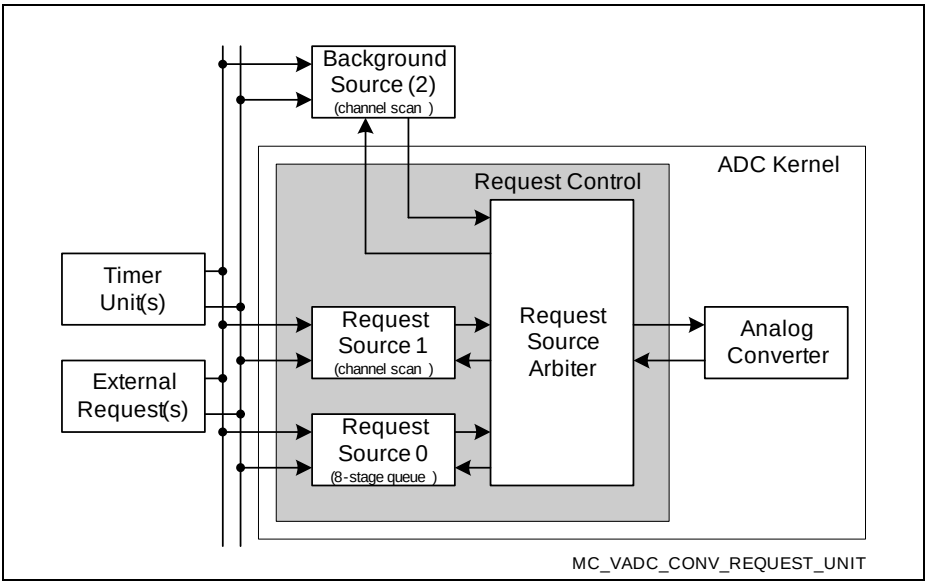

Figure 28-3 Conversion Request Unit

Input Channel Selection

The analog input multiplexer selects one of the available analog inputs (CH0 - CHx[1)]) to be converted. Three sources can select a linear sequence, an arbitrary sequence, or a specific channel. The priorities of these sources can be configured.

Additional external analog multiplexers can be controlled automatically, if more separate input channels are required than are built in (see **Section 28.10**).

*Note: Not all analog input channels are necessarily available in all packages, due to pin limitations. Refer to the implementation description in **Section 28.12**.*

Conversion Control

Conversion parameters, such as sample phase duration or result resolution can be configured for 4 input classes (2 group-specific classes, 2 global classes). Each channel can be individually assigned to one of these input classes.

Each channel can select either the standard reference voltage or the alternate reference voltage (restrictions see **"Product-Specific Configuration" on Page 28-146**).

1) The availablity of input channels depends on the package of the used product type. A summary can be found in **Section 28.12.3**.

The input channels can, thus, be adjusted to the type of sensor (or other analog sources) connected to the ADC.

This unit also controls the built-in multiplexer and external analog multiplexers, if selected.

Analog/Digital Converter

The selected input channel is converted to a digital value by first sampling the voltage on the selected input and then generating the selected number of result bits.

For 12-bit conversions, post-calibration is executed after converting the channel.

For broken wire detection (see **Section 28.9.1**), the converter network can be preloaded before sampling the selected input channel.

Result Handling

The conversion results of each analog input channel can be directed to one of 16 group-specific result registers and one global result register to be stored there. A result register can be used by a group of channels or by a single channel.

The wait-for-read mode avoids data loss due to result overwrite by blocking a conversion until the previous result has been read.

Data reduction (e.g. for digital anti-aliasing filtering) can automatically add up to 4 conversion results before issuing a service request.

Alternatively, an FIR or IIR filter can be enabled that preprocesses the conversion results before sending them to the result register.

Also, result registers can be concatenated to build FIFO structures that store a number of conversion results without overwriting previous data. This increases the allowed CPU latency for retrieving conversion data from the ADC.

Service Request Generation

Several ADC events can issue service requests to CPU or DMA:

- **Source events** indicate the completion of a conversion sequence in the corresponding request source. This event can be used to trigger the setup of a new sequence.
- **Channel events** indicate the completion of a conversion for a certain channel. This can be combined with limit checking, so interrupts are generated only if the result is within a defined range of values.
- **Result events** indicate the availability of new result data in the corresponding result register. If data reduction mode is active, events are generated only after a complete accumulation sequence.

Each event can be assigned to one of eight service request nodes. This allows grouping the requests according to the requirements of the application.

Safety Features

Safety-aware applications are supported with mechanisms that help to ensure the integrity of a signal path.

Broken-wire-detection (BWD) preloads the converter network with a selectable level before sampling the input channel. The result will then reflect the preload value if the input signal is no more connected. If buffer capacitors are used, a certain number of conversions may be required to reach the failure indication level.

Pull Down Diagnostics (PDD) connects an additional strong pull-down device to an input channel. A subsequent conversion can then confirm the expected modified signal level. This allows to check the proper connection of a signal source (sensor) to the multiplexer.

Multiplexer Diagnostics (MD) connects a weak pull-up or pull-down device to an input channel. A subsequent conversion can then confirm the expected modified signal level. This allows to check the proper operation of the multiplexer.

Converter Diagnostics (CD) connects an alternate signal to the converter. A subsequent conversion can then confirm the proper operation of the converter.

28.2 Electrical Models

Each conversion of an analog input voltage to a digital value consists of two consecutive phases:

- During the sample phase, the input voltage is sampled and stored.
  The **Input Signal Path** is a simplified model for this.
- During the conversion phase the stored voltage is converted to a digital result.
  The **Reference Voltage Path** is a simplified model for this.

Input Signal Path

The ADC of the TC27x uses a switched capacitor field represented by C_{AINSW} (small parasitic capacitances are present at each input pin). During the sample phase, the capacitor field C_{AINSW} is connected to the selected analog input CHx via the input multiplexer (modeled by ideal switches and series resistors R_{AIN}).

The switch to CHx is closed during the sample phase and connects the capacitor field to the input voltage V_{AINx}.

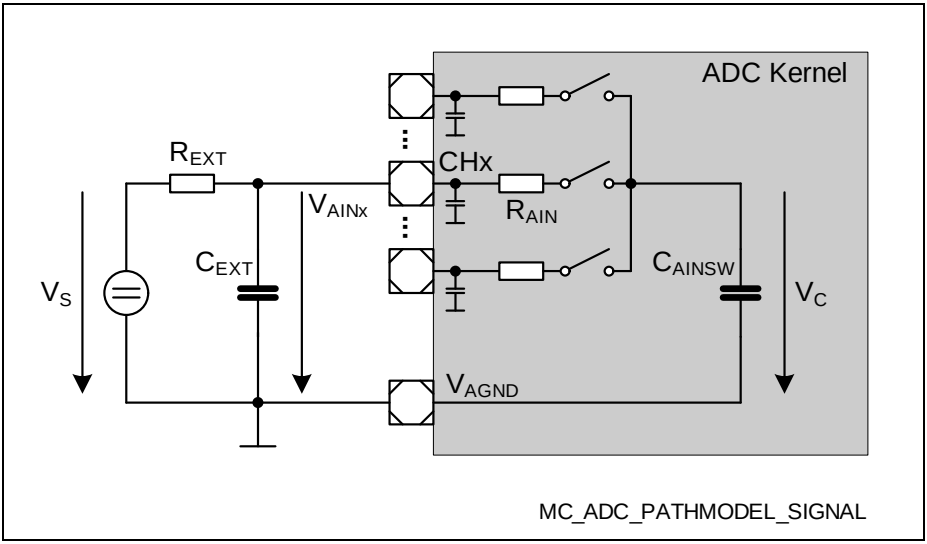

Figure 28-4 Signal Path Model

A simplified model for the analog input signal path is given in **Figure 28-4**. An analog voltage source (value V_S) with an internal impedance of R_{EXT} delivers the analog input that should be converted.

During the sample phase the corresponding switch is closed and the capacitor field C_{AINSW} is charged. Due to the low-pass behavior of the resulting RC combination, the

voltage V_C to be actually converted does not immediately follow V_S. The value R_{EXT} of the analog voltage source and the desired precision of the conversion strongly define the required length of the sample phase.

To reduce the influence of R_{EXT} and to filter input noise, it is recommended to introduce a fast external blocking capacitor C_{EXT} at the analog input pin of the ADC. Like this, mainly C_{EXT} delivers the charge during the sample phase. This structure allows a significantly shorter sample phase than without a blocking capacitor, because the low-pass time constant defining the sample time is mainly given by the values of R_{AIN} and C_{AINSW}.

The resulting low-pass filter of R_{EXT} (usually a parameter of the signal source) and C_{EXT} should be dimensioned according to the application's requirements:

- For quickly changing dynamic signals, a smaller capacitor allows V_{AINx} to follow V_S between two sample phases of the same analog input channel.
- For high-precision conversions, an external blocking capacitor C_{EXT} in the range of at least $2^n \times C_{AINSW}$ keeps the voltage change of V_{AINx} during the sample phase below 1 LSB_n. This voltage change is due to the charge redistribution between C_{EXT} and C_{AINSW}.

Leakage current through the analog input structure of the ADC can generate a voltage drop over R_{EXT}, introducing an error. The ADC input leakage current increases at high temperature and if the input voltage level is close to the analog supply ground V_{SS} or to the analog power supply V_{DDPA}. The input leakage current of an ADC channel can be reduced by avoiding input voltages close to the supplies.

An overload condition (input voltage exceeds the supply range) at adjacent analog inputs injects an additional leakage current (defined by a coupling factor) .

The capacitor C_{AINSW} is automatically precharged to a voltage of approximately half the standard reference voltage V_{AREF} while the converter is idle. Due to varying parameters and parasitic effects, the precharge voltage of C_{AINSW} is typically smaller than V_{AREF} / 2.

Note: When conversions are executed in a sequence, or when a conversion cancels a running conversion, the sample phase starts immediately.
The converter does not become idle in this case and C_{AINSW} is not precharged!

Reference Voltage Path

During the conversion phase, parts of the capacitor field (represented by C_{AREFSW}) are switched to a reference input (V_{AREF} or CH0) or to V_{AGND}. Using CH0 as alternate reference source allows conversions of 5.0 V and 3.3 V based analog input signals with the same ADC kernel.

Stable and noise-free reference and analog supply voltages support accurate conversion results. Because noise can also be introduced from other modules (e.g. switching pins), it is strongly recommended to carefully decouple analog from digital signal domains.

The switching of parts of C_{AREFSW} requires a dynamic current at the selected reference input. The impedance R_{REFEXT} of the reference voltage source V_R has to be low enough to supply the reference current during the conversion phase. An external blocking capacitor C_{REFEXT} can supply the peak currents and minimize the current to be delivered by the reference source.

The reference current I_{AREF} introduces a voltage drop at R_{REFEXT} that should not be neglected for the calculation of the overall accuracy. The average reference current during a conversion depends on the reference voltage level and the time t_{ADC} between two conversion starts: $I_{AREF} = C_{AREFSW} \times V_{AREF} / t_{ADC}$.

The reference current can be reduced by preloading the capacitor field from the supply voltage V_{DDM}. This feature is enabled by setting bit REFPC in register GLOBCFG. In this case the reference voltage and the supply voltage must be on the same level. The capacitor field is first preloaded from V_{DDM} in a first phase and then adjusted to V_{AREF} in a second phase.

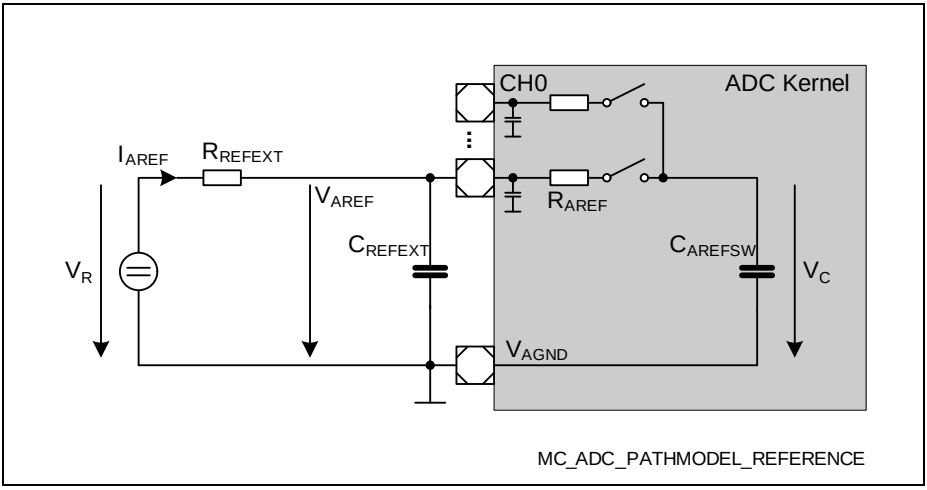

Figure 28-5 Reference Path Model

Reference Signal Connection

The reference voltages (V_{AREF}, V_{AGND}) have a strong influence on the digital result of a conversion. It is, therefore, recommended to carefully avoid noise of these inputs. The recommended filter structures (see figure) help to cancel high-frequency noise.

- Capacitors (C_{REFEXT}) between corresponding reference pins (V_{AREF}, V_{AGND}) provide peak currents for the conversion steps[1)]
- Capacitors (C_N) between reference ground and signal ground (V_{AGND}, V_{SS}) and the inductance of the connections attenuate noise
- Use low-ESR capacitors connected closely to the pins
- Connect reference pins via separate lines to star points close to the sensor supply
- Additional resistors in the reference lines (R_F) must be able to carry the average reference current, to avoid inaccuracy due to voltage drop
- The reference ground lines are connected to the signal ground in many applications

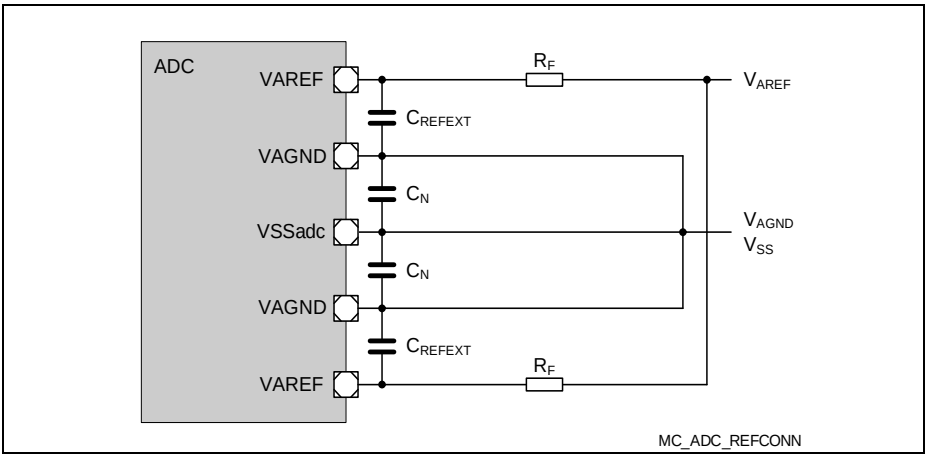

Figure 28-6 Connection of Reference Signals

Due to the charge redistribution between C_{REFEXT} and C_{AREFSW}, the voltage V_{AREF} decreases during the conversion phase. The error introduced by this effect is limited by the external blocking capacitor. $C_{REFEXT} \geq 2^n \times C_{AREFSW}$ limits this error to 1/2 LSB_n (double C_{REFEXT} to limit the error to 1/4 LSB_n).

Assuming 12-bit conversions and C_{AREFSW} = 30 pF leads to:
$C_{REFEXT} > 2^{12} \times 30$ pF = 123 nF, 100 nF are a good approximation.

The noise filtering capacitor C_N depends on the board properties (e.g. 100 nF).

1) The required capacitor value here depends on the resolution and accuracy.

Transfer Characteristics and Error Definitions

The transfer characteristic of the ADC describes the association of analog input voltages to the 2^n discrete digital result values (n bits resolution). Each digital result value (in the range of 0 to 2^n-1) represents an input voltage range defined by the reference voltage range divided by 2^n. This range (called quantization step or code width) represents the granularity (called LSB_n) of the ADC. The discrete character of the digital result generates a system-inherent quantization uncertainty of ±0.5 LSB_n for each conversion result.
The ideal transfer curve has the first digital transition (between 0 and 1) when the analog input reaches 0.5 LSB_n. The quantization steps are equally distributed over the input voltage range.
Analog input voltages below or above the reference voltage limits lead to a saturation of the digital result at 0 or 2^n-1.

The real transfer curve can exhibit certain deviations from the ideal transfer curve:

- The **offset error** is the deviation of the real transfer line from the ideal transfer line at the lowest code. This refers to best-fit lines through all possible codes, for both cases.
- The **gain error** is the deviation of the slope of the real transfer line from the slope of the ideal transfer line. This refers to best-fit lines through all possible codes, for both cases.
- The **differential non-linearity error** (DNL) is the deviation of the real code width (variation of the analog input voltage between two adjacent digital conversion results) from the ideal code width.
- The **integral non-linearity error** (INL) is the deviation of the real transfer curve from an adjusted ideal transfer curve (same offset and gain error as the real curve, but equal code widths).
- The **total unadjusted error** (TUE) describes the maximum deviation between a real conversion result and the ideal transfer characteristics over a given measurement range. Since some of these errors noted above can compensate each other, the TUE value generally is much less than the sum of the individual errors.
  The TUE also covers production process variations and internal noise effects (if switching noise is generated by the system, this generally leads to an increased TUE value).

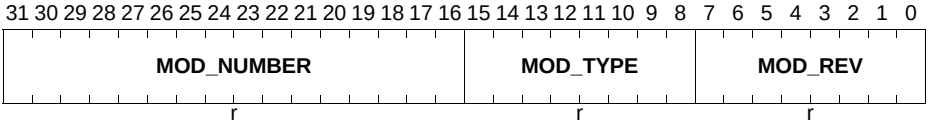
28.3 Configuration of General Functions

While many parameters can be selected individually for each channel, source, or group, some adjustments are valid for the whole ADC cluster.

28.3.1 Module Identification

The module identification register indicates the version of the ADC module that is used in the TC27x.

ID
Module Identification Register (0008$_H$) Reset Value: 00C5 C0XX$_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision** Indicates the revision number of the implementation. This information depends on the design step.
MOD_TYPE	[15:8]	r	**Module Type** This internal marker is fixed to C0$_H$.
MOD_NUMBER	[31:16]	r	**Module Number** Indicates the module identification number (00C5$_H$ = SARADC).

28.3.2 System Registers

A set of standardized registers provides general access to the module and controls basic system functions.

The Clock Control Register **CLC** allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. Register **CLC** controls the module clock signal and the reactivity to the sleep mode signal.

CLC
Clock Control Register **(0000_H)** **Reset Value: 0000 0003_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. Also the analog section is disabled by clearing ANONS. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	r	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
0	2	r	**Reserved, write 0, read as 0**
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	[31:4]	r	**Reserved, write 0, read as 0**

The OCDS control and status register OCS controls the module's behavior in suspend mode (used for debugging) and includes the module-related control bits for the OCDS Trigger Bus (OTGB).

The OCDS Control and Status (OCS) register is cleared by Debug Reset.
The OCS register can only be written when the OCDS is enabled.
If OCDS is being disabled, the OCS register value will not change.
When OCDS is disabled the OCS suspend control is ineffective.
Write access is 32 bit wide only and requires Supervisor Mode.

Individual Module Reset

The Kernel Reset Registers **KRST0/KRST1** are used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits in both Kernel Reset Registers. The RST bits will be cleared by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Registers 0 and 1 each include bit RST. To trigger a module reset, both RST bits must be set. They will be cleared automatically with the end of the BPI kernel reset sequence.

1) The Access Enable functionality controls only write transactions to registers CLC, OCS, KRSTx, and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Kernel Reset Register 0 includes a kernel reset status bit that is set in the same clock cycle the RST bit is cleared. This bit indicates that a kernel reset was processed. Bit RSTSTAT can be cleared by setting bit CLR in register **KRSTCLR**.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

28.3.3 General Clocking Scheme and Control

The A/D Converters of the TC27x are supplied with a global clock signal from the system f_{VADC}. Two clock signals are derived from this input and are distributed to all converters. The global configuration register defines common clock bases for all converters of the cluster. This ensures deterministic behavior of converters that shall operate in parallel.

The analog converter clock f_{ADCI} determines the performance of the converters and must be selected to comply with the specification given in the Data Sheet.

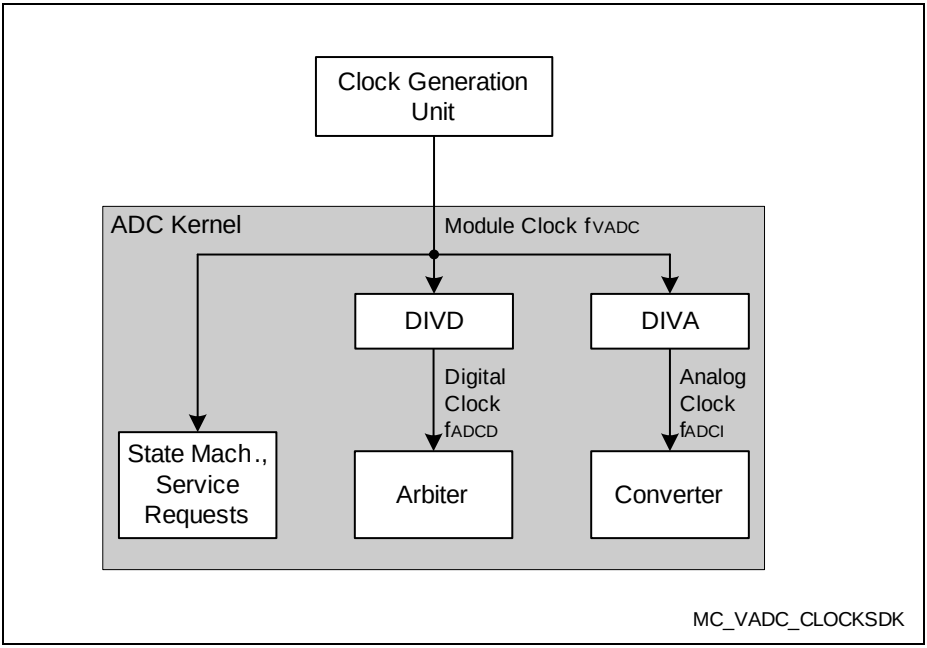

Figure 28-7 Clock Signal Summary

Global Configuration

The global configuration register provides global control and configuration options that are valid for all converters of the cluster.

28.3.4 Register Access Control

Several protection schemes are provided to prevent unintended write access to control bitfields of the VADC.

- The registers of the VADC are protected by the general access control mechanism that is configured by register **ACCEN0**.
- A specific register access control scheme provides a versatile protection scheme against unintended corruption of register contents. Registers ACCPROT0/1 allow the restriction of write accesses for several groups of registers. The registers to be protected can be selected by the user. **Table 28-3** lists the registers that belong to each register group.
  Registers ACCPROT0/1 themselves are protected by the Safety Endinit feature.
- Groups of bitfields within a register may also be protected by an associated write control bit. This write control bit (xxWC) must be written with 1 along with the write access to the intended bitfield(s).

Valid for TC27: 8 groups

28.4 Analog Module Activation and Control

The analog converter of the ADC is the functional block that generates the digital result values from the selected input voltage. It draws a permanent current during its operation and can be deactivated between conversions to reduce the consumed overall energy.

Note: After reset the analog converters are off. They must be enabled before triggering any action involving a converter.

The accuracy of the conversions is improved by calibrating the analog converter to compensate process, temperature, and voltage variations.

28.4.1 Analog Converter Control

The operating mode is determined by bitfield **GxARBCFG (x = 0 - 7)**.ANONS:

- ANONS = 11_B: **Normal Operation**
  The converter is active, conversions are started immediately.
  Requires no wakeup time.
- ANONS = 10_B or 01_B: **Reserved**
- ANONS = 00_B: **Converter switched Off** (default after reset)
  The converter is switched off. Furthermore, digital logic blocks are set to their initial state. If the arbiter is currently running, it completes the actual arbitration round and then stops.
  Before starting a conversion, select the active mode for ANONS.
  Requires the wakeup time (see below).

Note: Since switching off the analog part requires a wake-up phase, the optimum configuration depends on the actual application.

Entering Power Save Modes

To ensure proper operation of the converter, disable it (ANONS = 00_B) before putting the system into a power save mode. This makes sure that no conversion is disrupted by system activities.

Wakeup Time from Analog Powerdown

When the converter is activated, it needs a certain wakeup time to settle before a conversion can be properly executed. This wakeup time can be established by waiting the required period before starting a conversion, or by adding it to the intended sample time.

The wakeup time is approximately 15 µs.
Exact numbers can be found in the respective Data Sheets.

Note: The wakeup time is also required after initially enabling the converter.

28.4.2 Alternate Reference Selection

The VADC control features allow selecting an alternate reference for each channel. This reference signal is taken from channel 0 of a group.

28.4.3 Calibration

Calibration automatically compensates deviations caused by process, temperature, and voltage variations. This ensures precise results throughout the operation time.

An initial start-up calibration is required once after a reset for all converters. All converters must be enabled (ANONS = 11_B). The start-up calibration is initiated globally by setting bit SUCAL in register GLOBCFG. By setting bit SUCAL in register CALCTR the start-up calibration can be initiated for the corresponding cluster converter. Conversions may be started after the initial calibration sequence. This is indicated by bit CALS = 1_B AND bit CAL = 0_B.

The start-up calibration phase takes 4 352 cycles (4 352 × 10 ns = 43.5 µs).

After that, calibration cycles will compensate the effects of drifting parameters. The calibration cycles can be executed before or after (user configuration) a conversion sequence or can be disabled.

Note: The ADC error depends on the temperature. Therefore, the calibration must be repeated periodically.

28.5 Conversion Request Generation

The conversion request unit of a group autonomously handles the generation of conversion requests. Three request sources (2 group-specific sources and the background source) can generate requests for the conversion of an analog channel. The arbiter resolves concurrent requests and selects the channel to be converted next.

Upon a trigger event, the request source requests the conversion of a certain analog input channel or a sequence of channels.

- **Software triggers**
  directly activate the respective request source.
- **External triggers**
  synchronize the request source activation with external events, such as a trigger pulse from a timer generating a PWM signal or from a port pin.

Application software selects the trigger type and source, the channel(s) to be converted, and the request source priority. A request source can also be activated directly by software without requiring an external trigger.

The arbiter regularly scans the request sources for pending conversion requests and selects the conversion request with the highest priority. This conversion request is then forwarded to the converter to start the sampling and conversion of the requested channel.

Each request source can operate in single-shot or in continuous mode:

- **In single-shot mode**,
  the programmed conversion (sequence) is requested once after being triggered. A subsequent conversion (sequence) must be triggered again.
- **In continuous mode**,
  the programmed conversion (sequence) is automatically requested repeatedly after being triggered once.

For each request source of a group, external triggers are generated from one of 15 selectable trigger inputs (REQTRx[O:A]) and from one of 16 selectable gating inputs (REQGTx[P:A])[1]. The available trigger signals for the TC27x are listed in **Section 28.12.4**.

*Note: **Figure 28-3 "Conversion Request Unit" on Page 28-6** summarizes the request sources.*

1) The selected gating input can be used as a trigger signal (REQTRxP).

Two types of request sources are available:

- **A queued source** can issue conversion requests for an arbitrary sequence of input channels. The channel numbers for this sequence can be freely programmed[1]. This supports application-specific conversion sequences that cannot be covered by a channel scan source. Also, multiple conversions of the same channel within a sequence are supported.
  A queued source converts a series of input channels permanently or on a regular time base. For example, if programmed with medium priority, some input channels can be converted upon a specified event (e.g. synchronized to a PWM). Conversions of lower priority sources are suspended in the meantime.
  Request source 0 is a group-specific 8-stage queued source.
- **A channel scan source** can issue conversion requests for a coherent sequence of input channels. This sequence begins with the highest enabled channel number and continues towards lower channel numbers. All available channels[1] can be enabled for the scan sequence. Each channel is converted once per sequence.
  A scan source converts a series of input channels permanently or on a regular time base. For example, if programmed with low priority, some input channels can be scanned in a background task to update information that is not time-critical.
  – Request source 1 is a group-specific channel scan source.
  – Request source 2 is a global channel scan source (background source).
    The background source can request conversions of all channels of all groups.

1) The availablity of input channels depends on the package of the used product type. A summary can be found in **Section 28.12.3**.
The background source can only request non-priority channels, i.e. channels that are not selected in registers GxCHASS. Priority channels are reserved for the group-specific request sources 0 and 1.

28.5.1 Queued Request Source Handling

A queued request source supports short conversion sequences (up to 8) of arbitrary channels (contrary to a scan request source with a fixed conversion order for the enabled channels). The programmed sequence is stored in a queue buffer (based on a FIFO mechanism). The requested channel numbers are entered via the queue input, while queue stage 0 defines the channel to be converted next.

A conversion request is only issued to the request source arbiter if a valid entry is stored in queue stage 0.

If the arbiter aborts a conversion triggered by a queued request source due to higher priority requests, the corresponding conversion parameters are automatically saved in the backup stage. This ensures that an aborted conversion is not lost but takes part in the next arbitration round (before stage 0).

The trigger and gating unit generates trigger events from the selected external (outside the ADC) trigger and gating signals. For example, a timer unit can issue a request signal to synchronize conversions to PWM events.

Trigger events start a queued sequence and can be generated either via software or via the selected hardware triggers. The occurrence of a trigger event is indicated by bit QSRx.EV. This flag is cleared when the corresponding conversion is started or by writing to bit QMRx.CEV.

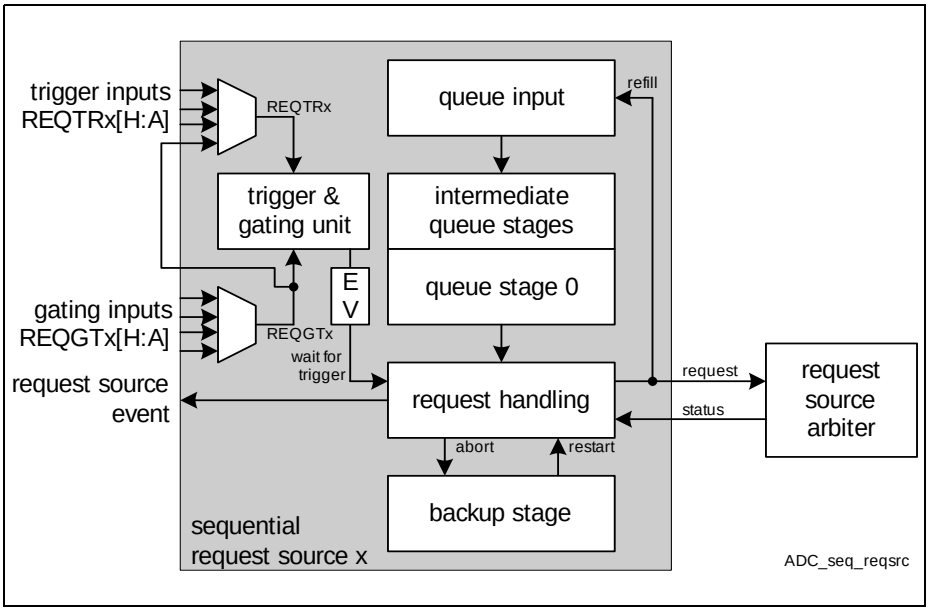

Figure 28-8 Queued Request Source

A sequence is defined by entering conversion requests into the queue input register (**GxQINR0 (x = 0 - 7)**). Each entry selects the channel to be converted and can enable an external trigger, generation of an interrupt, and an automatic refill (i.e. copy this entry to the top of the queue after conversion). The entries are stored in the queue buffer stages.

The content of stage 0 (**GxQ0R0 (x = 0 - 7)**) selects the channel to be converted next. When the requested conversion is started, the contents of this queue stage is invalidated and copied to the backup stage. Then the next queue entry can be handled (if available).

Note: The contents of the queue stages cannot be modified directly, but only by writing to the queue input or by flushing the queue.
*The current status of the queue is shown in register **GxQSR0 (x = 0 - 7)**.*
If all queue entries have automatic refill selected, the defined conversion sequence can be repeated without re-programming.

Properties of the Queued Request Source

Queued request source 0 provides 8 buffer stages and can handle sequences of up to 8 input channel entries. It supports short application-specific conversion sequences, especially for timing-critical sequences containing also multiple conversions of the same channel.

Queued Source Operation

Configure the queued request source by executing the following actions:

- Define the sequence by writing the entries to the queue input **GxQINR0 (x = 0 - 7)**. Initialize the complete sequence before enabling the request source, because with enabled refill feature, software writes to QINR0 are not allowed.
- If hardware trigger or gating is desired, select the appropriate trigger and gating inputs and the proper transitions by programming **GxQCTRL0 (x = 0 - 7)**.
  Enable the trigger and select the gating mode by programming bitfield ENGT in register **GxQMR0 (x = 0 - 7)**.[1)]
- Enable the corresponding arbitration slot (0) to accept conversion requests from the queued source (see register **GxARBPR (x = 0 - 7)**).

Start a queued sequence by generating a trigger event:

- If a hardware trigger is selected and enabled, generate the configured transition at the selected input signal, e.g. from a timer or an input pin.
- Generate a software trigger event by setting GxQMR0.TREV = 1.

1) If PDOUT signals from the ERU are used, initialize the ERU accordingly before enabling the gate inputs to avoid un expected signal transitions.

- Write a new entry to the queue input of an empty queue. This leads to a (new) valid queue entry that is forwarded to queue stage 0 and starts a conversion request (if enabled by GxQMR0.ENGT and without waiting for an external trigger).

Note: If the refill mechanism is activated, a processed entry is automatically reloaded into the queue. This permanently repeats the respective sequence (autoscan). In this case, do not write to the queue input while the queued source is running. Write operations to a completely filled queue are ignored.

Stop or abort an ongoing queued sequence by executing one of the following actions:

- If external gating is enabled, switch the gating signal to the defined inactive level. This does not modify the queue entries, but only prevents issuing conversion requests to the arbiter.
- Disable the corresponding arbitration slot (0) in the arbiter. This does not modify the queue entries, but only prevents the arbiter from accepting requests from the request handling block.
- Disable the queued source by clearing bitfield ENGT = 00_B.
  - Invalidate the next pending queue entry by setting bit GxQMR0.CLRV = 1. If the backup stage contains a valid entry, this one is invalidated, otherwise stage 0 is invalidated.
  - Remove all entries from the queue by setting bit GxQMR0.FLUSH = 1.

Queue Request Source Events and Service Requests

A request source event of a queued source occurs when a conversion is finished. A source event service request can be generated based on a request source event according to the structure shown in **Figure 28-9**. If a request source event is detected, it sets the corresponding indication flag in register **GxSEFLAG (x = 0 - 7)**. These flags can also be set by writing a 1 to the corresponding bit position, whereas writing 0 has no effect. The indication flags can be cleared by SW by writing a 1 to the corresponding bit position in register **GxSEFCLR (x = 0 - 7)**.
The interrupt enable bit is taken from stage 0 for a normal sequential conversion, or from the backup stage for a repeated conversion after an abort.

The service request output line SRx that is selected by the request source event interrupt node pointer bitfields in register **GxSEVNP (x = 0 - 7)** becomes activated each time the related request source event is detected (and enabled by GxQ0R0.ENSI, or GxQBUR0.ENSI respectively) or the related bit position in register **GxSEFLAG (x = 0 - 7)** is written with a 1 (this write action simulates a request source event).

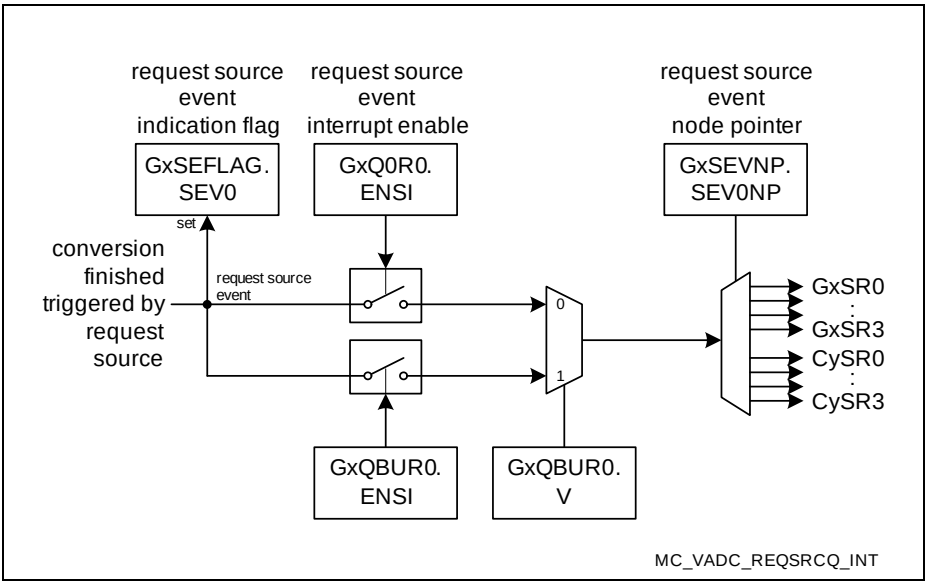

Figure 28-9 Interrupt Generation of a Queued Request Source

The control register of the queue source selects the external gate and/or trigger signals. Write control bits allow separate control of each function with a simple write access.

r	r	r	r	r	r	r	rh	rh	rh	rh	rh				

Field	Bits	Type	Description
REQCHNR	[4:0]	rh	**Request Channel Number** The channel number of the aborted conversion that has been requested by this request source
RF	5	rh	**Refill** The refill control bit of the aborted conversion
ENSI	6	rh	**Enable Source Interrupt** The enable source interrupt control bit of the aborted conversion
EXTR	7	rh	**External Trigger** The external trigger control bit of the aborted conversion
V	8	rh	**Request Channel Number Valid** Indicates if the entry (REQCHNR, RF, TR, ENSI) in the queue backup register is valid. Bit V is set when a running conversion (that has been requested by this request source) is aborted, it is cleared when the aborted conversion is restarted. 0_B Backup register not valid 1_B Backup register contains a valid entry. This will be requested before a valid entry in queue register 0 (stage 0) will be requested.
0	[31:9]	r	**Reserved, write 0, read as 0**

Note: Register QBUR0 shares addresses with register QINR0.
Read operations return the status bits from register QBUR0. Write operations target the control bits in register QINR0.

28.5.2 Channel Scan Request Source Handling

The VADC provides two types of channel scan sources:

- Source 1: Group scan source
  This scan source can request all channels of the corresponding group.
- Source 2: Background scan source
  This scan source can request all channels of all groups.
  Priority channels selected in registers **GxCHASS (x = 0 - 7)** cannot take part in background conversion sequences.

Both sources operate in the same way and provide the same register interface. The background source provides more request/pending bits because it can request all channels of all groups.

Each analog input channel can be included in or excluded from the scan sequence by setting or clearing the corresponding channel select bit in register **GxASSEL (x = 0 - 7)** or **BRSSELx (x = 0 - 7)**. The programmed register value remains unchanged by an ongoing scan sequence. The scan sequence starts with the highest enabled channel number and continues towards lower channel numbers.

Upon a load event, the request pattern is transferred to the pending bits in register **GxASPND (x = 0 - 7)** or **BRSPNDx (x = 0 - 7)**. The pending conversion requests indicate which input channels are to be converted in an ongoing scan sequence. Each conversion start that was triggered by the scan request source, automatically clears the corresponding pending bit. If the last conversion triggered by the scan source is finished and all pending bits are cleared, the current scan sequence is considered finished and a request source event is generated.

A conversion request is only issued to the request source arbiter if at least one pending bit is set.

If the arbiter aborts a conversion triggered by the scan request source due to higher priority requests, the corresponding pending bit is automatically set. This ensures that an aborted conversion is not lost but takes part in the next arbitration round.

The trigger and gating unit generates load events from the selected external (outside the ADC) trigger and gating signals. For example, a timer unit can issue a request signal to synchronize conversions to PWM events.

Load events start a scan sequence and can be generated either via software or via the selected hardware triggers. The request source event can also generate an automatic load event, so the programmed sequence is automatically repeated.

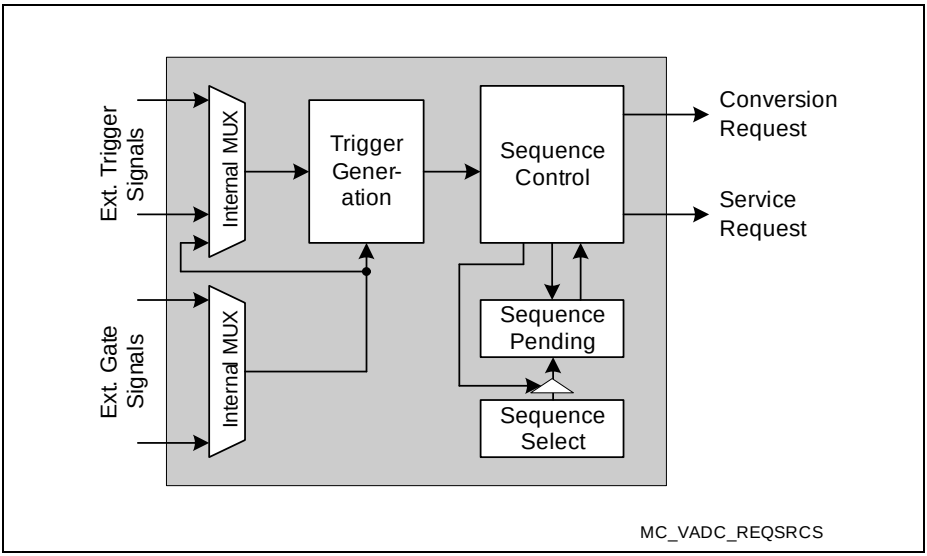

Figure 28-10 Scan Request Source

Scan Source Operation

Configure the scan request source by executing the following actions:

- Select the input channels for the sequence by programming **GxASSEL (x = 0 - 7)** or **BRSSELx (x = 0 - 7)**
- If hardware trigger or gating is desired, select the appropriate trigger and gating inputs and the proper signal transitions by programming **GxASCTRL (x = 0 - 7)** or **BRSCTRL**. Enable the trigger and select the gating mode by programming **GxASMR (x = 0 - 7)** or **BRSMR**.[1)]
- Define the load event operation (handling of pending bits, autoscan mode) by programming **GxASMR (x = 0 - 7)** or **BRSMR**.
  A load event with bit LDM = 0 copies the content of **GxASSEL (x = 0 - 7)** or **BRSSELx (x = 0 - 7)** to **GxASPND (x = 0 - 7)** or **BRSPNDx (x = 0 - 7)** (overwrite mode). This starts a new scan sequence and aborts any pending conversions from a previous scan sequence.
  A load event with bit LDM = 1 OR-combines the content of **GxASSEL (x = 0 - 7)** or **BRSSELx (x = 0 - 7)** to **GxASPND (x = 0 - 7)** or **BRSPNDx (x = 0 - 7)** (combine mode). This starts a scan sequence that includes pending conversions from a prvious scan sequence.
- Enable the corresponding arbitration slot (1) to accept conversion requests from the channel scan source (see register **GxARBPR (x = 0 - 7)**).

Start a channel scan sequence by generating a load event:

- If a hardware trigger is selected and enabled, generate the configured transition at the selected input signal, e.g. from a timer or an input pin.
- Generate a software load event by setting LDEV = 1 (**GxASMR (x = 0 - 7)** or **BRSMR**).
- Generate a load event by writing the scan pattern directly to the pending bits in **GxASPND (x = 0 - 7)** or **BRSPNDx (x = 0 - 7)**. The pattern is copied to **GxASSEL (x = 0 - 7)** or **BRSSELx (x = 0 - 7)** and a load event is generated automatically.
  In this case, a scan sequence can be defined and started with a single data write action, e.g. under PEC control (provided that the pattern fits into one register).

Note: If autoscan is enabled, a load event is generated automatically each time a request source event occurs when the scan sequence has finished. This permanently repeats the defined scan sequence (autoscan).

Stop or abort an ongoing scan sequence by executing the following actions:

- If external gating is enabled, switch the gating signal to the defined inactive level. This does not modify the conversion pending bits, but only prevents issuing conversion requests to the arbiter.

1) If PDOUT signals from the ERU are used, initialize the ERU accordingly before enabling the gate inputs to avoid un expected signal transitions.

- Disable the corresponding arbitration slot (1 or 2) in the arbiter. This does not modify the contents of the conversion pending bits, but only prevents the arbiter from accepting requests from the request handling block.
- Disable the channel scan source by clearing bitfield ENGT = 00_B. Clear the pending request bits by setting bit CLRPND = 1 (**GxASMR (x = 0 - 7)** or **BRSMR**).

Scan Request Source Events and Service Requests

A request source event of a scan source occurs if the last conversion of a scan sequence is finished (all pending bits = 0). A request source event interrupt can be generated based on a request source event. If a request source event is detected, it sets the corresponding indication flag in register **GxSEFLAG (x = 0 - 7)**. These flags can also be set by writing a 1 to the corresponding bit position, whereas writing 0 has no effect.

The service request output SRx that is selected by the request source event interrupt node pointer bitfields in register **GxSEVNP (x = 0 - 7)** becomes activated each time the related request source event is detected (and enabled by ENSI) or the related bit position in register **GxSEFLAG (x = 0 - 7)** is written with a 1 (this write action simulates a request source event).

The indication flags can be cleared by SW by writing a 1 to the corresponding bit position in register **GxSEFCLR (x = 0 - 7)**.[1)]

1) Refer to **“Service Request Generation” on Page 28-133**.

Registers of Group Scan Source

There is a separate register set for each group scan source. These sources can be operated independently.

The control register of the autoscan source selects the external gate and/or trigger signals.
Write control bits allow separate control of each function with a simple write access.

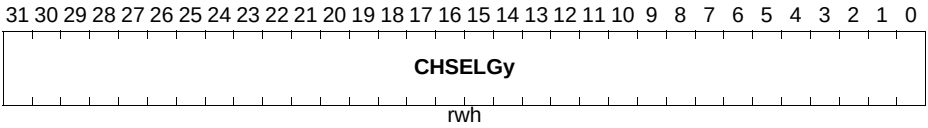
The Channel Select Registers select the channels to be converted by the background request source (channel scan source). Its bits are used to update the pending registers, when a load event occurs.

The number of valid channel bits depends on the channels available in the respective product type (refer to **“Product-Specific Configuration” on Page 28-146**).

*Note: Priority channels selected in registers **GxCHASS (x = 0 - 7)** will not be converted.*

BRSSELx (x = 0 - 7)
Background Request Source Channel Select Register, Group x
(0180_H + x * 0004_H) **Reset Value: 0000 0000_H**

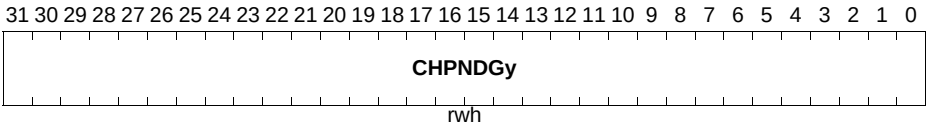


Field	Bits	Type	Description
CHSELGy	[31:0]	rwh	**Channel Selection Group x** Each bit (when set) enables the corresponding input channel of the respective group to take part in the background scan sequence. 0_B Ignore this channel 1_B This channel is part of the scan sequence

The Channel Pending Registers indicate the channels to be converted in the current conversion sequence. They are updated from the select registers, when a load event occurs.

BRSPNDx (x = 0 - 7)
Background Request Source Pending Register, Group x

($01C0_H$ + x * 0004_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CHPNDGy	[31:0]	rwh	**Channels Pending Group x** Each bit (when set) request the conversion of the corresponding input channel of the respective group. 0_B Ignore this channel 1_B Request conversion of this channel

Note: Writing to any of registers BRSPNDx automatically updates the corresponding register BRSSELx and generates a load event that copies all bits from all registers BRSSELx to BRSPNDx.
Use this shortcut only when writing the last word of the request pattern.

28.5.3 Request Source Arbitration

The request source arbiter regularly polls the request sources, one after the other, for pending conversion requests. Each request source is assigned to a certain time slot within an arbitration round, called arbitration slot. The duration of an arbitration slot is user-configurable via register GLOBCFG, see **Global Configuration**.

The priority of each request source is user-configurable via register **GxARBPR (x = 0 - 7)**, so the arbiter can select the next channel to be converted, in the case of concurrent requests from multiple sources, according to the application requirements.

An unused arbitration slot is considered empty and does not take part in the arbitration. After reset, all slots are disabled and must be enabled (register **GxARBPR (x = 0 - 7)**) to take part in the arbitration process.

Figure 28-11 summarizes the arbitration sequence. An arbitration round consists of one arbitration slot for each available request source. The synchronization source is always evaluated in the last slot and has a higher priority than all other sources. At the end of each arbitration round, the arbiter has determined the highest priority conversion request.

If a conversion is started in an arbitration round, this arbitration round does not deliver an arbitration winner. In the TC27x, the following request sources are available:

- Arbitration slot 0: **Group Queued source**, 8-stage sequences in arbitrary order
- Arbitration slot 1: **Group Scan source**, sequences in defined order within group
- Arbitration slot 2: **Background Scan source**, sequences in defined order, all groups
- Last arbitration slot: **Synchronization source**, synchronized conversion requests from another ADC kernel (always handled with the highest priority in a synchronization slave kernel).

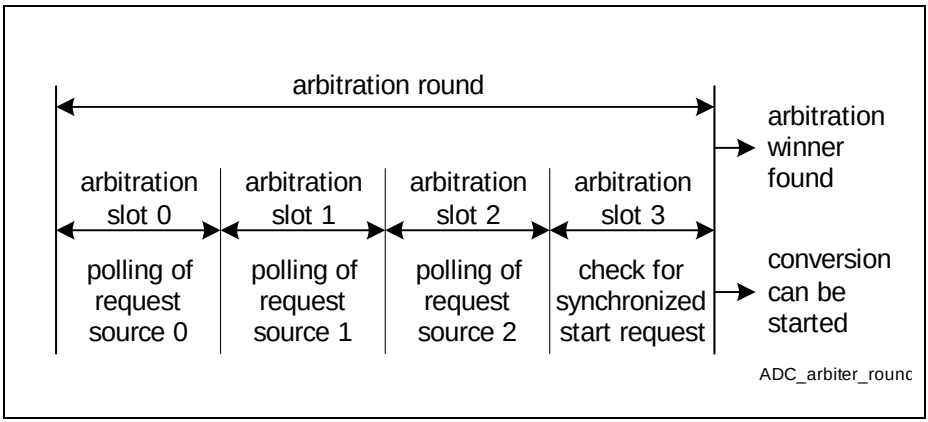


Figure 28-11 Arbitration Round with 4 Arbitration Slots

28.5.3.1 Arbiter Operation and Configuration

The timing of the arbiter (i.e. of an arbitration round) is determined by the number of arbitration slots within an arbitration round and by the duration of an arbitration slot.

An arbitration round consist of 4…20 arbitration slots (defined by bitfield **GxARBCFG (x = 0 - 7)**.ARBRND). 4 slots are sufficient for the TC27x, more can be programmed to obtain the same arbiter timing for different products.

The duration of an arbitration slot is configurable t_{Slot} = (DIVD+1) / f_{VADC}.
The duration of an arbitration round, therefore, is t_{ARB} = 4 × t_{Slot}.

The period of the arbitration round introduces a timing granularity to detect an incoming conversion request signal and the earliest point to start the related conversion. This granularity can introduce a jitter of maximum one arbitration round. The jitter can be reduced by minimizing the period of an arbitration round.

To achieve a reproducible reaction time (constant delay without jitter) between the trigger event of a conversion request (e.g. by a timer unit or due to an external event) and the start of the related conversion, mainly the following two options exist. For both options, the converter has to be idle and other conversion requests must not be pending for at least one arbiter round before the trigger event occurs:

- If bit **GxARBCFG (x = 0 - 7)**.ARBM = 0, the **arbiter runs permanently**. In this mode, synchronized conversions of more than one ADC kernel are possible.[1)]
  The trigger for a conversion request has to be generated synchronously to the arbiter timing. Incoming triggers should have exactly n-times the granularity of the arbiter (n = 1, 2, 3,...). In order to allow some flexibility, the duration of an arbitration slot can be programmed in cycles of f_{VADC}.
- If bit **GxARBCFG (x = 0 - 7)**.ARBM = 1, the **arbiter stops after an arbitration round** when no conversion request have been found pending any more. The arbiter is started again if at least one enabled request source indicates a pending conversion request. The trigger for a conversion request does not need to be synchronous to the arbiter timing.
  In this mode, parallel conversions are not possible for synchronization slave kernels.

Each request source has a configurable priority, so the arbiter can resolve concurrent conversion requests from different sources. The request with the highest priority is selected for conversion. These priorities can be adapted to the requirements of a given application (see register **GxARBPR (x = 0 - 7)**).

The **Conversion Start Mode** determines the handling of the conversion request that has won the arbitration.

1) For more information, refer to **"Synchronization of Conversions" on Page 28-117**.

The Arbitration Configuration Register selects the timing and the behavior of the arbiter.

GxARBCFG (x = 0 - 7)
Arbitration Configuration Register, Group x
(x * 0400_H + 0480_H) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
ANONC	[1:0]	rw	**Analog Converter Control** Defines the value of bitfield ANONS in a stand-alone converter or a converter in master mode. Coding see ANONS or **Section 28.4.1**.
0	[3:2]	r	**Reserved, write 0, read as 0**
ARBRND	[5:4]	rw	**Arbitration Round Length** Defines the number of arbitration slots per arb. round (arbitration round length = t_{ARB}).[1)] 00_B 4 arbitration slots per round (t_{ARB} = 4 / f_{ADCD}) 01_B 8 arbitration slots per round (t_{ARB} = 8 / f_{ADCD}) 10_B 16 arbitration slots per round (t_{ARB} = 16 / f_{ADCD}) 11_B 20 arbitration slots per round (t_{ARB} = 20 / f_{ADCD})
0	6	r	**Reserved, write 0, read as 0**

Field	Bits	Type	Description
ARBM	7	rw	**Arbitration Mode** 0_B The arbiter runs permanently. This setting is required for a synchronization slave (see **Section 28.8.1**) and for equidistant sampling using the signal ARBCNT (see **Section 28.8.2**). 1_B The arbiter only runs if at least one conversion request of an enabled request source is pending. This setting ensures a reproducible latency from an incoming request to the conversion start, if the converter is idle. Synchronized conversions are not supported.
0	[15:8]	r	**Reserved, write 0, read as 0**
ANONS	[17:16]	rh	**Analog Converter Control Status** Defined by bitfield ANONC in a stand-alone kernel or a kernel in master mode. In slave mode, this bitfield is defined by bitfield ANONC of the respective master kernel. See also **Section 28.4.1**. 00_B Analog converter off 01_B Reserved 10_B Reserved 11_B Normal operation (permanently on)
CSRC	[19:18]	rh	**Currently Converted Request Source** Indicates the arbitration slot number of the current (BUSY = 1) or of the last (BUSY = 0) conversion. This bitfield is updated when a conversion is started. 00_B Current/last conversion for request source 0 01_B Current/last conversion for request source 1 10_B Current/last conversion for background source 11_B Current/last conversion for synchronization request (slave converter)
CHNR	[24:20]	rh	**Channel Number** Indicates the current or last converted analog input channel. This bitfield is updated when a conversion is started.

Field	Bits	Type	Description
SYNRUN	25	rh	**Synchronous Conversion Running** Indicates that a synchronized (= parallel) conversion is currently running. 0_B Normal conversion or no conversion running 1_B A synchronized conversion is running (cannot be cancelled by higher priority requests!)
0	[27:26]	r	**Reserved, write 0, read as 0**
CAL	28	rh	**Start-Up Calibration Active Indication** Indicates the start-up calibration phase of the corresponding analog converter. 0_B Completed or not yet started 1_B Start-up calibration phase is active (set one clock cycle after setting bit SUCAL) *Note: Start conversions only after the start-up calibration phase is complete.*[2)]
CALS	29	rh	**Start-Up Calibration Started** Indicates that the start-up calibration has begun. 0_B Requested but not yet started 1_B Start-up calibration has begun *Note: Bit CALS is cleared when setting bit SUCAL and is set together with bit CAL.*
BUSY	30	rh	**Converter Busy Flag** 0_B Not busy 1_B Converter is busy with a conversion
SAMPLE	31	rh	**Sample Phase Flag** 0_B Converting or idle 1_B Input signal is currently sampled

1) The default setting of 4 arbitration slots is sufficient for correct arbitration. The duration of an arbitration round can be increased if required to synchronize requests.

2) The completion of the start-up calibration is indicated by CAL = 0 AND CALS = 1.
CAL = CALS = 0 indicates that the start-up calibration was requested but has not yet begun.
CAL = CALS = 1 indicates an ongoing calibration phase.

The Arbitration Priority Register defines the request source priority and the conversion start mode for each request source.

Note: Only change priority and conversion start mode settings of a request source while this request source is disabled, and a currently running conversion requested by this source is finished.

Pending conversion requests from the associated request source are arbitrated.
0	[31:27]	r	**Reserved, write 0, read as 0**

28.5.3.2 Conversion Start Mode

When the arbiter has selected the request to be converted next, the handling of this channel depends on the current activity of the converter:

- Converter is currently idle: the conversion of the arbitration winner is started immediately.
- Current conversion has same or higher priority: the current conversion is completed, the conversion of the arbitration winner is started after that.
- Current conversion has lower priority: the action is user-configurable:
  - **Wait-for-start mode**: the current conversion is completed, the conversion of the arbitration winner is started after that. This mode provides maximum throughput, but can produce a jitter for the higher priority conversion.
    Example in **Figure 28-12**:
    Conversion A is requested (t1) and started (t2). Conversion B is then requested (t3), but started only after completion of conversion A (t4).
  - **Cancel-inject-repeat mode**: the current conversion is aborted, the conversion of the arbitration winner is started after the abortion (3 f_{VADC} cycles).
    The aborted conversion request is restored in the corresponding request source and takes part again in the next arbitration round. This mode provides minimum jitter for the higher priority conversions, but reduces the overall throughput.
    Example in **Figure 28-12**:
    Conversion A is requested (t6) and started (t7). Conversion B is then requested (t8) and started (t9), while conversion A is aborted but requested again. When conversion B is complete (t10), conversion A is restarted.
    Exception: If both requests target the same result register with wait-for-read mode active (see **Section 28.7.3**), the current conversion cannot be aborted.

Note: A cancelled conversion can be repeated automatically in each case, or it can be discarded if it was cancelled. This is selected for each source by bit RPTDIS in the corresponding source's mode register.

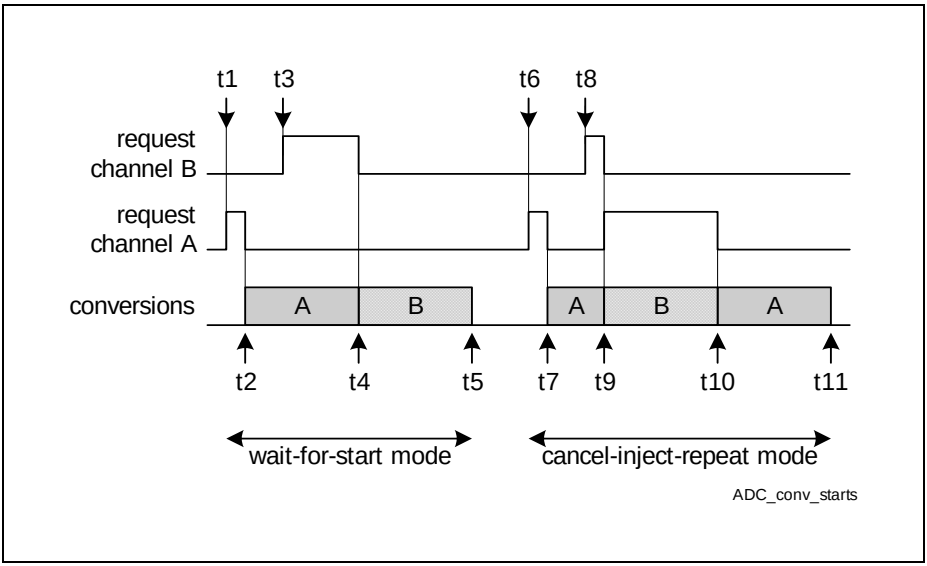

Figure 28-12 Conversion Start Modes

The conversion start mode can be individually programmed for each request source by bits in register **GxARBPR (x = 0 - 7)** and is applied to all channels requested by the source. In this example, channel A is issued by a request source with a lower priority than the request source requesting the conversion of channel B.

28.6 Analog Input Channel Configuration

For each analog input channel a number of parameters can be configured that control the conversion of this channel. The channel control registers define the following parameters:

- **Channel Parameters**: The sample time for this channel and the data width of the result are defined via input classes. Each channel can select one of two classes of its own group or one of two global classes.
- **Reference selection**: an alternate reference voltage can be selected for most channels (exceptions are marked in **Section 28.12.3**)
- **Result target**: The conversion result values are stored either in a group-specific result register or in the global result register. The group-specific result registers are selected in several ways:
  - channel-specific, selected by bitfield RESREG in register **G0CHCTRy (y = 0 - 7)** etc., with bitfield SRCRESREG = 0000_B
  - source-specific, selected by bitfield SRCRESREG in register **GxQCTRL0 (x = 0 - 7)**, **GxASCTRL (x = 0 - 7)** or **BRSCTRL** with bitfield SRCRESREG ≠ 0000_B
- **Result position**: The result values can be stored left-aligned or right-aligned. The exact position depends also on the configured result width and on the data accumulation mode.
  See also **Figure 28-19 “Result Storage Options” on Page 28-106**.
- **Compare with Standard Conversions (Limit Checking)**: Channel events can be generated whenever a new result value becomes available. Channel event generation can be restricted to values that lie inside or outside a user-configurable band.
  In Fast Compare Mode, channel events can be generated depending on the transitions of the (1-bit) result.
- **Broken Wire Detection**: This safety feature can detect a missing connection to an analog signal source (sensor).
- **Synchronization of Conversions**: Synchronized conversions are executed at the same time on several converters.

The **Alias Feature** redirects conversion requests for channels CH0 and/or CH1 to other channels.

28.6.1 Channel Parameters

Each analog input channel is configured by its associated channel control register.

*Note: For the safety feature “Broken Wire Detection”, refer to **Section 28.9.1**.*

The following features can be defined for each channel:

- The conversion class defines the result width and the sample time
- Generation of channel events and the result value band, if used
- Target of the result defining the target register and the position within the register

1) While BNDSELX ≠ 0000_B, bitfields BNDSELU and BNDSELL are concatenated and select the corresponding result register as lower boundary.

2) The boundary band is defined as the area where the result is less than or equal to the selected upper boundary and greater than or equal to the selected lower boundary, see **Section 28.6.4**.

3) The result is bit FCR in the selected result register.

4) Some channels cannot select an alternate reference.

Input Class Registers

The group-specific input class registers define the sample time and data conversion mode for each channel of the respective group that selects them via bitfield ICLSEL in its channel control register GxCHCTRx.

The global input class registers define the sample time and data conversion mode for each channel of any group that selects them via bitfield ICLSEL in its channel control register GxCHCTRx.

*Note: Find more information in section **"Conversion Timing" on Page 28-93**.*

28.6.2 Alias Feature

The Alias Feature redirects conversion requests for channels CH0 and/or CH1 to other channel numbers. This feature can be used to trigger conversions of the same input channel by independent events and to store the conversion results in different result registers.

- The same signal can be measured twice without the need to read out the conversion result to avoid data loss. This allows triggering both conversions quickly one after the other and being independent from CPU/DMA service request latency.
- The sensor signal is connected to only one analog input (instead of two analog inputs). This saves input pins in low-cost applications and only the leakage of one input has to be considered in the error calculation.
- Even if the analog input CH0 is used as alternative reference (see **Figure 28-13**), the internal trigger and data handling features for channel CH0 can be used.
- The channel settings for both conversions can be different (boundary values, service requests, etc.).

In typical low-cost AC-drive applications, only one common current sensor is used to determine the phase currents. Depending on the applied PWM pattern, the measured value has different meanings and the sample points have to be precisely located in the PWM period. **Figure 28-13** shows an example where the sensor signal is connected to one input channel (CHx) but two conversions are triggered for two different channels (CHx and CH0). With the alias feature, a conversion request for CH0 leads to a conversion of the analog input CHx instead of CH0, but taking into account the settings for CH0. Although the same analog input (CHx) has been measured, the conversion results can be stored and read out from the result registers RESx (conversion triggered for CHx) and RESy (conversion triggered for CH0). Additionally, different interrupts or limit boundaries can be selected, enabled or disabled.

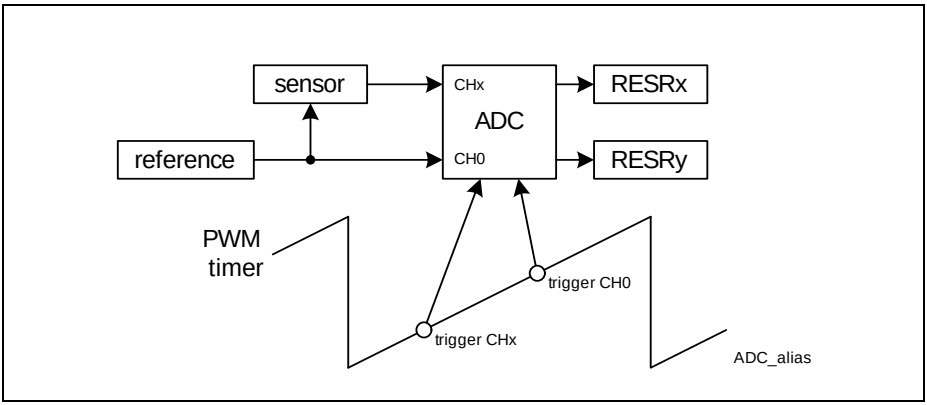

Figure 28-13 Alias Feature

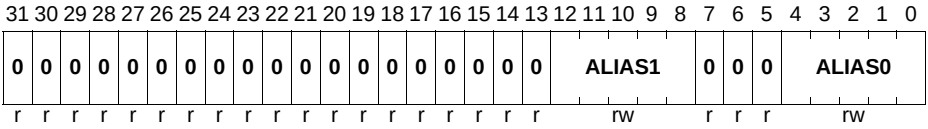
The alias register can replace the channel numbers of channels CH0 and CH1 with another channel number. The reset value disables this redirection.

GxALIAS (x = 0 - 7)
Alias Register, Group x **($x * 0400_H + 04B0_H$)** **Reset Value: $0000\ 0100_H$**



Field	Bits	Type	Description
ALIAS0	[4:0]	rw	**Alias Value for CH0 Conversion Requests** Indicates the channel that is converted instead of channel CH0. The conversion is done with the settings defined for channel CH0.
0	[7:5]	r	**Reserved, write 0, read as 0**
ALIAS1	[12:8]	rw	**Alias Value for CH1 Conversion Requests** Indicates the channel that is converted instead of channel CH1. The conversion is done with the settings defined for channel CH1.
0	[31:13]	r	**Reserved, write 0, read as 0**

28.6.3 Conversion Modes

A conversion can be executed in several ways. The conversion mode is selected according to the requested resolution of the digital result and according to the acceptable conversion time (**Section 28.6.7**).
Use bitfield CMS/CME in register **GxICLASS0 (x = 0 - 7)** etc. to select a mode.

Standard Conversions

A standard conversion returns a result value with a predefined resolution. 8-bit, 10-bit, and 12-bit resolution can be selected.

These result values can be accumulated, filtered, or used for digital limit checking and determination of extrema.

Note: The converters can operate with and without post-calibration.

Fast Compare Mode

In Fast Compare Mode, the selected input voltage is directly compared with a digital value that is stored in the corresponding result register. This compare operation returns a binary result indicating if the compared input voltage is above or below the given reference value. This result is generated quickly and thus supports monitoring of boundary values.

Fast Compare Mode uses a 10-bit compare value stored left-aligned at bit position 11. Separate positive and negative delta values define an arbitrary hysteresis band.

Selecting Compare Values

Values for digital or analog compare operations can be selected from several sources. The separate GxBOUND registers provide software-defined compare values. Compare values can also be taken from a result register where it can be provided by another channel building a reference.

In Fast Compare Mode, the result registers provide the compare value while the bitfields of local GxBOUND registers define positive and negative delta values.

The local boundary register GxBOUND defines group-specific boundary values or delta limits for Fast Compare Mode.
The global boundary register GLOBBOUND defines general compare values for all channels.

Depending on the conversion width, the respective left 12/10/8 bits of a bitfield are used. For 10/8-bit results, the lower 2/4 bits must be zero!

GxBOUND (x = 0 - 7)
Boundary Select Register, Group x
($x * 0400_H + 04B8_H$) **Reset Value: 0000 0000$_H$**

0	[15:12]	r	**Reserved, write 0, read as 0**
BOUNDARY1	[27:16]	rw	**Boundary Value 1 for Limit Checking** Standard Mode: This value is compared against the left-aligned conversion result. Fast Compare Mode: This value is subtracted from the reference value (lower delta).
0	[31:28]	r	**Reserved, write 0, read as 0**

28.6.4 Compare with Standard Conversions (Limit Checking)

The limit checking mechanism can automatically compare each digital conversion result to an upper and a lower boundary value. A channel event can then be generated when the result of a conversion/comparison is inside or outside a user-defined band (see bitfield CHEVMODE and **Figure 28-14**).

This feature supports automatic range monitoring and minimizes the CPU load by issuing service requests only under certain predefined conditions.

Note: Channel events can also be generated for each result value (ignoring the band) or they can be suppressed completely.

The boundary values to which results are compared can be selected from several sources (see register GxCHCTRy).

While bitfield BNDSELX = 0000_B, bitfields BNDSELU and BNDSELL select the valid upper/lower boundary value either from the group-specific boundary register **GxBOUND (x = 0 - 7)** or from the global boundary register **GLOBBOUND**. The group boundary register can be selected for each channel of the respective group, the global boundary register can be selected by each available channel.

Otherwise, the compare values are taken from result registers, where bitfield BNDSELX selects the upper boundary value (GxRES1 … GxRES15), the concatenated bitfields BNDSELU||BNDSELL select the lower boundary value (GxRES0 … GxRES15).

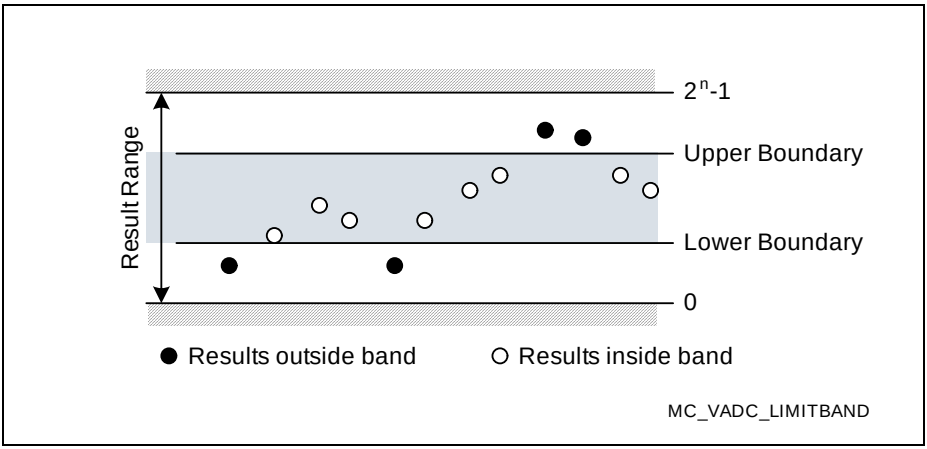

Figure 28-14 Result Monitoring through Limit Checking

A result value is considered inside the defined band when both of the following conditions are true:

- the value is less than or equal to the selected upper boundary
- the value is greater than or equal to the selected lower boundary

The result range can also be divided into two areas:
To select the lower part as valid band, set the lower boundary to the minimum value (000_H) and set the upper boundary to the highest intended value.
To select the upper part as valid band, set the upper boundary to the maximum value (FFF_H) and set the lower boundary to the lowest intended value.

Finding Extrema (Peak Detection)

The limit checking mechanism uses standard conversions and, therefore, always can provide the actual conversion result that was used for comparison. Combining this with a special FIFO mode, that only updates the corresponding FIFO stage if the result was above (or below) the current value of the stage, provides the usual conversion results and at the same time stores the highest (or lowest) result of a conversion sequence. For this operation the FIFO stage below the standard result must be selected as the compare value. Mode selection is done via bitfield FEN in register GxRCRy.

Before starting a peak detection sequence, write a reasonable start value to the result bitfield in the peak result register (e.g. 0000_H to find the maximum and $FFFF_H$ to find the minimum).

28.6.5 Utilizing Fast Compare Mode

In Fast Compare Mode, the input signal is directly compared to a value stored in bitfield RESULT in the associated result register. This comparison just provides a binary result (above/below), which is available in bit FCR in the same result register. If the exact result value is not required, this saves conversion time. A channel event can then be generated when the input signal becomes higher (or lower) than the compare value (see bitfield CHEVMODE and **Figure 28-15**).

The compare value in Fast Compare Mode is taken from the result register. Bitfields BOUNDARY1 and BOUNDARY0 in register **GxBOUND (x = 0 - 7)** define delta limits in this case. These deltas are added to (or subtracted from) the original compare value and allow defining an arbitrary hysteresis band.

The actual used compare value depends on the Fast Compare Result FCR (see registers **G0RESy (y = 0 - 15)**, etc.):

GxRESy.FCR = 0: reference value + upper delta
(GxRESy.RESULT + GxBOUND.BOUNDARY0)
GxRESy.FCR = 1: reference value - lower delta
(GxRESy.RESULT - GxBOUND.BOUNDARY1)

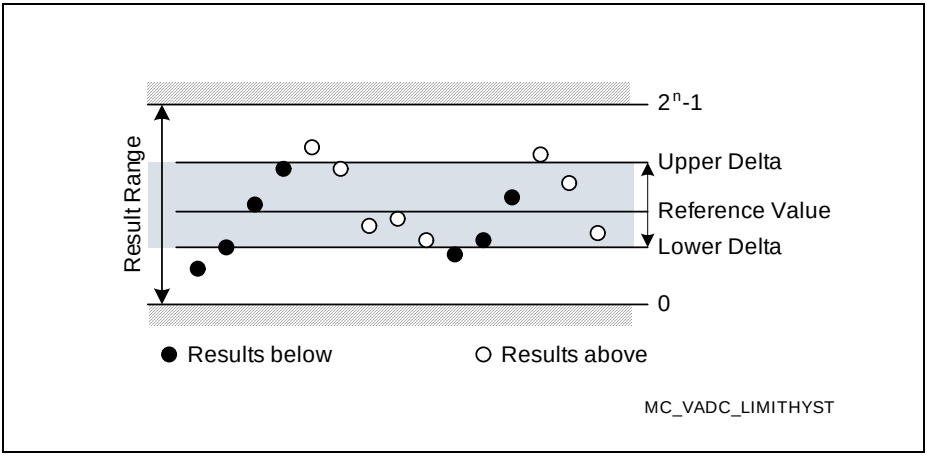

Figure 28-15 Result Monitoring through Compare with Hysteresis

28.6.6 Boundary Flag Control

Both limit checking mechanisms can be configured to automatically control the boundary flags. These boundary flags are also available as control signals for other modules. The flags can be set or cleared when the defined level is exceeded and the polarity of the output signal can be selected. A gate signal can be selected to enable the boundary flag operation while the gate is active.

Each boundary flag is available at group-specific output lines. Node pointers additionally route them to one of four boundary signals or one of the associated common service request lines, see register **GxBFLNP (x = 0 - 7)**.

For standard conversions, a boundary flag will be set/cleared when the conversion result is above the defined band, and will be cleared/set when the conversion result is below the defined band.

The band between the two boundary values defines a hysteresis for setting/clearing the boundary flags.

Using this feature on three channels that monitor linear hall elements can produce signals to feed the three hall position inputs of a unit that generates the corresponding PWM control signals.

In Fast Compare Mode, a boundary flag reflects the result of the comparisons, i.e. it will be set/cleared when the compared signal level is above the compare value, and will be cleared/set when the signal level is below the compare value. The delta values define a hysteresis band around the compare value.

Note: Clear register GxBOUND (i.e. the deltas) if a hysteresis is not wanted.

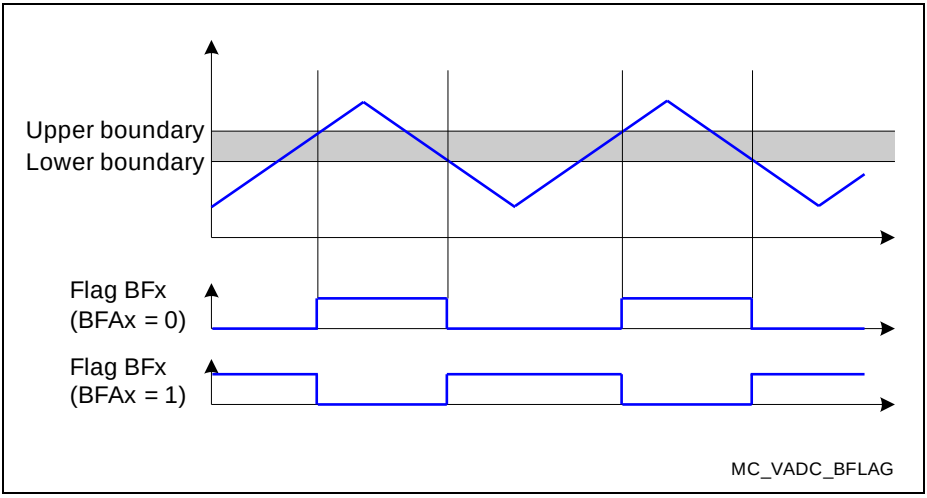

Figure 28-16 Boundary Flag Switching

Boundary flags can be switched by each compare operation, or the influence of compare operations can be restricted to the active phases of the corresponding request source gate signal (see **GxBFLC (x = 0 - 7)**).

Note: If a boundary flag is used together with Fast Compare Mode, it is recommended not to direct results from other channels to the corresponding result register.

The output signal derived from a boundary flag can be controlled by other modules. A select input and a data input are available to temporarily replace the boundary flag signal before sending it to the output pin (see **Figure 28-17**).

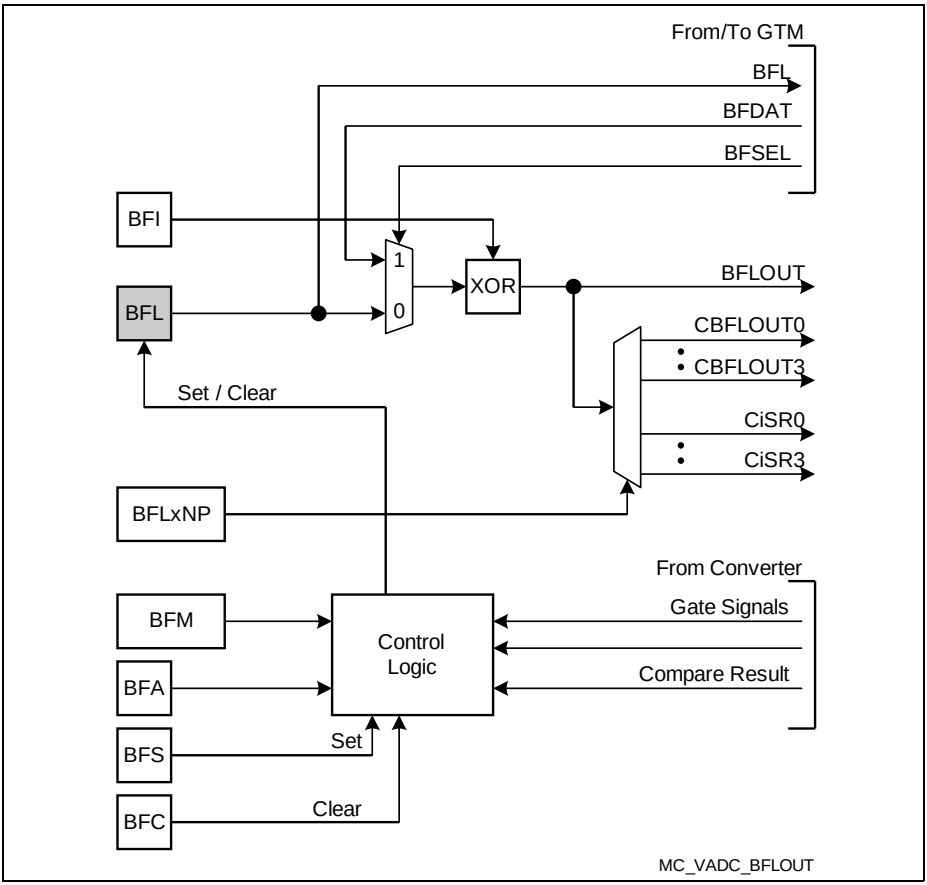

Figure 28-17 Boundary Flag Control

A boundary flag BFLy is assigned to result register GxRESy and thus to an arbitrary channel.

The Boundary Flag Register holds the boundary flags themselves together with bits to select the activation condition and the output signal polarity for each flag.

28.6.7 Conversion Timing

The total time required for a conversion comprises the time from the start of the sample phase[1] until the availability of the result.

The frequency at which conversions are triggered also depends on several configurable factors:

- The selected conversion time, according to the input class definitions. For conversions using an external multiplexer, also the extended sample times count.
- Delays induced by cancelled conversions that must be repeated.
- Delays due to equidistant sampling of other channels.
- The configured arbitration cycle time.
- The frequency of external trigger signals, if enabled.

The conversion timing depends on several user-definable factors:

- The ADC conversion clock frequency, where $f_{ADCI} = f_{VADC} / (DIVA+1)$[2]
- The selected sample time, where $t_S = (2 + STC) \times t_{ADCI}$ (STC = additional sample time, see also **Table 28-4**)
- The selected operating mode (normal conversion / fast compare mode)
- The result width N (8/10/12 bits) for normal conversions
- The post-calibration time PC, if selected (PC = 2, otherwise 0)
- Synchronization steps done at module clock speed

The conversion time is the sum of sample time, conversion steps, and synchronization. It can be computed with the following formulas:

Standard conversions: $t_{CN} = (2 + STC + N + PC) \times t_{ADCI} + 2 \times t_{VADC}$

Fast compare mode: $t_{CN} = (2 + STC + 2) \times t_{ADCI} + 2 \times t_{VADC}$

Timing Examples

System assumptions:
f_{VADC} = 100 MHz i.e. t_{VADC} = 10 ns, DIVA = 5, f_{ADCI} = 16.67 MHz i.e. t_{ADCI} = 60 ns
According to the given formulas the following minimum conversion times can be achieved:

12-bit calibrated conversion:
$t_{CN12C} = (2 + 12 + 2) \times t_{ADCI} + 2 \times t_{VADC} = 16 \times 60\ ns + 2 \times 10\ ns = 980\ ns$

10-bit uncalibrated conversion:
$t_{CN10} = (2 + 10) \times t_{ADCI} + 2 \times t_{VADC} = 12 \times 60\ ns + 2 \times 10\ ns = 740\ ns$

Fast comparison:
$t_{FCM} = (2 + 2) \times t_{ADCI} + 2 \times t_{VADC} = 4 \times 60\ ns + 2 \times 10\ ns = 340\ ns$

1) The time from the trigger event that requests the corresponding conversion until the start of the sample phase depends on the arbitration and can, therefore, only be determined when the system setup is known.

2) The minimum prescaler factor for calibrated converters is 2.

28.7 Conversion Result Handling

The A/D converters can preprocess the conversions result data to a certain extent before storing them for retrieval by the CPU or a DMA channel. This supports the subsequent handling of result data by the application software.

Conversion result handling comprises the following functions:

- **Storage of Conversion Results** to user-configurable registers
- **Data Alignment** according to result width and endianess
- **Wait-for-Read Mode** to avoid loss of data
- **Result Event Generation**
- Data reduction or anti-aliasing filtering (see **Section 28.7.6**)

28.7.1 Storage of Conversion Results

The conversion result values of a certain group can be stored in one of the 16 associated group result registers or in the common global result register (can be used, for example, for the channels of the background source (see **Selecting a Result Register**).

This structure provides different locations for the conversion results of different sets of channels. Depending on the application needs (data reduction, auto-scan, alias feature, etc.), the user can distribute the conversion results to minimize CPU load and/or optimize the performance of DMA transfers.

Each result register has an individual data valid flag (VF) associated with it. This flag indicates when “new” valid data has been stored in the corresponding result register and can be read out.

For standard conversions, result values are available in bitfield RESULT. Conversions in Fast Compare Mode use bitfield RESULT for the reference value, so the result of the operation is stored in bit FCR.

Result registers can be read via two different views. These views use different addresses but access the same register data:

- When a result register is read via the **application view**, the corresponding valid flag is automatically cleared when the result is read. This provides an easy handshake between result generation and retrieval. This also supports wait-for-read mode.
- When a result register is read via the **debug view**, the corresponding valid flag remains unchanged when the result is read. This supports debugging by delivering the result value without disturbing the handshake with the application.

The application can retrieve conversion results through several result registers:

- Group result register:
  Returns the result value and the channel number
- Global result register:
  Returns the result value and the channel number and the group number

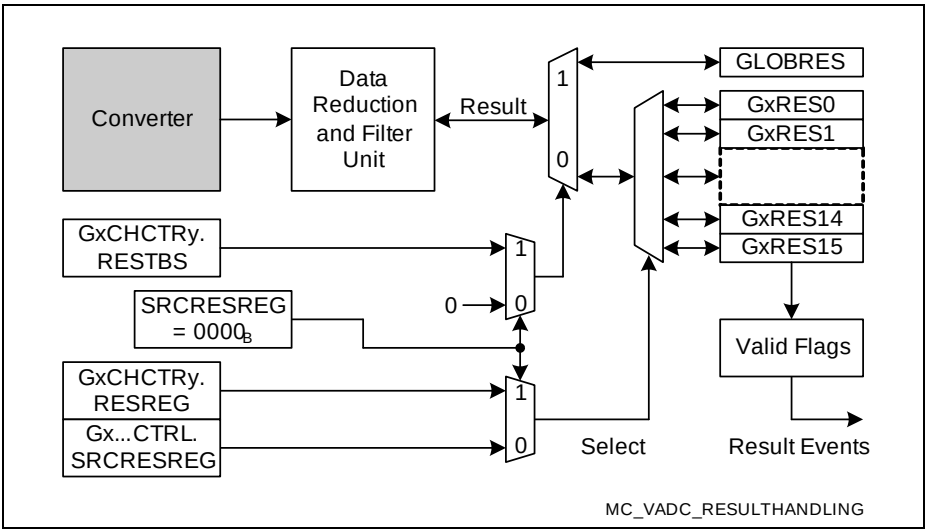

Figure 28-18 Conversion Result Storage

Selecting a Result Register

Conversion results are stored in result registers that can be assigned by the user according to the requirements of the application. The following bitfields direct the results to a register:

- SRCRESREG in register **GxQCTRL0 (x = 0 - 7)**, **GxASCTRL (x = 0 - 7)** or **BRSCTRL**
  Selects the group-specific result register GxRES1 … GxRES15
  when source-specific result registers are used
- RESTBS in register GxCHCTRy
  Selects the global result register for results requested by the background source
- RESREG in register GxCHCTRy
  Selects the group-specific result register GxRES0 … GxRES15
  when channel-specific result registers are used (see below).

Using source-specific result registers allows separating results from the same channel that are requested by different request sources. Usually these request sources are used by different tasks and are triggered at different times.

The group result control registers select the behavior of the result registers of a given group.

G0RCRy (y = 0 - 15)

0	[31:16]	r	**Reserved, write 0, read as 0**

28.7.2 Data Alignment

The position of a conversion result value within the selected result register depends on 3 configurations (summary in **Figure 28-19**):

- The selected result width (12/10/8 bits, selected by the conversion mode)
- The selected result position (Left/Right-aligned)
- The selected data accumulation mode (data reduction)

These options provide the conversion results in a way that minimizes data handling for the application software.

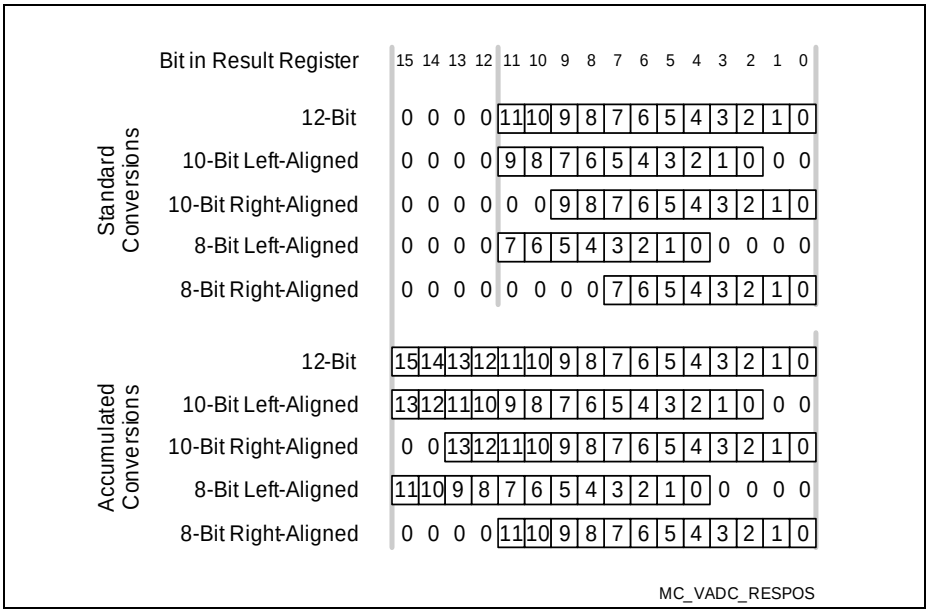

Figure 28-19 Result Storage Options

Bitfield RESULT can be written by software to provide the reference value for Fast Compare Mode. In this mode, bits 11-2 are evaluated, the other bits are ignored.

28.7.3 Wait-for-Read Mode

The wait-for-read mode prevents data loss due to overwriting a result register with a new conversion result before the CPU (or DMA) has read the previous data. For example, auto-scan conversion sequences or other sequences with “relaxed” timing requirements may use a common result register. However, the results come from different input channels, so an overwrite would destroy the result from the previous conversion[1)].

Wait-for-read mode automatically suspends the start of a conversion for this channel from this source until the current result has been read. So a conversion or a conversion sequence can be requested by a hardware or software trigger, while each conversion is only started after the result of the previous one has been read. This automatically aligns the conversion sequence with the CPU/DMA capability to read the formerly converted result (latency).

If wait-for-read mode is enabled for a result register (bit GxRCRy.WFR = 1), a request source does not generate a conversion request while the targeted result register contains valid data (indicated by the valid flag VF = 1) or if a currently running conversion targets the same result register.

If two request sources target the same result register with wait-for-read mode selected, a higher priority source cannot interrupt a lower priority conversion request started before the higher priority source has requested its conversion. Cancel-inject-repeat mode does not work in this case. In particular, this must be regarded if one of the involved sources is the background source (which usually has lowest priority). If the higher priority request targets a different result register, the lower priority conversion can be cancelled and repeated afterwards.

*Note: Wait-for-read mode is ignored for synchronized conversions of synchronization slaves (see **Section 28.8**).*

1) Repeated conversions of a single channel that use a separate result register will not destroy other results, but rather update their own previous result value. This way, always the actual signal data is available in the result register.

28.7.4 Result FIFO Buffer

Result registers can either be used as direct target for conversion results or they can be concatenated with other result registers of the same ADC group to form a result FIFO buffer (first-in-first-out buffer mechanism). A result FIFO stores several measurement results that can be read out later with a “relaxed” CPU response timing. It is possible to set up more than one FIFO buffer structure with the available result registers.

Result FIFO structures of two or more registers are built by concatenating result registers to their following “neighbor” result register (with next higher index, see **Figure 28-20**). This is enabled by setting bitfield GxRCRy.FEN = 01_B.
Conversion results are stored to the register with the highest index of a FIFO structure. Software reads the values from the FIFO register with the lowest index.

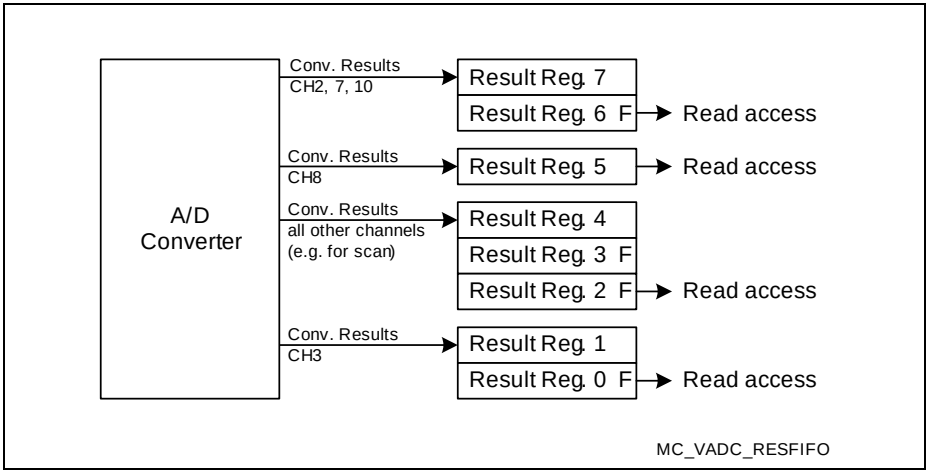

Figure 28-20 Result FIFO Buffers

In the example shown the result registers have been configured in the following way:

- 2-stage buffer consisting of result registers 7-6
- dedicated result register 5
- 3-stage buffer consisting of result registers 4-3-2
- 2-stage buffer consisting of result registers 1-0

Table 28-5 summarizes the required configuration of result registers if they are combined to build result FIFO buffers.

Table 28-5 Properties of Result FIFO Registers

Function	Input Stage	Intermed. Stage	Output Stage
Result target	YES	no	no
Application read	no	no	YES
Data reduction mode	YES	no	no
Wait-for-read mode	YES	no	no
Result event interrupt	no	no	YES
FIFO enable (FEN)	00_B	01_B	01_B
Registers in example	7, 4, 1	3	6, 2, 0

Note: If enabled, a result interrupt is generated for each data word in the FIFO.

28.7.5 Result Event Generation

A result event can be generated when a new value is stored to a result register. Result events can be restricted due to data accumulation and be generated only if the accumulation is complete.

Result events can also be suppressed completely.

28.7.6 Data Modification

The data resulting from conversions can be automatically modified before being used by an application. Several options can be selected (bitfield DMM in register **G0RCRy (y = 0 - 15)** etc.) which reduce the CPU/DMA load required to unload and/or process the conversion data.

- **Standard Data Reduction Mode (for GxRES0 … GxRES15):**
  Accumulates 2, 3, or 4 result values within each result register before generating a result interrupt. This can remove some noise from the input signal.
- **Result Filtering Mode (FIR, for GxRES7, GxRES15):**
  Applies a 3rd order Finite Impulse Response Filter (FIR) with selectable coefficients to the conversion results for the selected result register.
- **Result Filtering Mode (IIR, for GxRES7, GxRES15):**
  Applies a 1st order Infinite Impulse Response Filter (IIR) with selectable coefficients to the conversion results for the selected result register.
- **Difference Mode (for GxRES1 … GxRES15):**
  Subtracts the contents of result register GxRES0 from the conversion results for the selected result register. Bitfield DRCTR is not used in this mode.

Table 28-6 Function of Bitfield DRCTR

DRCTR	Standard Data Reduction Mode (DMM = 00_B)	DRCTR	Result Filtering Mode (DMM = 01_B)[1)]

1111_B	Reserved	1111_B	IIR filter: a=3, b=4

1) The filter registers are cleared while bitfield DMM ≠ 01_B.

Standard Data Reduction Mode

The data reduction mode can be used as digital filter for anti-aliasing or decimation purposes. It accumulates a maximum of 4 conversion values to generate a final result.

Each result register can be individually enabled for data reduction, controlled by bitfield DRCTR in registers **G0RCRy (y = 0 - 15)**ff and **GLOBRCR**. The data reduction counter DRC indicates the actual status of the accumulation.

Note: Conversions for other result registers can be inserted between conversions to be accumulated.

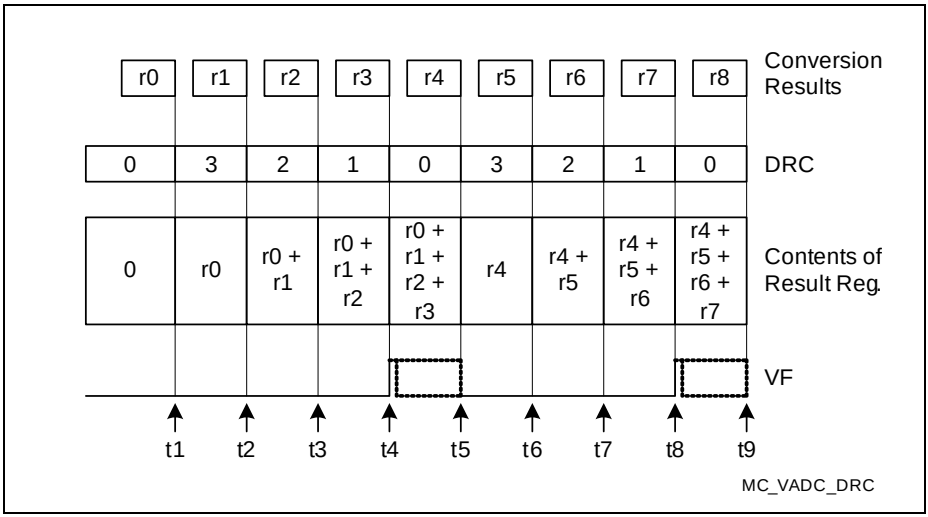

Figure 28-21 Standard Data Reduction Filter

This example shows a data reduction sequence of 4 accumulated conversion results. Eight conversion results (r0 … r7) are accumulated and produce 2 final results.

When a conversion is complete and stores data to a result register that has data reduction mode enabled, the data handling is controlled by the data reduction counter DRC:

- If DRC = 0 (t1, t5, t9 in the example), the conversion result is stored to the register. DRC is loaded with the contents of bitfield DRCTR (i.e. the accumulation begins).
- If DRC > 0 (t2, t3, t4 and t6, t7, t8 in the example), the conversion result is added to the value in the result register.
  DRC is decremented by 1.
- If DRC becomes 0, either decremented from 1 (t4 and t8 in the example) or loaded from DRCTR, the valid bit for the respective result register is set and a result register event occurs.

The final result must be read before the next data reduction sequence starts (before t5 or t9 in the example). This automatically clears the valid flag.

*Note: Software can clear the data reduction counter DRC by clearing the corresponding valid Flag (via **GxVFR (x = 0 - 7)**).*

The response time to read the final data reduction results can be increased by associating the adjacent result register to build a result FIFO (see **Figure 28-22**). In this case, the final result of a data reduction sequence is loaded to the adjacent register. The value can be read from this register until the next data reduction sequence is finished (t8 in the 2nd example).

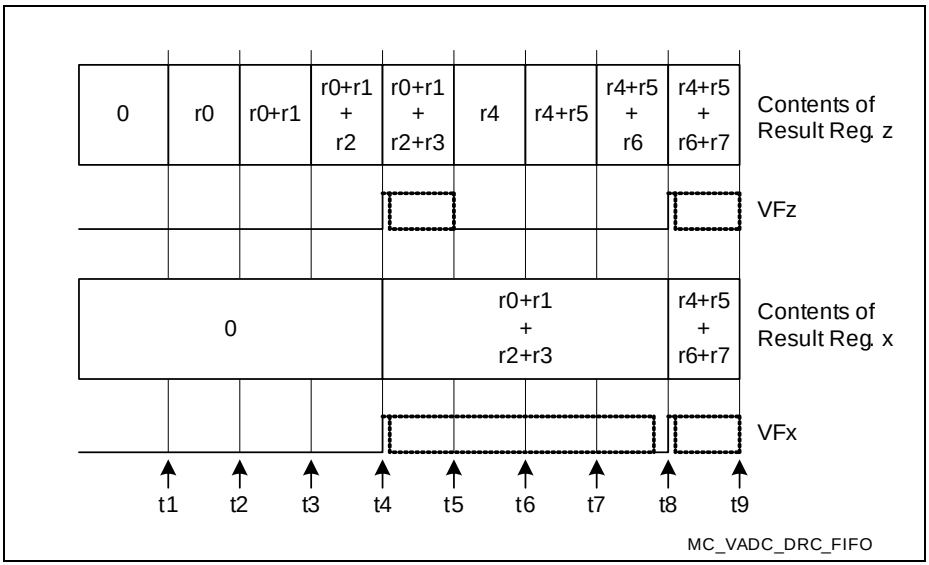

Figure 28-22 Standard Data Reduction Filter with FIFO Enabled

Finite Impulse Response Filter Mode (FIR)

The FIR filter (see **Figure 28-23**) provides 2 result buffers for intermediate results (RB1, RB2) and 3 configurable tap coefficients (a, b, c).

The conversion result and the intermediate result buffer values are added weighted with their respective coefficients to form the final value for the result register. Several predefined sets of coefficients can be selected via bitfield DRCTR (coding listed in **Table 28-6**) in registers **G0RCRy (y = 0 - 15)**ff and **GLOBRCR**. These coefficients lead to a gain of 3 or 4 to the ADC result producing a 14-bit value. The valid flag (VF) is activated for each sample after activation, i.e. for each sample generates a valid result.

Note: Conversions for other result registers can be inserted between conversions to be filtered.

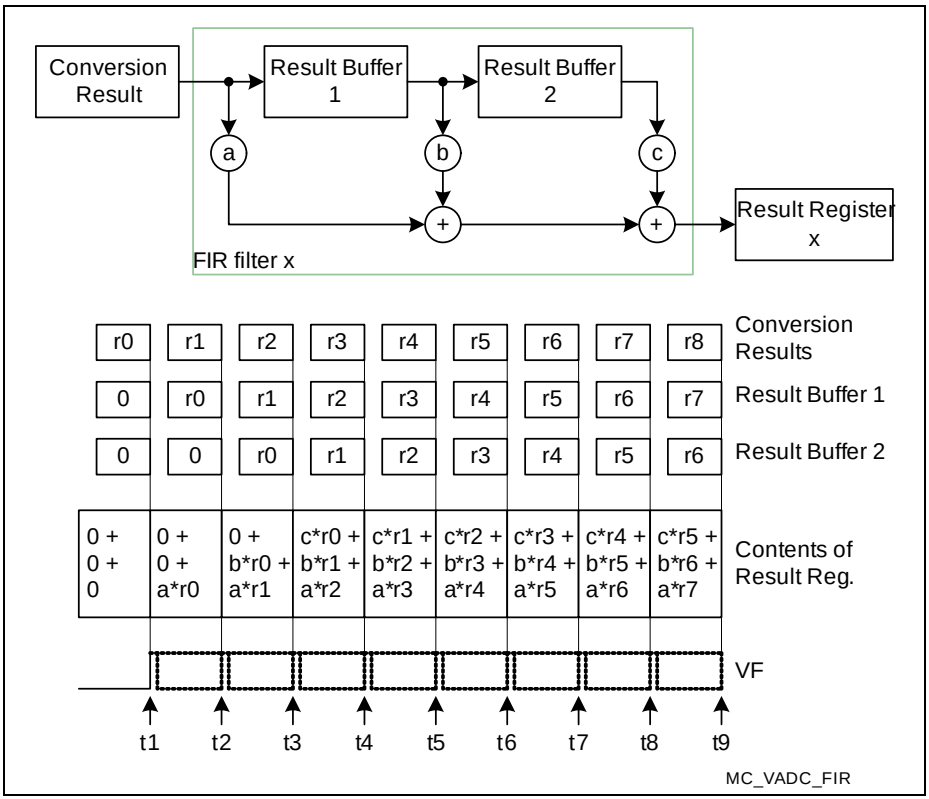

Figure 28-23 FIR Filter Structure

Note: The filter registers are cleared while bitfield DMM ≠ 01_B.

Infinite Impulse Response Filter Mode (IIR)

The IIR filter (see **Figure 28-24**) provides a result buffer (RB) and 2 configurable coefficients (a, b). It represents a first order low-pass filter.

The conversion result, weighted with the respective coefficient, and a fraction of the previous result are added to form the final value for the result register. Several predefined sets of coefficients can be selected via bitfield DRCTR (coding listed in **Table 28-6**) in registers **G0RCRy (y = 0 - 15)**ff and **GLOBRCR**. These coefficients lead to a gain of 4 to the ADC result producing a 14-bit value. The valid flag (VF) is activated for each sample after activation, i.e. for each sample generates a valid result.

Note: Conversions for other result registers can be inserted between conversions to be filtered.

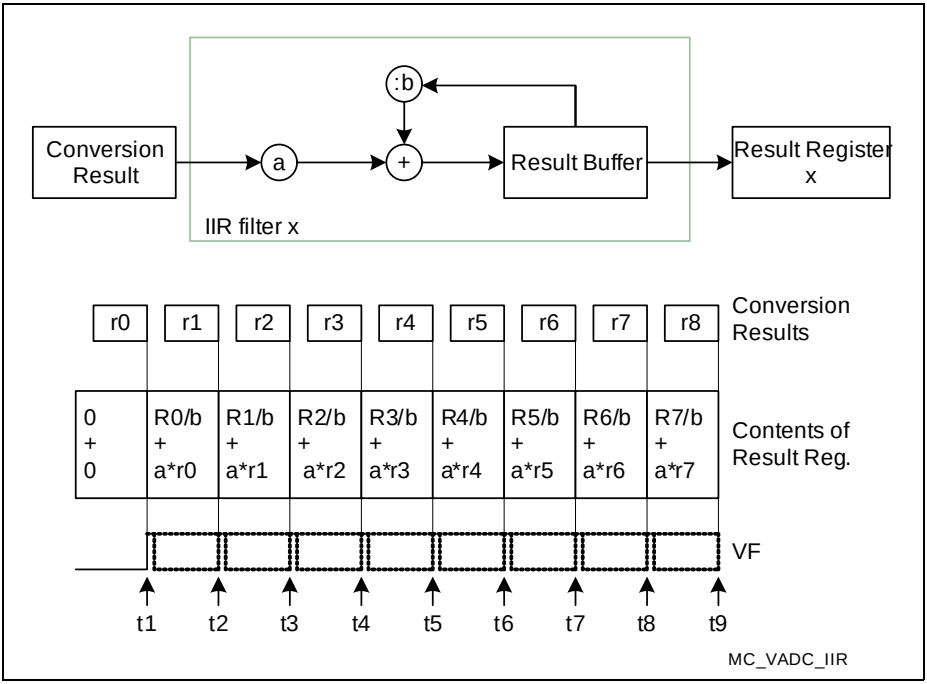

Figure 28-24 IIR Filter Structure

Note: The filter registers are cleared while bitfield DMM ≠ 01_B.

Difference Mode

Subtracting the contents of result register 0 from the actual result puts the results of the respective channel in relation to another signal. No software action is required.

The reference channel must store its result(s) into result register 0. The reference value can be determined once and then be used for a series of conversions, or it can be converted before each related conversion.

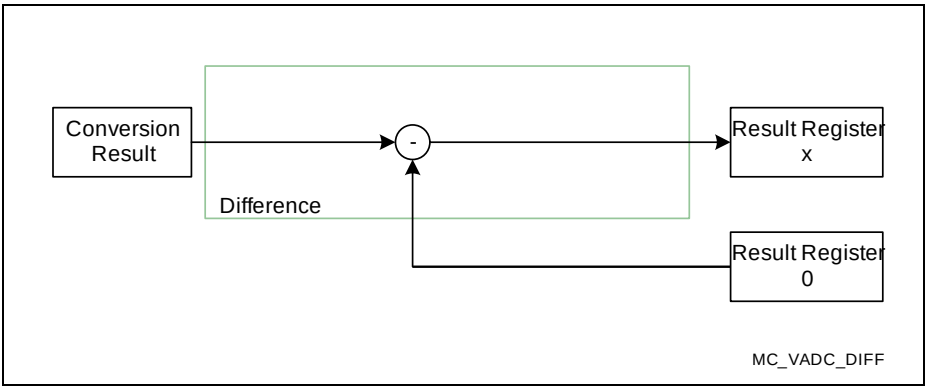

Figure 28-25 Result Difference

28.8 Synchronization of Conversions

The conversions of an ADC kernel can be scheduled either self-timed according to the kernel's configuration or triggered by external (outside the ADC) signals:

Synchronized Conversions for Parallel Sampling support parallel conversion of channels within a synchronization group[1]. This optimizes e.g. the control of electrical drives.

Equidistant Sampling supports conversions in a fixed raster with minimum jitter. This optimizes e.g. filter algorithms or audio applications.

28.8.1 Synchronized Conversions for Parallel Sampling

Several independent ADC kernels[1] implemented in the TC27x can be synchronized for simultaneous measurements of analog input channels. While no parallel conversion is requested, the kernels can work independently.

The synchronization mechanism for parallel conversions ensures that the sample phases of the related channels start simultaneously. Synchronized kernels convert the same channel that is requested by the master. Different values for the resolution and the sample phase length of each kernel for a parallel conversion are supported.

A parallel conversion can be requested individually for each input channel (one or more). In the example shown in **Figure 28-26**, input channels CH3 of the ADC kernels 0, 1, 2 are converted synchronously, whereas other input channels do not lead to parallel conversions.

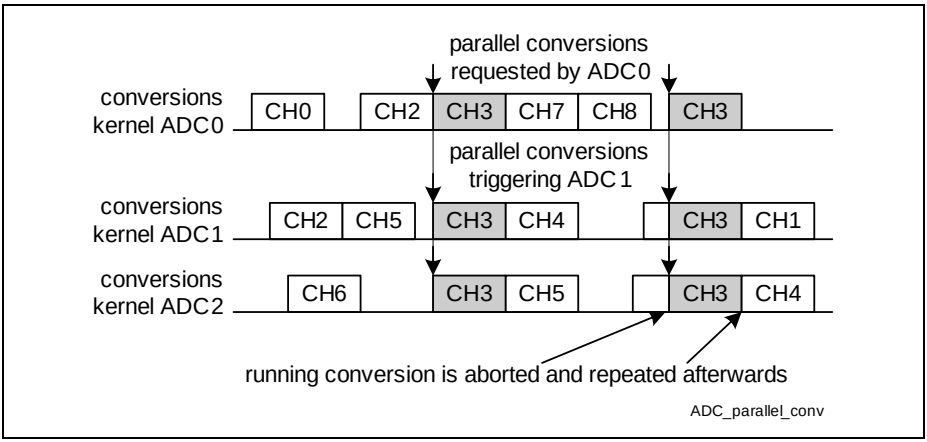

Figure 28-26 Parallel Conversions

1) For a summary, refer to **"Synchronization Groups in the TC27x" on Page 28-147**.

One kernel operates as synchronization master, the other kernel(s) operate(s) as synchronization slave. Each kernel can play either role. The arbiters of all involved kernels must run synchronously. This is achieved by switching off all involved kernels before the initialization and switching on the master kernel at the end of the initialization sequence.

Master and slave kernels form a “conversion group” to control parallel sampling:

- The arbiters must run permanently (bits **GxARBCFG (x = 0 - 7)**.ARBM = 0). Initialize the slave before the master to have the arbiters run synchronously. Set the master’s GxARBCFG.ANONC at the end of the initialization.
- **The synchronization master** controls the slave(s) by providing the control information **GxARBCFG (x = 0 - 7)**.ANONS (see **Figure 28-27**) and the requested channel number.
  - Bitfield **GxSYNCTR (x = 0 - 7)**.STSEL = 00_B selects the master’s ANON information as the source of the ANON information for all kernels of the synchronization group.[1)]
  - The ready signals indicate when a slave kernel is ready to start the sample phase of a parallel conversion. Bit **GxSYNCTR (x = 0 - 7)**.EVALRy = 1 enables the control by the ready signal (in the example, kernels 1 and 2 are slaves, so EVALR1 = EVALR2 = 1).
  - The master requests a synchronized conversion of a certain channel (SYNC = 1 in the corresponding channel control register GxCHCTRy), which is also requested in the connected slave ADC kernel(s).
  - Wait-for-read mode is supported for the master.
- **The synchronization slave** reacts to incoming synchronized conversion requests from the master. While no synchronized conversions are requested, the slave kernel can execute “local” conversions.
  - Bitfield **GxSYNCTR (x = 0 - 7)**.STSEL = $01_B/10_B/11_B$ selects the master’s ANON information as the source of the ANON information for all kernels of the synchronization group[1)] (in the example, kernel 0 is the master, so STSEL = 01_B).
  - The ready signals indicate when the master kernel and the other slave kernels are ready to start the sample phase of a parallel conversion. Bit **GxSYNCTR (x = 0 - 7)**.EVALRy = 1 enables the control by the ready signal (in the example, kernel 0 is the master, so EVALR1 = 1, kernel 1 and 2 are slaves, so EVALR2 = 1).
  - The slave timing must be configured according to the master timing (ARBRND in register **GxARBCFG (x = 0 - 7)**) to enable parallel conversions.
  - A parallel conversion request is always handled with highest priority and cancel-inject-repeat mode.

1) STSEL = 00_B selects the own ANON information. The other control inputs (STSEL = $01_B/10_B/11_B$) are connected to the other kernels of a synchronization group in ascending order (see also **Table 28-9 “Synchronization Groups in the TC27x” on Page 28-147**).

  – Wait-for-read mode is ignored in the slave. Previous results may be overwritten, in particular, if the same result register is used by other conversions.
- Once started, a parallel conversion cannot be aborted.

*Note: Synchronized conversions request the same channel number, defined by the master. Using the alias feature (see **Section 28.6.2**), analog signals from different input channels can be converted. This is advantageous if e.g. CH0 is used as alternate reference.*

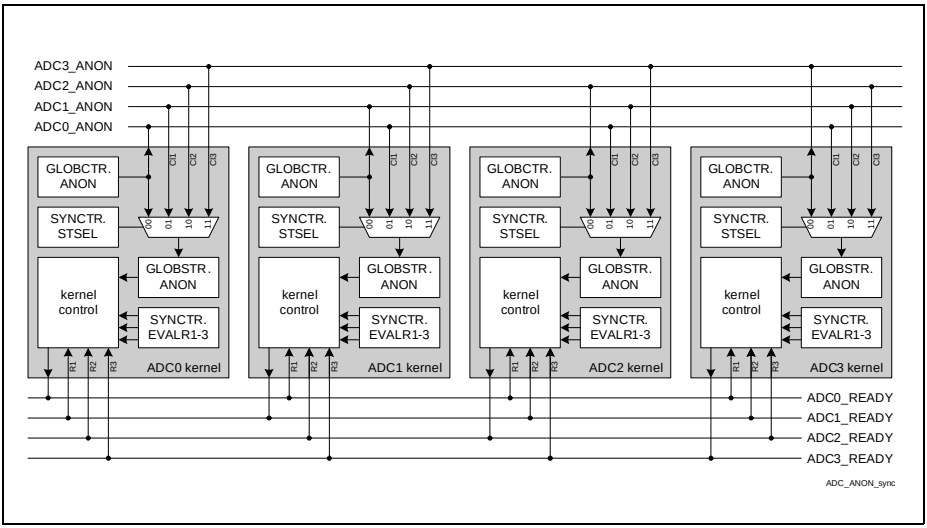

Figure 28-27 Synchronization via ANON and Ready Signals

The Synchronization Control Register controls the synchronization of kernels for parallel conversions.

Note: Program register GxSYNCTR only while bitfield GxARBCFG.ANONS = 00_B in all ADC kernels of the conversion group. Set the master's bitfield ANONC to 11_B afterwards.

1) Make sure to enable the ready inputs from the master and all selected slaves in the master and in all selected slaves.

28.8.2 Equidistant Sampling

To optimize the input data e.g. for filter or audio applications, conversions can be executed in a fixed timing raster. Conversions for equidistant sampling are triggered by an external signal (e.g. a timer). To generate the trigger signal synchronous to the arbiter, the ADC provides an output signal (ARBCNT) that is activated once per arbitration round and serves as timing base for the trigger timer. In this case, the arbiter must run permanently (**GxARBCFG (x = 0 - 7)**.ARBM = 0). If the timer has an independent time base, the arbiter can be stopped while no requests are pending. The preface time (see **Figure 28-28**) must be longer than one arbitration round and the highest possible conversion time.

Select timer mode (TMEN = 1 in register **GxQCTRL0 (x = 0 - 7)** or **GxASCTRL (x = 0 - 7)**) for the intended source of equidistant conversions. In timer mode, a request of this source is triggered and arbitrated, but only started when the trigger signal is removed (see **Figure 28-28**) and the converter is idle.

To ensure that the converter is idle and the start of conversion can be controlled by the trigger signal, the equidistant conversion requests must receive highest priority. The preface time between request trigger and conversion start must be long enough for a currently active conversion to finish.

The frequency of signal REQTRx defines the sampling rate and its high time defines the preface time interval where the corresponding request source takes part in the arbitration.

Depending on the used request source, equidistant sampling is also supported for a sequence of channels. It is also possible to do equidistant sampling for more than one request source in parallel if the preface times and the equidistant conversions do not overlap.

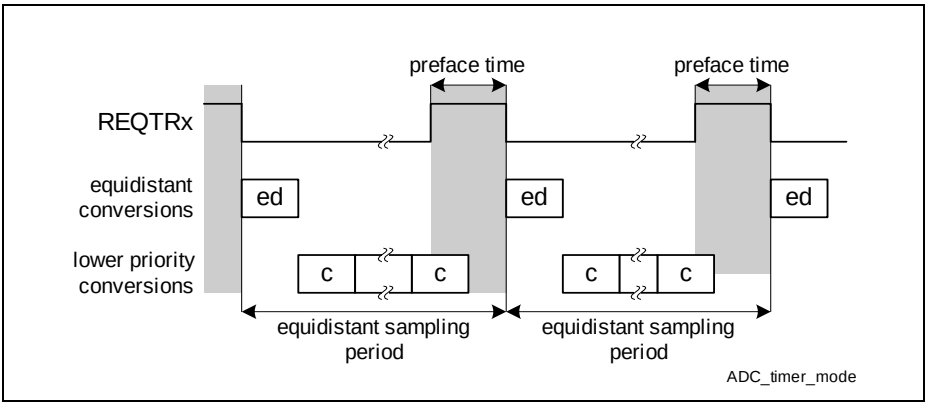

Figure 28-28 Timer Mode for Equidistant Sampling

28.9 Safety Features

Several test features can be enabled to verify the validity of the analog input signals of an application. These test features aim at different sections of the signal flow:

- **Broken Wire Detection** validates the connection from the sensor to the input pin,
- **Multiplexer Diagnostics** validates the operation of the internal analog input multiplexer,
- **Converter Diagnostics** validates the operation of the Analog/Digital converter itself.

28.9.1 Broken Wire Detection

To test the proper connection of an external analog sensor to its input pin, the converter's capacitor can be precharged to a selectable value before the regular sample phase. If the connection to the sensor is interrupted the subsequent conversion value will rather represent the precharged value than the expected sensor result. By using a precharge voltage outside the expected result range (broken wire detection preferably uses V_{AGND} and/or V_{AREF}) a valid measurement (sensor connected) can be distinguished from a failure (sensor detached).

While broken wire detection is disabled, the converter's capacitor is precharged to $V_{AREF}/2$.

Note: The duration of the complete conversion is increased by the preparation phase (same as the sample phase) if the broken wire detection is enabled. This influences the timing of conversion sequences.

Broken wire detection can be enabled for each channel separately by bitfield BWDEN in the corresponding channel control register (GxCHCTRy). Bitfield BWDCH selects the level for the preparation phase.

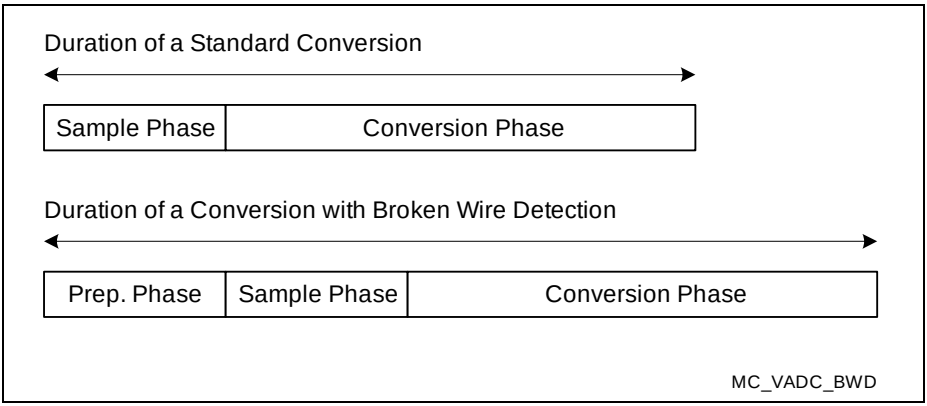

Figure 28-29 Broken Wire Detection

28.9.2 Signal Path Test Modes

Additional test structures can be activated to test the signal path from the sensor to the input pin and the internal signal path from the input pin through the multiplexer to the converter. These test structures apply additional loads to the signal path (see summary in **Figure 28-30**).

Multiplexer Diagnostics

To test the proper operation of the internal analog input multiplexer, additional pull-up and/or pull-down devices can be connected to channels CH1 and CH2. In combination with a known external input signal this test function shows if the multiplexer connects any pin to the converter input and if this is the correct pin.

Pull-Down Diagnostics

One single input channel provides a further strong pull-down (R_{PDD}) that can be activated to verify the external connection to a sensor.

Converter Diagnostics

To test the proper operation of the converter itself, several signals can be connected to the converter input. The test signals can be connected to the converter input either instead of the standard input signal or in parallel to the standard input signal.

To use the converter diagnostic without a connected input, select a non-existent channel number via the alias feature (**Section 28.6.2**). Redirect channel 0 or 1 to channel 24 (not connected), the conversion result can then be read from the selected result register for channel 0 or 1.

The test signal can be selected from four different signals as shown in **Figure 28-30**.

Attention: ***If the Multiplexer Diagnostics are used on channels that are overlaid on IO ports, enable these functions by setting the corresponding control bits in registers Pxx_PCSR.***
The corresponding control bits in registers Pxx_PDISC must be cleared for both Multiplexer Diagnostics and Pull-Down Diagnostics.

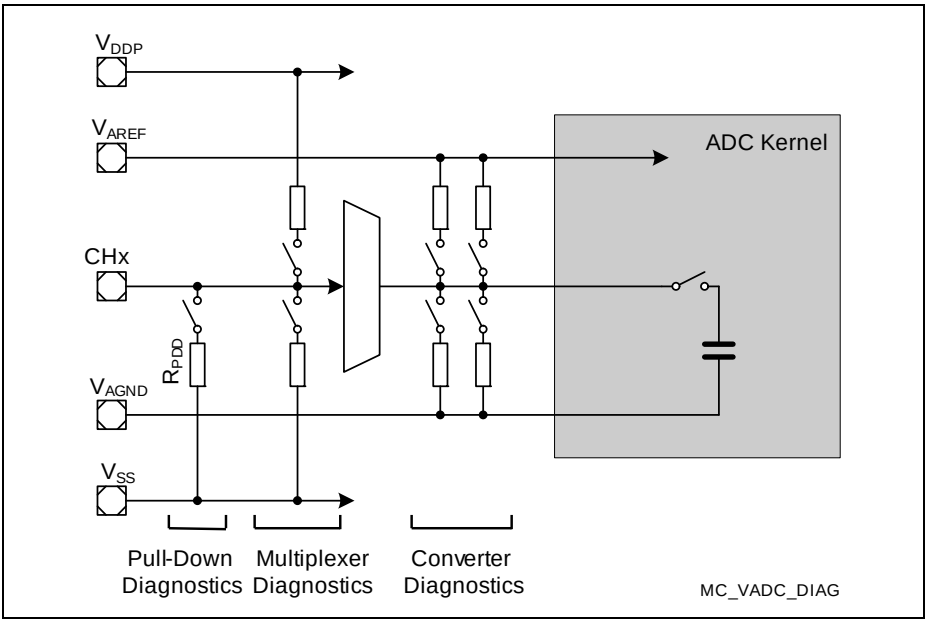

Figure 28-30 Signal Path Test

Note: When internal pull devices are activated, they may need some time to pull the input signal to the intended level, depending on the connected external circuitry. This can be accomplished by increasing the sample time for those conversions.

28.9.3 Configuration of Test Functions

The pull-up and pull-down devices for the test functions can be enabled individually under software control. Various test levels can be applied controlling the devices in an adequate way. Because these test functions interfere with the normal operation of the A/D Converters, they are controlled by a separate register set.

Not all test options are available for each channel. Selecting an unavailable function has no effect.

28.10 External Multiplexer Control

The number of analog input channels can be increased by connecting external analog multiplexers to an input MUX channel. The ADC can be configured to control these external multiplexers automatically.

For each available EMUX interface (see register **EMUXSEL**) one MUX channel or a set of MUX channels from one group can be selected for this operating mode. The ADC supports 1-out-of-8 multiplexers with several control options:

- **Sequence mode** automatically converts all configured external channels when the selected MUX channel is encountered. In the example in **Figure 28-31** the following conversions are done: --4-32-31-30-2-1-0--4-32-31-30-2-1-0--…
- **Single-step mode** converts one external channel of the configured sequence when the selected MUX channel is encountered. In the example in **Figure 28-31** the following conversions are done: --4-32-2-1-0--4-31-2-1-0--4-30-2-1-0--4-32-… (Single-step mode works best with one channel)
- **Steady mode** converts the configured external channel when the selected MUX channel is encountered. In the example in **Figure 28-31** the following conversions are done: --4-32-2-1-0--4-32-2-1-0--4-32-2-1-0--…

*Note: The example in **Figure 28-31** has an external multiplexer connected to MUX channel CH3. The start selection value EMUXSET is assumed as 2.*

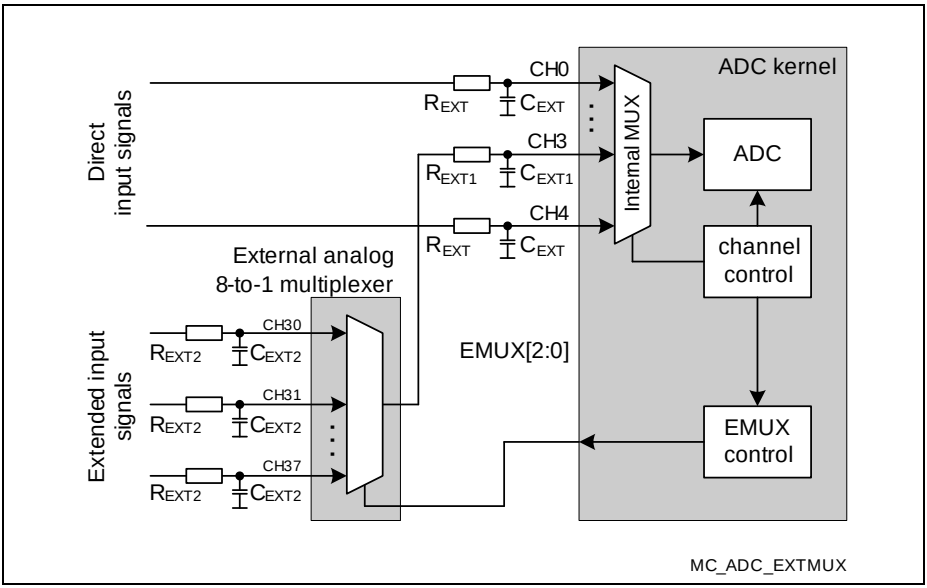

Figure 28-31 External Analog Multiplexer Example

Bitfield EMUXACT determines the control information sent to the external multiplexer. In single-step mode, EMUXACT is updated after each conversion of an enabled MUX channel. If EMUXACT = 000_B it is reloaded from bitfield EMUXSET, otherwise it is decremented by 1.

Additional external channels may have different properties due to the modified signal path. Local filters may be used at the additional inputs (R_{EXT2}-C_{EXT2} on CH3x in **Figure 28-31**). For applications where the external multiplexer is located far from the ADC analog input, it is recommended to add an RC filter directly at the analog input of the ADC (R_{EXT1}-C_{EXT1} on CH3 in **Figure 28-31**).

Note: Each RC filter limits the bandwidth of the analog input signal.

Conversions for external channels, therefore, use the alternate conversion mode setting CME. This automatically selects a different conversion mode if required.

Switching the external multiplexer usually requires an additional settling time for the input signal. Therefore, the alternate sample time setting STCE is applied each time the external channel is changed. This automatically fulfills the different sampling time requirements in this case.

Control Signals

The external channel number that controls the external multiplexer can be output in standard binary format or Gray-coded. Gray code avoids intermediate multiplexer switching when selecting a sequence of channels, because only one bit changes at a time. **Table 28-7** indicates the resulting codes.

Table 28-7 EMUX Control Signal Coding

Channel	0	1	2	3	4	5	6	7
Binary	000_B	001_B	010_B	011_B	100_B	101_B	110_B	111_B
Gray	000	001	011	010	110	111	101	100

Operation Without External Multiplexer

If no external multiplexers are used in an application, the reset values of the control registers provide the appropriate setup.

EMUXMODE = 00_B disables the automatic EMUX control.

Since the control output signals are alternate port output signals, they are only visible at the respective pins if explicitly selected.

In each group an arbitrary MUX channel or set of MUX channels can be assigned to external multiplexer control (register **GxEMUXCTR (x = 0 - 7)**). Each available port interface selects the group whose control lines are output (register **EMUXSEL**).

GxEMUXCTR (x = 0 - 7)
External Multiplexer Control Register, Group x
(x * 0400_H + $05F0_H$) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
EMUXSET	[2:0]	rw	**External Multiplexer Start Selection**[1)] Defines the initial setting for the external multiplexer.
0	[7:3]	r	**Reserved, write 0, read as 0**
EMUXACT	[10:8]	rh	**External Multiplexer Actual Selection** Defines the current value for the external multiplexer selection. This bitfield is loaded from bitfield EMUXSET and modified according to the operating mode selected by bitfield EMUXMODE.
0	[15:11]	r	**Reserved, write 0, read as 0**
EMUXCH	[25:16]	rw	**External Multiplexer Channel Select** Defines the channel(s) to which the external multiplexer control is applied. **EMXCSS = 0: Channel number**, the lower 5 bits select an arbitrary channel (valid numbers are limited by the number of available channels, unused bits shall be 0) **EMXCSS = 1: Channel enable**, each bit enables the associated channel (multiple channels can be selected/enabled)

Field	Bits	Type	Description
EMUXMODE	[27:26]	rw	**External Multiplexer Mode** 00_B Software control (no hardware action) 01_B Steady mode (use EMUXSET value) 10_B Single-step mode[1)2)] 11_B Sequence mode[1)]
EMXCOD	28	rw	**External Multiplexer Coding Scheme** 0_B Output the channel number in binary code 1_B Output the channel number in Gray code
EMXST	29	rw	**External Multiplexer Sample Time Control** 0_B Use STCE whenever the setting changes 1_B Use STCE for each conversion of an external channel
EMXCSS	30	r	**External Multiplexer Channel Selection Style** 0_B Channel number: Bitfield EMUXCH selects an arbitrary channel 1_B Channel enable: Each bit of bitfield EMUXCH selects the associated channel for EMUX control
EMXWC	31	w	**Write Control for EMUX Configuration** 0_B No write access to EMUX cfg. 1_B Bitfields EMXMODE, EMXCOD, EMXST, EMXCSS can be written

1) For single-step mode and sequence mode: Select the start value before selecting the respective mode.

2) Single-step mode modifies the EMUX channel number each time an EMUX-enabled channel is converted. Therefore, single-step mode works best with a single channel, because otherwise some external channels may be skipped.

Register EMUXSEL is a global register which assigns an arbitrary group to each of the EMUX interfaces.

Field	Bits	Type	Description
EMUXGRP0, EMUXGRP1	[3:0], [7:4]	rw	**External Multiplexer Group for Interface x** Defines the group whose external multiplexer control signals are routed to EMUX interface x.[1)]
0	[31:8]	r	**Reserved, write 0, read as 0**

1) The pins that are associated with each EMUX interface are listed in **Table 28-13 "Digital Connections in the TC27x" on Page 28-156**.

28.11 Service Request Generation

Each A/D Converter can activate up to 4 group-specific service request output signals and up to 4 shared service request output signals to issue an interrupt or to trigger a DMA channel. Two common service request groups are available, see **“Product-Specific Configuration” on Page 28-146**.

Several events can be assigned to each service request output. Service requests can be generated by three types of events:

- **Request source events:** indicate that a request source completed the requested conversion sequence and the application software can initiate further actions.
  For a scan source (group or background), the event is generated when the complete defined set of channels (pending bits) has been converted.
  For a group queue source, the event is generated according to the programming, i.e. when a channel with enabled source interrupt has been converted or when an invalid entry is encountered.
- **Channel events:** indicate that a conversion is finished. Optionally, channel events can be restricted to result values within a programmable value range. This offloads the CPU/DMA from background tasks, i.e. a service request is only activated if the specified conversion result range is met or exceeded.
- **Result events:** indicate a new valid result in a result register. Usually, this triggers a read action by the CPU (or DMA). Optionally, result events can be generated only at a reduced rate if data reduction is active.
  For example, a single DMA channel can read the results for a complete auto-scan sequence, if all channels of the sequence target the same result register and the transfers are triggered by result events.

Each ADC event is indicated by a dedicated flag that can be cleared by software. If a service request is enabled for a certain event, the service request is generated for each event, independent of the status of the corresponding event indication flag. This ensures efficient DMA handling of ADC events (the ADC event can generate a service request without the need to clear the indication flag).

Event flag registers indicate all types of events that occur during the ADC’s operation. Software can set each flag by writing a 1 to the respective position in register GxCEFLAG/GxRFLAG to trigger an event. Software can clear each flag by writing a 1 to the respective position in register GxCEFCLR/GxREFCLR. If enabled, service requests are generated for each occurrance of an event, even if the associated flag remains set.

REVGLBCLR	24	w	**Clear Global Result Event** 0_B No action 1_B Clear the result event flag REVGLB
0	[31:25]	r	**Reserved, write 0, read as 0**

Note: Software can set flags REVGLB and SEVGLB and trigger the corresponding event by writing 1 to the respective bit. Writing 0 has no effect.
Software can clear these flags by writing 1 to bit REVGLBCLR and SEVGLBCLR, respectively.
Setting both bits (e.g. SEVGLB and SEVGLBCLR) simultaneously clears the corresponding flag (e.g. SEVGLB).

Node Pointer Registers

Requests from each event source can be directed to a set of service request nodes via associated node pointers. Requests from several sources can be directed to the same node; in this case, they are ORed to the service request output signal.

28.12 Implementation into the TC27x

This section describes the actual implementation of the ADC module into the TC27x, i.e. the incorporation into the microcontroller system.

The following information is listed:

28.12.1 Product-Specific Configuration

The functional description describes the features and operating modes of the A/D Converters in a general way. This section summarizes the configuration that is available in this product (TC27x).

Each converter group is equipped with a separate analog converter module and a dedicated analog input multiplexer.

Table 28-8 General Converter Configuration in the TC27x

Converter Group	Input Channels	Channels w. Altern. Reference	Common Service Req. Group	Associated Standard Reference
G0	0 … 7	4	C0	V_{AREF2}, V_{AGND2}
G1	0 … 7	8	C1	V_{AREF2}, V_{AGND2}
G2	0 … 7	8	C0	V_{AREF2}, V_{AGND2}
G3	0 … 7	8	C1	V_{AREF2}, V_{AGND2}
G4	0 … 7	7	C0	V_{AREF2}, V_{AGND2}
G5	0 … 7	8	C1	V_{AREF2}, V_{AGND2}
G6	0 … 7	8	C0	V_{AREF2}, V_{AGND2}
G7	0 … 7	8	C1	V_{AREF2}, V_{AGND2}

Synchronization Groups in the TC27x

The converter kernels in the TC27x can be connected to synchronization groups to achieve parallel conversion of several input channels.

Not all channels can be synchronized to each other, but certain groups can be formed.

Table 28-9 summarizes which kernels can be synchronized for parallel conversions.

Table 28-9 Synchronization Groups in the TC27x

ADC Kernel	Synchr. Group	Master selected by control input CIx[1]			
		CI0[2]	CI1	CI2	CI3
ADC00	A	ADC00	ADC01	ADC02	ADC03
ADC01	A	ADC01	ADC00	ADC02	ADC03
ADC02	A	ADC02	ADC00	ADC01	ADC03
ADC03	A	ADC03	ADC00	ADC01	ADC02
ADC04	B	ADC04	ADC05	ADC06	ADC07
ADC05	B	ADC05	ADC04	ADC06	ADC07
ADC06	B	ADC06	ADC04	ADC05	ADC07
ADC07	B	ADC07	ADC04	ADC05	ADC06

1) The control input is selected by bitfield STSEL in register **GxSYNCTR (x = 0 - 7)**. Select the corresponding ready inputs accordingly by bits EVALRx.

2) Control input CI0 always selects the own control signals of the corresponding ADC kernel. This selection is meant for the synchronization master or for stand-alone operation.

28.12.2 Summary of Registers and Locations

The Versatile ADC is built from a series of converter blocks that are controlled in an identical way. This makes programming versatile and scalable. The corresponding registers, therefore, have an individual offset assigned (see **Table 28-11**). The exact register location is obtained by adding the respective register offset to the base address (see **Table 28-10**) of the corresponding group.

Due to the regular group structure, several registers appear within each group. Other registers are provided for each channel. This is indicated in the register overview table by placeholders:

- X###$_H$ means: x × 0400$_H$ + 0###$_H$, for x = 0 - 7
- ###Y$_H$ means: ###0$_H$ + y × 0004$_H$, for y = 0 - N (depends on register type)

Table 28-10 Registers Address Space

Module	Base Address	End Address	Note
VADC	F002 0000$_H$	F002 3FFF$_H$	

Table 28-11 Registers Overview

Register Short Name	Register Long Name	Offset Addr.	Access Mode		Page Num.

28.12.3 Analog Module Connections in the TC27x

The VADC module accepts a number of analog input signals. The analog input multiplexers select the input channels to be converted from the signals available in this product.

Note: If an analog input channel is connected to an I/O port pin, make sure the output driver and/or the digital input path are disabled.

The exact number of analog input channels and the available connection to port pins depend on the employed product type (see also **Section 28.12.1**). A summary of channels enclosing all versions of the TC27x can be found below.

Input channels marked “PDD” provide a pull-down device for pull-down diagnostics.

Input channels marked “MD” can activate the pullup and pulldown devices for multiplexer diagnostics.

Input channels marked “AltRef” can be selected as an alternate reference voltage for conversions on channels of the same group or for conversions on channels of the same cluster.

Input channels marked “noAltref” cannot select an alternate reference voltage, but only the corresponding standard reference voltage.

Table 28-12 Analog Connections in the TC27x

Signal	Dir.	Source/Destin.[1)]	Description
V_{AREF}	I	VAREF2	positive analog reference
V_{AGND}	I	VAGND2	negative analog reference
G0CH0 (AltRef)	I	AN0 (X)	analog input channel 0 of group 0

G7CH6	I	-	analog input channel 6 of group 7
G7CH7	I	-	analog input channel 7 of group 7

1) Channels marked "(X)" in this columns are overlaid with input channels of the DSADC.

28.12.4 Digital Module Connections in the TC27x

The VADC module accepts a number of digital input signals and generates a number of output signals. This section summarizes the connection of these signals to other on-chip modules or to external resources via port pins.

Note: The control bitfields for triggers and gates select the corresponding multiplexer input. Values 0000_B … 1111_B select inputs with suffix -A … -P.

Table 28-13 Digital Connections in the TC27x

28.13 Use Case Example for VADC

This section provides a code example for the VADC module to give an overview about the core functionality. The code example realizes an event triggered analog to digital conversion. The result is stored as a 12-bit digital value and triggers a result service request.

The VADC contains several ADC groups (G0 … G7). Each group is connected to up to 8 analog input channels via a multiplexer. The following code example initializes one of the groups and uses one static allocated analog channel as input.

The code example realizes an analog-to-digital conversion by using the background source. The conversion can either run continuously in autoscan mode or can be triggered by an event, like in the following example. This is useful if the conversion needs to be executed at certain times. The result from the most recent conversion is acceccible in the global result register **GLOBRES**. A result service request is activated after each conversion. The initialization is done in the following order:

1. Load the global VADC module registers
2. Enable the analog/digital converter 0 (G0)
3. Select channel 0 of G0 as analog input
4. Initialize the conversion result service request
5. Start first conversion

Step Description to Initialize the VADC Module:

(Line 1) reset ENDINIT to get access to ENDINIT protected registers. (see also ENDINIT protection in chapter SCU).

(Line 2) enable control of the module, in clock control register **CLC**.

(Line 3) read back (dummy variable has to be defined). The reading process ensures that the write process from line 2 is done.

(Line 4) set ENDINIT to lock the protected register again.

(Line 5) set group 0 to normal operation mode. This activates the converter of group 0. (see also **Section 28.4.1** and **GxARBCFG (x = 0 - 7)**).

(Line 6) load the global configuration register GLOBCFG with the divider factor for the analog internal clock (see also **Figure 28-7**). Set DIVWC[15] to enable write access and initiate the start-up calibration by setting SUCAL[31]. The calibration is necessary to get a precise conversion.

(Line 7) This line enables the arbitration slot 2, that's the background scan source slot which the examples uses. (see also Arbitration Priority Register **GxARBPR (x = 0 - 7)**)

(Line 8) This line sets RESTBS[20], so each conversion result from group 0 input channel 0 is now stored in the global result register GLOBRES. (see also GxCHCTRy)

(Line 9) This line selects input channel 0 of group 0 as part of the background scan sequence. (see also **BRSSELx (x = 0 - 7)**).

(Line 10) By setting ENGT[0..1]=01 a conversion request can be issued for every channel which was enabled in line 10. here only channel 0. (see also **BRSMR**)

(Line 11) This line enables the group 0 service request in the service request control register SRC_VADCG0SR0 and sets the interrupt priority to VADC0INT (1...255)

(Line 12) The interruptHandlerInstall function gets called (this function has to be written first, see interrupt handler example in chapter IR for more details). This function installs the interrupt service routine (ISR) entry address in the interrupt vector array with the priority VADC0INT.

(Line 13) This command enables the result interrupt. It occurs after a result event.

(Line 14) wait until start-up calibration (start in line 6) is done.

(Line 15) setting LDEV=1 generates a load event which starts a conversion.

Note: The conversion result ISR function prototype would be: void VADC_SCAN_irq (void); here could be your ISR code;

Basic Initialization of the VADC:

```
//=========================> Load global module registers
(1)  SCU_vResetENDINIT (0);     // Access to ENDINIT-prot. reg.
(2)  VADC_CLC = 0x0000;         // Enable module clock and ctrl.
(3)  dummy = VADC_CLC;          // Read back ensures write oper.
(4)  SCU_vSetENDINIT (0);       // Lock ENDINIT-protected reg.
//=========================> Enable converter for group 0
(5)  VADC_G0ARBCFG = 0x3;       // ANONC = 11, analog converter ON
(6)  VADC_GLOBCFG = (1<<31)     /* SUCAL = 1, start-up calib. */ \
                    |(1<<15)    /* DIVWC = 1, enable write */ \
                    | 0x9;      // DIVA = 9 (clock prescaler)
(7)  VADC_G0ARBPR = (1<<26);    // AREN2 = 1, enable arb. slot 2
                                //          (= background source)
(8)  VADC_G0CHCTR0 = (1<<20);   // RESTBS = 1, global result reg.
(9)  VADC_BRSSEL0 = 0x1;        // Select CH0 of group 0 for scan
(10) VADC_BRSMR = 0x1;          // ENGT = 10B, enable conv. req.
//=========================> Init and install service request
(11) SRC_VADCCG0SR0 = (1<<10)   /* Enable SR node 0, group 0 */ \
                    |VADC0INT; // Set prio to <VADC0INT>(1..255)
(12) interruptHandlerInstall (VADC0INT, & VADC_SCAN_irq);
(13) VADC_GLOBRCR = (1<<31);    // SRGEN = 1, result service requ.
//=========================> Wait for completion of startup cal.
(14) while((VADC_G0ARBCFG.U & 0x30000000) != 0x20000000);
                                // CALS = 1, CAL = 0: calibr. done
//=========================> Start a conversion
(15) VADC_BRSMR |= (1<<9);      // LDEV = 1, generate a load event
```

Note: Before a service request can occur, the service request system must be globally enabled. The Interrupt Control Register (ICR) holds the global interrupt enable bit (ICR.IE) which enables the CPU service request system. Most compilers support the attribute (or similar) to set this bit (see Architecture Manual for more details): ***__enable();***

29 Delta-Sigma Analog-to-Digital Converter (DSADC)

The Delta-Sigma Analog-to-Digital Converter module (DSADC) of the TC27x provides a series of analog input channels connected to on-chip modulators using the Delta/Sigma (DS) conversion principle.

The on-chip demodulator channels convert these inputs to discrete digital values.

The number of inputs and DSADC channels depends on the chosen product type (refer to **"Implementation into the TC27x" on Page 29-86**).

Each converter channel can operate independent of the others, controlled by a dedicated set of registers. The results of each channel can be stored in a dedicated channel-specific result register.

The on-chip filter stages generate digital results from the modulator signal. The on-chip modulators accept differential or single-ended input signals.

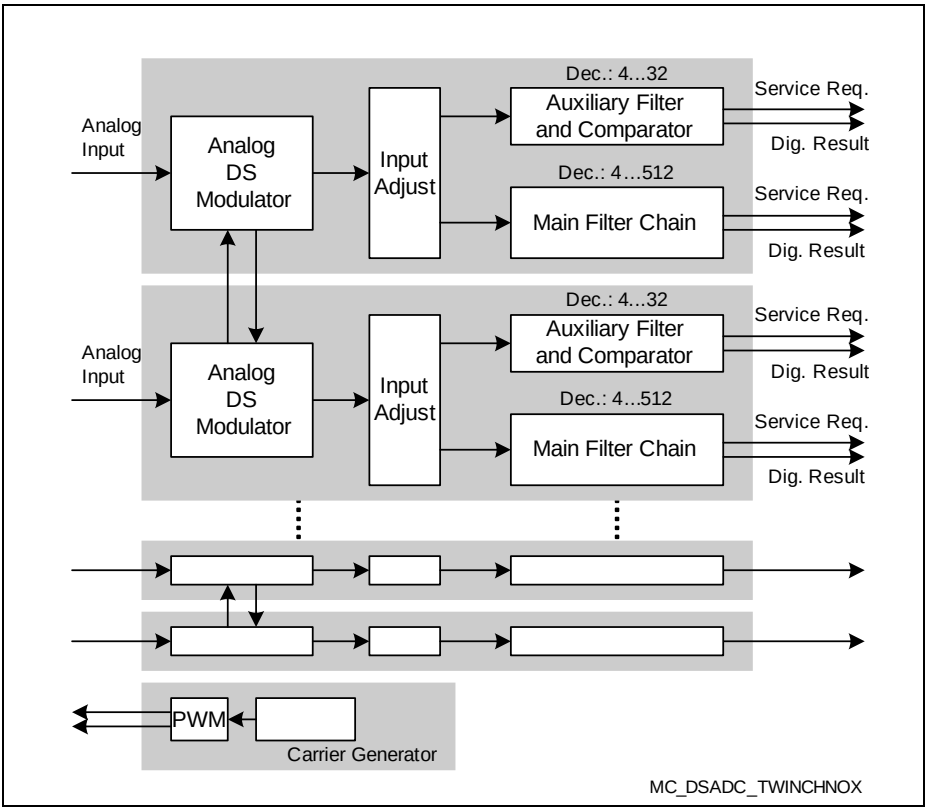

Figure 29-1 DSADC Module Overview

You will find the following major sections within this chapter:

Features

The following features describe the functionality of a DS Converter:

- Selectable connections for each input line (differential or single-ended inputs)
  - Input multiplexers to select input pins, switching controllable by external triggers
  - Alternate connection to supply voltage, half-scale voltage or reference ground
  - Common mode hold voltage selectable for each individual pin during idle phases
- Differential input amplifier
  - Input voltage range 0…5 V
  - Common mode voltage range selectable
  - Programmable gain (1/2/4/8/16)
  - DC Offset <5 mVDC, gain error < ±1%
  - Input impedance 100 kΩ
  - Calibration for offset and gain
- On-chip 3rd-order modulator
  - Sample frequency 10…20 MHz
  - High-performance and low-power modes
  - External run control
- Main demodulator (concatenated hardware filter stages)
  - Configurable CIC filter with decimation rates of 4…128
  - FIR filter with 8 coefficients (9-bit) with decimation rate 2
  - FIR filter with 28 coefficients (9-bit) with decimation rate 2
  - Optional high-pass filter for DC compensation ($f_{-3dB} = 10^{-5} \times f_d$)
  - Integration stage with external gating
  - Automatic offset correction
  - Time-stamp support
  - Pass Band 10…100 kHz, output sampling rate f_d = 30…300 kHz,
    Pass band ripple f_d: ±1%,
    Stop band attenuation: 0.5…1 × f_d: >40 dB / 1…1.5 × f_d: >45 dB /
    1.5…2 × f_d: > 50 dB / 2…2.5 × f_d: >55 dB / 2.5…OSR/2 × f_d: > 60 dB

- Parallel auxiliary demodulator for limit checking
  - Configurable CIC filter with decimation rates of 4…32
  - Two-level boundary comparator
- Built-in support for resolver applications
  - Carrier signal generator
  - Delay compensation for position signals
  - Carrier cancelation by integrator unit
- DMA/Service-requests
  - Result events on new valid results with external gating
  - Alarm events from limit checking

Table 29-1 Abbreviations used in DSADC chapter

Abbreviation	Meaning
ADC	Analog to Digital Converter
CIC	Cyclic Integrating Comb (filter)
DMA	Direct Memory Access (controller)
DNL	Differential Non-Linearity (error)
DSADC	Delta-Sigma (conversion principle) Analog to Digital Converter
FIR	Finite Impulse Response (filter)
INL	Integral Non-Linearity (error)
LSB_n	Least Significant Bit: finest granularity of the analog value in digital format, represented by one least significant bit of the conversion result with n bits resolution (measurement range divided in 2^n equally distributed steps)
OSR	Oversampling Ratio
PWM	Pulse Width Modulation
SNR	Signal-Noise Ratio

29.1 Introduction and Basic Structure

The Delta-Sigma Analog to Digital Converter module of the TC27x provides several channels with a main and an auxiliary demodulator including configurable filters for decimation (see **Figure 29-2**).

The on-chip buffered 3rd order modulator converts an analog input signal to a datastream.

The main chain of digital filters builds the demodulator which produces result values at a configurable output rate. The elements of the filter chain can be selected according to the requirements of the application. The filter chain configuration determines the attenuation and delay properties of the filter. The decimation at a configurable rate reduces the input sampling rate to a lower result data rate.

The configurable CIC filter provides the basic filtering and decimation with a selectable decimation rate.

Two FIR filters, each with a decimation rate of 2, allow effective signal shaping by attenuating the upper frequencies of the signal spectrum.

The high-pass filter provides offset compensation by removing the DC component of the input signal.

The integrator accumulates a configurable amount of result values. The number of samples is programmable or can be controlled by a hardware signal. This function supports resolver applications to get the baseband signal for the motor position calculation. Furthermore, the integrator can be also used in shunt current measurement applications.

A smaller but quicker parallel auxiliary filter with a comparator supports limit checking, e.g. for overcurrent detection. Two limit values can be defined to restrict the generation of service requests to result values within a configurable area. This saves CPU performance and/or DMA bandwidth.

A carrier signal can be generated to support resolver applications.

The on-chip carrier signal generator produces a selectable output signal (sine, triangle, rectangle) which can be used to drive a resolver. Synchronization of each input signal to the carrier signal ensures correct integration of the resolver input signals.

Service requests can be generated to trigger DMA transfers or to request CPU service.

The basic module clock f_{DSD} is connected to the system clock signal f_{SPB}.

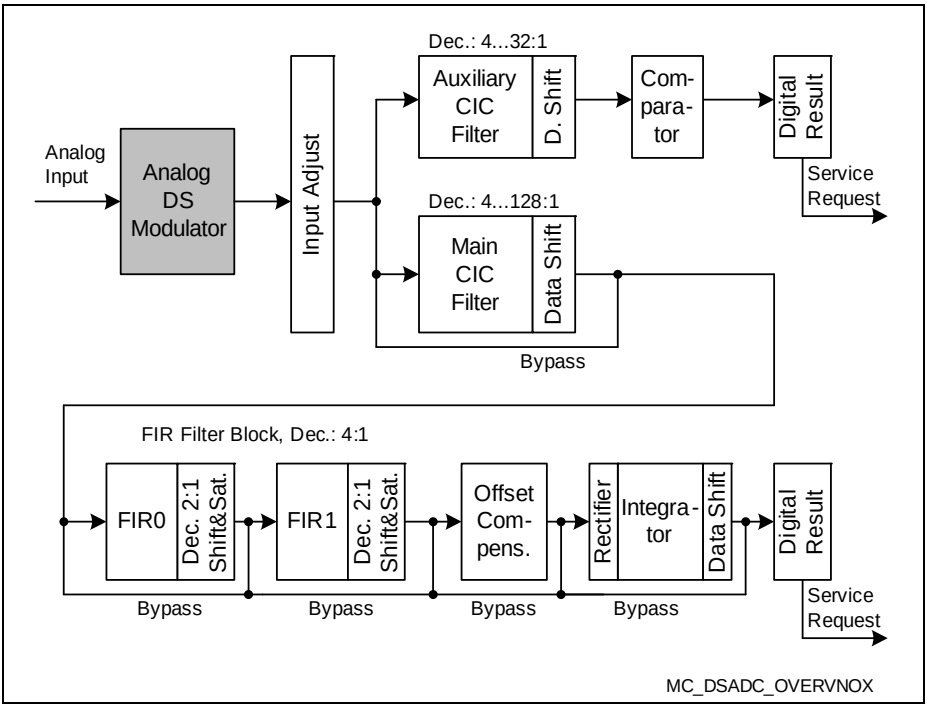

Figure 29-2 DSADC Structure Overview

29.2 Configuration of General Functions

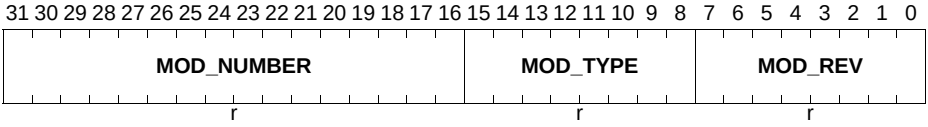
Several parameters can be configured to adapt the functionality of the DSADC to the requirements of the actual application (see **Section 29.2.4**).

29.2.1 Module Identification

The module identification register indicates the version of the DSADC module that is used in the TC27x.

ID

Module Identification Register (0008$_H$) Reset Value: 00C6 C0XX$_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision** Indicates the revision number of the implementation. This information depends on the design step.
MOD_TYPE	[15:8]	r	**Module Type** This internal marker is fixed to C0$_H$.
MOD_NUMBER	[31:16]	r	**Module Number** Indicates the module identification number (00C6$_H$ = DSADC)

29.2.2 System Registers

A set of standardized registers provides general access to the module and controls basic system functions.

The Clock Control Register **CLC** allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register **CLC** controls the module clock signal and the reactivity to the sleep signal.

CLC
Clock Control Register **(0000_H)** **Reset Value: 0000 0003_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**EDIS**	**0**	**DISS**	**DISR**
r	r	r	r	r	r	r	r	r	r	r	r	rw	r	r	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	r	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
0	2	r	**Reserved, write 0, read as 0**
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	[31:4]	r	**Reserved, write 0, read as 0**

The OCDS control and status register OCS controls the module's behavior in suspend mode (used for debugging).

The OCDS Control and Status (OCS) register is cleared by Debug Reset.
The OCS register can only be written when the OCDS is enabled.
If OCDS is being disabled, the OCS register value will not change.
When OCDS is disabled the OCS suspend control is ineffective.
Write access is 32 bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status Register (0028_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Field	Bits	Type	Description
0	[23:0]	r	**Reserved, write 0, read as 0**
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0000_B Will not suspend 0001_B Hard suspend: Clock is switched off immediately. 0010_B Soft suspend channel 0 0011_B Soft suspend channel 1 … 0111_B Soft suspend channel 5 Others Reserved *Note: In soft suspend mode, the respective channel is stopped after the next result has been stored.*
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[31:30]	r	**Reserved, write 0, read as 0**

Note: Register OCS is cleared by a Debug Reset. While OCDS is disabled, OCS is reset with each system reset. A system reset has no effect while OCDS is enabled. Write access requires supervisor mode.

The Access Enable Register 0 controls write access[1)] for transactions with the on-chip bus master TAG IDs 00 0000_B to 01 1111_B (see On-Chip Bus chapter for the mapping of product TAG ID <-> master peripheral). Register ACCEN0 provides one enable bit for each possible TAG ID encoding.
Register ACCEN0 itself is protected by the Safety Endinit feature.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 00 0000_B, EN1 -> TAG ID 00 0001_B , ... , EN31 -> TAG ID 01 1111_B (TAG IDs 1X $XXXX_B$ are not used).

ACCEN0
Access Enable Register 0 ($003C_H$) Reset Value: FFFF FFFF$_H$

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B No Write access 1_B Write access will be executed

1) The Access Enable functionality controls only write transactions to registers CLC, OCS, KRSTx, and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Individual Module Reset

The Kernel Reset Registers **KRST0**/**KRST1** are used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits in both Kernel Reset Registers. The RST bits will be cleared by the BPI with the end of the BPI kernel reset sequence.

Note: A module kernel reset does not reset registers that do not belong to the module kernel: CLC, OCS, ACCEN0 and, of course, the KRST registers.*

Kernel Reset Registers 0 and 1 each include bit RST. To trigger a module reset, both RST bits must be set. They will be cleared automatically with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set in the same clock cycle the RST bit is cleared. This bit indicates that a kernel reset was processed. Bit RSTSTAT can be cleared by setting bit CLR in register **KRSTCLR**.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **(0034_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved, write 0, read as 0**

29.2.3 Register Access Control

Several protection schemes are provided to prevent unintended write access to control bitfields of the DSADC.

- The registers of the DSADC are protected by the general access control mechanism that is configured by register **ACCEN0**.
- A specific register access control scheme provides a versatile protection scheme against unintended corruption of register contents. Register ACCPROT allows the restriction of write accesses for several groups of registers. The registers to be protected can be selected by the user. The table below lists the registers that belong to each register group.
  Register ACCPROT itself is protected by the Safety Endinit feature.
- Groups of bitfields within a register may also be protected by an associated write control bit. This write control bit (xxWC) must be written with 1 along with the write access to the intended bitfield(s).

ACCPROT
Access Protection Register (0090_H) Reset Value: $0000\ 0000_H$

RG11	CGCFG	Carrier generator control

29.2.4 Global Configuration Registers

The global configuration register GLOBCFG selects the source for the internal clock signal which can be used to drive the modulators.

It also selects internal measurement modes.

The global run control register GLOBRC controls the general operation of the available channels.

GLOBCFG
Global Configuration Register (0080_H) Reset Value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**PS WC**	**ICT**	**0**	**LO SUP**	**IBSEL**			
r	r	r	r	r	r	r	r	w	rw	r	rw	rw

0	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**CH5 RUN**	**CH4 RUN**	**CH3 RUN**	**CH2 RUN**	**CH1 RUN**	**CH0 RUN**
r	r	r	r	r	r	r	r	r	r	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
CHxRUN (x = 0 - 5)	x	rw	**Channel x Run Control** Each bit (when set) enables the corresponding demodulator channel. 0_B Stop channel x 1_B Demodulator channel x is enabled and runs When CHxRUN is set, all filter blocks are cleared.
0	[15:6]	r	**Reserved, write 0, read as 0**
MxRUN (x = 0 - 5)	16 + x	rw	**Modulator x Run Control** Each bit (when set) enables the corresponding modulator. 0_B Stop on-chip modulator x 1_B Modulator x is enabled and can run[1)]
0	[31:22]	r	**Reserved, write 0, read as 0**

1) Additional run control via the selected gate signal is possible by the automatic power control feature (bit APC in register **MODCFGx (x = 0 - 5)**).

The Initial Configuration Registers IGCFG and ICCFGx[1] control specific setup features of the on-chip modulators. Use the default values unless other values are recommended by additional documentation. The write enable bit helps to prevent unintended write access after writing the intended configuration.

IGCFG
Initial Global Config. Register (00D0$_H$) Reset Value: 8000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

29.3 Input Channel Configuration

The input data for a channel is obtained from the on-chip modulator.

The on-chip modulator can directly convert a differential or single-ended input signal to an input data stream. The performance can be increased by connecting two modulators to a pair. In this case, one of the two channels operates in 4th order mode while the other one operates in 2nd order mode.
The on-chip modulator runs on an internal clock.
The figure below summarizes the data path through the on-chip modulator.

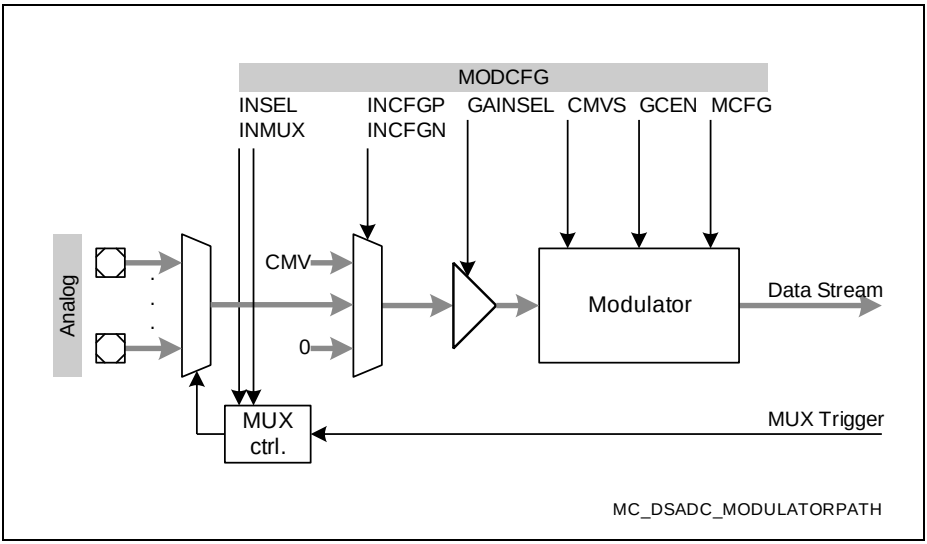

Figure 29-3 Analog Input Path

The modulator clock can be generated in different ways:

- The modulator clock is derived on-chip from the internal clock f_{CLK} (module clock, ERAY PLL clock, oscillator clock).
- The internal clock (f_{CLK}) is also used for the on-chip modulators and for the carrier generator. To ensure a stable modulator clock, it can optionally be derived from the FlexRay clock or directly from oscillator OSC0.
- The used modulator clock also drives the on-chip carrier generator. This enables synchronous operation of carrier generator and integrator.

A trigger signal can be input from a selectable input. These inputs are connected to on-chip peripherals or to pins (see **Section 29.11.4**). This trigger signal can be used for different purposes:

- Integration trigger:
  The external signal defines the integration window, i.e. the timespan during which result values are integrated.
- Timestamp trigger:
  The external signal requests the actualization of the timestamp register.
- Input multiplexer trigger:
  The external signal requests the switching of the analog input multiplexer to the next lower input or to the defined start value, respectively.
- Modulator run gate:
  The on-chip modulator can be controlled by an external gate signal while it is enabled. In this case it can be disabled temporarily to save power.
- Service request gate:
  Service requests for the main filter chain can be restricted to the high or low times of the selected trigger signal.

Note: To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

The figure below summarizes these three signal paths and indicates the source of the corresponding control information.

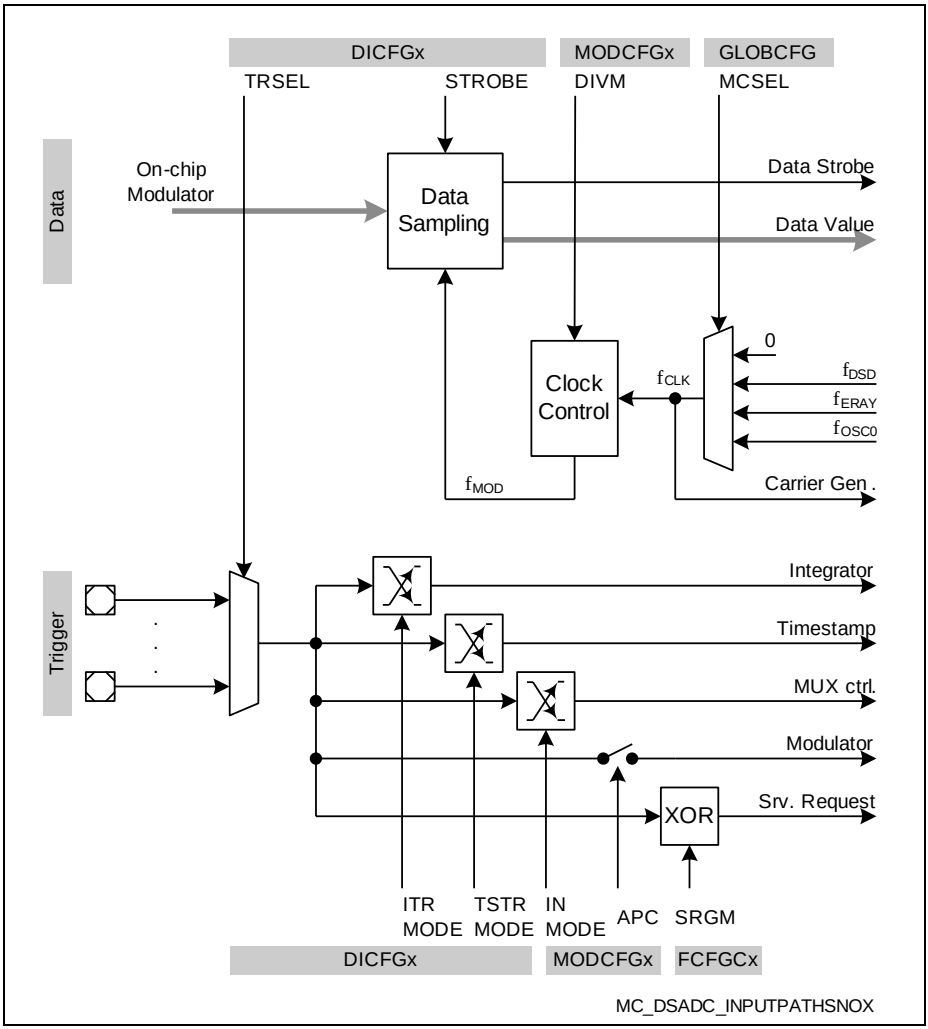

Figure 29-4 Input Path Summary

29.3.1 Modulator Clock Selection and Generation

The modulator clock signal is generated on-chip by a programmable prescaler. The on-chip clock signal is enabled by bitfield MCSEL.

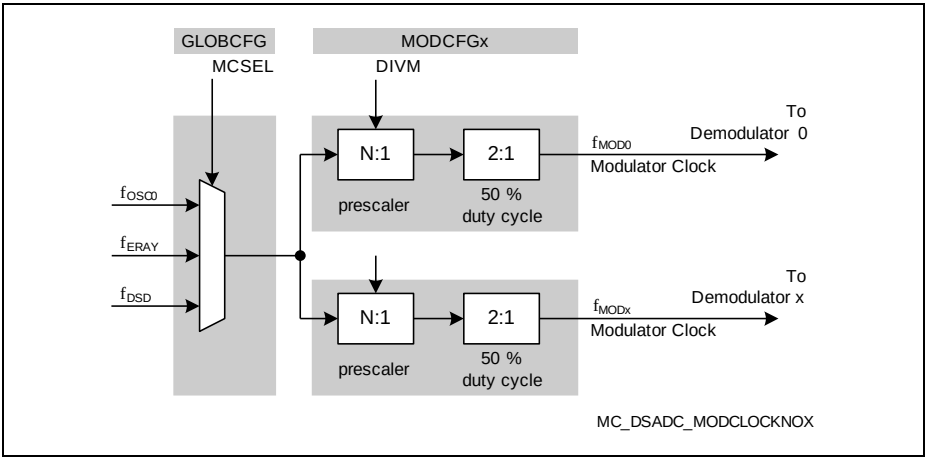

Figure 29-5 Modulator Clock Configuration

The selected clock source (f_{CLK}) is synchronized to the module clock. A configurable edge detector selects the clock signal edges that generate the data strobes which read the next input data and trigger the demodulator (see **Figure 29-6**).

Bitfield CSRC in register **DICFGx (x = 0 - 5)** selects the clock source for each channel. Bitfield STROBE selects the clocking mode, i.e. the clock edges that put a new input data sample into the filter chain.

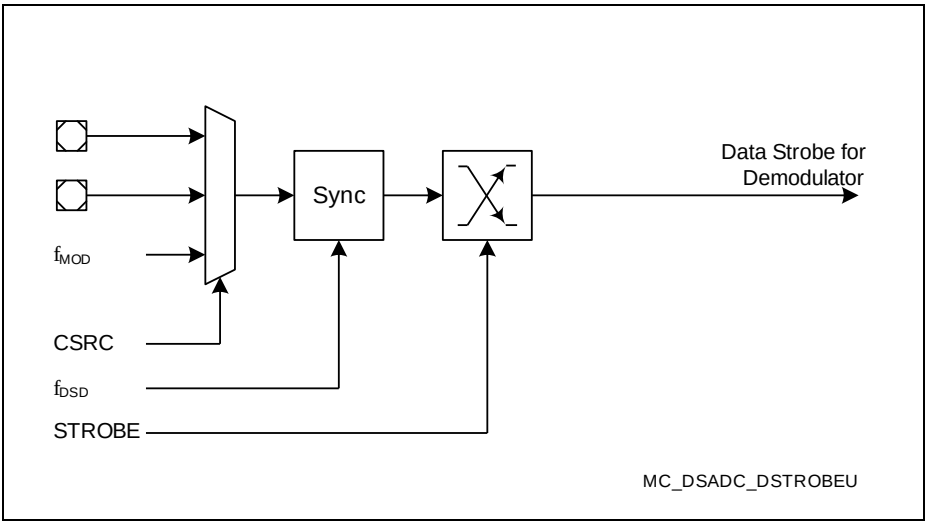

Figure 29-6 Demodulator Data Strobe Selection

Note: The modulator frequency can be selected for each channel separately. To avoid errors caused by cross-coupling, it is recommended to run the on-chip modulator at the same modulator frequency. Using frequencies with a ratio of 2:1 is a compromise.

29.3.2 Input Data Selection

The data stream is generated by the on-chip modulator and is converted to the CIC filter's input format.

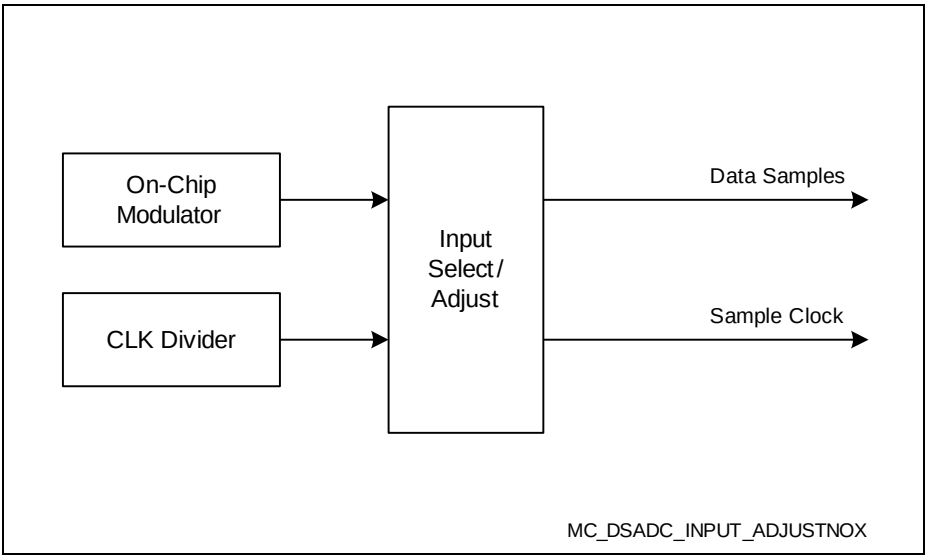

Figure 29-7 Input Control Unit

All options are configured by the demodulator input configuration register **DICFGx (x = 0 - 5)**.

29.3.3 On-Chip Modulator

The on-chip modulator operates at a frequency range of 10 MHz to 20 MHz. This sample frequency is derived from the actual module frequency (see **"Modulator Clock Selection and Generation" on Page 29-24**).

The analog input signal is fed to the sample stage via input resistors and a differential input buffer. This buffer can also operate in single-ended mode with the input signal fed to one input and the other input internally grounded.

Analog input multiplexers connect the input buffer to different pins. Section **"Product-Specific Configuration" on Page 29-86** details the available inputs. The input multiplexers are controlled by register **MODCFGx (x = 0 - 5)**.

The gain factor of the input stage can be programmed to 1, 2, 4, 8, 16. Three common mode voltages can be selected.

Note: The buffer's feedback path mirrors the selected common mode voltage permanently to the analog signal source through the input resistors.

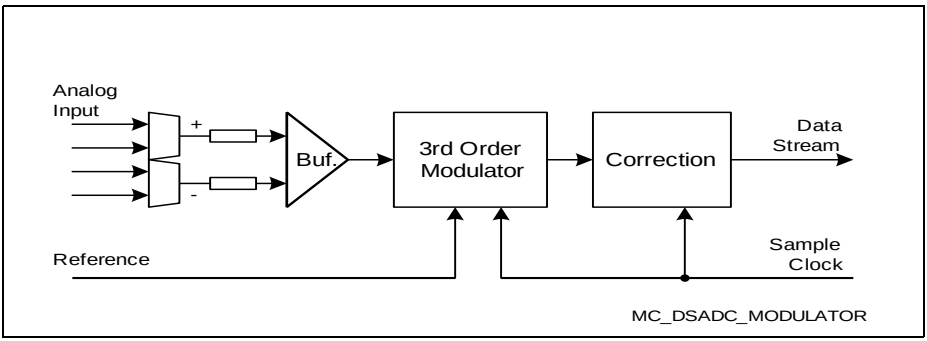

Figure 29-8 Structure of the On-Chip Modulator

Offset correction and gain correction improve the performance of the modulator. Offset measurement mode can be enabled (both inputs to V_{CM} via bitfields INCFGP and INCFGN in register **MODCFGx (x = 0 - 5)**) during the initialization phase and also during operation, e.g. to compensate temperature drift. The measured offset value can be written to register OFFMx for automatic offset correction. Gain correction is accomplished by using a factory-provided compensation value (see **Section 29.3.7**).

Operating Modes

The on-chip modulator can run in standard performance mode or in high performance mode. High performance mode achieves the maximum specified SNR, while standard performance mode reduces the power consumption by approx. 2 mA per channel.

The on-chip passive analog anti-alias filter can be enabled to precondition the input signals. The analog anti-alias filter has a typical 3-dB cutoff frequency of approx. 500 kHz.

Both functions are controlled by bitfield MCFG in register **MODCFGx (x = 0 - 5)**.

Power Reduction via External Run Control

To reduce the amount of power consumed by the modulator, the modulator can be controlled (enabled/disabled) by an external gate signal (see bit APC in register **MODCFGx (x = 0 - 5)**).

Whenever the modulator is enabled, either initially during initialization or repeatedly via automatic power control, it needs a settling time of approx. 1 µs before delivering proper data.

Make sure to include this settling time in the on-off cycles of the gate signal.

Internal Dithering

Static or low-frequency input signals can generate so-called idle tones which could degrade the SNR. The internal dithering avoids this phenomenon. Internal dithering is enabled by default, see bits DIiEN in register **ICCFGx (x = 0 - 5)**.

29.3.4 Input Path Control

The input for the DSADC is fed through several stages before being evaluated and filtered. Registers MODCFGx and DICFGx select the available options for these signal stages.

The following features can be configured:

- Signal input pin selection
- Configuration of input buffer and on-chip modulator
- Modulator clock source and/or frequency
- Trigger input pin selection

Signal Input Pin Selection

Some modulator inputs provide analog input multiplexers which connect them to several input pins. These input multiplexers can be controlled directly by software or can be switched triggered by an external control signal. Software selects the desired position via bitfield INSEL, bitfield INMUX indicates the actual setting of the input multiplexer. Bitfield INMODE defines the condition for a trigger event, bitfield INMAC selects the way in which the multiplexer is controlled:

- Software control:
  Control bitfield INMUX follows bitfield INSEL, software directly selects the intended input pins.
- Preset mode:
  The (software-written) value in bitfield INSEL is copied to bitfield INMUX upon a trigger event. Software can preselect the next intended multiplexer setting which then becomes active when the next trigger event occurs.
- Single-step mode:
  Bitfield INMUX is decremented upon each trigger event. If INMUX = 00_B when the trigger occurs, it is loaded from bitfield INSEL instead. In this mode, a predefined sequence of input pins can be scanned automatically.

The trigger signal itself is selected by bitfield TRSEL in register **DICFGx (x = 0 - 5)**.

Note: Not all channels provide input multiplexers. Also, the width of the input multiplexers may differ from channel to channel.
*Refer to **"Product-Specific Configuration" on Page 29-86** for a description of the available input paths.*

The modulator configuration register selects the operation mode of the on-chip modulator:

- Input line clamping
- Gain factor of input signal path
- Modulator operating mode
- Divider factor for modulator clock

1) The limit values for f_{MOD} must not be exceeded when selecting the module input frequency and the prescaler setting. f_{MOD} is the clock signal selected by MCSEL.

2) Due to the pair-coupled structure of the on-chip twin-modulators, the common mode voltage is selected for each modulator pair. Therefore, bitfield CMVS is active in registers MODCFG for even channels only. Each bitfield controls the modulator of its own channel and the modulator of the next higher channel.
For example, MODCFG0.CMVS controls the modulators of channel 0 and channel 1, MODCFG1.CMVS has no function.

The demodulator input configuration register selects input signal sources for each channel:

- Source of data stream
- Trigger signal source and mode
- Sample clock source
- Data strobe generation mode

1) The integration trigger mode controls bit INTEN in register **IWCTRx (x = 0 - 5)** and hence the operation of the integrator:
Bit INTEN is set when the selected trigger signal transition occurs (INTEN remains 1 while ITRMODE = 11_B).
Bit INTEN is cleared when the inverse trigger signal transition occurs or when the repeat counter expires (INTEN remains 0 while ITRMODE = 00_B). Refer to **"Integrator Stage" on Page 29-55** for more information.

2) The timestamp trigger mode controls capturing the timestamp information to register **TSTMPx (x = 0 - 5)**.

3) To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

29.3.5 Common Mode Voltage

The common mode voltage V_{CM} is derived from the analog reference voltage V_{AREF}. The relational factor, i.e. the V_{CM} level, is selected by bitfield CMVS in register **MODCFGx (x = 0 - 5)**.

The optimum choice depends on the application. It is recommended to select V_{CM} = V_{AREF}/2.27 to achieve best results for SNR/SFDR. For passive signal sources, the maximum signal amplitude is limited then.

Passive Signal Sources

For passive signal sources the common mode voltage defines the center of the signal range. To avoid non-linearities at the top of the input voltage range, a lower common mode voltage can be selected. This depends on the range of the actual input signal.

For V_{DDM} = 3.3 V, the modulator is supplied directly by the external voltage (bit LOSUP must be set, see **Section 29.2.4**).

For V_{DDM} = 5.0 V, the modulator is supplied by an on-chip regulator.

Active Signal Sources

If the differential signal source itself generates the common mode voltage, there might be a difference between the external and the internal common mode voltage. This voltage difference leads to currents through the external and internal circuitry. An asymmetry of this circuitry can generate an additional gain error.

To limit this effect, select the common mode voltage according to the signal source. The maximum input voltage range depends on the selected common mode voltage.

For single-ended signals the common mode voltage generates an additional error that can be compensated by software (see **“Correction for Single-Ended Operation” on Page 29-46**).

29.3.6 Common Mode Hold Voltage

The input channel’s common mode voltage is connected to an input pin while this pin is used for the conversions. It is disconnected from the common mode voltage when

- the modulator is inactive, e.g. when using the automatic power control feature
- the input path is disconnected during calibration phases
- the pin is not currently selected via the analog input multiplexer

Pins that are intended to be used for the DSADC can be connected to the common mode hold voltage V_{CMH} under these circumstances. The connection to the common mode hold voltage ensures that the sensor input does not float away while the respective input line is disconnected.

Registers GLOBVCMH0/GLOBVCMH1/GLOBVCMH2 select the connection to V_{CMH} for each of the possible input pins. Two nibbles are assigned to each channel (positive and

negative inputs) and contain the control bits for each possible input of the respective channel.

Note: Enabling the common mode hold voltage source (GLOBVCMH2.ON = 1) eliminates crosscoupling between inputs of analog input multiplexers.

Bitfield GLOBVCMH2.VCMHS selects the level of the applied common mode hold voltage. The correct setting depends on the available supply voltage and the intended input voltage.

*Note: The available channels provide different numbers of input pins. For a summary, refer to **"Product-Specific Configuration" on Page 29-86**. Only those bits in GLOBVCMHn are valid that correspond to an existing input pin.*

A pin is connected to the common mode hold voltage when:

- The common mode hold voltage is selected for this pin (GLOBVCMHn.INxPVCy = 1 or GLOBVCMHn.INxNVCy = 1)
- *AND*
  - The respective pin is not currently connected to the channel (MODCFGx.INMUX)
  - *OR* the respective modulator is disabled (in powerdown)

A pin is disconnected from the common mode hold voltage in other cases.

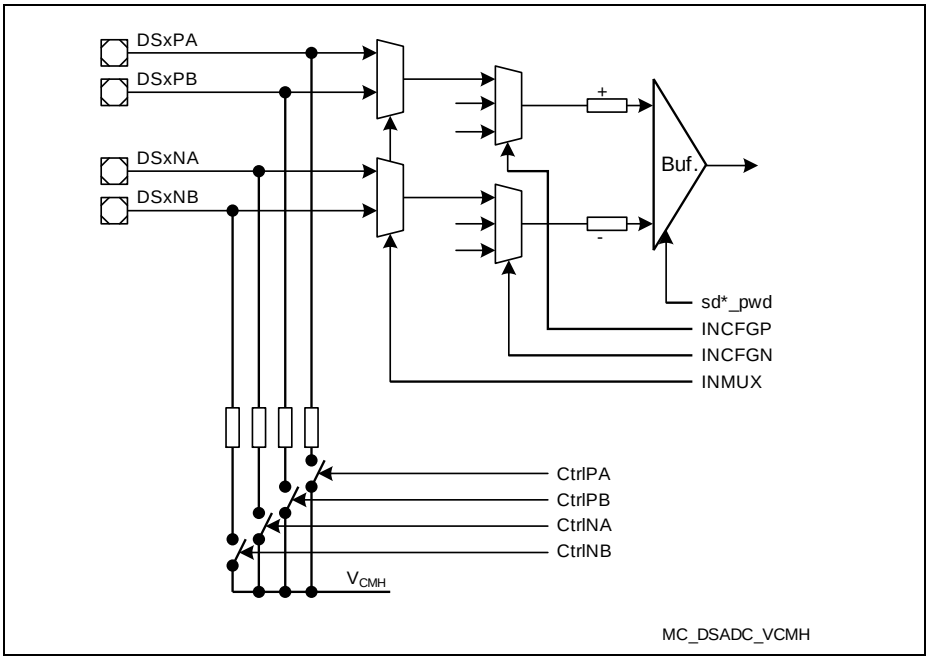

Figure 29-9 Control of VCMH Switches

The common mode hold voltage registers select which input pins are connected to the common mode hold voltage while they are not used for conversions, and which common mode hold voltage is generated:

29.3.7 Calibration Support

The performance of the DSADC can be improved by applying some calibration techniques. Several possibilities are provided:

- Offset compensation can automatically remove the DC component of an AC signal. This is done by the offset compensation filter.
- Offset calibration compensates shifted result values by using results from zero-input measurements.
- Gain calibration uses a calibration factor which is obtained from actual measurements and stored device-specific correction values. The application can multiply the result values by this factor.
- Gain adjustment compensates the variation of the input resistors with stored device-specific correction values.

Note: To compensate temperature effects it is recommended to repeat the calibration sequence when the device temperature has changed by approximately 20 °C.

Offset Calibration Support

The input structures of a channel can shift the input voltage which causes an offset error. This can be compensated by determining the shift by measuring a zero-input. This is done by connecting both input lines to the same signal, e.g. the internal common mode voltage:

- Select the same voltage for both differential input lines (MODCFGx.INCFGP = MODCFGx.INCFGN)
  - For differential operation, select common mode voltage (INCFGP/N = 10_B)
  - For single-ended operation, select reference ground (INCFGP/N = 11_B)
- Calculate the average value from a set of measurements (exclude values that differ more than 10% from the mean value)
- Store the calculated average value in register **OFFMx (x = 0 - 5)**

Note: Disable the offset compensation filter for this measurement (FCFGMx.OCEN = 0).

Gain Calibration Support

The overall accuracy can be improved by correcting the specific gain error of a channel via software. This is done by multiplying the result values by a specific gain calibration factor.

Gain calibration is based on a high-precision squarewave generator that generates a reference signal (V_{AREF} / 10) for gain factor measurements. Alternatively, the reference voltage V_{AREF} can be directly selected for a full-scale calibration with an analog gain factor 1.

The digital gain calibration factor (DGCF) for a channel (CHNr) is calculated from the device-specific square wave amplitudes stored in the user Flash area (ASQ) and the actual square wave amplitude value AM measured in the application:

DGCF = (ASQ / 20) / AM [mV] (ASQ is given in steps of 50 µV).

The actual digital gain correction factor is determined by executing the following sequence:

- Select the intended operating configuration: modulator frequency, decimation rate, data shifter setting, etc.
- Configure the intended (analog) gain factor (MODCFGx.GAINSEL)
  Note: Select factors 1…8 (500 mV × factor 16 leads to overload)
- Select an internal voltage (e.g. MODCFGx.INCFGP = MODCFGx.INCFGN = 01_B, V_{AREF})
- Enable gain calibration mode (MODCFGx.GCEN = 1)
  This disconnects the input pins[1] and connects the channel input to an internal square wave signal source with an amplitude of nominally V_{AREF} / 10 (exact voltage stored in UCB_IFX) and a frequency of f_{MOD} / 8192.
- Determine the actual amplitude by converting the high level and the low level of the square wave signal. Result = AM.
  – Read a sequence of result values.[2]
  – Ignore the values close to the signal transitions to exclude the overshoots/undershoots caused by the Gibbs phenomenon (see **Figure 29-10**).
  – Average the high values and the low values to eliminate noise from this measurement, the difference is the measured amplitude value AM.
- Compute the digital gain calibration factor by dividing the device-specific amplitude by the converted amplitude value:
  DGCF [mV/LSB] = (ASQ / 20) / AM.

Note: ASQ is determined with V_{AREF} = 5.00 V. If a different reference voltage is used in the application, the full scale value must be scaled accordingly (V_{AREF} / 5.00 V).

The result value range for a full-scale input (e.g. ±5.0 V for an analog gain factor of 1) is, therefore, AFS = ±(V_{AREF} / DGCF) = ±(5 000 × AM × 20 / ASQ)[3].

Note: Gain calibration can be executed for both modulators of a twin at the same time. It is recommended to use the same modulator frequency in this case.

1) Selecting a pin instead of the internal voltage (INCFGP/INCFGN = 00_B) will connect the square wave signal to the respective pin. In an application this usually must be avoided.

2) The number of result values per period depends on the configured decimation rate. For example, at a decimation rate of 64, 128 values (8192 / 64) cover one period of the square wave signal.

3) Assuming a reference voltage of V_{AREF} = 5.00 V. AFS = full-scale amplitude value.

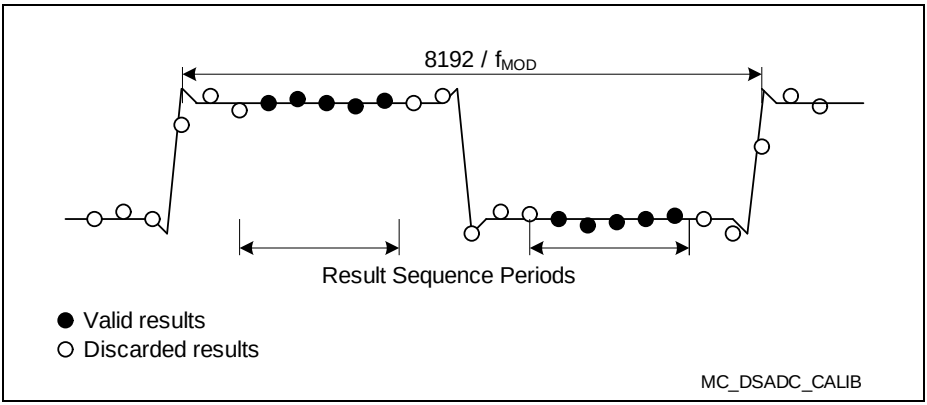

Figure 29-10 Gain Calibration Measurement

Alternate Gain Calibration

For an analog gain factor of 1, the actual digital gain correction factor is alternatively determined by executing the following sequence:

- Select the intended operating configuration: modulator frequency, decimation rate, data shifter setting, etc.
- Select the internal reference voltages as inputs (MODCFGx.INCFGP = 01_B: V_{AREF}, MODCFGx.INCFGN = 11_B: V_{AGND})
- Determine the actual full-scale value by converting the reference voltage. Average a sequence of values to eliminate noise from this measurement. Result = AM.[1)]
- Compute the digital gain calibration factor by dividing the full-scale amplitude by the converted full-scale value:
  DGCF [mV/LSB] = V_{AREF} / AM = 5 000 / AM.[2)]

The gain calibration sequence must be executed after each startup.

Using the Calibration Values

The offset calibration value is written into **OFFMx (x = 0 - 5)** and is subtracted automatically.

With the gain calibration factor the input amplitude A_{IN} can now be computed from the digital result value AIN as:
A_{IN} = AIN × DGCF.

The full-range result value is AFS = ±(V_{AREF} / DGCF).

1) Offset calibration must be done before executing this measurement.

2) Assuming a reference voltage of V_{AREF} = 5.00 V.

Gain Adjustment

The input resistors of a channel can cause an additional gain error due to the variation of their values. The actual value of the input resistors is measured during production test. The device-specific 16-bit gain adjustment values (RIN) are stored in the user Flash area (UCB_IFX) at offset 84_H + 8×CHNr. The respective value of R_{IN} (R_{IN} [kOhm] = RIN / 100) can then be used together with the sensor impedance to calculate more accurate results.

The actual input resistance depends on the chip temperature. Therefore, RIN calibration values in the user Flash are stored for two temperatures (HOT and COLD). To increase the precision for this parameter, use these values in the following way:

- Compute the linear interpolation factor FLIN:
  FLIN = (RIN_COLD - RIN_HOT) / (T_{HOT} - T_{COLD})
- Compute the temperature deviation DT:
  DT = T_{HOT} - T_{ACTUAL}
- Compute the actual resistance value R_{IN}:
  R_{IN} = (RIN_HOT + DT×FLIN×0.1 + DT^2×FLIN×0.005) / 100 [kOhm]

The temperature during the calibration sequence (T_{ACTUAL}) can be measured via the on-chip die temperature sensor (DTS) or can be estimated according to a known operating condition of the application.

Note: These values are generated at T_{COLD} = -40°C and T_{HOT} = +125°C.

Correction for Single-Ended Operation

The built-in calibration support is optimized for differential operation. Single-ended operation incurs an asymmetry caused by the external circuitry (only attached to one input pin, see R_{EXT} in **Figure 29-11**). An additional compensation factor can be calculated from the different resistances present in the analog input path:

R_{FL} = Resistance of the feedback loop
R_{CM} = Resistance of the common mode voltage path
R_{AIN} = Resistance of the analog input line
R_{EXT} = Resistance of the external circuitry.

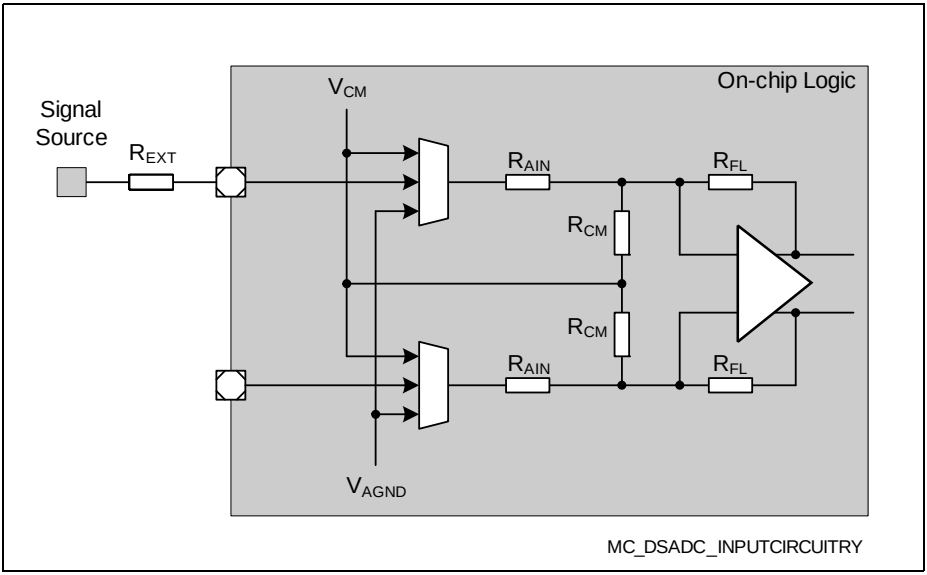

Figure 29-11 Overview of the Input Circuitry of a Channel

Note: This description assumes the sensor signal to be connected to the positive input and the negative input to be grounded internally.

General Algorithm for Resistances of $R_{EXT} \leq$ 10 kOhm:

- Calculate auxiliary resistance values:
  Equivalent input path resistance: $R_{Aequ} = R_{AIN} + R_{EXT} / 2$
  Equivalent common mode resistance: $R_{Cequ} = R_{AIN} \times 0.110553$
- Calculate auxiliary common mode voltage values:
  Equivalent for low input: $V_{CML} = V_{CM} \times R_{AIN} / (R_{AIN} + R_{Cequ}) = V_{CM} \times 0.900452$
  Equivalent for high input: $V_{CMH} = V_{CM} + (V_{AREF} / 2 - V_{CM}) \times R_{Cequ} / (R_{Cequ} + R_{Aequ})$

- Determine the additional offset value based on the full-scale value
  OFFS = AFS × (R_{EXT} / R_{Aequ}) × (V_{CML} / V_{AREF})
  This additional offset value can be added to the value in register OFFMx.
- Determine the additional gain factor based on the various resistances
  GFS = R_{Aequ} / {R_{AIN} × [1 - (R_{EXT} / R_{Aequ}) × (0.5 - V_{CMH}/V_{AREF} + V_{CML}/V_{AREF})]}
  This additional gain factor can be multiplied with the existing factor DGCF

Note: Using on-chip paths (e.g. the internal grounding of an input line) may incur an inaccuracy due to voltage drops over the on-chip paths.

Example for R_{AIN} = 131 kOhm, R_{EXT} = 10 kOhm, V_{CM} = V_{AREF} / 2.27, V_{AREF} = 5.0 V:

- R_{Aequ} = R_{AIN} + R_{EXT} / 2 = 131 kOhm + 10 kOhm / 2 = 136 kOhm
- R_{Cequ} = R_{AIN} × 0.110553 = 131 kOhm × 0.110553 = 14.48 kOhm
- V_{CML} = V_{CM} × 0.900452 = V_{AREF} × 0.396675
- V_{CMH} = V_{CM} + (V_{AREF} / 2 - V_{CM}) × R_{Cequ} / (R_{Cequ} + R_{Aequ})
  = V_{AREF} / 2.27 + (V_{AREF} / 2 - V_{AREF} / 2.27) × R_{Cequ} / (R_{Cequ} + R_{Aequ})
  = 2.202643 V + 0.297357 V × 14.48 kOhm / 150.48 kOhm
  = 2.231256 V
- OFFS = AFS × (R_{EXT} / R_{Aequ}) × (V_{CML} / V_{AREF})
  = AFS × 0.029167
- GFS = R_{Aequ} / {R_{AIN} × [1 - (R_{EXT} / R_{Aequ}) × (0.5 - V_{CMH}/V_{AREF} + V_{CML}/V_{AREF})]}
  = 136 kOhm / {131 kOhm × [1 - 0.073529 × (0.5 - 0.446251 + 0.396675)]}
  = 136 kOhm / (131 kOhm × 0.966881)
  = 1.073729

Simplified Algorithm for Resistances of $R_{EXT} \leq$ 1 kOhm:

- Determine the additional offset value based on the full-scale value
  OFFS = AFS × [R_{EXT} / (2×R_{AIN} + R_{EXT})]
  This additional offset value can be added to the value in register OFFMx.
- Determine the additional gain factor based on the various resistances
  GFS = (R_{AIN} + R_{EXT}/2) / [R_{AIN}×(1 - R_{EXT} / 2×R_{AIN})]
  This additional gain factor can be multiplied with the existing factor DGCF

Example for R_{AIN} = 131 kOhm, R_{EXT} = 1 kOhm, V_{CM} = V_{AREF} / 2.27, V_{AREF} = 5.0 V:

- OFFS = AFS × [R_{EXT} / (2×R_{AIN} + R_{EXT})]
  = AFS × 0.003802
- GFS = (R_{AIN} + R_{EXT}/2) / [R_{AIN}×(1 - R_{EXT} / 2×R_{AIN})]
  = 131.5 kOhm / (131 kOhm × 0.996183)
  = 1.007266

Range Adaptation

The scaling factor to normalize the result values according to a given format (e.g. ±32 767 or 1Q15) is then the relation of the format's limit value and the full scale result (e.g. the scaling factor is 32 767 / AFS).

The above calculations result in a gain calibration factor giving the input voltage in millivolts: DGCF [mV/LSB]. If another unit is required by the application, the range adaptation factor can be adjusted accordingly.

Stored Calibration Values

The device-specific calibration values are stored in the User Configuration Block (UCB_IFX) within the on-chip Flash memory. The area assigned to the DSADC begins at offset 80_H and provides records of 2 words per channel. The channel-specific records, therefore, can be read from offset 80_H + 8×CHNr. The table below shows the structure of a record.

Table 29-3 Structure of DSADC Calibration Records

	Halfword 3	Halfword 2	Halfword 1	Halfword 0
Location CH0	86_H	84_H	82_H	80_H
Location CH1	$8E_H$	$8C_H$	$8A_H$	88_H
:	:	:	:	:
Stored value	RIN_HOT	RIN_COLD	Reserved	ASQ

The parameters are stored in the following format:

Resistance = RIN_* × 10 Ohm, i.e. $32C8_H$ = 130 kOhm.

Amplitude = ASQ × 50 µV, i.e. 2710_H = 500 mV.

29.4 Main Filter Chain

The result data words are generated by feeding the input data stream through a chain of filter elements and decimating it by a selectable ratio.

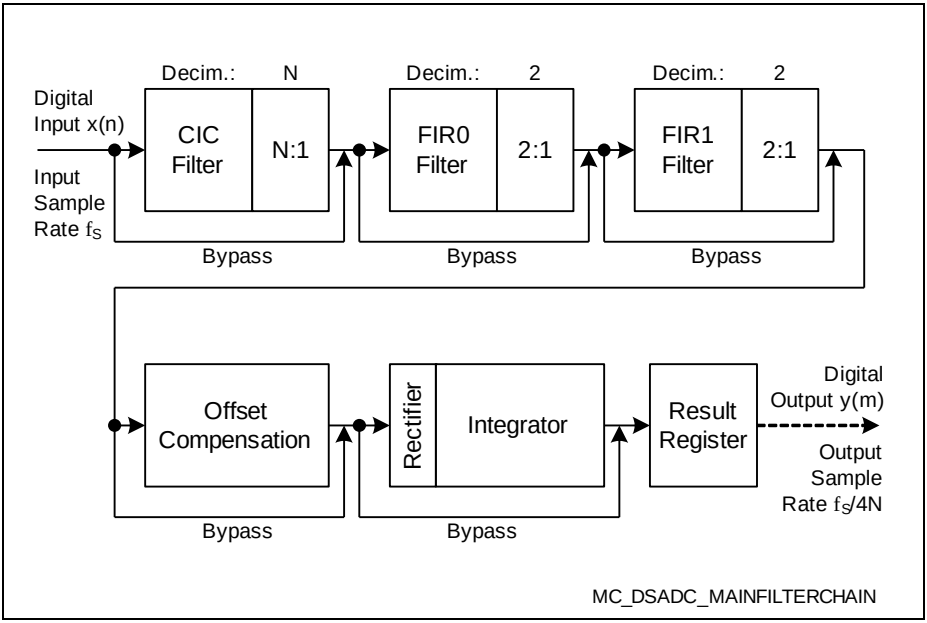

Figure 29-12 Structure of the Main Filter Chain

The elements of the filter can be bypassed, i.e. the filter chain is configurable and its behavior can be adapted to the requirements of the actual application. This comprises the frequency attenuation as well as the total decimation rate.

Note: Only configure or reconfigure filter parameters while the channel is inactive. After the configuration, start the channel by setting the corresponding bit CHxRUN.

29.4.1 CIC Filter

The Cyclic Integrating Comb filter (CIC filter, a.k.a. SINC filter) is a simple but very efficient low-pass filter. Up to three comb filter stages can be cascaded to improve the frequency characteristics. The number of active filter stages can be selected (CIC1, CIC2, CIC3) to find the optimum tradeoff between delay and frequency characteristics.

In addition, a combined mode can be selected (CICF) which represents a compromise between a 2-stage and a 3-stage filter.

To synchronize filters of different channels with fine granularity, the decimation counter starts from an arbitrary start value. This start value can be different from the decimation factor and is loaded only once when the counter is started.

The decimation counter is also restarted (i.e. loaded with the start value) when an integration starts (see **Section 29.4.4**).

The decimation factor can be selected in a wide range from 4 to 128.

Table 29-4 Data Shifter Position[1] Dep. on Filter Mode and Decimation

Decimation	CIC1	CIC2	CIC3	CICF
4	17:2	19:4	21:6	20:5
5	18:3 *	20:5 *	22:7 *	21:6 *

102 - 128	22:7	29:14	36:21 *	30:15

1) * indicates a change. Input data width is 16 bits.

29.4.2 FIR Filters

The FIR filter further attenuates the higher frequency bands that pass the CIC filter. This improves the overall frequency response of the main filter chain.

The FIR filter is realized as two subsequent FIR blocks. Each FIR filter block adds a decimation factor of 2, so the total decimation factor (i.e. the oversampling rate, including the CIC filter) is 4×N.

A shift unit at the output of each block (see **Figure 29-13**) selects 16 bits from the filter block's output data. This selected portion (usually the upper 16 bits) is used for further processing. To reduce the clipping in case of known limited data values, the selected data portion can be moved down (1 bit after FIR0, up to 3 bits after FIR1). This effectively increases the gain. Bitfields FSH and DSH in register **FCFGMx (x = 0 - 5)** select the position of the data portions.

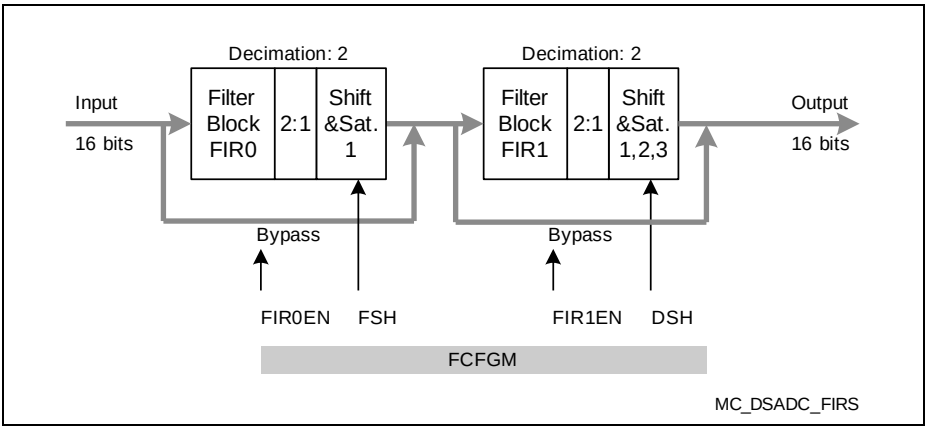

Figure 29-13 FIR Filter Blocks

If an FIR filter block is bypassed, the associated data shifter is also bypassed and its shift control has no effect.

The FIR filters can be described as:

$$y_1(m_1) = \sum_{i=0}^{N_1-1} a_1(i)\,x(2m_1 - i) \qquad y(m) = \sum_{i=0}^{N_2-1} a_2(i)\,y_1(2m - i)$$

Figure 29-14 shows the FIR filter structure. The first stage FIR has N1 = 8 coefficients, and the second stage has N2 = 28 coefficients.

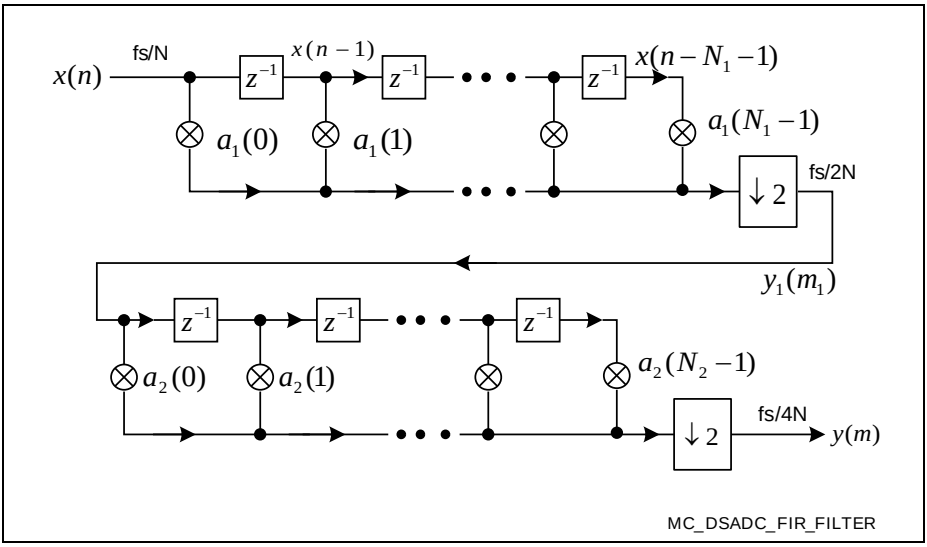

Figure 29-14 FIR Filter Structure

The coefficients of both FIR filters are fixed (see **Table 29-5** and **Table 29-6**). The filters are symmetric and have linear phase.

Table 29-5 Coefficients of FIR0

a0	a1	a2	a3	a4	a5	a6	a7
-17	-25	83	256	256	83	-25	-17

Table 29-6 Coefficients of FIR1

a0, a27	a1, a26	a2, a25	a3, a24	a4, a23	a5, a22	a6, a21	a7, a20	a8, a19	a9, a18	a10, a17	a11, a16	a12. a15	a13, a14
-3	-2	2	9	-1	-14	-8	19	25	-13	-55	-12	126	256

The resolution of the CIC filter does not represent the resolution of the Delta-Sigma converter. The resolution or the effective number of bits (ENOB) of the Delta-Sigma converter depends on the Signal to Noise Ratio (SNR) of the Delta-Sigma converter including modulator and decimation filter (CIC filter and FIR filter).

The maximum filter output value of a filter depends on the sum of absolute filter coefficients (762 for FIR0, 1090 for FIR1) and the input data width (15-bit + sign), resulting in 24 969 216 for FIR0 and 35 717 120 for FIR1. Therefore, the required data

width of the filters is 26 bits for FIR0 and 27 bits for FIR1. To handle both filters with the same MAC unit, the data width shall be 27 bits + sign.

29.4.3 Offset Compensation

The offset compensation stage is a high-pass filter that removes the DC component of the input signal, in particular in case of a differential input signal.

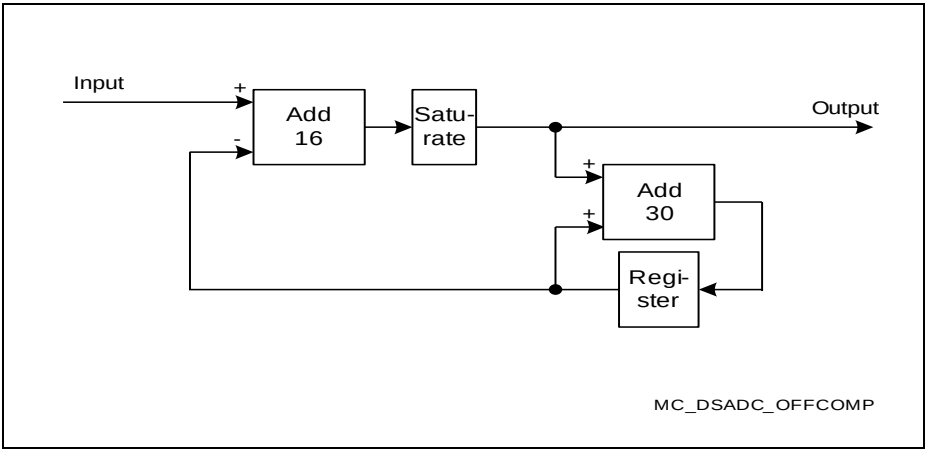

Figure 29-15 Offset Compensation

*Note: When using the offset compensation stage, clear the offset register (**OFFMx (x = 0 - 5)**) to avoid over-compensation.*
When running the offset calibration, disable the offset compensation stage to avoid wrong measurements.

29.4.4 Integrator Stage

The integrator integrates the result values generated during the defined integration window by adding a configurable number of values to build the final result value. The integration window can be started triggered by an internal or external signal.

A configurable number of values can automatically be discarded after the trigger before the integration window is started. This positions the integration window exactly into a timeframe where the filter is stable or where the signal to be measured is free of system-generated noise.

Integration can be used to measure currents through shunt resistors at defined positions in the signal waveform. It also can remove the carrier signal component in resolver applications. In this case, the values to be integrated can be rectified to yield the maximum amplitude of the receiver signal. The delay between the carrier signal (generated by the on-chip carrier generator) and the received position signals can be compensated automatically. Also refer to **Section 29.9**.

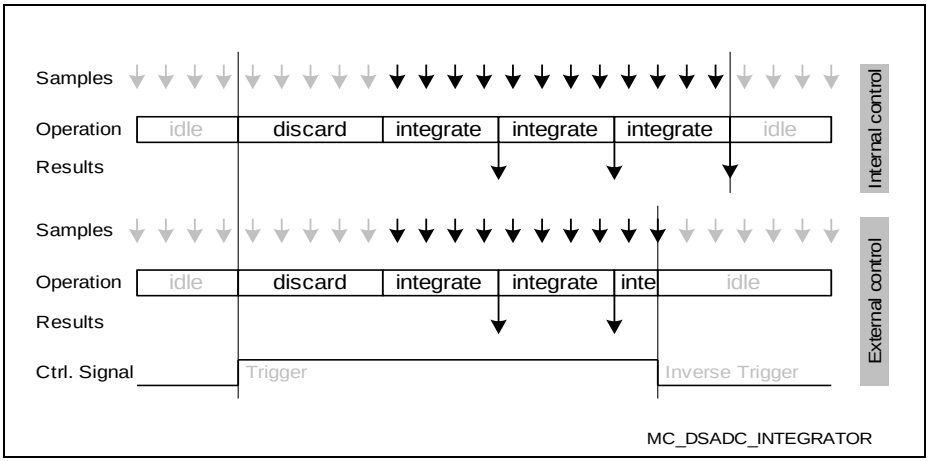

Figure 29-16 Integrator Operation

Note: The integrator can add up to 64 values, while enabled. Its output, therefore, is shifted by 6 bits (ld 64). This leads to reduced result magnitudes when less than 64 values are accumulated.

Starting the Integration Window

The integration window starts when bit INTEN becomes 1:

- Software-Controlled Mode:
  Select software-controlled integration mode by setting bitfield ITRMODE = 11_B
- Trigger-Controlled Mode:
  Select trigger-controlled integration mode (ITRMODE = 01_B or 10_B)
  and generate the selected trigger edge at the configured trigger input

The external integration trigger signal is selected by bitfield TRSEL in register **DICFGx (x = 0 - 5)**. Bitfield ITRMODE selects the transition of the selected signal to generate the trigger event. Select the trigger source first before enabling it.

Also, the decimation counter of the CIC filter is restarted, i.e. loaded with its start value (see **Section 29.4.1**).

When the integration window is started (INTEN becomes 1) the integration counter starts counting. After <NVALDIS> values the counter is reset and the integrator is started (if NVALDIS is zero the integration starts immediately).

Executing Integration Cycles

During an integration cycle <NVALINT+1> input values are integrated. After that, the integration result is stored in the result register and the integrator and the counter are cleared. If bit INTEN = 1 the next integration cycle is started.

Stopping the Integration Window

The integration window stops when bit INTEN becomes 0:

- Software-Controlled Mode:
  Disable software-controlled integration mode by setting bitfield ITRMODE = 00_B
- Trigger-Controlled Mode:
  – Internally controlled end-of-integration (IWS = 0, see upper part of **Figure 29-16**): After <REPVAL+1> integration cycles INTEN is cleared and the integration window closes, after (<NVALINT+1> × <REPVAL+1>) input values
  – Externally controlled end-of-integration (IWS = 1, see lower part of **Figure 29-16**): Generate the selected inverse trigger edge at the configured trigger input (ITRMODE = 01_B or 10_B)
  – Integration may also be stopped by software by setting bitfield ITRMODE = 00_B

Note: When the integration window is closed by an external signal (INTEN cleared by inverse trigger), the integrator and the counter are cleared also.

IWCTRx (x = 0 - 5)

1) For the control of bit INTEN, see also bitfield ITRMODE in register **DICFGx (x = 0 - 5)**.

29.5 Auxiliary Filter

The parallel auxiliary filter uses a CIC filter for decimation, similar to the one used in the main filter chain. The decimation rate is restricted to 32. This also reduces the filter delay, so the auxiliary filter can be used to supervise the input signal and detect abnormal input values earlier than the main filter chain.

The subsequent comparator provides automatic limit checking by comparing each result to two configurable reference values. The comparator can generate a separate service request.

The two values are defined in the boundary select register and determine the valid result value band if limit checking is enabled.

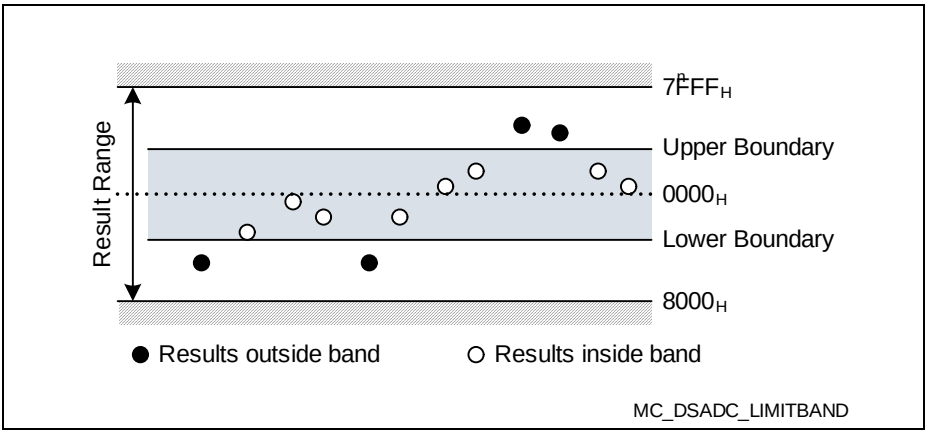

Figure 29-17 Result Monitoring through Limit Checking

A result value is considered inside the defined band when both of the following conditions are true:

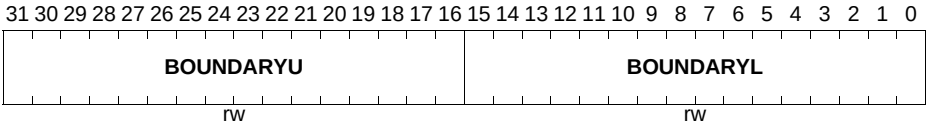
- the value is less than or equal to the selected upper boundary
- the value is greater than or equal to the selected lower boundary

The result range can also be divided into two areas:
To select the lower part as valid band, set the lower boundary to the minimum value (8000_H) and set the upper boundary to the highest intended value.
To select the upper part as valid band, set the upper boundary to the maximum value ($7FFF_H$) and set the lower boundary to the lowest intended value.

The auxiliary filter can generate two types of output:

- Service requests, optionally restricted by the comparators
- Range signals, indicating when the results are above the upper limit (SAULx) or below the lower limit (SBLLx)

BOUNDSELx (x = 0 - 5)
Boundary Select Register x **(x * 0100_H + 0128_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
BOUNDARYL	[15:0]	rw	**Lower Boundary Value for Limit Checking** This (two's complement) value is compared to the results of the parallel filter.
BOUNDARYU	[31:16]	rw	**Upper Boundary Value for Limit Checking** This (two's complement) value is compared to the results of the parallel filter.

An alarm event can be generated when a new conversion result becomes available. Alarm events can be restricted to result values that are inside or outside a user-defined band (see **Figure 29-17**). This feature supports automatic range monitoring and minimizes the CPU load by issuing service requests only under certain conditions. For example, an input value can be monitored and an alarm indicates a certain threshold.

Note: Limit checking uses the parallel auxiliary filter at a low decimation rate and, therefore, the alarm is generated earlier than the threshold values are seen at the output of the regular filter chain.

Alarm events can also be suppressed completely (see **FCFGAx (x = 0 - 5)**).

The range signals are generated independent of service requests.

Signal SAULx is active while the results are above the upper limit,
signal SBLLx is active while the results are below the lower limit.

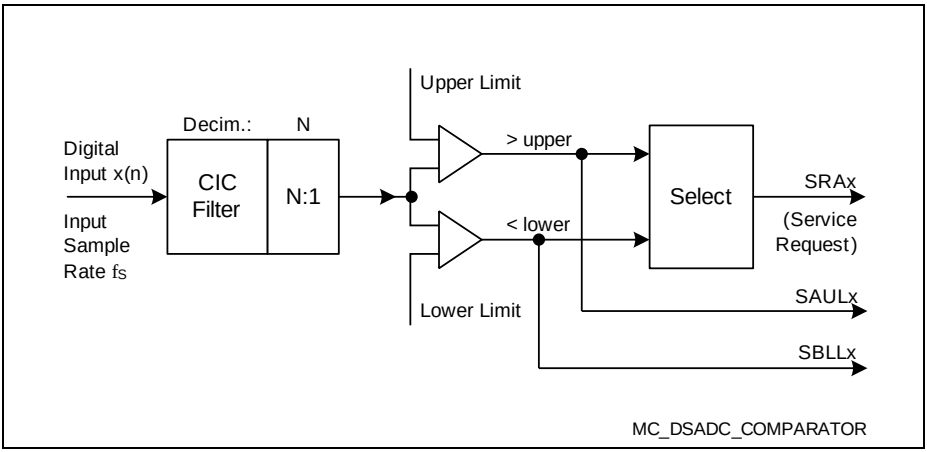


Figure 29-18 Comparator Structure

29.6 Filter Configuration and Control

Both filter chains (main and auxiliary) can be configured for the intended application. The following pages describe the available bitfields in the control registers, **Section 29.6.2** provides recommended settings to obtain best results.

Note: The main filter chain, of course, provides more configuration options than the auxiliary filter.

29.6.1 Filter Configuration Options

Both filter paths can be configured according to the requirements of the application. The stages of the main filter chain can be selected.

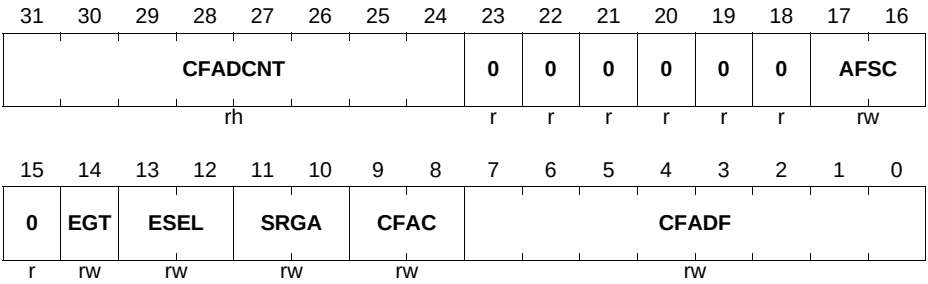
0	11	r	**Reserved, write 0, read as 0**
MFSC	[13:12]	rw	**Main Filter Shift Control** Selects the displacement caused by the data shifter at the main CIC filter output. 00_B No shift, use full range 01_B Shift by 1 10_B Shift by 2 11_B Shift by 3
SRGM	[15:14]	rw	**Service Request Generation Main Chain** 00_B Never, service requests disabled 01_B While gate (selected trigger signal) is high 10_B While gate (selected trigger signal) is low 11_B Always, for each new result value
CFMSV	[23:16]	rw	**CIC Filter (Main Chain) Start Value** The decimation counter begins counting at value CFMSV, when started or restarted. Valid values are 03_H to CFMDF (4 to selected decimation factor).
CFMDCNT	[31:24]	rh	**CIC Filter (Main Chain) Decimation Counter** The decimation counter counts the filter cycles until an output is generated, i.e. the oversampling rate. CFMDCNT counts down from the respective start value.

FCFGAx (x = 0 - 5)
Filter Configuration Register x, Auxiliary Filter
(x * 0100_H + 0118_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CFADF	[7:0]	rw	**CIC Filter (Auxiliary) Decimation Factor** The decimation factor of the Auxiliary CIC filter is CFADF +1. Valid values are 03_H to $1F_H$ (4 to 32).
CFAC	[9:8]	rw	**CIC Filter (Auxiliary) Configuration** 00_B CIC1 01_B CIC2 10_B CIC3 11_B CICF
SRGA	[11:10]	rw	**Service Request Generation Auxiliary Filter** 00_B Never, service requests disabled 01_B Auxiliary filter: As selected by bitfields ESEL and EGT (if integrator enabled) 10_B Alternate source: Capturing of a sign delay value to register **CGSYNCx (x = 0 - 5)** 11_B Reserved
ESEL	[13:12]	rw	**Event Select** Defines when an event for the auxiliary filter is generated (see also bit EGT). 00_B Always, for each new result value 01_B If result is inside the boundary band 10_B If result is outside the boundary band 11_B Reserved

Field	Bits	Type	Description
EGT	14	rw	**Event Gating** Defines if events for the auxiliary filter are coupled to the integration window. 0_B Separate: generate events according to ESEL 1_B Coupled: generate events only when the integrator is enabled and after the discard phase defined by bitfield NVALDIS[1)]
0	15	r	**Reserved, write 0, read as 0**
AFSC	[17:16]	rw	**Auxiliary Filter Shift Control** Selects the displacement caused by the data shifter at the auxiliary CIC filter output. 00_B No shift, use full range 01_B Shift by 1 10_B Shift by 2 11_B Shift by 3
0	[23:18]	r	**Reserved, write 0, read as 0**
CFADCNT	[31:24]	rh	**CIC Filter (Auxiliary) Decimation Counter** The decimation counter counts the filter cycles until an output is generated, i.e. the oversampling rate.

1) While the integrator is bypassed, event gating is disabled, i.e. service requests are generated according to bitfield ESEL. The event gating suppresses service requests, result values are still stored in register RESAx.

29.6.2 Recommended Settings

The digital filters, in particular the main filter chain, provide a number of configuration options to control their operation. However, not all combinations achieve the performance the filters can deliver. The following recommendations describe the dependence of the performance on the configuration settings as well as some standard operating modes.

The digital result values that represent the input signal depend on the configuration of the filter chain, i.e. on the decimation factor, the involved filter elements, and the settings of the data shifters.

Modulator Values

The full-scale values produced by the on-chip modulator are subject to a certain variation due to the involved analog circuitry and also depend on the operating mode:

- $\pm 3\,600_D$ as an uncalibrated average value
- $\pm 4\,096_D$ in case of an overload condition (IREN = 1)

The example calculations below use a full-scale value of $\pm 3\,800_D$ ($0ED8_H/F128_H$) to avoid filter overflows.

Note: The modulator output value variation is compensated by the calibration sequence.

Gain Factor of the CIC Filter

The gain factor of the CIC filter is 1.0 for decimation rates of 2^N.

The automatic data shifter after the CIC filter compensates the variation of the result magnitude caused by different decimation factors. This compensation, however, can only be done by powers of 2, while the decimation rate itself can be selected arbitrarily. The gain of the CIC filter, therefore, ranges from 1.0 (decimation rate is 2^N, e.g. 32 or 64) down to approximately 0.5 (decimation rate is $2^N + 1$, e.g. 33 or 65).

The influence of this varying gain on the result magnitude can be computed by using the following approach:

- Compute the factor according to the selected filter configuration and decimation rate (For CIC3 and a decimation rate of 45, the factor is 45^3 =91 125)[1)]
- Determine the next higher power of 2 (e.g. 2^{17} = 131 072 > 91 125)
- Compute the relation of the actual factor and the next power of 2 (e.g. 91 125 / 131 072 = 0.695228577)

1) Formula for CIC1: 1 × N, for CIC2: N^2, for CIC3: N^3, for CICF: 2 × N^2.

Gain Factor of FIR Filters and Data Shifters

The gain factor of the FIR filters is defined by their coefficients (see **Section 29.4.2**).

For FIR0 the gain factor is:
2 × (-17 - 25 + 83 + 256) / 1 024
= 0.580078125

For FIR1 the gain factor is:
2 × (-3 - 2 + 2 + 9 - 1 - 14 - 8 + 19 + 25 - 13 - 55 - 12 + 126 + 256) / 1 024
= 0.642578125

Shifting the data values by one bit equals a gain factor of 2.0. Therefore, the resulting gain factor is 2^S, where S is the selected value of the respective data shifter.

Avoiding Clipping

To avoid overflow and clipping of values within the filter chain, the magnitude of the result values must not exceed $\pm 2^{15}$ at any stage. This is the basis for selecting the correct settings for the data shifters. See also the example in **Table 29-7**.

Total Gain Factor of the Digital Filter Chain

Multiplying the gain factors of the individual enabled elements of the filter chain results in the total gain factor:

$G_{TOT} = G_{CIC} \times G_{SC} \times G_{FIR0} \times G_{SF0} \times G_{FIR1} \times G_{SF1}$

$G_{TOT} = G_{CIC} \times 2^{MFSC} \times 0.580078125 \times 2^{FSH} \times 0.642578125 \times 2^{DSH}$

Note: When defining the settings for the data shifters, try to generate the maximum possible data values without exceeding the limits of the 16-bit data format at each stage. This minimizes errors induced by quantization.

Table 29-7 Example Setup Main Filter Chain, On-chip Modulator

Bitfield	Possible Values	Recommendation[1)]	Notes
MODCFGx.GAINSEL	1, 2, 4, 8, 16	1 (0000_B)	Analog gain factor (valid for this example)
f_{MOD}	10 … 20 MHz	20 MHz	Modulator sample frequency
FCFGCx.CFMC	CIC1, CIC2, CIC3, CICF	CIC3 (10_B)	CIC filter grade
FCFGCx.CFMDF	4 … 128	50 (31_H)	CIC filter decimation rate (OSR) Gain factor: 125 000 / 131 072 = 0.953674316

Table 29-7 Example Setup Main Filter Chain, On-chip Modulator (cont'd)

Bitfield	Possible Values	Recommen-dation[1)]	Notes
FCFGCx.MFSC	0, 1, 2, 3	3 (11_B)	Data shifter steps after CIC filter Gain factor: $2^3 = 8.0$ (Magnitude = 28 992: OK)
FCFGMx.FSH	0, 1	0	Data shifter steps after FIR0 Gain factor: 0.580078125 (Magnitude = 16 817: OK; FSH = 1 would lead to 33 635!!)
FCFGMx.DSH	0, 1, 2, 3	1 (01_B)	Data shifter steps after FIR1 Gain factor: $2^1 = 2.0 \times 0.642578125$ $= 1.28515625$ (Magnitude = 21 613: OK)
Total gain factor	-	-	0.953674316×8.0 $\times 0.580078125 \times 1.28515625$ $= 5.687645168$
RESMx.RESULT	-	-	$\pm 3\,800_D \times 5.687645168$ $= \pm 21\,613\ (546D_H)$[2)]

1) Bitfield values in parentheses.

2) These values are given after offset correction and refer to the nominal modulator output values. The final result values are adjusted by the complete calibration sequence.

Dithering Control

The dithering features reduces the idle tones caused by low-frequency input signals. After reset, dithering is enabled, but the dithering trim value is 000_B. To optimize the effect, set the trim value to 011_B.

29.6.3 Group Delay

Data that enter a digital filter need a certain number of filter clocks before they appear at the filter's output and can be used by the system. The effective group delay depends on the configuration of the filter chain. **Table 29-8** summarizes the delays incurred by the elements of the filter chain. "N" indicates the selected oversampling rate (decimation factor) of the CIC filter. Delays are listed in modulator clock cycles.

Table 29-8 Group Delay Summary

Filter Chain Element	Delay [t_{MOD}]	Notes
On-chip modulator	7	Delay of analog frontend
Input select/adjust unit	1	Synchronization
CIC1	1 × (N-1) / 2	
CIC2	2 × (N-1) / 2	
CIC3	3 × (N-1) / 2	
CICF	(2 × N) - 1	
FIR0	(3.5 × N) + C0	C0 = 3 To be added to CIC delay
FIR1	(27 × N) + C1	C1 = N + 5 To be added to CIC / FIR0 delay
OC	0	
Integrator	X	Depending on the selected number of discarded and integrated values
Offset correction	0	

Example

f_{MOD} = 16.66 MHz, t_{MOD} = 60 ns, OSR(CIC3) = 32, FIR active, OC off, no integration.

Group delay:

[7 + 1 + (3 × 31 / 2) + (3.5 × 32 + 3) + (28 × 32 + 5)] × t_{MOD} =

(7 + 1 + 46.5 + 115 + 901) × t_{MOD} = 1 070.5 × t_{MOD} = 64.23 µs

At the given oversampling rate of 32×2×2 = 128 this equals a delay of 8.36 × t_D (data output rate cycles).

29.7 Conversion Result Handling

The DSADC preprocesses the conversion result data before storing them for retrieval by the CPU or a DMA channel.

Conversion result handling comprises the following functions:

- Filtering and Post-Processing
- Storage of Conversion Results
- Result Event Generation

The result data words are generated by feeding the input data stream through a chain of filter elements and decimating it by a selectable ratio. The selectable integrator can further reduce the output data rate.

The elements of the main filter chain after the initial CIC filter can be bypassed, i.e. the filter chain is configurable and its behavior can be adapted to the requirements of the actual application.

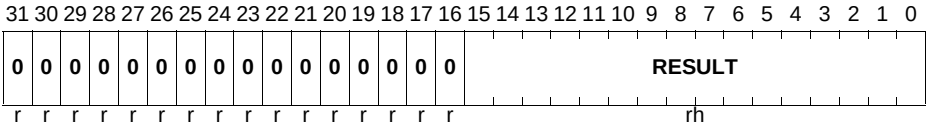
A programmable offset is subtracted automatically from each result value before being stored in the result register. This offset value is stored in the corresponding register OFFMx. It may be an arbitrary value defined by the application.

The offset value can also be obtained by using the offset measurement mode (both inputs to V_{CM} via bitfields INCFGP and INCFGN in register **MODCFGx (x = 0 - 5)**).

The auxiliary filter is fixed. The result values of the auxiliary filter are also available for the application, although in many cases the comparator output signal will be sufficient.

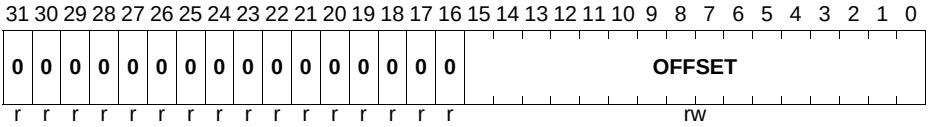
The conversion result values are stored in result register RESMx and RESAx, respectively.

RESMx (x = 0 - 5)
Result Register x Main Filter **($x * 0100_H + 0130_H$)** **Reset Value: $0000\ 0000_H$**



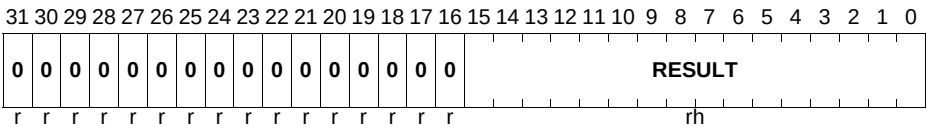
Field	Bits	Type	Description
RESULT	[15:0]	rh	**Result of most recent conversion** Signed value (two's complement)
0	[31:16]	r	**Reserved, write 0, read as 0**

OFFMx (x = 0 - 5)
Offset Register x Main Filter **($x * 0100_H + 0138_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
OFFSET	[15:0]	rw	**Offset Value** This signed value is subtracted from each result before being written to the corresponding result register RESMx.
0	[31:16]	r	**Reserved, write 0, read as 0**

RESAx (x = 0 - 5)
Result Register x Auxiliary Filter
($x * 0100_H + 0140_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RESULT	[15:0]	rh	**Result of most recent conversion** Signed value (two's complement)
0	[31:16]	r	**Reserved, write 0, read as 0**

Result Representation

Due to the differential input stage, the results are signed values stored in a 16-bit two's complement format. The CIC filter's output value depends on the selected filter parameters and decimation factor. An automatic data shifter extracts the most significant bits from this filter result.

29.8 Service Request Generation

The DSADC can activate service request output signals to issue an interrupt, to trigger a DMA channel, or to trigger other on-chip modules.

Service request connections can be found in **Table 29-13 “Digital Connections in the TC27x” on Page 29-91**.

Several events can be assigned to each service request output. Service requests can be generated by several types of events:

- **Result events:** indicate a new valid result in a result register. Usually, this triggers a read action by the CPU (or DMA). Result events are generated at the output rate of the configured filter chain.
  Can be issued via SRAx and SRMx.
- **Alarm events:** indicate that a conversion result value is within a programmable value range. This offloads the CPU/DMA from background tasks, i.e. a service request is only activated if the specified conversion result range is met or exceeded.
  Can be issued via SRAx.
- **Special events:** indicate specific circumstances of previously configured functions.
  – Timestamp trigger event can generate a service request.
  Can be issued via SRMx.
  – Capture event for sign delay measurement can generate a service request.
  Can be issued via SRAx.

Each event is indicated by a dedicated flag that can be cleared by software. If a service request is enabled for a certain event, the service request is generated for each event, independent of the status of the corresponding event indication flag. This ensures efficient DMA handling of DSADC events (the event can generate a service request without the need to clear the indication flag).

Note: For service request signals to occur, they must be activated via bitfields SRGM and/or SRGA.

Gating Requests of Auxiliary Channel

Result/Alarm events on service request SRAx can be suppressed while the integrator is enabled and is controlled by an external signal. When bit EGT in register **FCFGAx (x = 0 - 5)** is set, result events (ESEL = 00_B) or alarm events (ESEL = 01_B or ESEL = 10_B) only generate service requests while the integrator is active after the programmed discard phase.

This prevents alarm requests from being generated while the signal is not evaluated via the main filter chain.

Note: While the integrator is disabled (ITRMODE = 00_B), bit EGT has no effect on the generation of auxiliary service requests.

The following registers provide a set of bits for each available channel.
The number of available channels depends on the chosen device type.

EVFLAG
Event Flag Register **($00E0_H$)** **Reset Value: $0000\ 0000_H$**

0	[31:22]	r	**Reserved, write 0, read as 0**

Note: Software can set flags RESEVx and ALEVx and trigger the corresponding event by writing 1 to the respective bit. Writing 0 has no effect.
Software can clear these flags by writing 1 to bit RESECx and ALECx, respectively.

29.9 Resolver Support

Resolver applications determine the rotation angle by evaluating the signals from two orthogonally placed coils. These coils are excited by the magnetic field of a third coil.
The DSADC can read the two return signals using two input channels and can also generate the excitation sine signal (carrier). It also provides synchronization logic to compensate the delay between the generated carrier signal and the received position signals. The integrator stage converts the carrier-based return signals to position-based values (carrier cancellation).

29.9.1 Carrier Signal Generation

The carrier signal generator (CG) is supplied with the selected internal clock signal (f_{CLK}) and outputs a PWM signal that induces a sine signal in the excitation coil of the resolver. Alternatively, it can generate PWM patterns that resemble triangle or square signals (see **Figure 29-20**). The polarity of the carrier signal can be selected.

A carrier signal period consists of 32 steps. Each step equals a PWM period of 32 cycles.

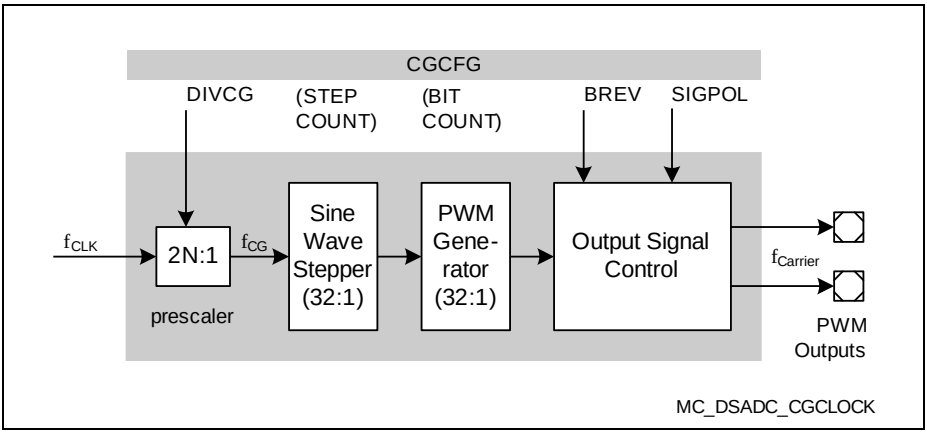

Figure 29-19 Carrier Generator Block Diagram

Bit-reverse generation mode increases the frequency spectrum to yield a smoother induced sine signal. This is done by distributing the 0 and 1 bits over the 32 cycles of a PWM period.

The generated pattern is actually a cosine signal, i.e. it starts at the maximum output value. This is advantageous if the output pin is pulled high before the carrier signal is generated. In case of a pull-down the inverted output signal should be selected.

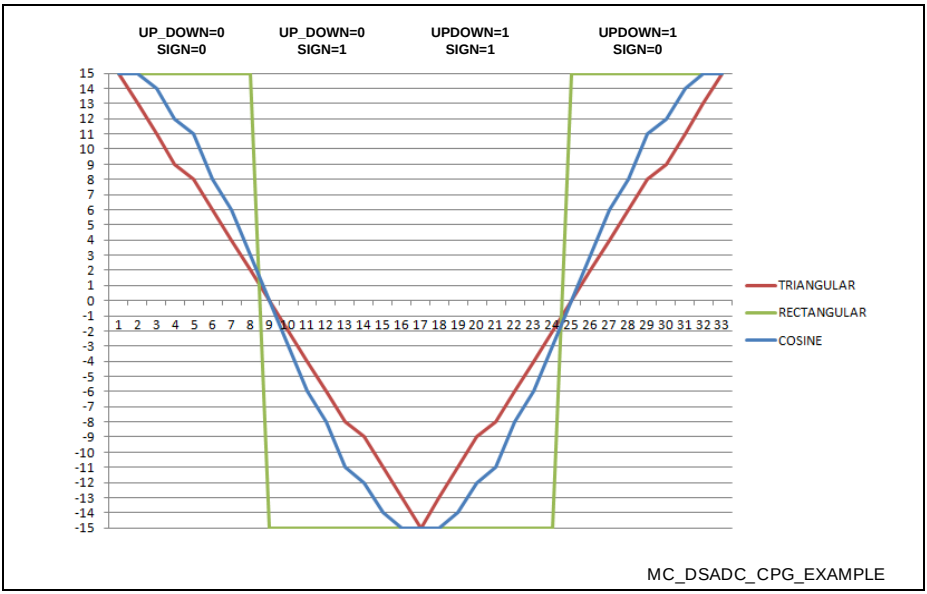

Figure 29-20 Example Pattern/Waveform Outputs

29.9.2 Return Signal Synchronization

In a resolver, the received return signals are induced by the carrier signal and their amplitudes are modulated with the sine and cosine magnitudes corresponding to the current resolver position. These amplitudes are determined by integrating the return signals over a carrier signal period.

To properly integrate their magnitude, the return signals must be rectified. For this purpose the carrier generator provides the sign information of the generated carrier signal (SGNCG in register **CGCFG**).

Alternatively, an external carrier signal generator can be used. If this generator delivers a sign signal, this can be input to a pin and is then used as external carrier sign signal. If no sign signal is available, the carrier signal itself can be converted by the next adjacent input channel and its sign signal is then used as alternate carrier sign signal.

*Note: The resulting sign signal is called SGNCS in **Figure 29-21**.*

The rectification of the received signals must be delayed to compensate the round trip delay through the system (driver, resolver coils, cables, etc.). For the rectification, the received values are multiplied with the delayed carrier sign signal (SGND in register **RECTCFGx (x = 0 - 5)**). This synchronization is done for each channel separately, to achieve the maximum possible amplitudes for each signal.

Note: The rectification unit is part of the integrator stage. Therefore, it is only active while the integrator is active.

The delay is realized with the sign delay counter SDCOUNT. SDCOUNT is cleared and started upon a falling edge of the selected sign signal (SGNCS in **Figure 29-21**), i.e. at the begin of the positive halfwave of the carrier signal. After counting SDPOS results from the filter chain, also the rectification signal (SGND) is cleared, indicating positive values from now on. After counting SDNEG values, the rectification signal is set, indicating negative values (see **Figure 29-21**).

The compare values SDPOS and SDNEG are stored by the application software. SDPOS is the delay value that accounts for the resolver signal's round trip delay. This delay is constantly measured by capturing the current counter value into bitfield SDCAP when the first positive result (after negative results) is received in the respective channel. Software can read these value and compute a delay value e.g. by averaging a series of measured values to compensate noise. The delay for the negative halfwave (SGND = 0) is determined by adding the duration of a carrier signal halfwave. This value is written to bitfield SDNEG.

A new captured value is indicated by setting the flag SDCVAL. This flag is cleared when reading register CGSYNCx.

Capturing a new value can trigger a service request. The service request line of the auxiliary channel is used for this purpose. This alternate request source is selected by bitfield SRGA in register **FCFGAx (x = 0 - 5)**.

SDPOS	[23:16]	rw	**Sign Delay Value for Positive Halfwave** Defines the content of SDCOUNT to generate a low delayed sign signal SGND (positive values).
SDNEG	[31:24]	rw	**Sign Delay Value for Negative Halfwave** Defines the content of SDCOUNT to generate a high delayed sign signal SGND (negative values).

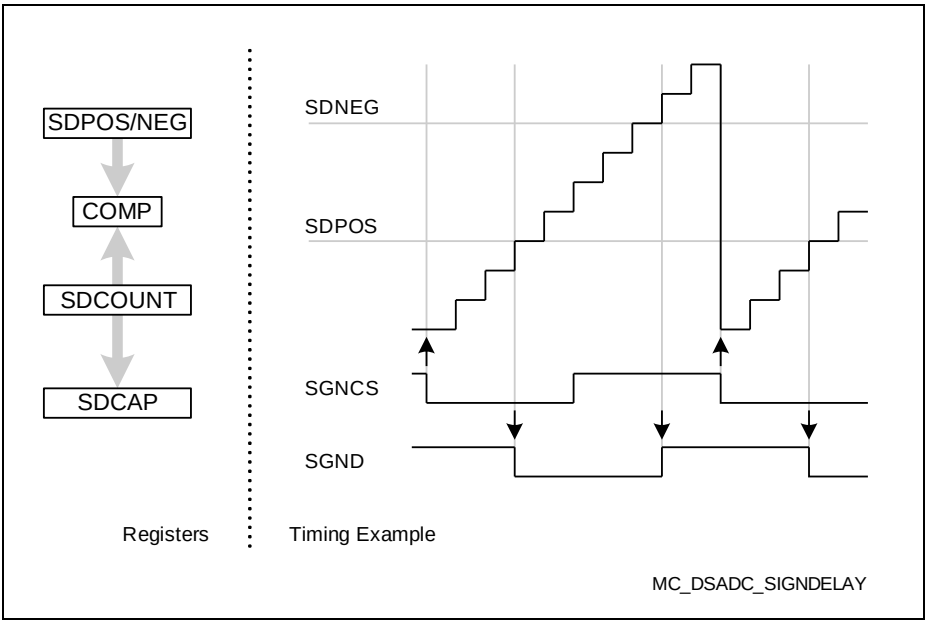

Figure 29-21 Sign Delay Example

Note: Whenever a new result value becomes available from the filter chain, the rectification counter (SDCOUNT) is updated and the rectified value is forwarded to the integrator.

29.10 Time-Stamp Support

Some applications need to determine the result value at certain points of time inbetween two regular output values. The interpolation algorithm needs to determine the position of the required point of time in relation to the regular results.

This interpolation is supported by providing a timestamp that marks the delay since the last regular output value. This timestamp is composed of:

- the last regular result value
- the current decimation counter value
- the current integrator counter value

All timestamp information is combined into one register, so the complete timestamp can easily be stored away by a single DMA transfer. The timestamp information is captured into register TSTMPx upon a hardware trigger. For this purpose, the trigger signal is used, which is selected by bitfield TRSEL in register **DICFGx (x = 0 - 5)**. Bitfield TSTRMODE selects the edge(s) that capture timestamp information.

The valid flag TSVAL is set when timestamp information is stored and is cleared when register TSTMP is read. This indicates to the application software if or not a timestamp trigger has occurred before the corresponding result value was generated.

When timestamp information is stored, a service request can optionally be generated. This allows application software to operate on all result data, even if multiple timestamp triggers occur before a regular result service request.

TSTMPx (x = 0 - 5)

29.11 Implementation into the TC27x

This section describes the actual implementation of the ADC module into the TC27x, i.e. the incorporation into the microcontroller system.

The following information is listed:

- **“Product-Specific Configuration” on Page 29-86**
- **“Summary of Registers and Locations” on Page 29-87**
- **“Analog Module Connections in the TC27x” on Page 29-90**
- **“Digital Module Connections in the TC27x” on Page 29-91**

29.11.1 Product-Specific Configuration

The functional description describes the features and operating modes of the DSADC in a general way. This section summarizes the configuration that is available in this product (TC27x).

The DSADC features a number of twin-modulators that handle 2 input channels each.

Table 29-9 General Converter Configuration in the TC27x

Channel	Analog Inputs[1)]	Reference Voltages	Notes
0	1	V_{AREF1}, V_{AGND1}	
1	1	V_{AREF1}, V_{AGND1}

5	1	V_{AREF1}, V_{AGND1}	

1) Differential input pin pairs.

29.11.2 Summary of Registers and Locations

The DSADC is built from a series of channels that are controlled in an identical way. This makes programming versatile and scalable. The corresponding registers, therefore, have an individual offset assigned (see **Table 29-11**). The exact register location is obtained by adding the respective register offset to the base address (see **Table 29-10**) of the corresponding channel.

Due to the regular structure, several registers appear within each channel. This is indicated in the register overview table by placeholders:

- $0X\#\#_H$ means: $x \times 0100_H + 01\#\#_H$, for x = 0 - 5

29.11.3 Analog Module Connections in the TC27x

The DSADC module accepts a positive and a negative analog input signal to be used as a differential input. Each analog input can also be used in single-ended mode.

The exact number of analog input channels and the available connection to port pins depend on the employed product type.

Table 29-12 lists the available inputs for each DSADC channel.

Table 29-12 Analog Connections in the TC27x

Signal	Dir.	Source/Destin.	Description

30 Inter-Integrated Circuit Module (I2C)

This chapter describes the Inter-Integrated Circuit (short I2C) Module of the TC27x. The I2C module is not available in some variants. In these variants registers are still accessible but functionality cannot be guaranteed. The I2C module contains the following sections:

- Overview (see **Page 30-1**)
- I2C module functional specification (see **Page 30-5**) including:
  - I2C protocol (see **Page 30-5**)
  - Clock and timing control (see **Page 30-12**)
  - I2C kernel control logic (see **Page 30-16**)
  - FIFO operation (see **Page 30-29**)
  - Service request block operation (see **Page 30-46**)
- I2C module internal registers (see **Page 30-52**)
- I2C module implementation (see **Page 30-82**).

This specification is fully compliant with the I2C-bus specification version 2.1 **[3]**.

Note: The I2C module register names described in this chapter are referenced in the TC27x User's Manual by the module name prefix "I2Cm_" with m being the number of the module.

30.1 Overview

This section gives an overview of the I2C-bus and of the I2C module.

30.1.1 I2C-bus Overview

The I2C protocol was developed to provide a simple and efficient data transfer between multiple devices over a short distance. It uses a bidirectional serial bus with two wires.

A serial data line (SDA) and a serial clock line (SCL) carry the information between the devices. These lines are connected to a positive supply voltage via pull-up resistors. In quiescent state, when the bus is free, both lines are high. During communication the lines are alternatively pulled to low. The output stages of devices connected to the bus must have an open-drain (CMOS) or open-collector (bipolar) to perform a wired-AND function.

A device can work as master or as slave. The master initiates the transfer, generates the clock pulses and terminates the transfer; it addresses a slave via a 7-bit or 10-bit address. Data can flow in either direction. In many applications there is only one master, typically a single-chip microcontroller, which communicates with several slaves, e.g. general purpose peripherals or application specific circuits. But also multi-master systems with arbitration and collision detection are possible.

Data on the I2C-bus can be transferred at rates of up to 100 kbit/s in standard mode, up to 400 kbit/s in fast mode and up to 3.4 Mbit/s in high-speed mode. A slow slave may

stretch the clock period. The number of devices connected to the same I2C-bus is limited only by a maximum bus capacitance of 400 pF.

30.1.2 I2C Module Overview

Figure 30-1 shows a block diagram of the I2C module.

The I2C module works in accordance with I2C-bus specification version 2.1 **[3]**. It supports master mode, multi-master mode and slave mode. Communication is possible at different speed ranges: standard mode, fast mode and high-speed mode. Not only 7-bit I2C-bus addresses, but also 10-bit addresses can be handled. The module relieves the CPU from many time-critical tasks.

The clock for the kernel of the I2C module is derived from the system clock via a prescaler. An additional fractional divider generates the desired bit rate. The exact timing of the I2C-bus signals can be adjusted.

A FIFO is used for data transfer between CPU and I2C module during transmission and reception. This allows writing and reading of multiple bytes. Data alignment and data sizes can be configured.

Six separate interrupt requests are available: for filling or emptying the FIFO, for reacting on certain protocol events and for handling of errors.

External hardware is connected to the I2C module via a pair of receive and transmit pins.

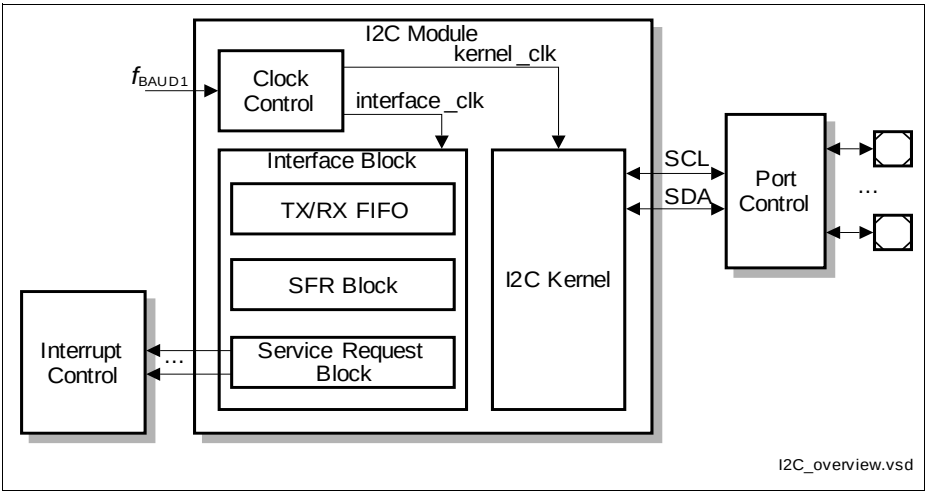

Figure 30-1 Block Diagram of the I2C Module

Features

- Compatible with I2C-bus specification version 2.1 **[3]**
- Master mode, multi-master mode and slave mode supported
- Different speed ranges available for data transfer:
  - Standard mode (0-100 kbit/s)
  - Fast mode (0-400 kbit/s)
  - High-speed mode (0-3.4 Mbit/s)
- 7-bit and 10-bit I2C-bus addressing supported
- Automatic execution of low-level tasks like:
  - (De)Serialization of the bus data
  - Generation/detection of start and stop signal
  - Generation/detection of acknowledge signal
  - Bus state detection
  - Bus access arbitration in multi-master mode
  - Recognition of device address in slave mode
  - Configurable detection of general call address
  - Configurable repeated start in master mode
- Flexible clock and timing control:
  - Prescaler for I2C kernel clock
  - Bit rate generation via fractional divider
  - I2C-bus signal timing adjustment
- TX/RX FIFO for buffering data from/to CPU with following features:
  - 8 FIFO stages
  - Configurable data alignment (byte, half word, word)
  - Configurable sizes for burst, transmit and receive package
  - FIFO usable as flow controller
- Advanced interrupt handling:
  - 4 data transfer interrupts (burst, last burst, single, last single)
  - Protocol interrupt with 7 sources (address match, general call, master code, arbitration lost, not-acknowledge received, transmission end, receive mode)
  - Error interrupt with 4 sources (FIFO transmit/receive overflow/underflow)

[3] I2C-bus specification version 2.1 standard (released January-2000
http://www.nxp.com/acrobat_download2/literature/9398/39340011.pdf

30.2 I2C Module Functional Specification

This specification is fully compatible with the I2C-bus specification version 2.1 **[3]**.

30.2.1 I2C Protocol

Data is transmitted bit-by-bit on line SDA in conjunction with the clock on line SCL. To start communication, a master device generates a so called start condition. Subsequently data transfer starts. Therefore the data on the SDA line must be stable during the high period of the clock and may only change during SCL low phase. After all data have been transferred, the master closes transmission with a stop condition (see **Figure 30-2**).

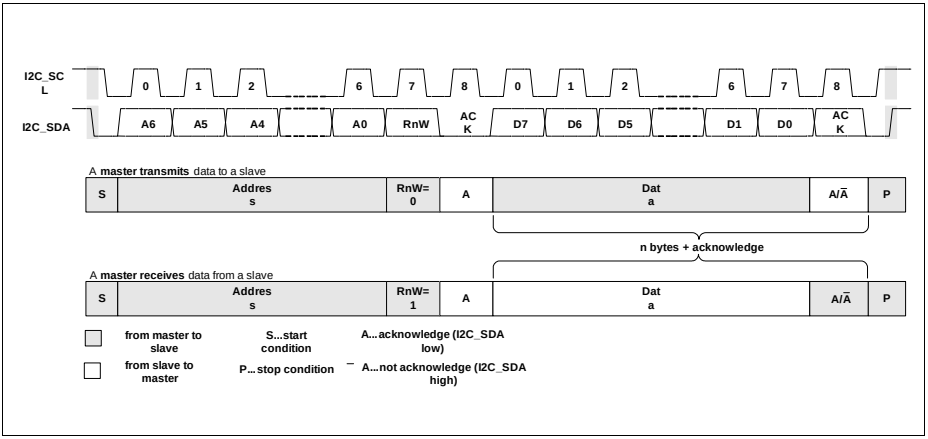

Figure 30-2 A Complete I2C Data Transfer

Start, Restart and Stop Conditions

A start condition is indicated by a high to low transition on line SDA while SCL remains high, a stop condition is defined by low to high transition under the same condition of high level on line SCL. The bus is considered to be busy after a start condition and to be free again after a stop condition. To allow continuous data transmission or reception without first generating a stop condition, a third condition has been introduced - the restart condition. The bus stays busy if this condition is generated and the same or another slave can be addressed. Start and restart condition are functionally identical.

Address Transmission

After the start condition a slave address is sent. Normally the address is 7 bits long followed by an 8th bit that is a data direction bit (Read/not Write see **Figure 30-3**). A zero indicates a transmission (write operation); a one indicates a request to data (read

operation). Following the address transmission the addressed device responds with an acknowledge (low on line SDA). If no acknowledge is returned, the master can then generate either a stop condition to abort the transfer or a repeated start condition to start another new transfer.

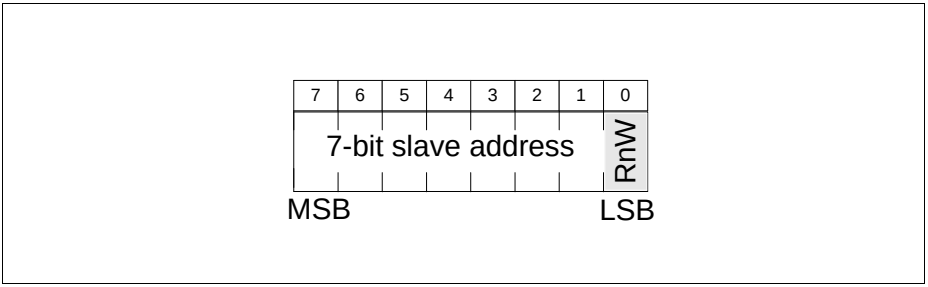

Figure 30-3 Address Byte Composition

Two groups of eight addresses are reserved for purposes, as shown in **Table 30-1**. For example the bit combination “11110XX” is reserved for 10-bit addressing mode.

Table 30-1 Reserved I2C-bus Addresses

Address	RnW	Description
0000000	0	General call address
0000000	1	Start byte - no device is allowed to acknowledge
0000001	x	CBUS address - I2C-bus devices may not respond
0000010	x	Reserved for different bus format
0000011	x	Reserved for future use
00001XX	x	High-speed mode master code
11111XX	x	Reserved for future use
11110XX	x	10-bit slave addressing mode

General Call

A general call is characterized by transmission of address “0000000” and RnW bit = 0. It is used for addressing every device connected to the I2C-bus. However, if a device doesn’t need any of the data supplied within the general call structure, it can ignore this address by not issuing an acknowledgement. Otherwise it acknowledges this general call and the following data bytes (if required) and behaves like a slave-receiver. The received data (e.g. programmable part of slave address, address of I2C-bus master) has to be handled by software. For further information the reader is referred to the I2C-bus specification version 2.1 **[3]**.

Data Transmission

Each byte transferred over the I2C-bus has to be 8 bits long whereby the number of bytes transmitted per transfer is unrestricted. Bytes are transferred MSB (Most Significant Bit) first. If the slave cannot receive or transmit a data byte until it has performed another function, it can hold the clock line SCL low (wired AND connection) to force the master into a wait state. Data transfer continues when the slave releases the clock line.

Acknowledge

Each transferred respectively received byte has to be followed by an acknowledge bit that is set by the recipient (master or slave depending on the transmission direction) onto the data line SDA. The acknowledge-related clock pulse is generated by the master. The device that has to set the acknowledge bit must pull down the SDA line during the acknowledge clock pulse so that it remains stable low during the high period of this clock pulse. Therefore in case of a slave the clock line may be held low until an acknowledge is released.

When the recipient of data doesn't acknowledge the data, for example because it was unable to receive the data or to transmit any data, the data line must be left high. A master-receiver that does not acknowledge the data from a transmitting slave device thereby tells the slave to stop transmission. The master then generates a stop condition to abort transfer or a repeated start condition to continue.

Clock Synchronization

To transfer messages a master generates its own clock on the SCL line. Data is only valid during the high period of the clock. Therefore data on line SDA has to be stable during this period and may only be changed during the low period of clock.

Two special cases must be considered. First, slave devices (or master devices operating as slaves) never generate clocks but are permitted to delay them. According to **Figure 30-4**, if device 1 as master device for example sets line SCL to low, device 2 as slave device may extend the low phase by setting its SCL output to low. A device such as a microcontroller with limited hardware for the I2C-bus can thereby slow down the bus clock and adapt the master to the internal operating rate of this device.

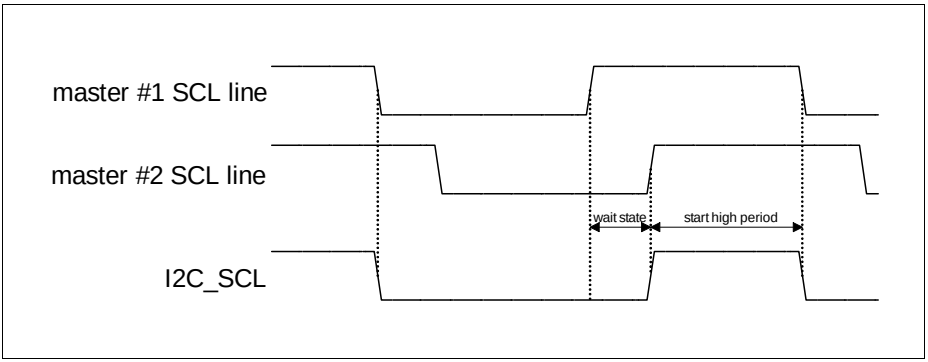

Figure 30-4 Clock Synchronization

Second, if several master devices access the I2C-bus at the same time, the SCL line is influenced by more than one device. As shown in the previous example, the SCL line will be held low by the device with the longest SCL low period. Devices with shorter periods enter a wait state during this time. In this way a synchronized SCL clock is generated.

Arbitration

To allow multi-master mode operation, bus arbitration is required. A master may start a transfer only if the bus is free. Two or more masters may generate a defined start condition simultaneously within a minimum hold time.

Arbitration takes place on the SDA line while SCL line is high, when one master transmits a high level while another master transmits a low level. Because of the wired AND functionality, the low level dominates the high level. As result the device that was trying to transmit a high level recognizes a different level on the SDA line and switches off its SDA and SCL output (see **Figure 30-5**).

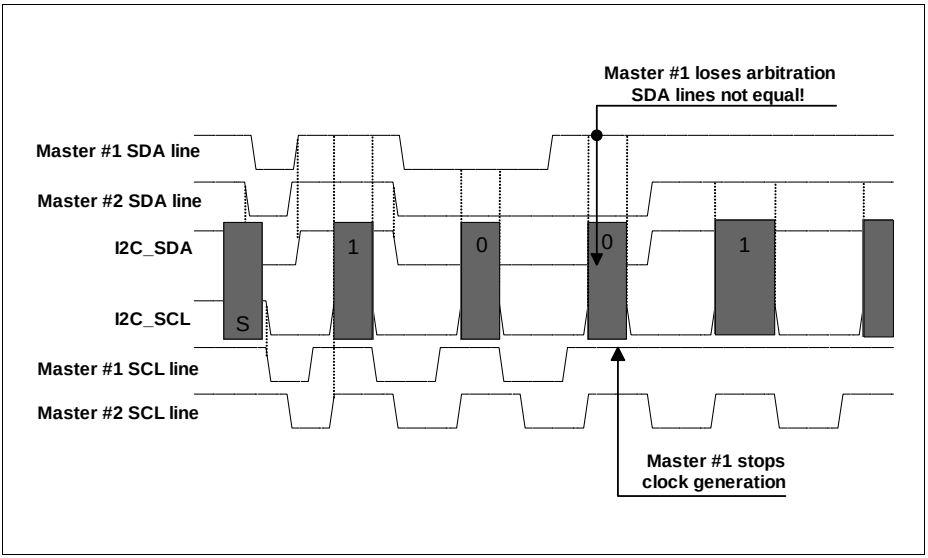

Figure 30-5 Example of an Arbitration Procedure

Arbitration may occur in different stages of transmission. A different level may potentially first appear during comparison of the address bits. If the masters are each trying to address the same device, arbitration continues with comparison of the RnW bit and subsequent data bits (if the masters are transmitting) or acknowledge bits (if the masters are receiving). Because information on the I2C-bus is determined by the winning master, no information is lost during the arbitration process. Since control of the I2C-bus is decided only by comparison of the data transmission stream over line SDA, there is no central master or any order of priority on the bus.

I2C-bus Formats

With the described rule types the formats shown in **Figure 30-6** are possible.

- Master-transmitter transmits to slave-receiver and stops after not-acknowledge.
- Master reads slave immediately after transmission of the RnW bit (high level) and the acknowledge from the slave, whereas the master becomes master-receiver and the slave becomes slave-transmitter.
- In combined format the just described regular sequences are handled, except for the repeated start condition instead of the stop condition between two sequences.

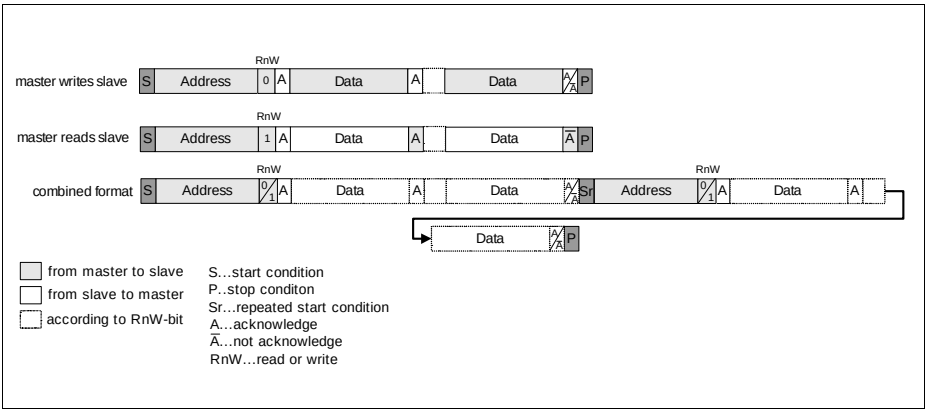

Figure 30-6 Types of I2C-bus Formats

10-bit Addressing Mode

The I2C address area is restricted to 112 applicable addresses with the 7-bit address mechanism described above. It turned out, that more combinations were required to prevent problems with the allocation of slave addresses for new devices. This problem was resolved with the 10-bit addressing scheme that is compatible with 7-bit addressing. Both modes may be used simultaneously. The following formats are possible:

To use 10 bits for addressing, the preamble address “11110XX” with RnW bit = 0 has to be used, including the two most significant bits “XX” of the 10-bit address, followed by an acknowledge from at least one 10-bit address matching slave and the second address byte containing the eight least significant bits. Only the (combined) 10-bit address matching slave now acknowledges. Data packages may now be transmitted to the addressed slave until stop condition or restart condition. If the master needs to read the slave, a combined format with a restart condition is necessary to

- First transmit the 10-bit address (first data package after preamble address contains 2nd address byte, RnW bit is 0) and (after the restart condition)
- Receive the requested data packages. Note that after the restart condition the preamble address “11110XX” has to be sent one more time, now with RnW bit = 1; the matching slave remembers that it was addressed before (see **Figure 30-7**). In case of a non matching preamble address, a not-acknowledge is returned.

The slave remains active as slave-transceiver until a stop condition or a restart condition occurs. According to the value of the following RnW bit a new slave may be addressed or the same slave is requested to transmit more data. Additionally the following combined formats (and mixtures of these formats) are allowed (**Figure 30-7**):

- A master transmits data to a slave and then reads back data from the same slave. The transfer direction is changed after the restart condition.

- A master transmits data to one slave and then transmits data to another slave.
- 10-bit and 7-bit addressing combined in one serial transfer. After restart condition the new addressing mode is selected by the address itself.

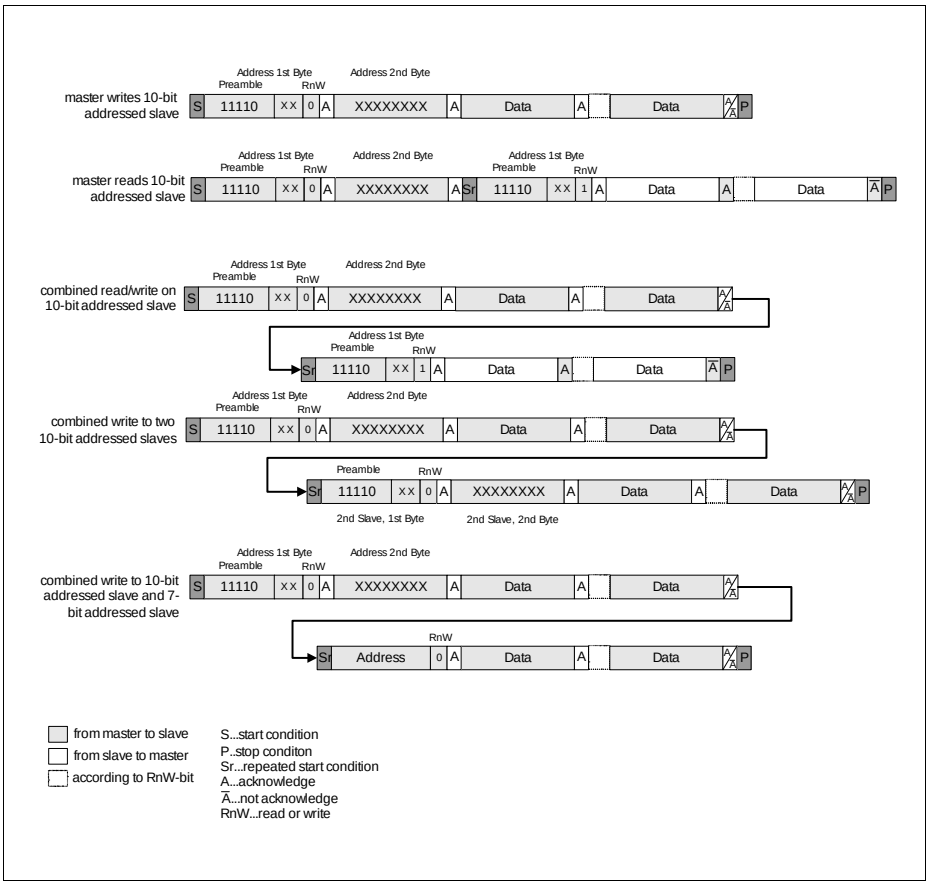

Figure 30-7 Types of I2C-bus 10-bit Address Formats

High-speed Mode

To support higher baud rates on the I2C-bus (up to 3.4 MBaud) the specification introduces the high-speed mode. To communicate at this higher baud rate the protocol uses a so called master code in place of the address byte to indicate that a master wants to change to the high-speed mode.

Special attention must be paid to meet the requirements of rise and fall times of the signal edges and other timing characteristics when working in high-speed mode. Also it is necessary to disconnect I2C-bus devices which are not able to follow the fast communication.

After the master sends this master code, no device is allowed to acknowledge it. The involved devices change to high-speed mode and the master starts the communication. The high-speed mode transmission behavior is the same as at lower baud rates with the exception that only restart conditions and stop conditions appear (no start condition). Since the master code determines a unique master device to control the bus, the arbitration process is finished after the master code sequence is put on the bus and must not be continued when working at the new communication speed.

Improvements to the regular I2C-bus specification for high-speed mode are given in section 13.1 of the I2C-bus specification version 2.1 **[3]**.

For high-speed mode there exists a separate configuration register **FDIVHIGHCFG** to program the baud rate; see also **Baudrate Generation**.

30.2.2 Clock and Timing Control

The I2C module offers the following features to control clock and timing:

- Module clock control for integration logic clock and I2C kernel clock (see **Section 30.4.2**)
- Baud rate generation
- I2C signal timing adjustment

30.2.2.1 Baudrate Generation

A baudrate generation unit in the I2C kernel generates the SCL signal from the kernel_clk, controlled by settings of parameters INC, DEC, and FS_SCL_LOW in registers **FDIVCFG** (normal and fast mode), **FDIVHIGHCFG** (high speed mode), and **TIMCFG**.

The I2C standard has some special requirements for the clock, like

- asymmetric duty cycle
- slave or other masters can delay the clock by extending the low period

Therefore, the mechanism of baudrate generation is not quite simple, and needs some explanation, as given hereafter. Please refer also to **Figure 30-8**.

The baudrate generator produces a clock output SCL_OUT, and also uses the feedback clock SCL_IN from the pad. SCL_IN is delayed with respect to SCL_OUT by the chip internal delays, to for SCL_OUT and ti for SCL_IN, and by the pad rise and fall time. The pad times depend on the pad design, and on the external load and the pullup resistor. Also, the pad times may be different for normal/full speed mode and for high speed mode, if a dedicated high speed pad is being used.

SCL is the clock visible on the PCB.

The timing diagram in **Figure 30-8** shows the relations between these 3 clock signals, using nominal low and high times for the clock, as produced internally by the baudrate generator.

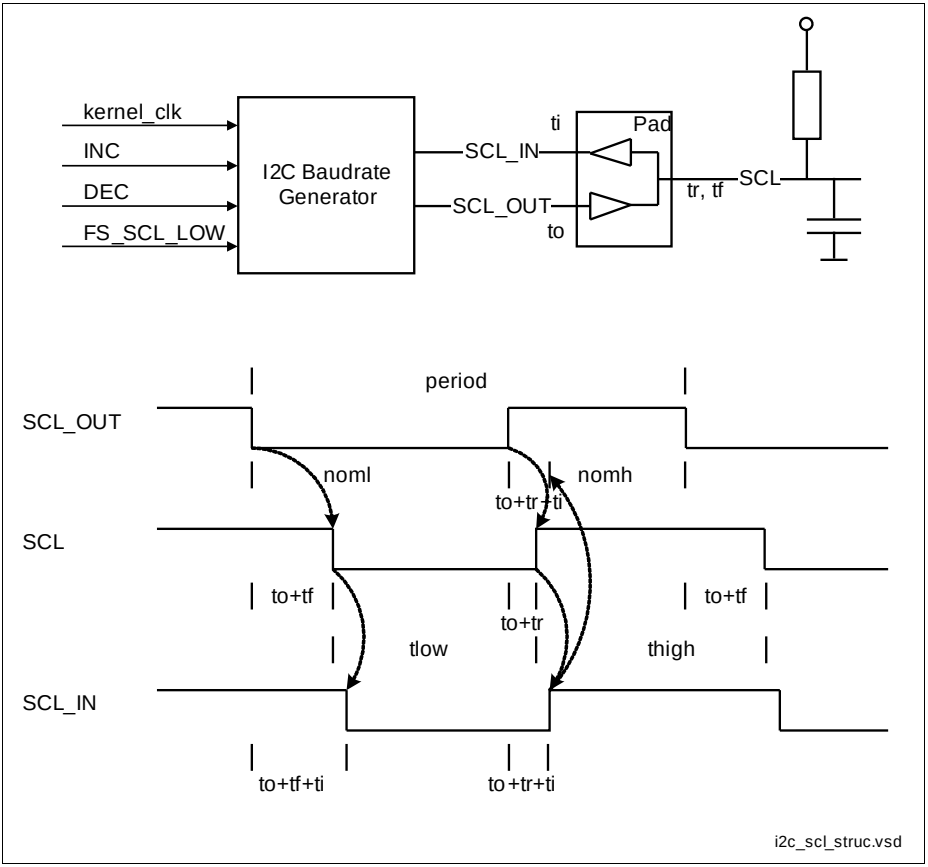

Figure 30-8 SCL Generation

The baudrate generator sets the internal SCL_OUT signal to low for the time noml, with

- Normal and full speed mode:
  – noml = (DEC + LTC) / INC kernel_clk cycles
- High Speed mode:
  – noml = (5*DEC - 3*INC) / INC - 1 kernel_clk cycles when DEC <= 4*INC
  – noml = (4*DEC + INC) / INC - 1 kernel_clk cycles when DEC > 4*INC

Note: The operator div denotes the integer division: a div b = greatest integer not greater than a/b.

Note: These and the following formulas show the mean values over a longer period of time. These may be non-integer multiples of a kernel_clk cycle. The actual value of each clock phase is always an integer multiple of a kernel_clk cycle. It is either the next smaller or the next larger one, compared to the mean value.

When the low time has passed, SCL_OUT is set to high and the baudrate generator waits until the feedback clock SCL_IN goes to high. Next the baudrate generator continues to keep SCL_OUT at high for

- Normal and full speed mode:
  - nomh = (DEC + 3*INC - LTC) / INC kernel_clk cycles
- High Speed mode:
  - nomh = 6 kernel_clk cycles when DEC <= 4*INC
  - nomh = (DEC - 3*INC) / INC + 5 kernel_clk cycles when DEC > 4*INC

Then the next low phase starts.

The Low Time Correction term LTC for normal and fullspeed mode is

- LTC = SCL_LOW_LEN when EN_SCL_LOW_LEN = 1
- LTC = DEC div 4 when EN_SCL_LOW_LEN = 0 and FS_SCL_LOW = 1
- LTC = DEC div 8 when EN_SCL_LOW_LEN = 0 and FS_SCL_LOW = 0

In full speed mode, EN_SCL_LOW_LEN should be set to 1 or FS_SCL_LOW should be set to 1 in order to meet the high requirement for the SCL low time in this mode.

SCL_LOW_LEN must not be greater than DEC, when enabled via EN_SCL_LOW_LEN is set to 1.

SCL_LOW_LEN and EN_SCL_LOW_LEN are set in register **TIMCFG**.

This ends up in a period

- Normal and full speed mode:
  - period = (2*DEC + 3*INC) / INC kernel_clk cycles + to + tr + ti
- High Speed mode:
  - period = (5*DEC - 3*INC) / INC + 5 kernel_clk cycles + to + tr + ti when DEC <= 4*INC
  - period = (5*DEC - 2*INC) / INC + 4kernel_clk cycles + to + tr + ti when DEC > 4*INC

The mechanism to enlarge the SCL_OUT high time by the time needed until the external clock has safely reached the high value ensures, that external slaves or masters can delay the clock, as requested by the standard. As a side effect, it introduces also a frequency reduction even if no external device keeps SCL at low level. This reduction is affected by process/voltage/temparature (PVT) variations on chip, and by the external load and pullup resistor.

Therefore, a perfect formula for the baudrate cannot be given. The best settings of INC and DEC for a given system should be found by measurements, taking as a start value the above formula for period with a rough estimate for to + tr + ti. It has to be accepted, that there is some PVT variation.

Note: In normal and full speed mode, the actual low and high times tlow and thigh of the the external clock SCL are significantly influenced by tf and tr. The fall time of the pad is strongly depending on the pad driver characteristic. The rise time is mostly affected by the external circuitry.
In high speed mode, this impact is less critical, due to high speed pad characteristics.

30.2.2.2 I2C Signal Timing Adjustment

The I2C standard includes a number of requirements for the SCL and the SDA timing. These cannot always be fulfilled by the timing of the pads. Therefore, additional timing adjustment options are provided in the controller logic.

Some signal timings can be shifted by multiples of kernel_clk cycles, as defined in register **TIMCFG**.

The proper settings have to be determined during chip evaluation.

30.2.3 I2C Kernel Control Logic

The I2C kernel can work in four different modes:

- Master-transmitter
- Master-receiver
- Slave-transmitter
- Slave-receiver

A state machine description can give a good and fast overview of the functionality. Also nearly all possible conditions can be rebuilt by stepping through the state machine and most of the error handling is covered by it. So this method is used to describe the I2C kernel.

Beginning with the top-level state machine, the starting up procedure is covered and together with the slave process and the master process sub-state machines, the active operations are comprehensible. These three state machines and their state transitions are described in the following.

As the I2C-bus working principle is packet orientated, the FIFO is typically configured as flow controller and so it issues the burst- and single-requests. This configuration is established by programming the bits RXFC and TXFC of the **FIFOCFG** register. Writing to the TPS bit-field of the **TPSCTRL** register starts the transfer.

Note: In principle it is possible to use the FIFO in non flow controller mode. When the FIFO is not configured to operate as flow controller, the behavior of the FIFO operation has to be considered. The update of the FIFO fill level is only done when a stage is filled completely. In case of a (not protocol compliant) stopped transfer of the transmitter, the device is not able to evaluate the valid bytes since the FIFO issues interrupts/updates fill level only when a stage is filled completely. To prevent this behavior, the FIFO can be, for example, programmed to word alignment, so every received byte issues an interrupt/update. Anyway the software has to take care of such upcoming not protocol compliant data transmission stops, and has to handle this for example by programming an appropriate time-out.

The Top-level State Machine

Figure 30-9 shows the top-level state machine. There are four states in the top-level state machine:

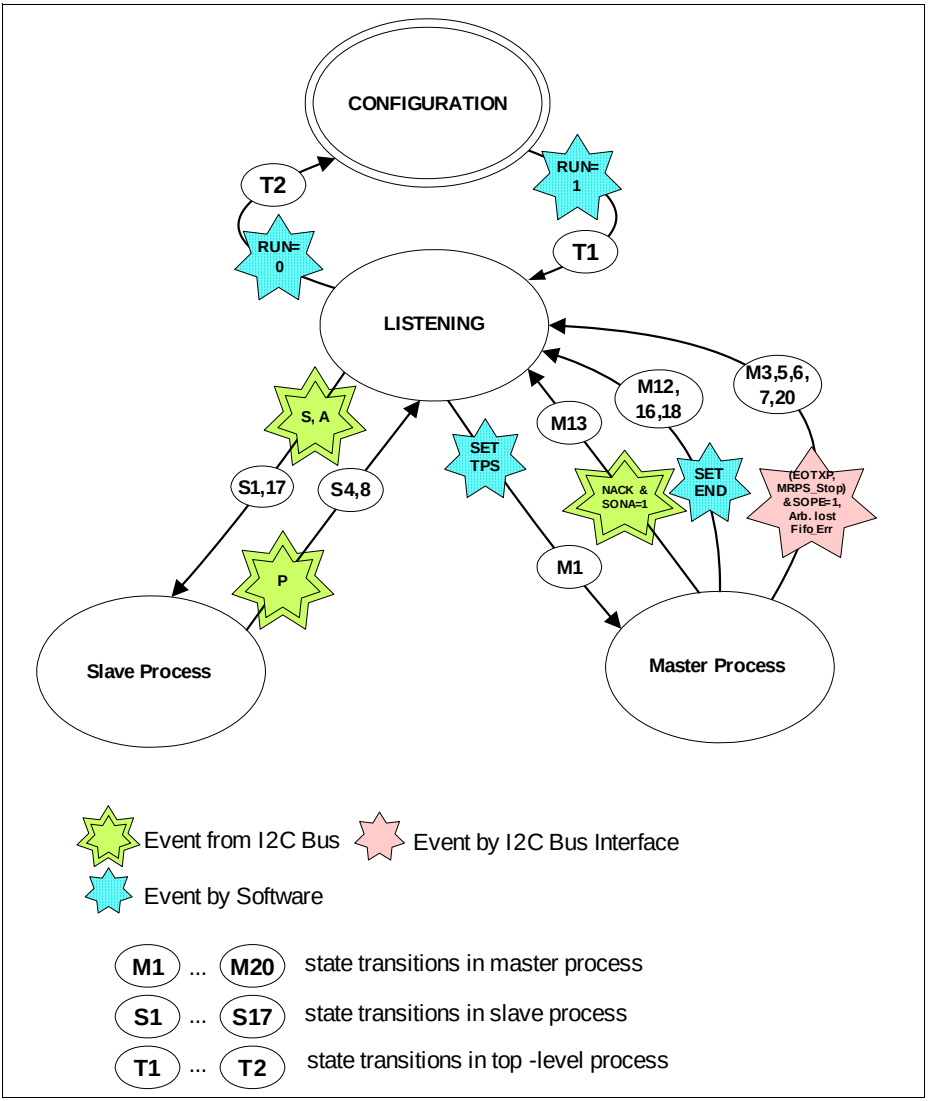

Figure 30-9 Top-level State Machine

CONFIGURATION: The peripheral is inactive; this is indicated by the RUN bit in **RUNCTRL** register, which is set to 0. In this state the peripheral should be configured by software by writing appropriate data words to the **ADDRCFG**, **FDIVCFG**, **FDIVHIGHCFG** and **FIFOCFG** registers. This determines the following features:

- Peripheral is master or slave
- Address when accessed by another device
- Answering behavior to master calls and general calls
- Operating speed on the I2C-bus
- FIFO behavior

LISTENING: The peripheral has been activated by software. This state is entered in master and slave mode. The peripheral has to observe the bus for a certain time[1)] to ensure that there is no running transmission on the bus after this state has been entered. If no transitions on the I2C-bus are detected during this time period, the bus is supposed to be free. Otherwise the bit-field BS (bus status) in register **BUSSTAT** is set to 01_B (bus busy). Further functionality depends on the configuration: If the peripheral is a slave, only the slave process can be entered. If the device works as master, slave and master processes can be entered.

SLAVE PROCESS: A Start condition has been detected. The device is waiting for commands from the I2C-bus. This state represents the operation when acting as slave-transmitter or slave-receiver and is itemized in an own sub state machine.

MASTER PROCESS: The device is able to control the bus and work either as master-receiver or master-transmitter. Before the master can control the bus it has to set its clock frequency by programming its fractional divider with the appropriate value by writing it to the **FDIVCFG** register (when the I2C-bus is also operating in high-speed mode the appropriate values for INC and DEC have to be written to **FDIVHIGHCFG**). The master process state is itemized in an own sub state machine.

The transition between the three states on the top-level are:

T1. The RUN bit has been set to 1 by software. The peripheral is activated and ready to observe the I2C-bus or react on transmission start commands.

T2. The RUN bit has been set to 0 again. I.e., because of new configuration effort, the peripheral is switched back to CONFIGURATION mode.

IMPORTANT: When “turning off” the peripheral it must be assured that no I2C-bus control responsibility is owned by the interface! Therefore the shut off process has to change the peripheral into a “secure” state and free the I2C-bus if necessary (generate a stop condition if in master mode). There are signals provided by the interface block which can be used to guarantee a secure shut off when turning off the I2C kernel.

1) One period of 1/100 kHz should be sufficient.

Slave Process Sub-state Machine

Figure 30-10 shows the slave process sub-state machine. There are 5 plus 1 (the listening state belongs to master and slave) different states in this sub-state machine:

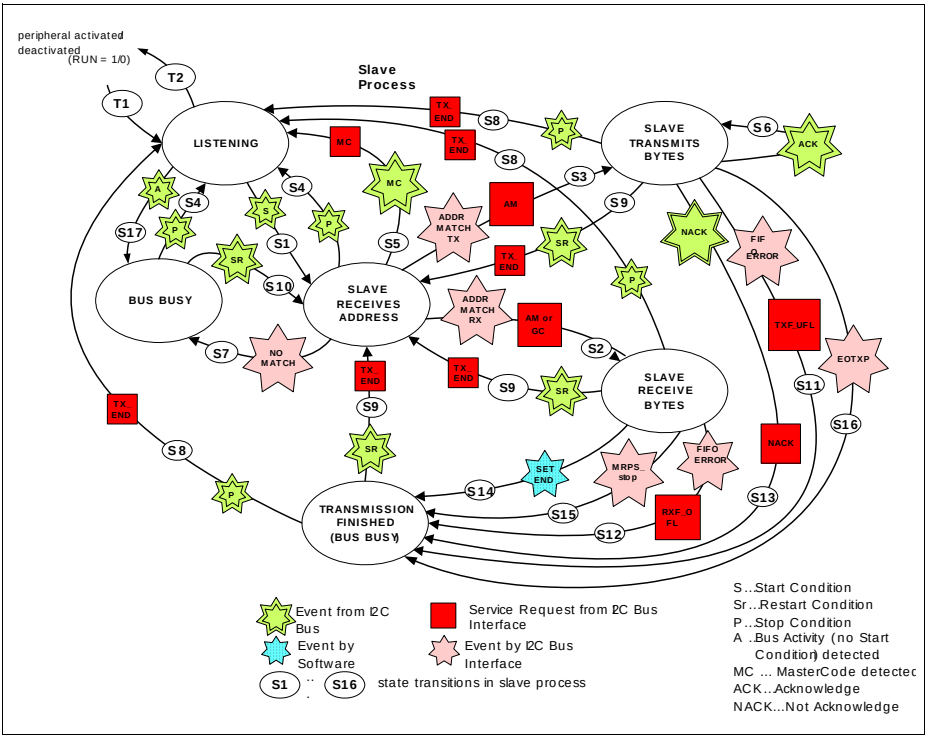

Figure 30-10 Slave Process Sub-state Machine

LISTENING: This state has been previously described (**Figure 30-9**). If the device is configured as slave, the module is listening only to the bus activity.

SLAVE RECEIVES ADDRESS: The module is shifting in the serial bits from the I2C-bus and acknowledges if the received byte(s) (first one in 7-bit address mode, first and second one in 10 bit address mode) match the adjusted address. During address matching the slave-receiver has the possibility to slow down the master clock by holding the SCL line low after each bit, since this can be used as a bit-by-bit handshake procedure.

Note: The address byte(s) is (are) not shifted into the FIFO.

SLAVE RECEIVES BYTES: The module is shifting in the serial bits from the I2C-bus and acknowledges when the whole data byte has been transported to the FIFO. The

slave-receiver has the possibility to slow down the master clock by holding the SCL line low after each bit since this can be used as a bit-by-bit handshake procedure.

SLAVE TRANSMITS BYTES: The slave is allowed to hold down the SCL line when preparing the data for transmission. When valid data is available the slave releases the SCL line and waits for the clock cycles from the master. The interrupt routine which proceeds when entering this state may write to the **TPSCTRL** register to initiate a transmission. This is only allowed if the bit-field BS (bus status) in register **BUSSTAT** in combination with the RnW clearly identifies the slave-transmitter mode of the peripheral. Otherwise writing to this register has no effect. First the I2C kernel gets a byte from the FIFO and puts it into a shift register. The module is then putting single data bits onto the I2C-bus and releases the SDA line after the 8th bit is sent.

*Note: Since the data flow control responsibility is task of the master device the slave should not stop transmitting bytes until the master tells it to do so. Therefore the TPS value in register **TPSCTRL** should be large enough to not run out of data bytes. In case of running out of data, the TRANSMISSION FINISHED state is reentered. The I2C data line is released to high level. The master continues receiving wrong values (0xFF).*

BUS BUSY: The bus is busy and the module is not involved in any data transfer. This is also the entry state when the bus is not free when starting up procedure is taking place (see state S17).

TRANSMISSION FINISHED (BUS BUSY): The module was involved in any data transfer. In distinction to the BUS BUSY state, the slave is still addressed by a master. Every time this state is left, caused due to a stop/restart condition, a TX_END request is generated as indication that the previous transmission has been closed.

The transitions which are connecting the several states are in detail:

S1: The module is detecting a start condition on the bus. It has to set the bit-field BS (bus status) in register **BUSSTAT** to 01_B. When this situation is occurring the I2C kernel is initialized since this indicates a new data transmission.

S2: The address which has been received matches the one stored in the address field in the **ADDRCFG** register. The RnW bit (8th bit in the first received byte) was set to 0. This means that the master wants to write to the slave. The corresponding bit RnW in register **BUSSTAT** is set to 1, i.e. the device continues working as slave-receiver. Also an acknowledge has to be set on the I2C-bus in the appropriate place (9th clock cycle). The I2C kernel sets the bit-field BS (bus status) in register **BUSSTAT** to 11_B and generates an AM (address match) request.

If the general call (GC) address matching is enabled by setting bit GCE in the **ADDRCFG** register, the device has to react also when it receives a general call (0x00). The GC request is issued and also an acknowledge has to be set on the I2C-bus when the GC is detected.

S3: The address which has been received matches the one stored in the address field in the **ADDRCFG** register and the SDA line was at a high level when the RnW bit was sent. This means that the remote master wants to read from the slave. The corresponding bit RnW in the **BUSSTAT** register has to be set to 0 (write). Also an acknowledge has to be set on the I2C-bus in the appropriate place (9th clock cycle). The I2C kernel sets the bit-field BS (bus status) in register **BUSSTAT** to 11_B and generates an AM (address match) request. The device is now working as a slave-transmitter.

S4: The device detects a stop condition on the I2C-bus and switches back to SLAVE LISTENING state. No interrupt is generated after the device was not addressed. The bit-field BS (bus status) in register **BUSSTAT** is set to 00_B (bus free).

S5: If the device is configured via bit MCE (master code enable) in the **ADDRCFG** register to react on a master code, the device can change baud rate to high-speed (Hs) mode when a remote master sends a master code. No device is allowed to acknowledge this master call. The interrupt routine which is called (MC request issued), has to handle the clearing of the interrupt bit in register **PIRQSC**. The LISTENING state is reentered. From now on the device works as slave in high-speed mode until a stop condition occurs.

S6: The slave-transmitter has received an acknowledge from the master-receiver and continues transmission.

S7: After the reception of the address bytes has been finished and no address match has taken place, the device changes to BUS BUSY state.

S8: The device has detected a stop condition on the I2C-bus after/while it was addressed. A TX_END (transmission end) request is generated, the bus is free again respectively the bit-field BS (bus status) in register **BUSSTAT** has to be set to 00_B again. The slave is now in LISTENING state.

S9: The slave has received a restart condition (repeated start condition) after/while it was addressed. A TX_END (transmission end) request is generated, the state switches back to SLAVE RECEIVES ADDRESS. The slave is reset again to a new transmission pending state (bit-field BS in register **BUSSTAT** = 01_B.). When the TBAM is activated (configuration register) the slave has to remember that it was addressed before because this event may be followed by a read access of the master to this device. So the address procedure after reset can be shortened and the transition S3 occurs one byte earlier (master sends 10-bit address mode byte with RnW bit = 1 (read)).

S10: A running transmission is ended by a remote master and this device wants to continue without losing control of the I2C-bus. The slave was not in transmission and resets to receive address bytes again since the new data transmission is concerning all connected slaves.

S11: The peripheral has problems to read data bytes from the FIFO (underflow/not ready). This is indicated by generating a TXF_UFL (TX FIFO underflow) request. It also changes to TRANSMISSION FINISHED state.

*Note: The device is still addressed by a master (bit-field BS in register **BUSSTAT** = 11_B.) until a stop or restart condition occurs.*

S12: The peripheral has problems to write the received byte into the FIFO (overflow/not ready). This is indicated by generating a RXF_OFL (RX FIFO overflow) request. The slave-transmitter puts a not-acknowledge on the I2C-bus to indicate its situation to the controlling master. This byte is not valid and will be discarded.

*Note: The device is still addressed by a master (bit-field BS in register **BUSSTAT** = 11_B.) until a stop or restart condition occurs.*

S13: The remote master wishes to close the connection to this slave and sets a not-acknowledge on the I2C-bus. The device generates a NACK (not-acknowledge) request and changes to TRANSMISSION FINISHED state (bit-field BS in register **BUSSTAT** = 01_B.). The interrupt routine can clear the appropriate bit via the corresponding bit in the **PIRQSC** register.

S14: The slave wants to stop the transmission and sets the SETEND bit in register **ENDDCTRL**. It puts a not-acknowledge on the I2C-bus after the next received byte. With this the slave gets the possibility to cancel the transmission via software intervention.

S15: The value of received bytes is equal to bit-field MRPS (maximum receive packet size) of the FIFO register **MRPSCTRL**. The FIFO part of the interface generates the signal MRPS_stop to the I2C kernel, which indicates the end of the received packet capacity. The slave produces a not-acknowledge to the master and changes to TRANSMISSION FINISHED. For more details on FIFO MRPS operation see **Section 30.2.4.5**.

S16: The number of transmitted bytes is equal to the TPS bit-field of the FIFO register **TPSCTRL**. The FIFO controller generates the EOTXP (end of transmit packet) signal to the I2C kernel, which indicates the last byte to transmit. After the last byte the device changes to TRANSMISSION FINISHED. For more details on FIFO EOTXP operation see **Section 30.2.4.2**.

Note: The master is not informed about this situation. Since the data flow control responsibility is task of the master device, it may continue receiving wrong values (0xFF).

S17: The module detects bus activity; no start condition has been detected before. A transmission may be currently in progress. The device changes to BUS BUSY state. This transition is performed if a start condition has been missed because the device was not activated (CONFIGURATION state).

Master Process Sub-state Machine

Figure 30-11 shows the master process sub-state machine. There are four different states in this sub-state machine:

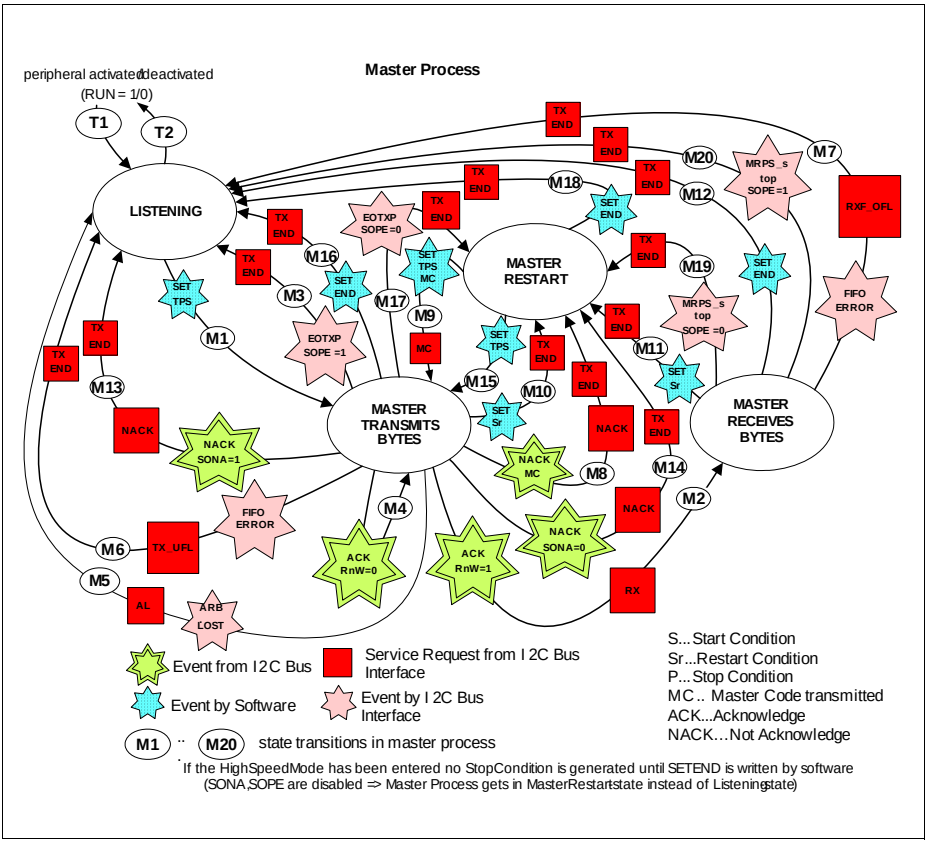

Figure 30-11 Master Process Sub-state machine

LISTENING: This state has been previously described (**Figure 30-9**). If the device is configured as master, it is listening to events either from software (writing to **TPSCTRL** register) or from the I2C-bus.

MASTER TRANSMITS BYTES: The device has started a transmission on the I2C-bus by software. The first byte after a start condition contains the address byte including the RnW bit. According to this bit (RnW bit in **BUSSTAT** register is set by hardware) the direction of the following transfer is determined. Bytes are transmitted on the I2C-bus until the FIFO is empty or a stop is initiated by software.

If bit MCE (master code enable) is set in the **ADDRCFG** register, the device has to check if the transmitted address byte is a master code.

MASTER RESTART: The device wants to restart a transmission without losing the control over the I2C-bus. The clock SCL stays low as long as no further communication is requested. The only event that should occur in this state is writing to the **TPSCTRL** register. Nevertheless the device can give up the I2C-bus control by writing to bit SETEND in the **ENDDCTRL** register. Of course, when this situation occurs, the peripheral produces a stop condition on the I2C-bus.

If bit MCE (master code enable) is set in the **ADDRCFG** register, the device has to check if the transmitted address byte is a master code.

MASTER RECEIVES BYTES: The master has ordered bytes from the slave and handles the data transfer from the I2C-bus to the FIFO. This means that the bits are shifted into a buffer register in the I2C kernel and afterwards are passed to the FIFO. Every time a byte was transferred to the FIFO successfully the master-receiver produces an acknowledge in the according position.

The state transitions in the master process are:

M1: The software has written the number of bytes which have to be transmitted over the I2C-bus into the control register **TPSCTRL**. The FIFO generates appropriate data transfer requests which transfers valid data into the FIFO. A start condition is set on the bus and the bit-field BS (bus status) in register **BUSSTAT** is set to 10_B (busy master). The first (the first and the second) byte is (are) the 7-bit (10-bit) address of the slave which shall be accessed.

If the master wishes to initiate a transition to high-speed mode, the transition is only valid in combination with the MCE (master code enable) bit in the **ADDRCFG** register. The software has to write the master code into the FIFO, this means also the value of the **TPSCTRL** is predetermined with 1.

M2: The master receives an acknowledge from slave and the bit RnW in the **BUSSTAT** register was set to 1 during the addressing phase. A slave has been addressed successfully as transmitter, the state moves to MASTER RECEIVES BYTES. An RX (Receive) request is generated to distinguish between transmit- and receive-FIFO requests in non flow controller mode.

M3: The valid data packet from the FIFO was transferred successfully to the I2C-bus and the FIFO indicates this by the EOTXP (end of transmit packet) signal. If the RnW bit was set to 0 (writing to a slave) and bit SOPE (stop on packet end) in register **ADDRCFG** was set to 1, the transfer is closed by putting a stop condition on the bus. After this stop condition has been detected the peripheral indicates this successful transfer to the software via the TX_END (transmission end) request. The bus status bit-field is set to 0x0 (bus free).

M4: After the master transmits a byte it releases the SDA line to allow the addressed slave to pull down the SDA line (acknowledge). If this event occurs (and RnW in register **BUSSTAT** was set to 0), the master can continue to transfer bytes on the I2C-bus.

M5: The SDA line level is not equal to the one that is set by the master. This means that another master also tries to control the I2C-bus. This is indicated by the AL (arbitration lost) request and the device switches to the LISTENING state. The interrupt routine has to clear bit AL in the **PIRQSC** register. The Arbitration lost indication is not executable when the device works in high-speed mode (no arbitration procedure in high-speed mode since there is only one master remaining). The arbitration process must be operating at each bit which is sent by the master! Before interrupting the CPU, the bit-field BS (bus status) in register **BUSSTAT** is set to 01_B.

Note: It could be the case that the other master tried to address this device at the same time. Since this device could not check the transmitted address bytes till arbitration lost, no acknowledge is generated. The other master has to address this device once more.

M6: If the master wants to transmit bytes but the FIFO is empty (underflow), it has to generate a TXF_UFL (TX FIFO underflow) request. The bit-field BS (bus status) in register **BUSSTAT** is reset to 00_B, and a TX_END (transmission end) request is generated after the master has put a stop condition on the bus.

M7: The I2C kernel wants to transfer bytes to the FIFO but without success. Then it has to produce an RXF_OFL (RX FIFO overflow) request. The current byte is not-acknowledged and a stop condition is put on the bus (bit-field BS in register **BUSSTAT** is set to 00_B and a TX_END (transmission end) request is generated). (

M8: If master code has been transmitted by the device and a NACK (not-acknowledge) has been received, the MASTER RESTART state is entered. The clock SCL stays low as long as no further communication is requested. This is done by writing bit-field TPS in register **TPSCTRL** (see transition M9).

M9: A new communication in high-speed mode is started by writing bit-field TPS in register **TPSCTRL** when a master code has been previously transmitted (M8). The switch into high-speed mode (MC request) is done as soon as clock and data are released to high (see **Figure 30-12**). State MASTER TRANSMITS BYTES is entered. During high-speed mode, all fast and standard mode devices must be disconnected from the bus. This can be done in the MC request.

M10: Bit SETRSC has been set during the transmission of the data (the software wants to change direction/slave and therefore writes to the **ENDDCTRL** register). The I2C kernel resets and changes to MASTER RESTART state and a TX_END (transmission end) request is generated. Therefore, the master does not lose the control of the I2C-bus after the transmission has ended. The master stops transmission after the current byte was acknowledged/not acknowledged. Valid data in the FIFO are discarded. In this situation the FIFO is flushed to produce an initial situation.

M11: If the master wants to change direction/slave immediately in this state, it has to write to bit SETRSC in the **ENDDCTRL** register. The master puts a not-acknowledge on the appropriate place during the current transmitted byte. This indicates the slave-transmitter to stop transmission. The master switches to MASTER RESTART state; a TX_END (transmission end) request is generated.

M12: By sending a not-acknowledge on the bus, the master indicates the slave an upcoming stop of the transmission. This is established by writing to bit SETEND in register **ENDDCTRL**. This end of transmission is indicated to the FIFO which then transports the remaining valid data to the memory (indicating the data end either by a LSREQ or a LBREQ). Stop condition and TX_END (transmission end) request are generated. The LISTENING state is entered; the bit-field BS (bus status) in register **BUSSTAT** is set to 00_B.

M13: If the master is receiving a not-acknowledge and bit SONA (stop on not-acknowledge) in the **ADDRCFG** register is 1, it produces a stop condition, resets the bit-field BS (bus status) in register **BUSSTAT** and issues a NACK (not-acknowledge) request and a TX_END (transmission end) request. The FIFO is flushed; remaining data in the FIFO stages are discarded.

M14: If bit SONA (stop on not-acknowledge) in the **ADDRCFG** register is 0, the peripheral wants to remain the controlling master of the I2C-bus after receiving a not-acknowledge. The next state is MASTER RESTART. A NACK (not-acknowledge) request and a TX_END (transmission end) request indicate this event to the software. The FIFO transfers the valid data to the memory.

M15: The master decided to transfer data on the bus again and writes to the **TPSCTRL** register. The first byte is interpreted as address byte (the 8th bit indicates RnW). The appropriate data transfer requests are activated by the FIFO controller. After the SCL line is high again (slave can stretch the low period) the master is allowed to put a restart condition onto the bus and is again in the MASTER TRANSMITS BYTES state starting to transmit bytes again.

M16: The software has written the SETEND bit in the **ENDDCTRL** register. The peripheral stops transmission of bytes after the current byte has been written on the bus. The I2C kernel flushes the FIFO since the remaining data in the FIFO is invalid. A TX_END (transmission end) request is generated.

M17: The FIFO indicates the end of the data packet and the peripheral was configured to go into MASTER RESTART state after that event. Since the data transfer has ended as intended a TX_END (transmission end) request is produced.

M18: The master has no data to send anymore but still controls the I2C-bus. Therefore it can use the SETEND bit to give up the I2C-bus control by setting a stop condition. A TX_END (transmission end) request is generated.

M19: A value different to zero is programmed to bit-field MRPS (maximum receive packet size) of the **MRPSCTRL** register. If the number of received bytes is equal to the MRPS bit-field, the FIFO produces the MRPS_stop signal. When bit SOPE (stop on

packet end) in the **ADDRCFG** register is set to 0, the master generates a not-acknowledge and changes to MASTER RESTART state, so the master does not lose the control over the I2C-bus. A TX_END (transmission end) request is generated.

M20: (See also M19.) The FIFO produces the MRPS_stop signal which indicates that the desired amount of received data bytes is reached. The peripheral generates a not-acknowledge and changes to LISTENING state because bit SOPE (stop on packet end) in the **ADDRCFG** register is set to 1. Of course, the interface produces a stop condition; so the I2C-bus is free again (change also the bus status bit-field!). A TX_END (transmission end) request is also generated. The LBREQ or the LSREQ indicate the completed reception of data. For more details on FIFO MRPS operation see **Section 30.2.4.5**.

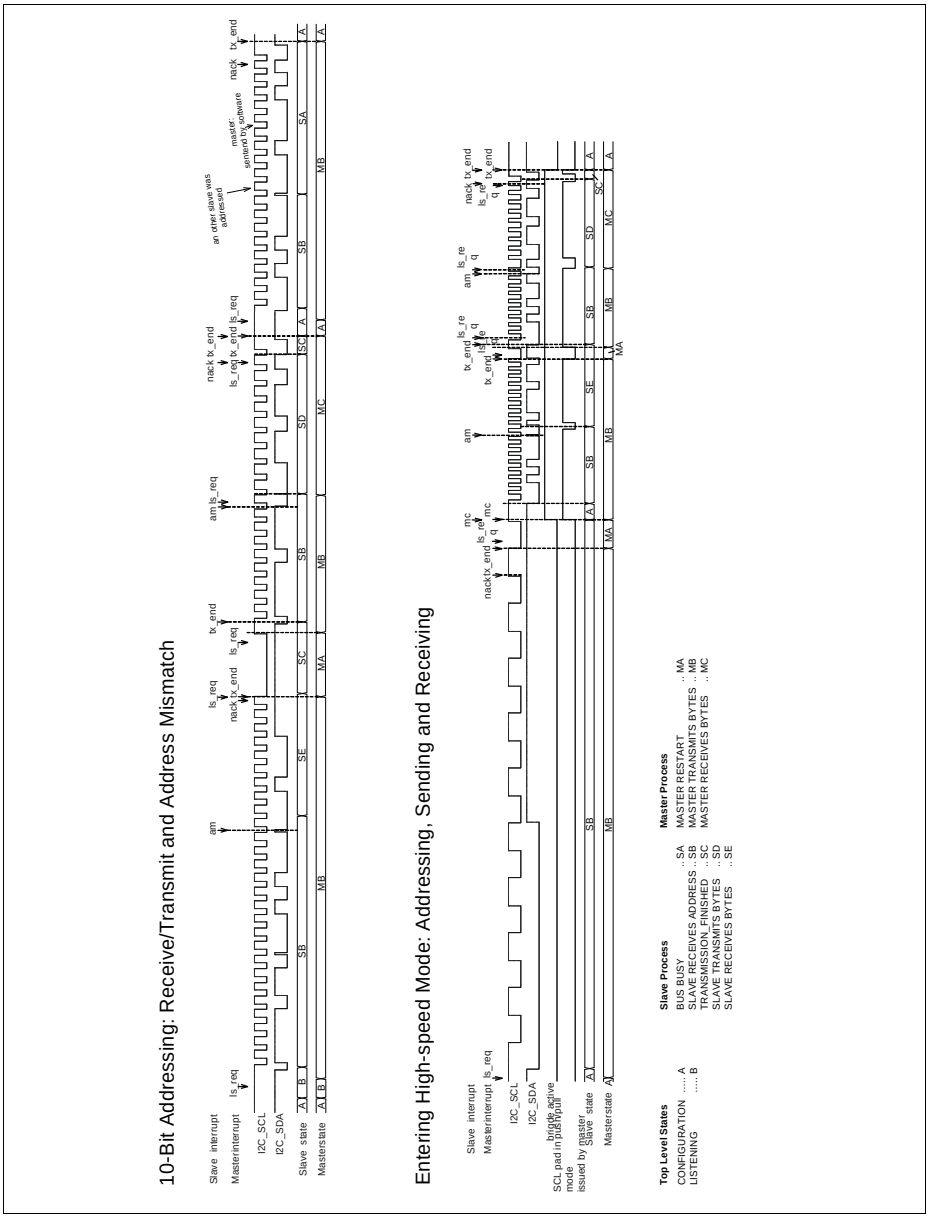

Figure 30-12 Connection Examples including Requests in Master and Slave Mode

30.2.4 FIFO Operation

The I2C module uses a FIFO between its kernel and the bus, in order to adapt the character processing speed of the peripheral to the transfer rate of the bus system. The FIFO has a transmission state and a reception state. **Figure 30-13** shows the bidirectional half duplex TX/RX FIFO unit with the input and output lines and with the corresponding FIFO registers.

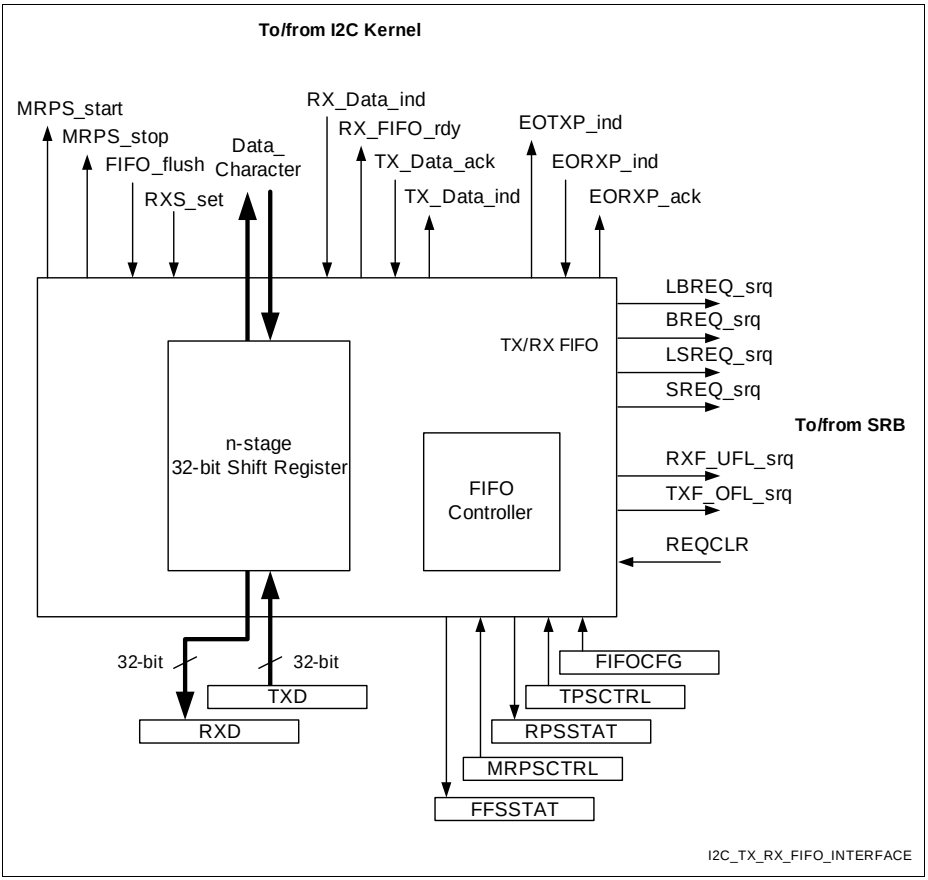

Figure 30-13 Bidirectional Half Duplex TX/RX FIFO

30.2.4.1 Data Transmission

The software can move transmit data to the FIFO by writing to the Transmission Data Register **TXD**. Moving data to the FIFO can be done according to the data transfer request signals generated by the FIFO controller as described in **Section 30.2.4.2**. But with the register **FFSSTAT**, which indicates the number of full FIFO stages, the data transfer to the FIFO can be handled completely without data transfer requests. The data alignment within the FIFO is described in **Section 30.2.4.3**. The FIFO shifts data to the I2C kernel by means of the handshake lines tx_data_ind and tx_data_ack.

With the signal FIFO_flush the I2C kernel is able to clear the FIFO content. But if a data transfer request (see **Section 30.2.4.2**) is pending, then the FIFO is not cleared until the corresponding signal REQCLR has been set by software.

The I2C-bus interface should know when it is receiving the last character of a data packet from the FIFO. Therefore the software should define a transmit packet size in bit-field TPS of register **TPSCTRL** and then the FIFO controller indicates the last character of the packet to the I2C kernel by setting the EOTXP (end of transmit packet) signal.

Since TPS is double buffered the software can write the size of the next packet into TPS as soon as the TPS value of the current packet has been loaded into the TPS counter, i.e. reading TPS returns 0. This happens a few clock cycles after the previous packet has been transmitted.

Also the characters of the next packet can be moved to the FIFO immediately after the current packet characters as indicated in **Figure 30-14**. If byte or half word alignment is used as described in **Section 30.2.4.3**, then the characters of two different packets must not be aligned in a single stage.

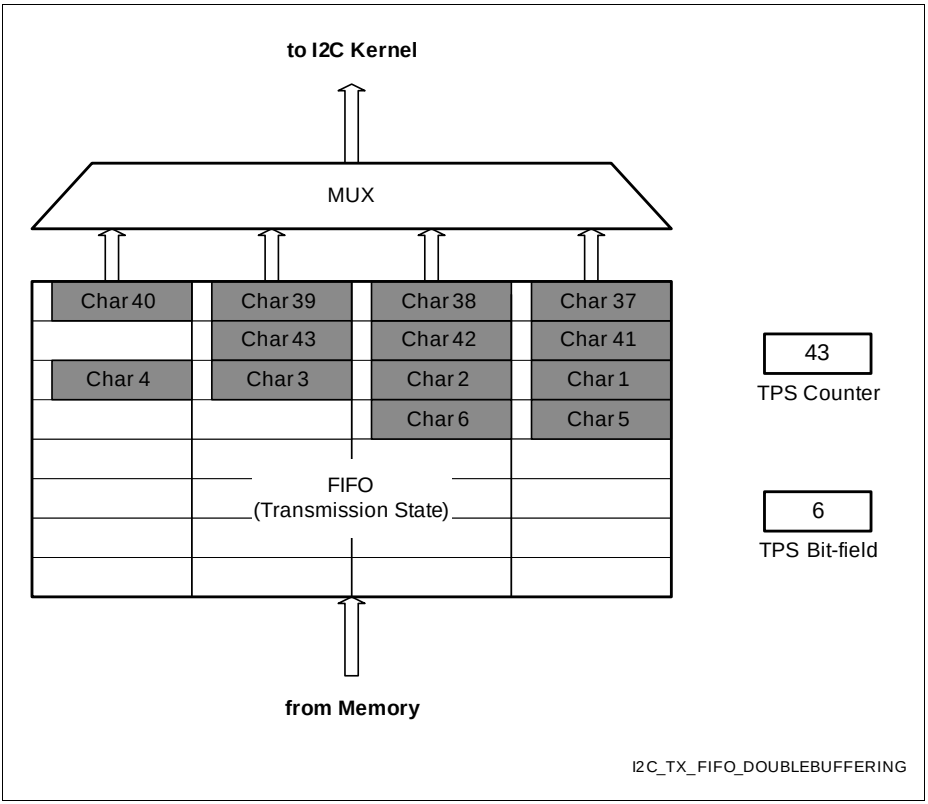

Figure 30-14 FIFO Containing Data of Two Different Transmit Packets

Error Handling

- If a TX FIFO overflow occurs (i.e. the software writes data too fast to the FIFO), then the new incoming character is discarded and a TX FIFO overflow interrupt request is generated.
- If a TX FIFO underflow occurs (i.e. the I2C kernel tries to read from an empty FIFO), then the I2C kernel generates a TX FIFO underflow interrupt request.

30.2.4.2 Transmit Request Generation

For the following it is assumed that the FIFO is used as flow controller, selected via bit TXFC of the **FIFOCFG** register.

In this case the bit-field TPS of the **TPSCTRL** register is not only used for the generation of the EOTXP (end of transmit packet) signal (see **Section 30.2.4.1**), but also to initiate

the whole data transfer. I.e. the software indicates that it wants to transmit a data packet by writing the packet size to the bit-field TPS. Then the FIFO unit asserts burst requests BREQ until the amount of data still to be transferred is less than or equal to the burst size set in bit-field TXBS of register **FIFOCFG**. At this point, if the remaining data is equal to the burst size, then a last burst request LBREQ is issued. Otherwise, single requests SREQ and a last single request LSREQ will be issued.

Notes

1. *The next request is only generated if previous request was cleared.*
2. *Pre-loading TPS with the packet size of the next frame, before the current packet has been transmitted completely, enables a continuous data throughput (e.g. of audio data).*
3.
4. *If the FIFO is not used as flow controller, the I2C-bus interface should use bit-field TPS of the TPSCTRL register to set the EOTXP signal. A burst request BREQ is generated each time the number of empty FIFO stages is equal or greater than the burst size set in bit-field TXBS and the previous request was cleared. No single requests SREQ and LSREQ will be issued.*

30.2.4.3 Transmit Data Alignment

Depending on bit-field TXFA (TX FIFO Alignment) in register **FIFOCFG**, the FIFO can deal with byte aligned, half word aligned or word aligned characters (or even more) as it is described in the following.

Note: Byte alignment is synonymous with character alignment, half word alignment with character alignment of two data characters, and word alignment with character alignment of four characters.

Byte Aligned TX Characters

If the TX characters are byte aligned, then the FIFO extracts the bytes and shifts them to the I2C kernel via a multiplexer as it is shown in **Figure 30-15**.

Since the number of characters of the packet to be transmitted is not necessarily a multiple of 4, the last word must be filled up with dummy bytes if necessary. The FIFO transmits only the valid bytes of the last word depending on the setting of the bit-field TPS of the **TPSCTRL** register.

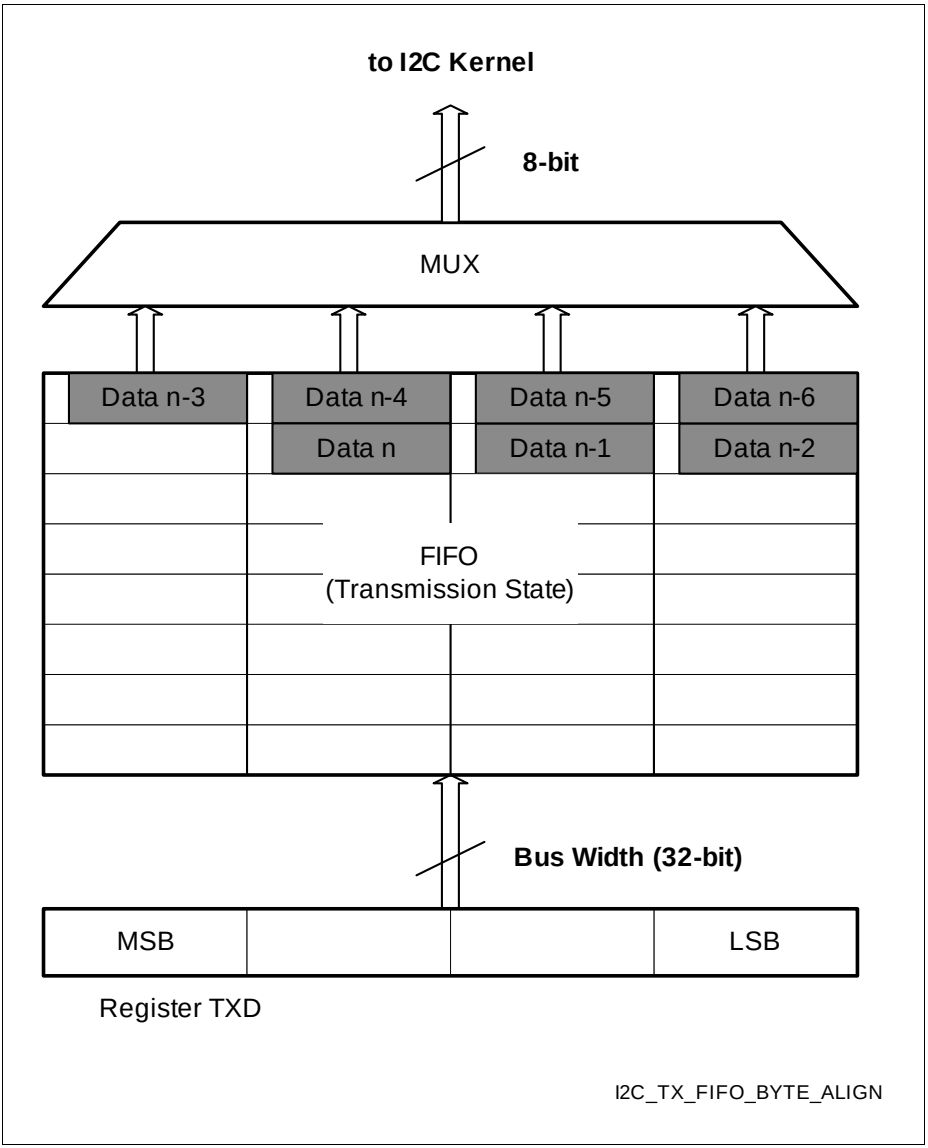

Figure 30-15 FIFO in Transmission State with Byte Aligned Data

Half Word Aligned

If the TX characters are half word aligned, then the FIFO extracts the half words and shifts them to the I2C kernel via a multiplexer as it is shown in **Figure 30-16**.

Note: The I2C kernel extracts the right data bits from the half word it receives from the FIFO.

Since the number of characters of the packet to be transmitted is not necessarily a multiple of 2, the last word must be filled up with a dummy half word if necessary. The FIFO transmits only the valid half words of the last word depending on the setting of the bit-field TPS.

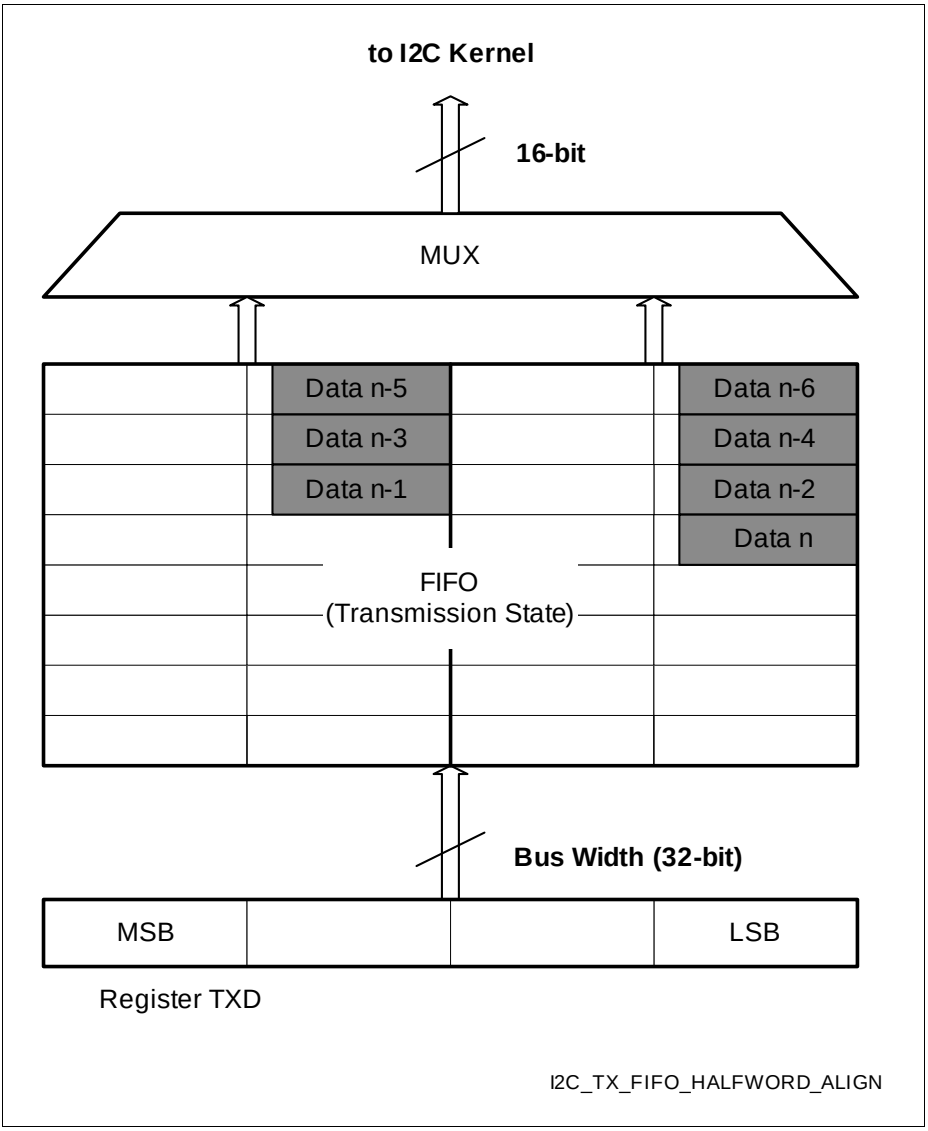

Figure 30-16 FIFO in Transmission State with Half Word Aligned Data

Word Aligned

If the TX characters are word aligned, then the FIFO shifts them to the I2C kernel as it is shown in **Figure 30-17**.

Note: The I2C kernel extracts the right data bits from the word it receives from the FIFO.

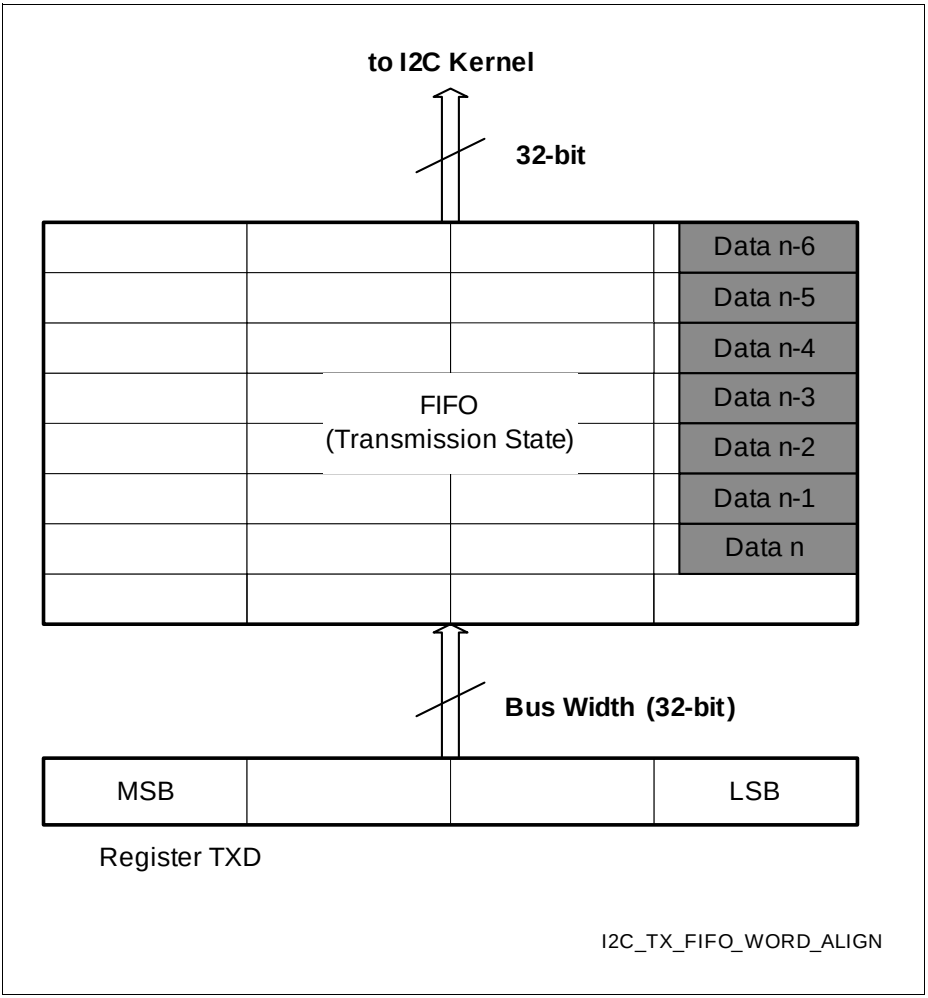

Figure 30-17 FIFO in Transmission State with Word Aligned Data

30.2.4.4 Data Reception

The software can read received data from the FIFO by reading the Reception Data Register **RXD**. Reading data from the FIFO should be done according to the data transfer request signals generated by the FIFO controller. The register **FFSSTAT** indicates the number of filled FIFO stages. The data alignment within the FIFO is described in **Section 30.2.4.6**. The I2C kernel shifts data into the FIFO by means of the handshake signals RX_FIFO_rdy and RX_Data_ind.

Before the first reception starts, the I2C kernel has to set the RXS_set line. This causes the assertion of RX_FIFO_rdy to indicate the I2C kernel that one data character can be written into the FIFO.

With the signal FIFO_flush the I2C kernel is able to clear the FIFO content. But if a data transfer request is pending and the FIFO is configured as flow controller, then the FIFO is not cleared until the corresponding signal REQCLR has been set by software.

Error Handling

- If the RX FIFO is completely full (i.e. the software reads out the data too slow), then the I2C kernel generates an RX FIFO overflow interrupt request.
- If an RX FIFO underflow occurs (i.e. the software reads from empty FIFO), then an RX FIFO underflow interrupt request is generated.
- If an error (including the FIFO overflow condition described above) is detected in the I2C kernel and the current reception is stopped, then it also has to generate an EORXP_ind signal, so that the remaining characters in the FIFO can be moved out by means of data transfer requests.

30.2.4.5 Receive Request Generation

If the whole data of the current received packet has been moved into the buffer, then the I2C kernel will set the EORXP_ind (end of receive packet indication) signal. The received characters, which are shifted in the FIFO, are counted by anRPS (received packet size) counter. If an EORXP_ind occurs, then the content of the RPS counter is moved to the register **RPSSTAT** and the counter is reset. If data alignment in the FIFO is used, then the **RPSSTAT** value can be used to check for valid characters in the last read word (see **Section 30.2.4.6**).

For the following it is assumed that the FIFO is used as flow controller, selected via bit RXFC of the **FIFOCFG** register.

The FIFO unit asserts burst requests BREQ each time the FIFO filling level is greater than the burst size set in bit-field RXBS of register **FIFOCFG**. An EORXP_ind causes the FIFO unit to assert burst requests BREQ until the amount of data still to be transferred is less than or equal to the burst size. At this point, if the remaining data is equal to the burst size, a last burst request LBREQ is issued. Otherwise, single requests SREQ and a last single request LSREQ will be issued.

When the packet has been shifted out of the FIFO by software, the FIFO controller provides the EORXP_ack (end of receive packet acknowledge) signal to the I2C kernel, which allows the kernel to set the next EORXP_ind.

The next received packet may be shifted into FIFO immediately after the current packet, so that the FIFO contains data of two different packets. But the EORXP_ind of the next packet must not be asserted before the EORXP_ind of the current packet has been acknowledged. The RPS counter is counting the characters of the next packet, while in the register **RPSSTAT** the packet size of the current packet remains readable. The first character of the new packet is always shifted in a new FIFO stage as indicated in **Figure 30-18**. (The FIFO data alignment is described in **Section 30.2.4.6**.)

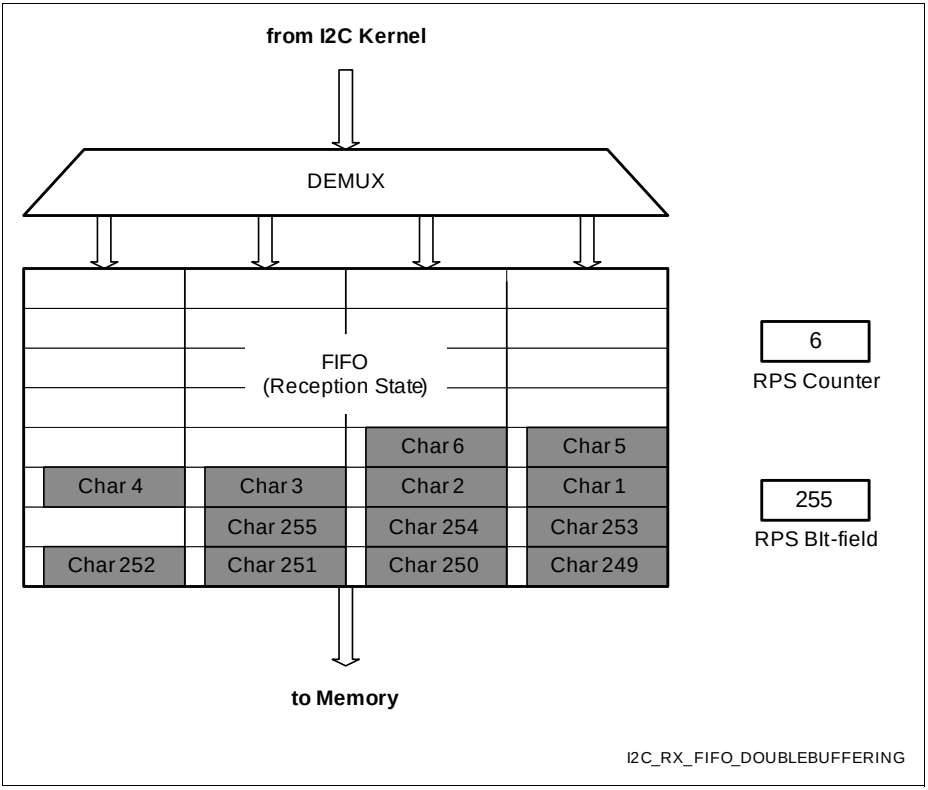

Figure 30-18 FIFO Containing Data of Two Different Receive Packets

If the number of the received characters of one packet is equal to the maximum received packet size, which is defined by bit-field MRPS in register **MRPSCTRL**, then the FIFO controller gets into the state, where it generates LBREQ or SREQ and LSREQ. If the I2C

kernel generates an EORXP_ind in this state, then this indication is valid for the received packet and the FIFO accepts no more characters from the I2C kernel until the current packet has been moved out of the FIFO or the start of a new packet has been detected by asserting RXS_set.

The bit-field MRPS is double buffered, i.e. the software can write the MRPS value of the next packet as soon as the current MRPS value has been loaded, i.e. reading MRPS returns 0. This happens a few clock cycles after all data of the previous packet have been read from the FIFO. If an MRPS overflow occurs (one character before the last character is received), then the MRPS_stop trigger to the I2C kernel is generated. But if the next MRPS value is written to MRPS before the last data character of current frame has been completely received, then no MRPS_stop is generated. The I2C-bus interface will use the MRPS_stop trigger to stop the reception of the corresponding data packet.

But the MRPS bit-field can also be used to initiate a reception, when the peripheral is master-receiver. Therefore writing to MRPS generates a trigger MRPS_start to the I2C kernel. The next MRPS value written to MRPS generates only an MRPS_start when an MRPS_stop was generated before.

The MRPS features can only be used if the FIFO is the flow controller.

Notes

1. *When the MRPS control feature of the FIFO is used to limit the packet size of a continuous incoming data stream (MRPS is only written once and left unchanged), characters exceeding MRPS are discarded . The FIFO can not handle more than two packets. When the FIFO is filled with data characters of two packets then a further RXS_set will be overseen by the FIFO. Additionally the FIFO does not set the RX_FIFO_rdy.*
2. *If the FIFO is not used as flow controller, a single request SREQ is always generated as soon as the readable FIFO stage is filled up with characters. Additionally, a burst request BREQ is generated as soon as the number of filled FIFO stages is equal to or greater than the burst size set in bit-field RXBS of register FIFOCFG. When the I2C kernel sets EORXP_ind, the FIFO controller provides the EORXP_ack (end of receive packet acknowledge) signal to the I2C kernel, which allows the kernel to set the next EORXP_ind.*

30.2.4.6 Receive Data Alignment

Depending on bit-field RXFA (RX FIFO Alignment) in register **FIFOCFG**, the FIFO can deal with byte aligned, half word aligned or word aligned characters (or even more) as it is described in the following.

Byte Aligned

If the RX data should be byte aligned, then the characters from the I2C kernel are aligned and shifted to the FIFO by a demultiplexer as it is shown in **Figure 30-19**.

Since the number of characters of the received packet is not necessarily a multiple of 4, the upper bytes of the last word can be invalid. The software has to check for invalid bytes of the last word by means of the bit-field RPS (received packet size) in register **RPSSTAT**.

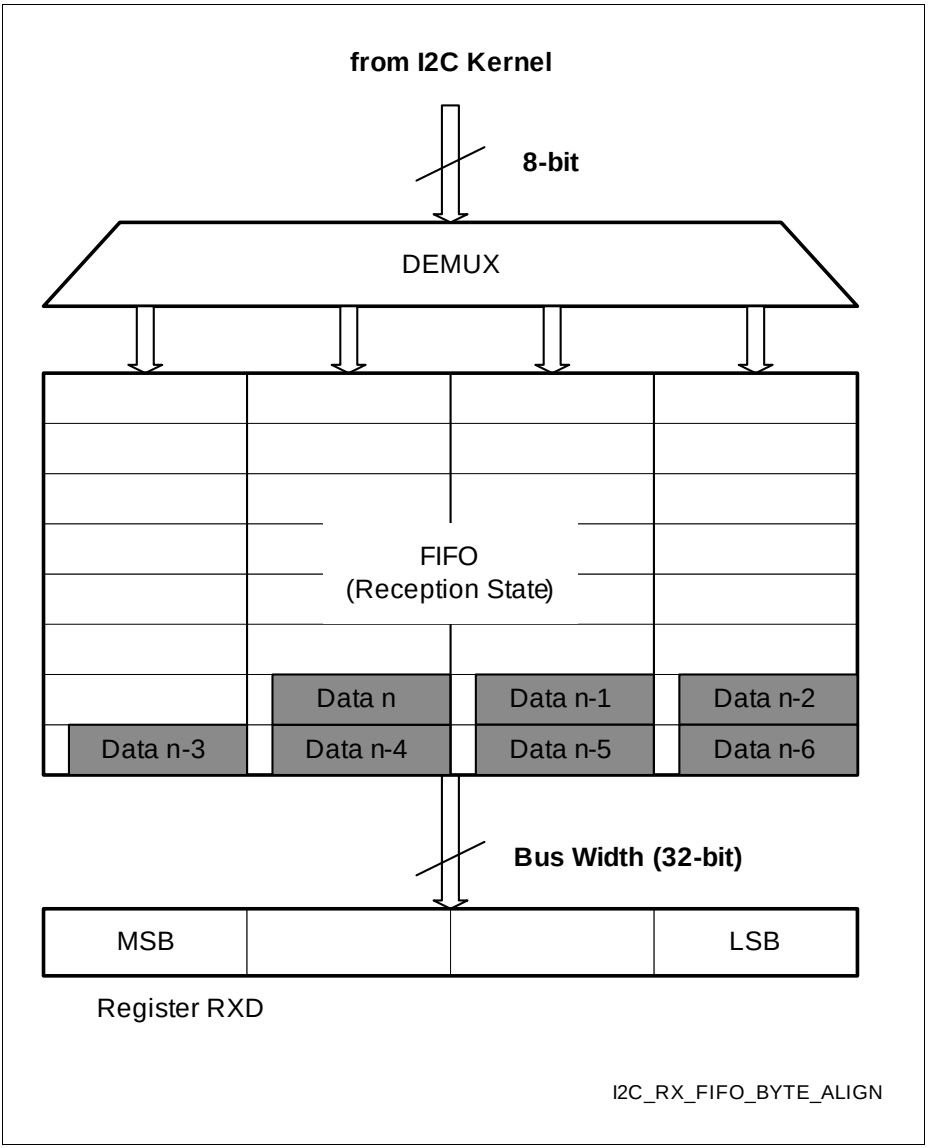

Figure 30-19 FIFO in Reception State with Byte Aligned Data

Half Word Aligned

If the RX data should be half word aligned, then the characters from the I2C kernel are aligned and shifted to the FIFO by a demultiplexer as it is shown in **Figure 30-20**.

Note: The I2C kernel fills up the half words with dummy bits.

Since the number of characters of the received packet is not necessarily a multiple of 2, the upper bytes of the last word can be invalid. The software has to check for invalid half words of the last word by means of the bit-field RPS (received packet size) in register **RPSSTAT**.

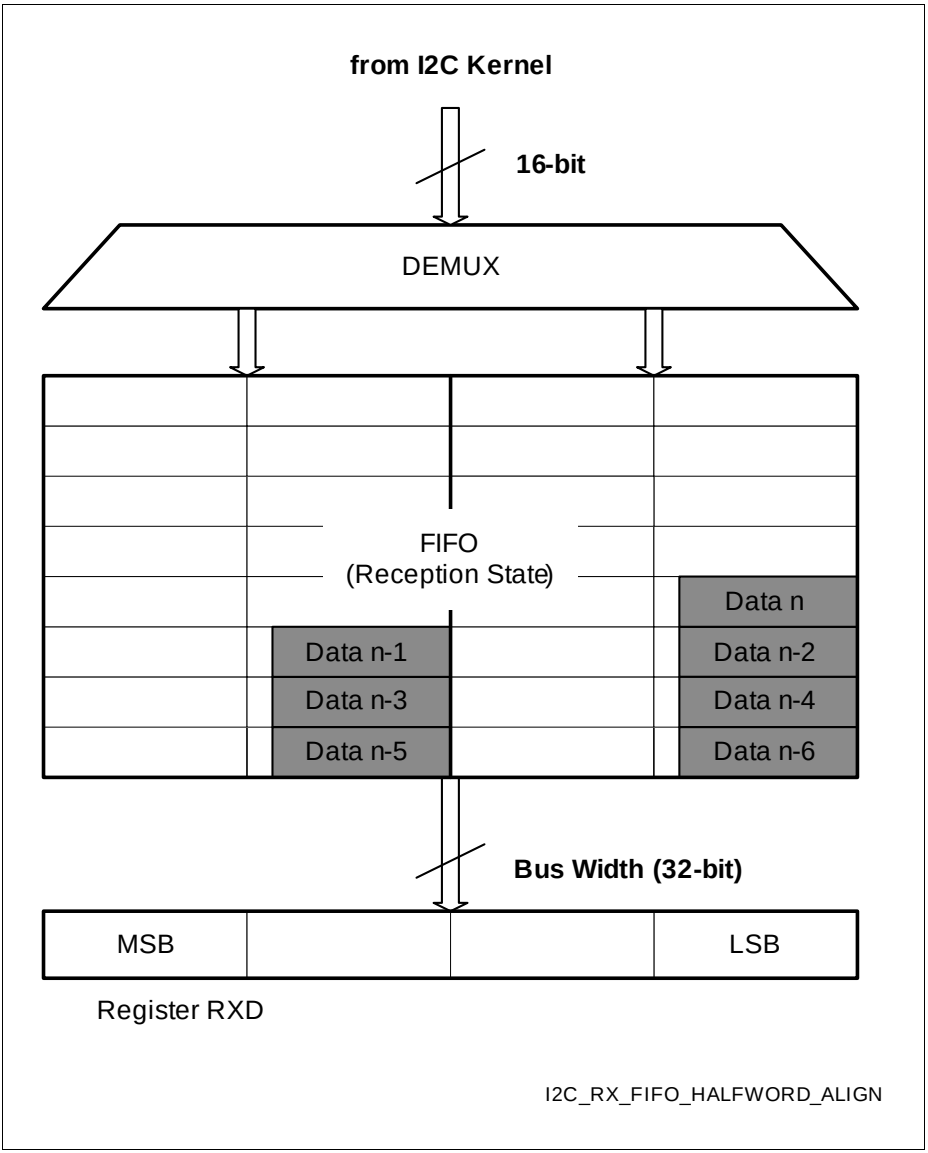

Figure 30-20 FIFO in Reception State with Half Word Aligned Data

Word Aligned

If the RX data should be word aligned, then the characters from the I2C kernel are shifted to the FIFO as it is shown in **Figure 30-21**.

Note: The I2C kernel fills up the words with dummy bits.

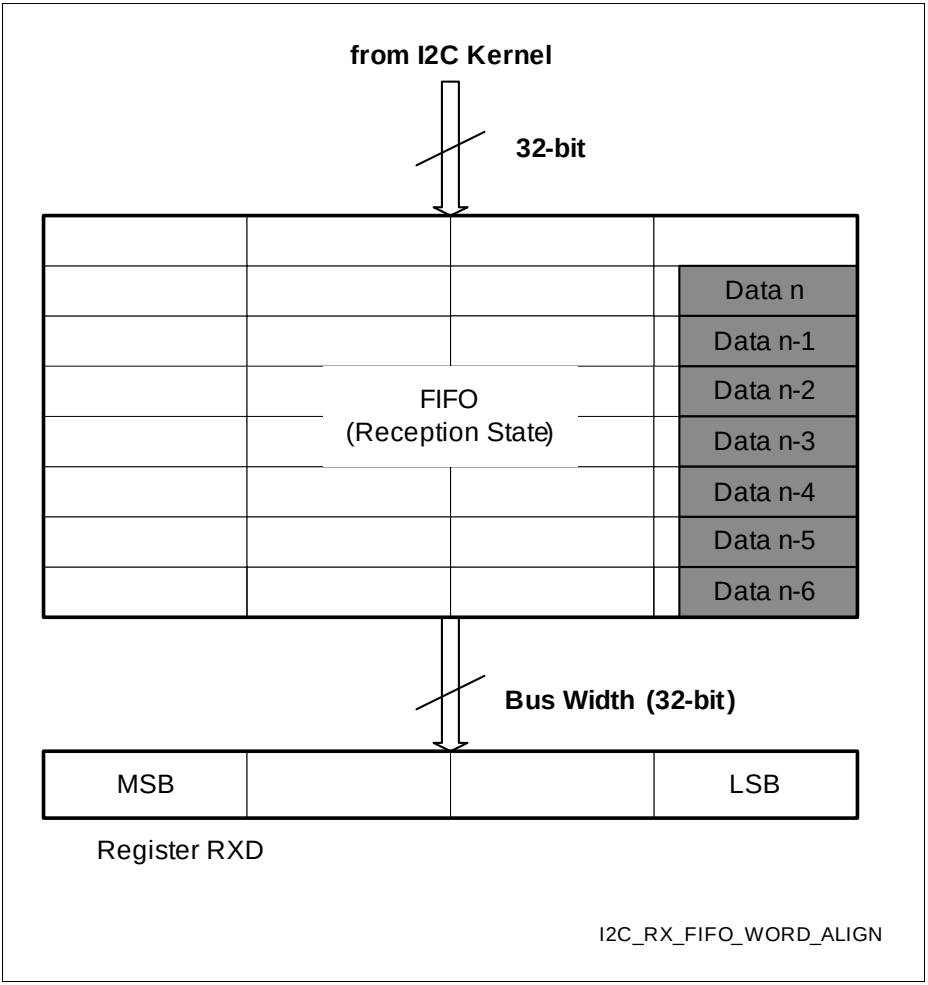

Figure 30-21 FIFO in Reception State with Word Aligned Receive Data

30.2.4.7 Switching between Transmission and Reception

Initially, the FIFO is in the TX state, so that the software can initiate a TX transfer simply by writing data to the bit-field TXD. If the I2C kernel wants the FIFO to switch to the RX state in the meantime, then it can set the RXS_set line and even if transmission is ongoing the TX transfer is aborted. This causes the FIFO to flush its content, switch to the RX state and reset the received packet size counter. If the software wants to write to the register **TXD** when the FIFO is in RX state, then this causes a bus error. As soon as the FIFO has received an EORXP_ind signal from the kernel and the software has moved all RX characters out of the FIFO via the register **RXD**, the FIFO automatically switches back into the TX state.

If the software writes to the register **TPSCTRL** when the FIFO is in the RX state, the TPS value is pending until the FIFO returns to the TX state. Then the transmission is initiated, if the FIFO is the flow controller.

If the FIFO is flow controller and the software writes to the register **MRPSCTRL**, then an MRPS_start is generated independent of the state of the FIFO.

With the signal FIFO_flush the I2C kernel is able to clear the FIFO content. But if a data transfer request (xREQ) is pending, then the FIFO is not cleared until the corresponding signal REQCLR has been set by software. If the FIFO has been cleared in the RX state, then it switches back to the TX state afterwards.

30.2.5 Service Request Block Operation

The SRB (Service Request Block) of the I2C module is used to prepare the interrupt and data transfer requests for the interrupt controller.

30.2.5.1 Overview of Service Requests

The I2C service requests are partially combined in the SRB (see **Section 30.3.4** and **Section 30.3.5**). **Figure 30-22** shows an overview of the service requests. **Table 30-2** provides a list of all service requests of the I2C module.

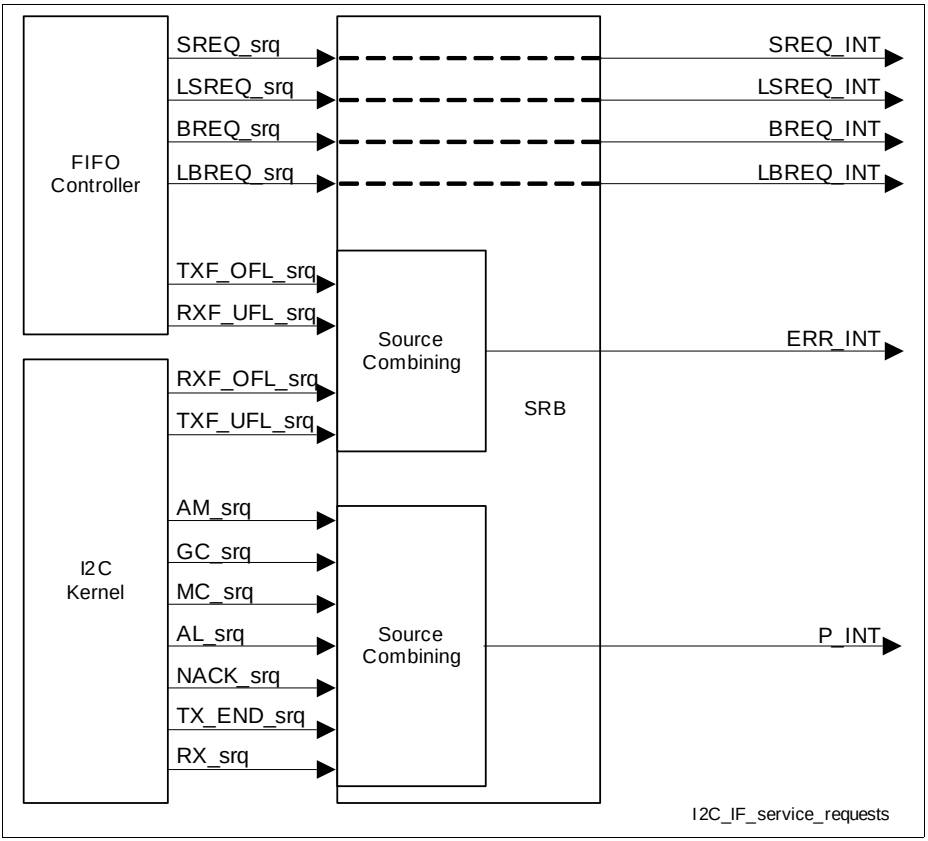

Figure 30-22 Overview of I2C Module Service Requests

Table 30-2 I2C Module Service Requests

Service Request	InterruptRequest	Description
BREQ_srq	BREQ_INT	**Burst Data Transfer Request** FIFO requests a transfer of a programmed burst number of words from/to the memory.
LBREQ_srq	LBREQ_INT	**Last Burst Data Transfer Request** FIFO requests a last burst transfer from/to the memory.

Table 30-2 I2C Module Service Requests (cont'd)

Service Request	InterruptRequest	Description
SREQ_srq	SREQ_INT	**Single Data Transfer Request** FIFO requests a single transfer of a word from/to the memory.
LSREQ_srq	LSREQ_INT	**Last Single Data Transfer Request** FIFO requests a last single transfer from/to the memory.
TXF_OFL_srq	ERR_INT	**TX FIFO Overflow Request** FIFO has detected a TX FIFO overflow.
TXF_UFL_srq	ERR_INT	**TX FIFO Underflow Request** I2C kernel has detected a TX FIFO underflow. The transmission is finished after the current byte. A stop condition is generated if the kernel works as master. The kernel changes to listening state.
RXF_OFL_srq	ERR_INT	**RX FIFO Overflow Request** I2C kernel has detected an RX FIFO overflow and the incoming character is discarded. The kernel puts a not-acknowledge on the bus and changes to listening state. A stop condition is generated if the kernel works as master.
RXF_UFL_srq	ERR_INT	**RX FIFO Underflow Request** FIFO has detected an RX FIFO underflow.
AM_srq	P_INT	**Address Match Request** Device (master/slave) has been addressed by a remote master (also indicated in bit-field BS in register **BUSSTAT**).
GC_srq	P_INT	**General Call Request** When the general call matching process is activated this interrupt indicates that another master has put a general call on the I2C-bus.
MC_srq	P_INT	**Master Code Request** When the master code matching process is activated this interrupt indicates the appearing of a master code on the I2C-bus issued by a remote master. The request is generated after a not-acknowledge and the clock is released to high again.

Table 30-2 I2C Module Service Requests (cont'd)

Service Request	InterruptRequest	Description
AL_srq	P_INT	**Arbitration Lost Request** Arbitration is lost after the device has tried to start a transmission on the I2C_bus.
NACK_srq	P_INT	**Not-acknowledge Received Request** Not-acknowledge received when working as transmitter (i.e. RnW bit is 0).
TX_END_srq	P_INT	**Transmission End Request** In master mode this event is produced by the I2C kernel to indicate that the transmission of the current packet has ended properly after the stop condition has been put on the I2C-bus or MASTER RESTART state has been entered. (At this point, a restart condition can be generated or the connection can be finished by generating a stop condition). This request is created in master mode at any stop condition to indicate that the bus is free again and it could be obtained. In slave mode this event is produced by the I2C kernel if it was addressed by a master and the current transmission was terminated by a stop or restart condition.
RX_srq	P_INT	**Receive Mode Request** I2C kernel indicates to the FIFO switching from transmit to receive mode. When FIFO is operating in non flow controller mode, this service request can be used to distinguish between transmit and receive FIFO data requests.

The generation of these events is visualized in the state machine **Figure 30-9**, **Figure 30-10** and **Figure 30-11**. The timing is shown in **Figure 30-12**.

30.2.5.2 Interrupt Service Request Structure

The I2C module provides level based service request lines, which can be processed by an interrupt controller. The service requests must be cleared in the interrupt service routine. For test purposes, all service requests can also be set by SW via a register bit. All service requests can be masked within the peripheral. Furthermore, requests that are not necessarily mutually exclusive are combined in order to reduce the number of request lines.

Flow of Data Transfer Requests

Figure 30-23 shows the flow of a data transfer request, which comes from the FIFO controller.

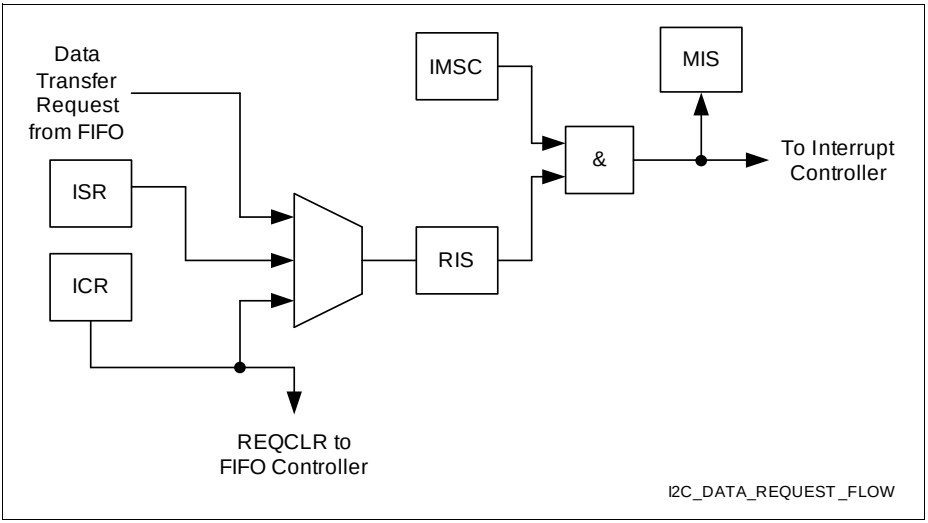

Figure 30-23 Data Transfer Request Flow

A data transfer request sets the corresponding status bit in the Raw Interrupt Status Register **RIS**. The status bit can also be set by writing 1 to the corresponding bit in the Interrupt Set Register **ISR**. It will be cleared by writing 1 to the corresponding bit in the Interrupt Clear Register **ICR**.

The Interrupt Mask Control Register **IMSC** enables or disables the requests to the interrupt controller. The Masked Interrupt Status Register **MIS** contains the current masked values of the requests.

If a request is disabled via register **IMSC** while the request is active, the request will be removed but only until the **IMSC** bit is set again, unless the request has been cleared in the meantime.

If a request is disabled via register **IMSC** and the source becomes active, then the request bit will only be set in the **RIS** register. If the corresponding **IMSC** bit is later enabled, the request will consequently become active in the **MIS** register.

Before enabling a request, it is good practice to always first clear the corresponding bit in the **RIS** register via **ICR**.

Multiple Source Interrupt Requests

For error and protocol interrupt requests which have multiple sources, the interrupt structure is extended. Additional register sets are implemented within the SRB.

Figure 30-24 gives an overview of the combining of several request sources to a single request.

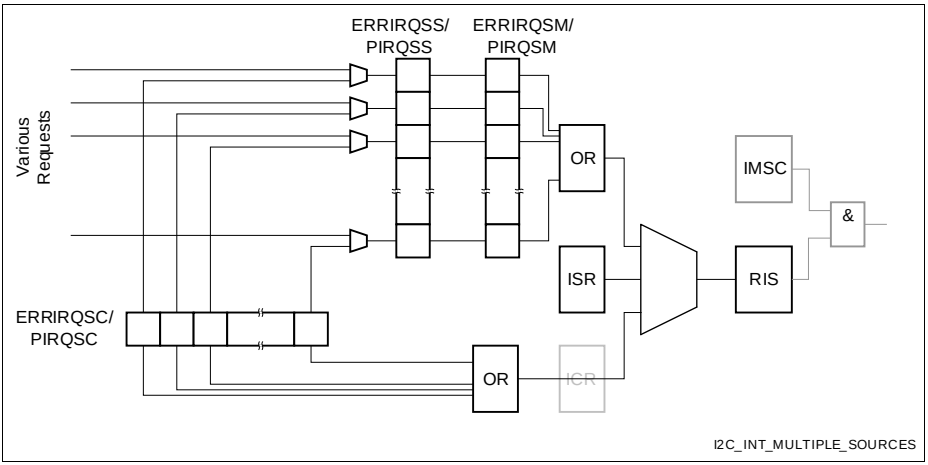

Figure 30-24 Interrupt Request with Multiple Sources

An interrupt request sets the corresponding raw status bit in the Interrupt Request Source Status Register **ERRIRQSS** (for error) or **PIRQSS** (for protocol).

The status bits can be cleared via the Interrupt Request Source Clear Register **ERRIRQSC** (for error) or **PIRQSC** (for protocol). If no further error/protocol request sources are active, the whole error/protocol interrupt request is cleared. This register replaces the functionality of the bit I2C_ERR_INT (for error) or bit I2C_P_INT (for protocol) in the Interrupt Clear Register **ICR**.

The Interrupt Request Source Mask Register **ERRIRQSM** (for error) or **PIRQSM** (for protocol) enables or disables the interrupt requests. The request lines from the enabled sources are combined (OR) to a single level sensitive request line, which acts as input for the corresponding bit I2C_ERR_INT (for error) or I2Cm_bit I2C_P_INT (for protocol) in the Raw Interrupt Status Register **RIS**.

30.3 I2C Module Internal Registers

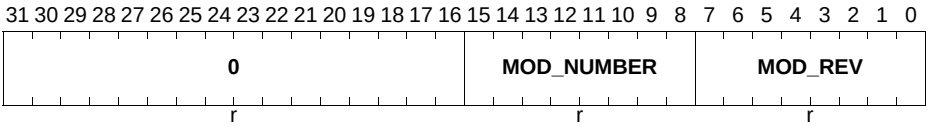
This section describes the internal registers of the I2C module. All register names described in this section are also referenced in other parts of the TC27x User's Manual by the module name prefix "I2Cm_". For an overview of all module registers, see **Section 30.4.4**.

30.3.1 Global Module Control Registers

Module Identification Register

This register contains read-only information about the module and its revision.

ID
Module Identification Register **(08_H)** **Reset Value: 0000 5703$_H$**

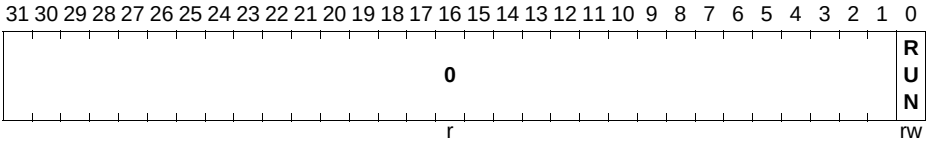


Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision Number** This bit-field defines the revision number.
MOD_NUMBER	15:8	r	**Module Number** This bit-field defines the module identification number..
0	31:16	r	**Reserved** Read as 0; should be written with 0.

RUN Control Register

This register selects configuration mode or run mode.

RUNCTRL
RUN Control Register **(10_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RUN	0	rw	**Enable I2C-bus Interface** 0_B I2C-bus interface disabled; write access to configuration registers enabled 1_B Participation in I2C-bus communication enabled (if properly configured); write access to configuration registers disabled
0	31:1	r	**Reserved** Read as 0; should be written with 0.

End Data Control Register

This register is used to either turn around the data transmission direction or address another slave without sending a stop condition. Also the software can stop the slave-transmitter by sending a not-acknowledge when working as master-receiver or even stop data transmission immediately when operating as master-transmitter. The writing to the bits of this control register is only effective in certain states.

ENDDCTRL
End Data Control Register **(14_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														SET END	SET RSC
r														w	w

Field	Bits	Type	Description
SETRSC	0	w	**Set Restart Condition** This bit is always read as 0. 0_B Has no effect. 1_B The master wants to restart a data transmission (changing slave/direction). The effect depends on the current state. MASTER RECEIVES BYTES: The master puts a not-acknowledge on the bus and switches to MASTER RESTART state. MASTER TRANSMITS BYTES: After the current byte has been sent, the master switches to MASTER RESTART state.
SETEND	1	w	**Set End of Transmission** This bit is always read as 0. *Note: Do not write 1 to this bit when bus is free. This will cause an abort after the first byte when a new transfer is started.* 0_B Has no effect. 1_B The effect depends on the current state. MASTER RECEIVES BYTES: After receiving the current byte, the master puts a not-acknowledge on the bus to indicate the transmission end to the slave-transmitter. Next it produces a stop condition on the bus and changes its state to LISTENING. MASTER TRANSMITS BYTES: After sending the current byte and receiving an acknowledge or not-acknowledge from the slave-receiver, the master puts a stop condition on the bus to close the data transmission and changes its state to LISTENING. MASTER RESTART: The master puts a stop condition on the bus to close the data transmission and changes its state to LISTENING. SLAVE RECEIVES BYTES: The slave-receiver puts a not-acknowledge on the bus after the received byte and changes its state to TRANSMISSION FINISHED.

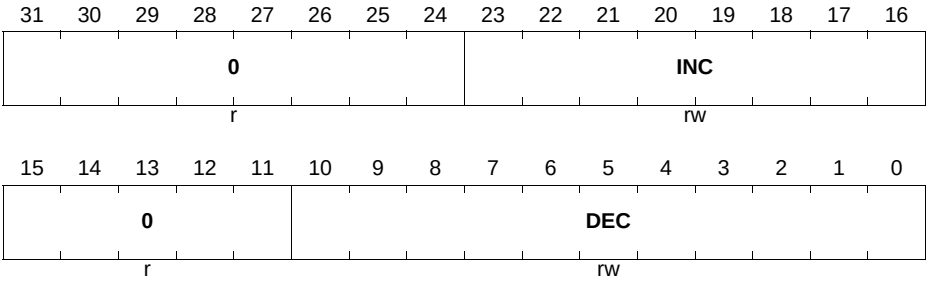
Field	Bits	Type	Description
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider Configuration Register

This configuration register is used to program the fractional divider of the I2C-bus for standard and fast mode. Before the peripheral is switched on by setting the RUN bit, the register should be configured.

FDIVCFG
Fractional Divider Configuration Register

(18_H) **Reset Value: 0000 0000$_H$**



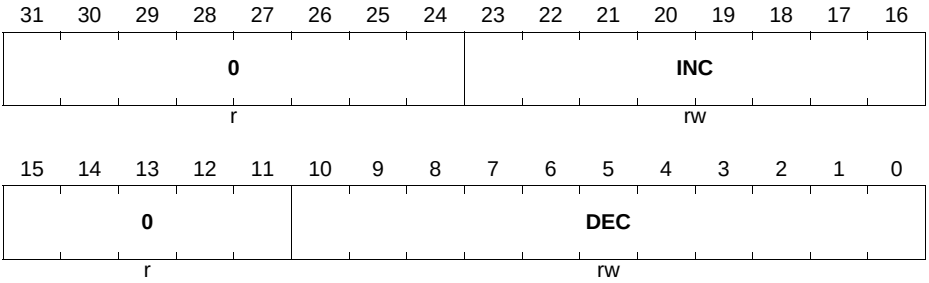
Field	Bits	Type	Description
DEC	10:0	rw	**Decrement Value of Fractional Divider** For standard/fast mode, see **Baudrate Generation**.
INC	23:16	rw	**Increment Value of Fractional Divider** For standard/fast mode, see **Baudrate Generation**.
0	15:11, 31:24	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider High-speed Mode Configuration Register

This configuration register is used to program the fractional divider of the I2C-bus for high-speed mode. Before the peripheral is switched on by setting the RUN bit, the register should be configured if high-speed mode is used.

FDIVHIGHCFG
Fractional Divider High-speed Mode Configuration Register

($1C_H$) **Reset Value: 0000 0000$_H$**

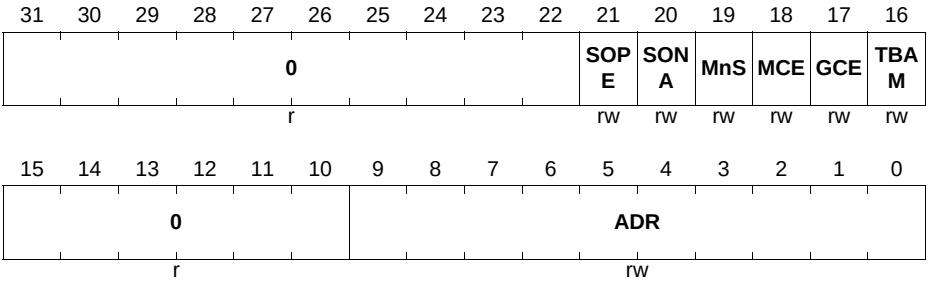


Field	Bits	Type	Description
DEC	10:0	rw	**Decrement Value of Fractional Divider** For high-speed mode, see **Baudrate Generation**.
INC	23:16	rw	**Increment Value of Fractional Divider** For high-speed mode, see **Baudrate Generation**.
0	31:24, 15:11	r	**Reserved** Read as 0; should be written with 0.

Address Configuration Register

This configuration register contains the I2C-address (when addressed as a slave) and some bits that control the basic operation of the peripheral.

ADDRCFG
Address Configuration Register (20$_H$) **Reset Value: 0000 0000$_H$**



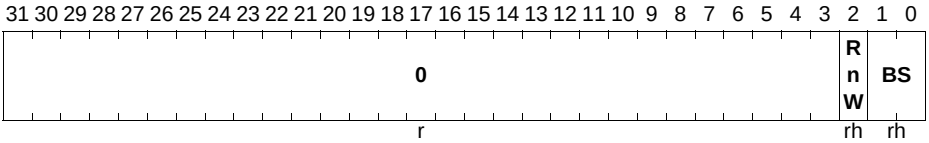
Field	Bits	Type	Description
ADR	9:0	rw	**I2C-bus Device Address** This bit-field determines the address of the device when addressed as a slave. (Watch out for reserved addresses by referring to I2C-bus spec V2.1.) Depending on setting of TBAM, this is either a 7-bit address (bits [7:1]) or a 10-bit address (bits [9:0]).
TBAM	16	rw	**Ten Bit Address Mode** *Note: When this bit is zero, only bits 7 down to 1 of the ADR field are valid.* 0_B 7-bit address mode enabled. 1_B 10-bit address mode enabled.
GCE	17	rw	**General Call Enable** 0_B Ignore general call occurrence. 1_B Enable general call detection; when detected, an acknowledge will be put on the bus
MCE	18	rw	**Master Code Enable** 0_B Device is not able to get along with high-speed mode 1_B Device is able to handle master code

Field	Bits	Type	Description
MnS	19	rw	**Master / not Slave** 0_B Peripheral is configured as slave 1_B Peripheral is configured as master
SONA	20	rw	**Stop on Not-acknowledge** *Note: After successful transmission of a master code (during high-speed mode) SONA is not considered till a stop condition is manually generated by SETEND.* 0_B Device changes to MASTER RESTART state. 1_B Device puts a stop condition on the bus and changes to LISTENING state.
SOPE	21	rw	**Stop on Packet End** *Note:* *1. If device works as receiver a not-acknowledge is always generated on package end.* *2. After successful transmission of a master code (during high-speed mode) SOPE is not considered till a stop condition is manually generated by SETEND.* 0_B Device enters MASTER RESTART state when the data packet end is indicated by the FIFO. 1_B Device puts a stop condition on the bus when the data packet end is indicated by the FIFO and changes to MASTER LISTENING state.
0	15:10, 31:22	r	**Reserved** Read as 0; should be written with 0.

Bus Status Register

This register contains status information of the I2C-bus. This additional information can be used by software to start appropriate actions.

BUSSTAT
Bus Status Register **(24_H)** **Reset Value: 0000 0000$_H$**

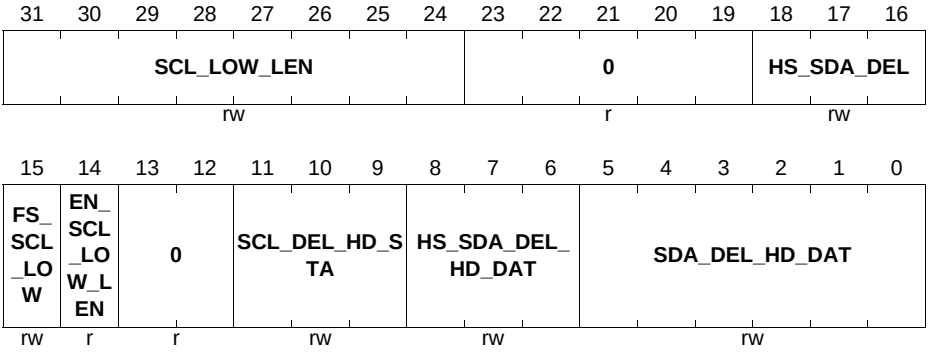


Field	Bits	Type	Description
BS	1:0	rh	**Bus Status** Shows the current status on the I2C-bus. 00_B I2C-bus is free (no start condition detected). 01_B A start condition has been detected on the bus (bus busy). 10_B The device is working as master and has claimed the control on the I2C-bus (busy master). 11_B A remote master has accessed this device as slave.
RnW	2	rh	**Read/not Write** Set by hardware automatically after address byte has been sent/received. 0_B Working as transmitter (Write to I2C-bus). 1_B Working as receiver (Read from I2C-bus).
0	31:3	r	**Reserved** Read as 0; should be written with 0.

Timing Configuration Register

This configuration register adjusts sone timings of the I2C-bus signals SCL and SCA. The delays are given in kernel_clk cycles (denoted as stages below).

TIMCFG
Timing Configuration Register (40_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
SDA_DEL_HD_DAT	5:0	rw	**SDA Delay Stages for Data Hold Time** SDA delay stages for data hold time in standard and fast mode. 000000_B 3 stages delay 000001_B 4 stages delay $XXXXXX_B$ ... 111111_B 66 stages delay
HS_SDA_DEL_HD_DAT	8:6	rw	**SDA Delay Stages for Data Hold Time in High-speed Mode** 000_B 3 stages delay 001_B 4 stages delay XXX_B ... 111_B 10 stages delay
SCL_DEL_HD_STA	11:9	rw	**SCL Delay Stages for Hold Time Start (Restart) Bit** 000_B 2 stages delay 001_B 3 stages delay XXX_B .. 111_B 9 stages delay

Field	Bits	Type	Description
EN_SCL_LOW_LEN	14	rw	**Enable Direct Configuration of SCL Low Period Length in Fast Mode** 0B **DIS**, SCL low period is a fixed part of the whole period, as defined by FS_SCL_LOW 1B **EN**, SCL low period is determined by the setting of SCL_LOW_LEN
FS_SCL_LOW	15	rw	**Set Fast Mode SCL Low Period Timing** 0_B Standard mode SCL low period timing 1_B Fast mode SCL low period timing
HS_SDA_DEL	18:16	rw	**SDA Delay Stages for Start/Stop bit in High-speed Mode** 000_B 3 stages delay 001_B 4 stages delay XXX_B ... 111_B 10 stages delay
SCL_LOW_LEN	31:24	rw	**SCL Low Length in Fast Mode** If enabled by EN_SCL_LOW_LEN setting, this field determines the extension of the SCL low time. In case of INC = 1, the low time is extended by the number of kernel_clk cycles. In general, there is a more complex formula, as given in the functional specification. The total period time is not changed, i.e., the SCL high period is reduced accordingly. Setting SCL low time to period length or higher is not supported and would lead to unpredictable results. Reset: 00_H
0	13:12, 23:19	r	**Reserved** Read as 0; should be written with 0.

The delayed stages may have +/- 1 stage deviation.

30.3.2 FIFO Registers

Transmission Data Register

The software has to write the characters to be transmitted into this register.

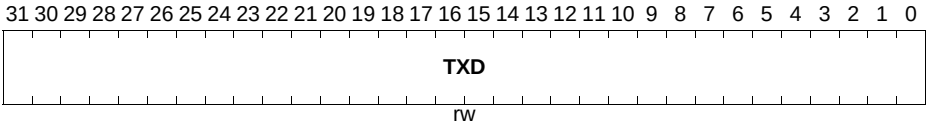
A larger address range (8000_H to $BFFC_H$) is reserved for the FIFO. Accessing any address in the defined range has the same effect as accessing the first address.

A read access to TXD register is not possible, it will return 0 in all cases. Reading has no effect on the FIFO.

When using byte or half word access from the bus, the TX FIFO pointer will only be increased, if one of the following conditions is fulfilled:

- The most significant byte or half word of the FIFO stage is written
- The packet end is reached

TXD
Transmission Data Register (8000_H) Reset Value: 0000 0000_H



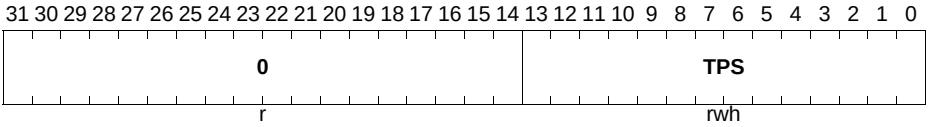
Field	Bits	Type	Description
TXD	31:0	rw	**Transmission Data** Characters to be transmitted

Transmit Packet Size Control Register

This register is used to indicate the peripheral the size of the packet to be transmitted. Writing the packet size to this register if the FIFO controller is configured for flow controller mode initiates the data requests (BREQ, SREQ, ...).

Writing to this register in configuration state has no impact.

TPSCTRL
Transmit Packet Size Control Register(34_H) **Reset Value: $0000\ 0000_H$**



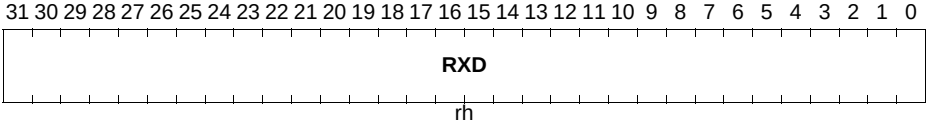
Field	Bits	Type	Description
TPS	13:0	rwh	**Transmit Packet Size** Length in characters of the transmit packet, write value range: 1 to 16383 Reading returns the written value as long as it is not loaded to an internal counter. After that, reading returns 0 and a new value can be written.
0	31:14	r	**Reserved** Read as 0; should be written with 0.

Reception Data Register

The software can read the received characters from this register.

A larger address range ($C000_H$ to $FFFC_H$) is reserved for the FIFO. Reading from any address in the defined range has the same effect as reading from the first address.

RXD
Reception Data Register **($C000_H$)** **Reset Value: $0000\ 0000_H$**



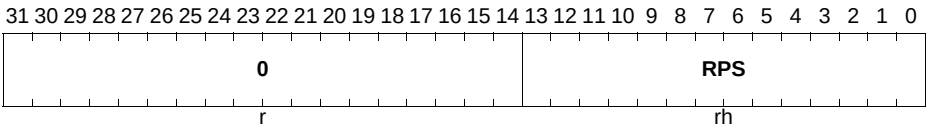
Field	Bits	Type	Description
RXD	31:0	rh	**Reception Data** Received characters

Received Packet Size Status Register

This register indicates the size of the received data packet to the software. The software should read this register after the last request of a packet.

RPSSTAT
Received Packet Size Status Register

(30_H) **Reset Value: 0000 0000_H**

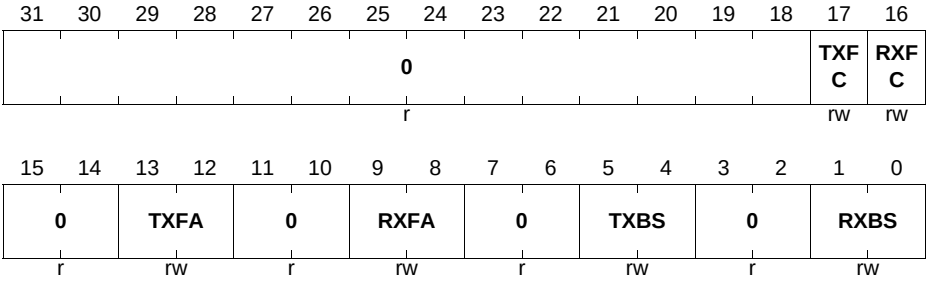


Field	Bits	Type	Description
RPS	13:0	rh	**Received Packet Size** Length in characters of the received packet (0 to 16383)
0	31:14	r	**Reserved** Read as 0; should be written with 0.

FIFO Configuration Register

This configuration register is used to set up the FIFO before the peripheral is enabled and data is received or transmitted.

FIFOCFG
FIFO Configuration Register (28$_H$) Reset Value: 0000 0022$_H$



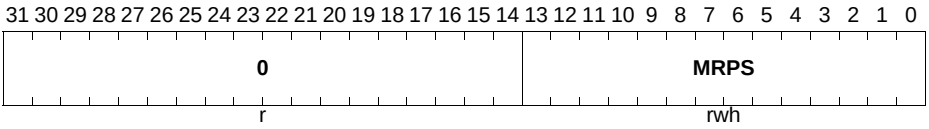
Field	Bits	Type	Description
RXBS	1:0	rw	**RX Burst Size** 00_B 1 word 01_B 2 words 10_B 4 words 11_B Do not use this combination
TXBS	5:4	rw	**TX Burst Size** 00_B 1 word 01_B 2 words 10_B 4 words 11_B Do not use this combination
RXFA	9:8	rw	**RX FIFO Alignment** Use byte alignment wherever it is possible. 00_B Byte aligned (character alignment) 01_B Half word aligned (character alignment of two characters) 10_B Word aligned (character alignment of four characters) 11_B Do not use this combination

Field	Bits	Type	Description
TXFA	13:12	rw	**TX FIFO Alignment** Use byte alignment wherever it is possible. 00_B Byte aligned (character alignment) 01_B Half word aligned (character alignment of two characters) 10_B Word aligned (character alignment of four characters) 11_B Do not use this combination
RXFC	16	rw	**RX FIFO Flow Control** 0_B RX FIFO not as flow controller 1_B RX FIFO as flow controller
TXFC	17	rw	**TX FIFO Flow Control** 0_B TX FIFO not as flow controller 1_B TX FIFO as flow controller
0	3:2, 7:6, 11:10, 15:14, 31:18	r	**Reserved** Read as 0; should be written with 0.

Maximum Received Packet Size Control Register

This register is used to limit the received packet size. The register value may be changed in any state of the FIFO.

MRPSCTRL
Maximum Received Packet Size Control Register
($2C_H$) **Reset Value: $0000\ 0000_H$**



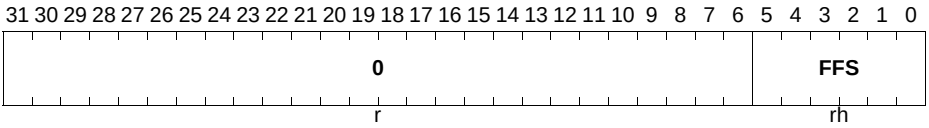
Field	Bits	Type	Description
MRPS	13:0	rwh	**Maximum Received Packet Size** Length in characters of packet to be received; write value range: 0 (unlimited size) to 16383 Reading returns the written value as long as the previous packet has not been read completely from the FIFO. After that, MRPS is loaded to an internal register, reading returns 0 and a new value can be written.
0	31:14	r	**Reserved** Read as 0; should be written with 0.

Filled FIFO Stages Status Register

This register is used to indicate the number of filled FIFO stages.

FFSSTAT
Filled FIFO Stages Status Register

(38_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
FFS	5:0	rh	**Filled FIFO Stages** Number of filled FIFO stages (0 to 8)
0	31:6	r	**Reserved** Read as 0; should be written with 0.

30.3.3 Basic Interrupt Registers

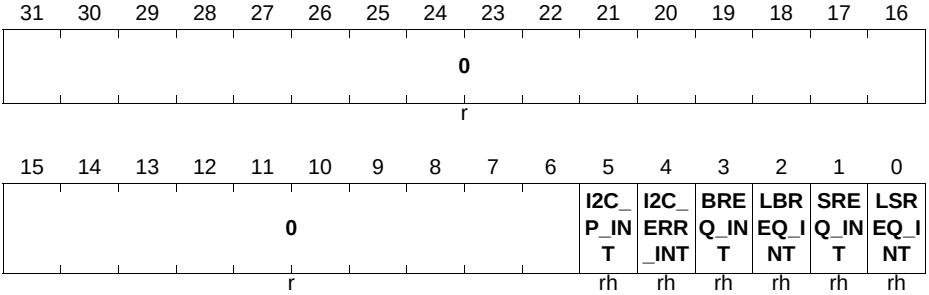
For an overview of the Service Request Block (SRB) see **Section 30.2.5**.

Raw Interrupt Status Register

This read-only register returns the current raw status value (without reflecting the mask) of the interrupt request sources. One status bit is provided for each request. A write to this register has no effect. The status bits are set by hardware or software (via register **ISR**) and can be cleared by software (via register **ICR**).

RIS

Raw Interrupt Status Register **(80_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
LSREQ_INT	0	rh	**Last Single Request Interrupt** 0_B No interrupt request 1_B Interrupt request pending
SREQ_INT	1	rh	**Single Request Interrupt** 0_B No interrupt request 1_B Interrupt request pending
LBREQ_INT	2	rh	**Last Burst Request Interrupt** 0_B No interrupt request 1_B Interrupt request pending
BREQ_INT	3	rh	**Burst Request Interrupt** 0_B No interrupt request 1_B Interrupt request pending

Field	Bits	Type	Description
I2C_ERR_INT	4	rh	**I2C Error Interrupt** This is the combined bit for indication of FIFO errors due to overflow and underflow. 0_B No interrupt request 1_B Interrupt request pending
I2C_P_INT	5	rh	**I2C Protocol Interrupt** This is the combined bit for indication of a protocol event in the I2C kernel. 0_B No interrupt request 1_B Interrupt request pending
0	31:6	r	**Reserved** Read as 0; should be written with 0.

Interrupt Mask Control Register

A write of 1 to a particular bit of this register enables the corresponding interrupt request; a write of 0 disables it. A read to this register returns the current mask bits. After reset all requests are disabled.

IMSC
Interrupt Mask Control Register **(84_H)** **Reset Value: 0000 0000$_H$**

BREQ_INT	3	w	**Burst Request Interrupt** 0_B No change 1_B Set interrupt request
I2C_ERR_INT	4	w	**I2C Error Interrupt** 0_B No change 1_B Set interrupt request
I2C_P_INT	5	w	**I2C Protocol Interrupt** 0_B No change 1_B Set interrupt request
0	31:6	r	**Reserved** Read as 0; should be written with 0.

30.3.4 Error Interrupt Source Registers

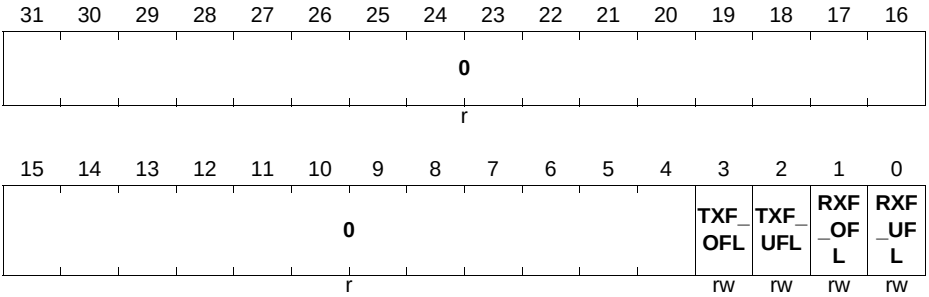
For an overview of the source register operation see **Section 30.2.5.2**.

Error Interrupt Request Source Mask Register

A write of 1 to a particular bit of this register enables the corresponding error interrupt request source; a write of 0 disables it. A read to this register returns the current mask bits. After reset all sources are enabled.

The interrupts are explained in detail in description of register **ERRIRQSS**.

ERRIRQSM
Error Interrupt Request Source Mask Register
(60_H) **Reset Value: 0000 000F$_H$**



Field	Bits	Type	Description
RXF_UFL	0	rw	**RX FIFO Underflow** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
RXF_OFL	1	rw	**RX FIFO Overflow** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
TXF_UFL	2	rw	**TX FIFO Underflow** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
TXF_OFL	3	rw	**TX FIFO Overflow** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
0	31:4	r	**Reserved** Read as 0; should be written with 0.

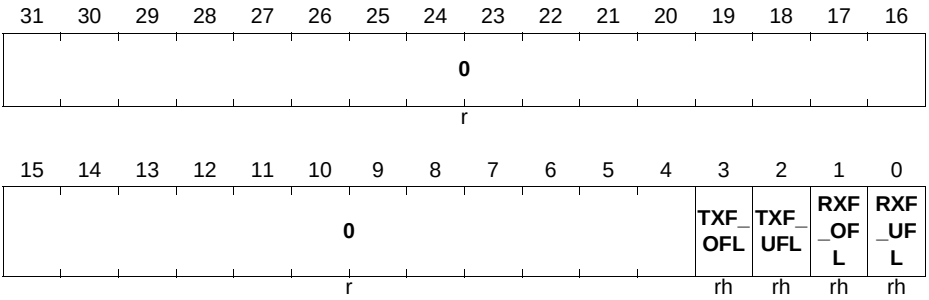
Error Interrupt Request Source Status Register

This read-only register returns the current raw status value (without reflecting the mask) of the error interrupt request sources. A write to this register has no effect. The error status bits are set by hardware and can be cleared by software (via register **ERRIRQSC**).

ERRIRQSS

Error Interrupt Request Source Status Register

(64_H) **Reset Value: 0000 0000$_H$**



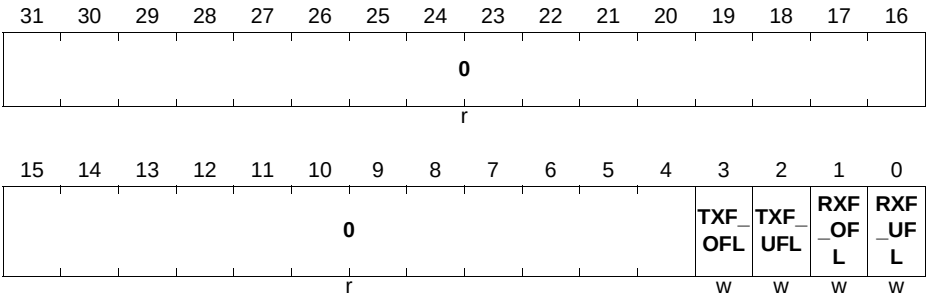
Field	Bits	Type	Description
RXF_UFL	0	rh	**RX FIFO Underflow** 0_B No interrupt request 1_B Interrupt request pending
RXF_OFL	1	rh	**RX FIFO Overflow** 0_B No interrupt request 1_B Interrupt request pending
TXF_UFL	2	rh	**TX FIFO Underflow** The I2C kernel has detected a TX FIFO underflow. 0_B No interrupt request 1_B Interrupt request pending
TXF_OFL	3	rh	**TX FIFO Overflow** 0_B No interrupt request 1_B Interrupt request pending
0	31:4	r	**Reserved** Read as 0; should be written with 0.

Error Interrupt Request Source Clear Register

On a write of 1 to a particular bit of this write-only register, the corresponding error interrupt request source is cleared and if no further error interrupt request sources are active, the whole error interrupt is cleared. If the corresponding bit is set by SW via the **ISR** register, then it can be cleared by setting any non-reserved bit of the interrupt request source clear register**.** A write of 0 has no effect. Reading the register returns 0.

The interrupts are explained in detail in description of register **ERRIRQSS**.

ERRIRQSC
Error Interrupt Request Source Clear Register
(68_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RXF_UFL	0	w	**RX FIFO Underflow** 0_B No change 1_B Clear interrupt request source
RXF_OFL	1	w	**RX FIFO Overflow** 0_B No change 1_B Clear interrupt request source
TXF_UFL	2	w	**TX FIFO Underflow** 0_B No change 1_B Clear interrupt request source
TXF_OFL	3	w	**TX FIFO Overflow** 0_B No change 1_B Clear interrupt request source
0	31:4	r	**Reserved** Read as 0; should be written with 0.

30.3.5 Protocol Interrupt Source Registers

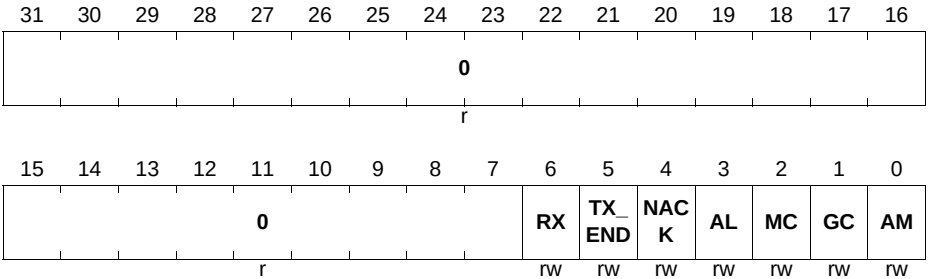
For an overview of the source register operation see **Section 30.2.5.2**.

Protocol Interrupt Request Source Mask Register

A write of 1 to a particular bit of this register enables the corresponding protocol interrupt request source; a write of 0 disables it. A read to this register returns the current mask bits. After reset all sources are enabled.

The interrupts are explained in detail in description of register **PIRQSS**.

PIRQSM
Protocol Interrupt Request Source Mask Register
(70_H) **Reset Value: 0000 007F$_H$**



Field	Bits	Type	Description
AM	0	rw	**Address Match** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
GC	1	rw	**General Call** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
MC	2	rw	**Master Code** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
AL	3	rw	**Arbitration Lost** 0_B Interrupt request source disabled 1_B Interrupt request source enabled

Field	Bits	Type	Description
NACK	4	rw	**Not-acknowledge Received** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
TX_END	5	rw	**Transmission End** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
RX	6	rw	**Receive Mode** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
0	31:7	r	**Reserved** Read as 0; should be written with 0.

Protocol Interrupt Request Source Status Register

This read-only register returns the current raw status value (without reflecting the mask) of the protocol interrupt request sources. A write to this register has no effect. The protocol interrupt status bits are set by hardware and can be cleared by software (via register **PIRQSC**).

PIRQSS
Protocol Interrupt Request Source Status Register
(74_H) **Reset Value: 0000 0000$_H$**

r									rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
AM	0	rh	**Address Match** Device (in master or slave mode) is addressed by remote master (matching device address). Accordingly, bit-field BS in register **BUSSTAT** is set to 11_B. 0_B No interrupt request 1_B Interrupt request pending
GC	1	rh	**General Call** Remote master has transmitted a general call. 0_B No interrupt request 1_B Interrupt request pending
MC	2	rh	**Master Code** Remote master has transmitted a master call. 0_B No interrupt request 1_B Interrupt request pending
AL	3	rh	**Arbitration Lost** Device (master mode) lost the control on the I2C-bus due to losing arbitration procedure. Accordingly, bit-field BS in register **BUSSTAT** is set to 01_B. 0_B No interrupt request 1_B Interrupt request pending
NACK	4	rh	**Not-acknowledge Received** When working as transmitter this interrupt indicates a not-acknowledge from the remote receiver. The SW has to decide what further steps have to be taken. 0_B No interrupt request 1_B Interrupt request pending
TX_END	5	rh	**Transmission End** The device has ended the data transfer properly (after stop condition has been put on the bus or the MASTER RESTART state has been entered.) 0_B No interrupt request 1_B Interrupt request pending

Field	Bits	Type	Description
RX	6	rh	**Receive Mode** I2C kernel indicates switching from transmitting data to receiving data. 0_B No interrupt request 1_B Interrupt request pending
0	31:7	r	**Reserved** Read as 0; should be written with 0.

Protocol Interrupt Request Source Clear Register

On a write of 1 to a particular bit of this write-only register, the corresponding protocol interrupt request source is cleared and if no further protocol interrupt request sources are active, the whole protocol interrupt is cleared. If the corresponding **RIS** bit is set by SW via the **ISR** register, then it can be cleared by setting any non-reserved bit of the interrupt request source clear register**.** A write of 0 has no effect. Reading the register returns 0.

The interrupts are explained in detail in description of register **PIRQSS**.

30.4 I2C Module Implementation

This section describes I2C module interfaces with the clock control, port control and interrupt control. TC27x provides one module I2C0.

30.4.1 Interfaces of the I2C Module(s)

Figure 30-25 shows the TC27x specific implementation details and interconnections of the I2C module(s):

- A clock control block generates the clock signals required for the module.
- For the I2C-bus lines SCL and SDA, different I/O lines can be selected.
- The interrupt outputs of the module are connected to the interrupt control unit.

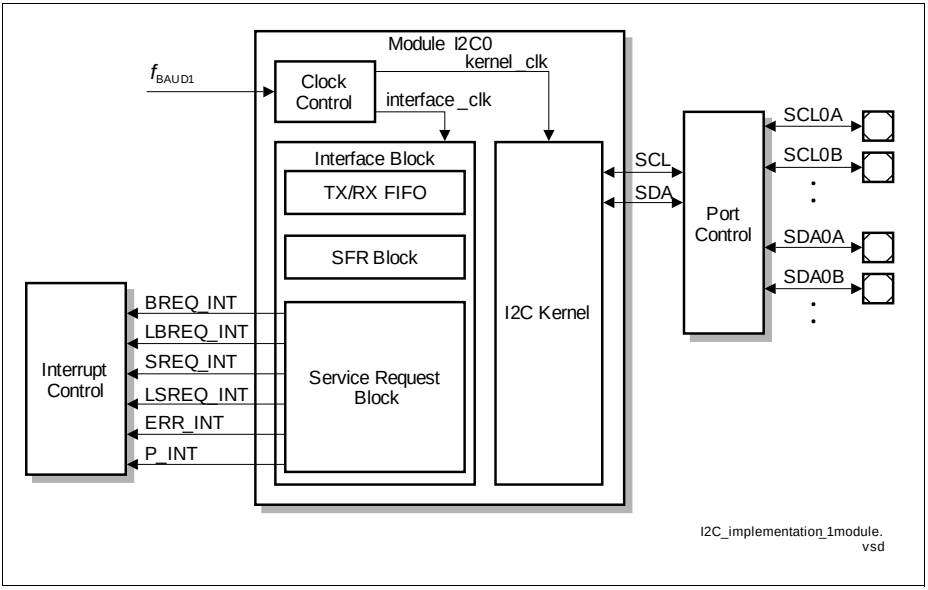

Figure 30-25 I2C Module Implementation and Interconnections

30.4.2 Module Clock Control

The clock control allows the programmer to adapt the peripheral´s functionality and power consumption to the application's requirement. The clock f_{BAUD1} is connected to the bus clock, which generates the clock for the interface block, and to the module clock, from which the I2C kernel clock is derived. By programming the kernel's operating frequency, an optimal ratio between power consumption, EMC behavior and functionality can be achieved. Furthermore, for power saving reasons the peripheral can be disabled as a whole by switching off the peripheral's clocks via clock gating cells.

A simplified description of the clock control is shown in **Figure 30-26**. See register **CLC1** for a description of the clock control parameters.

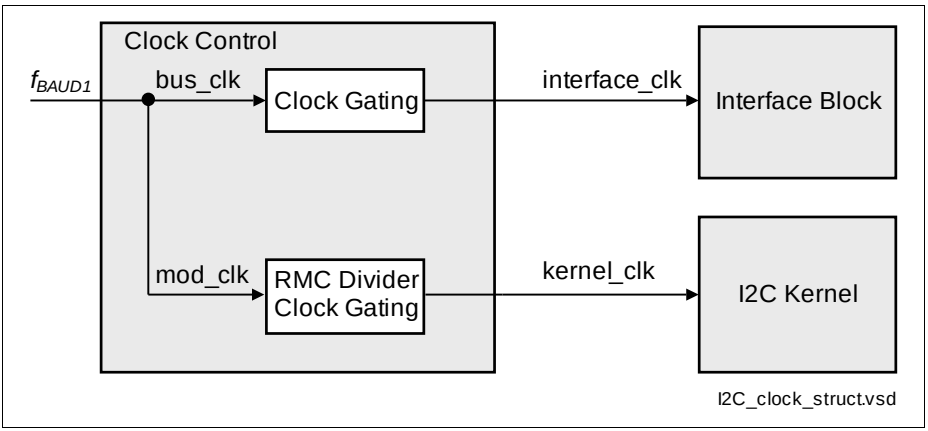

Figure 30-26 Module Clock Control

The following clocking modes are supported for the peripheral:

- Standard run mode
- Disable mode
- OCDS suspend mode

Standard Run Mode

In this mode the module clock is divided by the value of bit-field RMC in register **CLC1**. The value written to this bit field is equal to the dividing factor (e.g. RMC=04_H is equal to dividing by factor 4). If 00_H is written into RMC, the kernel clock is stopped.

Kernel Clock Calculation in Standard Run Mode:

$$f_{kernel\_clk} = \frac{f_{mod\_clk}}{RMC}; (RMC > 0) \quad (30.1)$$

I2C_FORMULA_RMC

Disable Mode

In this mode the clocks are switched off. It can be entered by either activating the module disable input (if not disabled by setting bit EDIS in register **CLC1**) or by setting bit DISR in register **CLC1**. Note that a secure clock shut off with handshake is performed before it is disabled (see “Secure Clock Shut Off” in **OCDS Suspend Mode**).

Additionally a peripheral can be disabled without handshake (see “Fast Clock Shut Off” in **OCDS Suspend Mode**) by setting the bit field of the clock divider to 00_H.

OCDS Suspend Mode

In this mode the clocks are disabled. If bit SPEN in register **CLC1** is set, the mode can be entered by activating the input module_ocds.

In OCDS suspend mode all registers of the suspended module can be read. Note that each read during disabled clock can not affect hardware. For example multiple reads to FIFO port registers always return the same value as the FIFO control is not working.

No write access to the registers is supported during suspend mode, except writes to the **CLC1** register. For writing other registers the suspend mode for the module has to be removed first by clearing bit SPEN. After the write access is executed, bit SPEN should be set again.

OCDS suspend mode supports two different disable features, selectable by bit FSOE in register **CLC1**:

- **Fast Clock Shut Off**

Selecting the fast clock shut off stops the clock immediately after all pending read and write accesses are finished (including synchronization mechanisms with the I2C kernel). This shut off mode can be activated by setting bit DISR in register **CLC1**.

- **Secure Clock Shut Off**

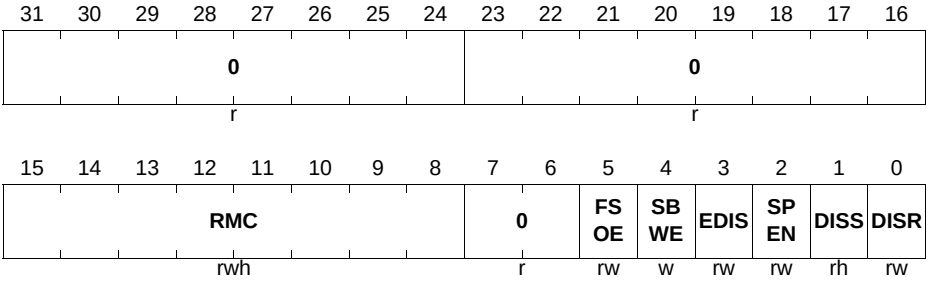
Disabling the clock via secure clock shut off additionally activates the handshake mechanism with the peripheral. The peripheral is switched to a secure state before disabling the clock.

*Note: To write to SPEN or FSOE, bit SBWE in register **CLC1** must also be set in the same write access.*

30.4.3 Bus Peripheral Interface Registers

This register controls the clock gating and dividing circuitry of the peripheral.

CLC1
Clock Control 1 Register **(00_H)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B Module disable not requested 1_B Module disable requested
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module. 0_B Module enabled 1_B Module disabled
SPEN	2	rw	**Module Suspend Enable Bit for OCDS** 0_B Module suspend disabled 1_B Module suspend enabled
EDIS	3	rw	**External Request Disable** 0_B External clock disable request is enabled 1_B External clock disable request is disabled
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** This bit is always read as 0. 0_B Bits SPEN and FSOE are write protected 1_B Bits SPEN and FSOE are overwritten by respective value of SPEN or FSOE

Field	Bits	Type	Description
FSOE	5	rw	**Fast Switch Off Enable** 0_B FSOE Clock switch off in OCDS suspend mode via Disable Control Feature (Secure Clock Switch Off) 1_B Fast clock switch off in OCDS suspend mode
RMC	15:8	rwh	**Clock Divider for Standard Run Mode** Max. 8-bit divider value If RMC is set to 0 the module is disabled. *Note: As long as the new divider value RMC is not valid, reading register returns 0000 00XX$_H$*
0	7:6, 31:16	r	**Reserved** Read as 0; should be written with 0.

30.4.4 I2C Module Registers Overview

In the following, the registers of the I2C module are listed. First of all, some explanation on the access conditions is given.

Special I2C Register Access Condition

Besides the general register protection, the I2C module has two main modes that must be considered when programming the peripheral:

- **Configuration Mode:** In this mode the peripheral can be prepared for transmission and reception via the configuration registers, which are only writable in this mode. The peripheral is in the configuration mode when bit RUN is set to 0.
- **Run Mode:** In this mode the peripheral is ready to transmit or receive data. Its configuration registers are locked for write access which will generate a bus error. The peripheral is in the run mode when bit RUN is set to 1.

I2C Registers Overview

There are the following blocks of registers (see **Figure 30-27**):

- Bus Peripheral Interface Registers
- Global Module Control Registers
- FIFO Registers
- Basic Interrupt Registers
- Error Interrupt Source Registers
- Protocol Interrupt Source Registers

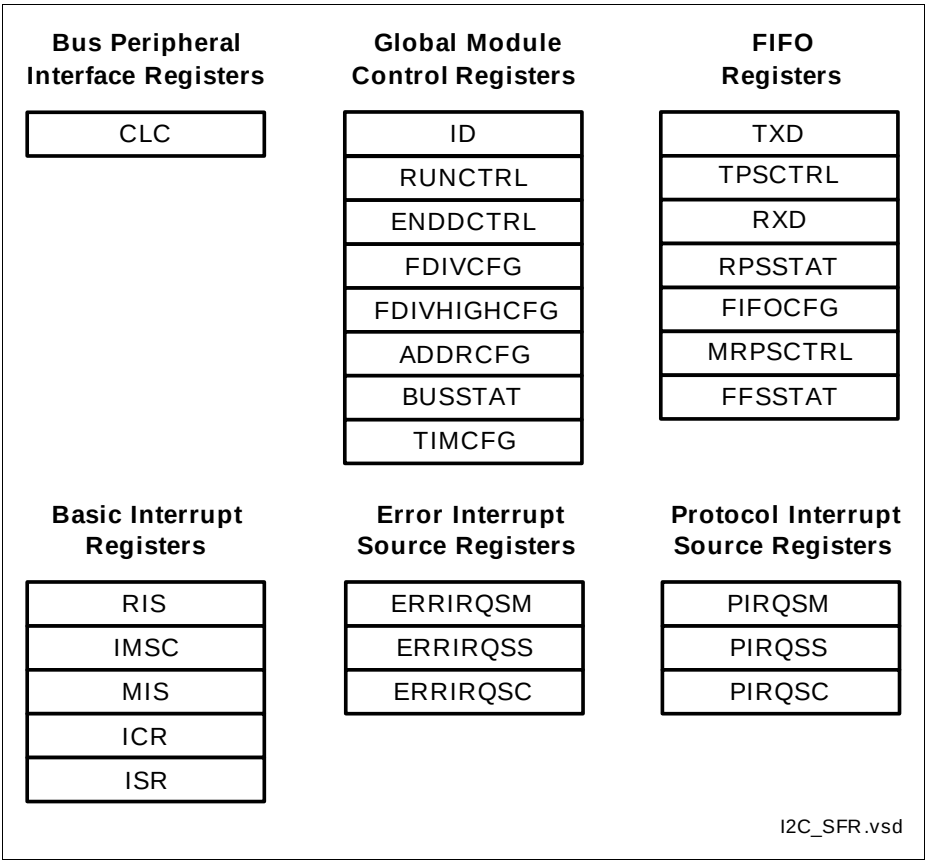


Figure 30-27 I2C Module Registers

The registers address space of the modules is defined in **Table 30-3**.

The registers overview in **Table 30-4** shows the register names of the module instances, the offset addresses and the links to the names used in this specification.

An access to an address in the address range of this module which is not given in the table causes a bus error.

Table 30-3 Registers Address Space of I2C Module

Module	Base Address	End Address	Note
I2C0	$F00C\ 0000_H$	$F00D\ 00FF_H$	~64 KByte

Table 30-4 Registers Overview of I2C Module

I2C0_KRSTCLR	Kernel Reset Status Clear Register	$1001C_H$	SV	SV, E, P	0000 0000_H

Note: The base address of the I2C0 BPI registers is F00D 0000_H.

Note: All I2C registers are Reset Class 3 registers.

30.4.5 Port and I/O Line Control

Not only the interconnections between the I2C module and the port I/O lines have to be configured, but also the function and the characteristics of the port pins. The following control operations must be executed for the used port pins:

- Selection of I2C module via output port multiplexer
- Configuration of output port function with open drain
- Configuration of pad driver characteristics
- Selection of I2C input lines

30.4.6 Interrupt Control

The interrupt functionality is described in the chapter for the interrupt router (IR).

The signal names used in the interrupt router description are explained in **Table 30-6**.

Table 30-6 Interrupt Router Signal Names for I2Cm Module (m = 0/1)

Signal Name	Name in Module	Explanation
SRC_I2CmBREQ	BREQ_INT	Burst Data Transfer
SRC_I2CmLBREQ	LBREQ_INT	Last Burst Data Transfer
SRC_I2CmSREQ	SREQ_INT	Single Data Transfer
SRC_I2CmLSREQ	LSREQ_INT	Last Single Data Transfer
SRC_I2CmERR	ERR_INT	Error
SRC_I2CmP	P_INT	Protocol

30.5 Module Integration

This section describes the topics regarding the integration of the module on chip.

30.5.1 Integration Overview

The I2C module consists of a delivery providing an AHB bus interface integrated into the FPI bus system by using an FPI2AHB adapter.

The adapter contains a slave bus interface providing translation between the FPI and the AHB bus protocols. The module supports addtionally the following features:

- power saving (sleep mode)
- debug suspend
- local module reset
- PISEL - port input selection regarding the serial data input

The power saving and debug suspend features are suported by the AHB based I2C module itself, and the local module reset and PISEL features are supported by the FPI2AHB adapter, see **Figure 30-28**.

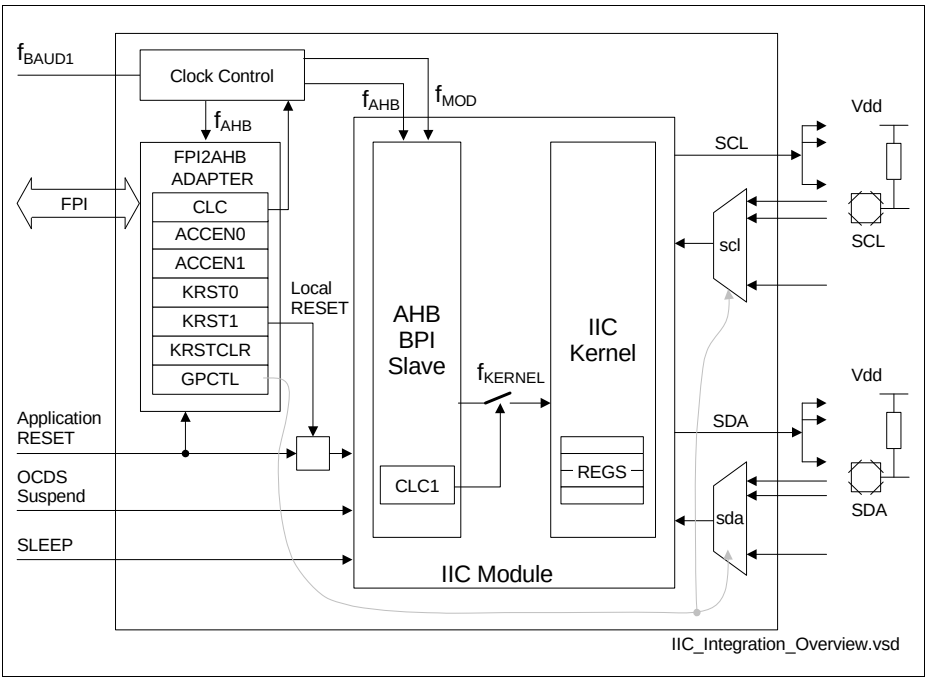

Figure 30-28 Integration Overview

30.5.2 BPI_SPB Module Registers

This section describes the registers implemented in the slave (FPI2AHB) adapter component.

30.5.2.1 System Registers

Figure 30-29 shows all registers associated with the BPI_FPI module, configured for one kernel. See also **Table 30-5** for the address mapping.

BPI_FPI Registers Overview

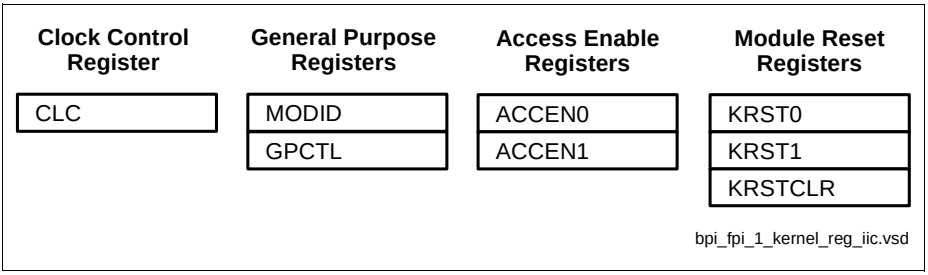

Figure 30-29 BPI_FPI Registers

Kernel Reset

If a kernel reset is requested, the adapter will synchronously assert the internal kernel reset output and error any ongoing accesses on the FPI bus not addressed to the adapter's internal SFRs.

The method of using the kernel reset output from the adapter to initialise the associated AHB module is module specific and outside the scope of this specification.

Any AHB accesses in progress will be synchronously terminated.

GPCTL

A single, adapter specific, SFR is implemented in the adaptor.

The SFR contains general purpose read/write control bits without ENDINIT protection. All the bits are connected to output ports on the FPI2AHB entity. The SFR will implement no safety requirements and is not be suitable for controlling hardware related to safety functions. The SFR supports, byte, half word and word transactions only. All other transactions are rejected with an FPI error termination.

Note: In the I2C module, this register implements the PISEL functionality. The SDA and SCL input multiplexors are controlled in parallel with each PISEL setting. Since 3 bits are implemented for PISEL, up to 8 sets of SDA and SCL pins can be defined.

Principle of Operation

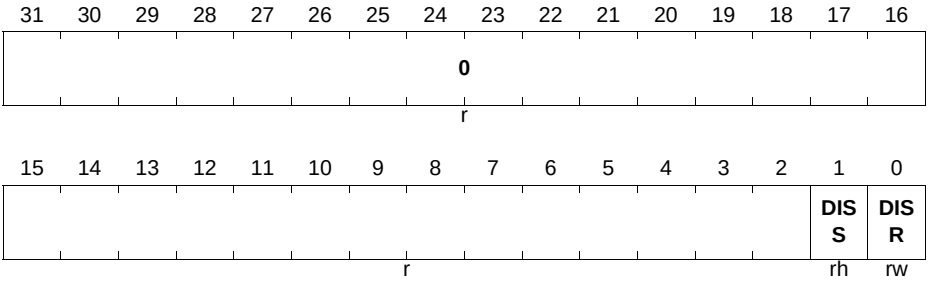
When the controlling state machine detects an FPI access, it compares the address to the address of the SFR. In the case that the address matches the SFR address, the normal state machine transitions are interrupted and the access is not passed to the AHB bus.

If the access opcode is not SDTB, SDTH or SDTW, then the access is terminated with an FPI error. If the opcode is supported, the SFR data will be returned on the FPI bus if the transaction is a read or the appropriate bits of the register will be updated if the access is a write.

Clock Control Register (CLC)

The Clock Control Register, CLC, acts globally and allows the complete AHB module to be disabled to reduce power consumption when the module is not required. When the module is disabled (DISS=1_B), only register accesses to the adapter register addres space are permitted. All other accesses to the module address space will be errored.

I2C0_CLC
Clock Control Register **(10000_H)** **Reset Value: 0000 0003$_H$**



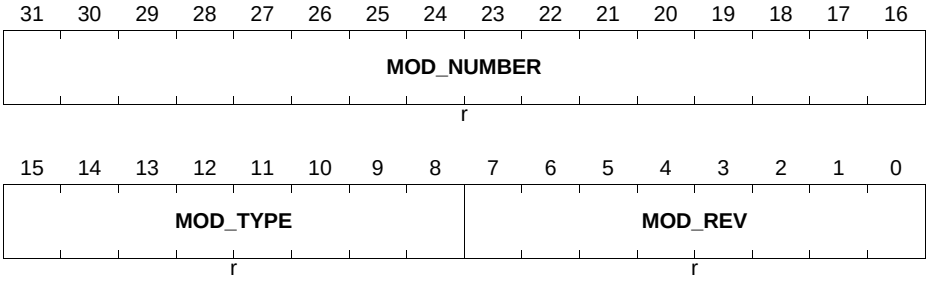
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Module Identification Register (ID)

The identification register allows the programmer version-tracking of the module.

I2C0_MODID

Module Identification Register (10004$_H$) Reset Value: 00C2 C0XX$_H$

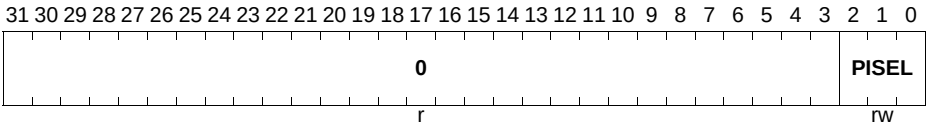


Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MOD_TYPE	[15:8]	r	**Module Type** The bit field is set to C0$_H$ which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number.

General Purpose Control Register

I2C0_GPCTL

General Purpose Control Register (10008_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
PISEL	[2:0]	rw	**Port Input Select** Used to select the input pins providing the serial data and clock input signals, in the range of 0 to 7. 000_B SDA0A and SCL0A are selected. 001_B SDA0B and SCL0B are selected. 010_B SDA0C and SCL0C are selected. 011_B SDA0D and SCL0D are selected. 100_B SDA0E and SCL0E are selected. 101_B SDA0F and SCL0F are selected. 110_B SDA0G and SCL0G are selected. 111_B SDA0H and SCL0H are selected. *Note: In TC27x, not all PISEL options are available. See the Ports chapter.*
0	[31:3]	r	**reserved** Reads 0. Should be written with 0.

Access Enable Register 0

The Access Enable Register 0 controls write access[1)] for transactions to registers with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The adapter is prepared for an 6 bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... ,EN31 -> TAG ID 011111_B.

I2C0_ACCEN0
Access Enable Register 0 ($1000C_H$) Reset Value: FFFF FFFF$_H$

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

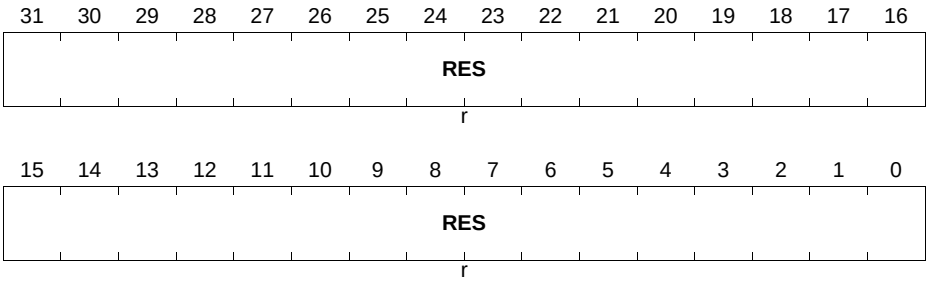
Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module register addresses for transactions with the Master TAG ID n 0_B Write access will not be executed. Read accesses will be executed. 1_B Write and read accesses will be executed

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Access Enable Register 1

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). These tags are not used in this system and so no programmable bits are provided.

I2C0_ACCEN1
Access Enable Register 1 (10010_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
RES	31:0	r	**Reserved** Read as 0; should be written with 0.

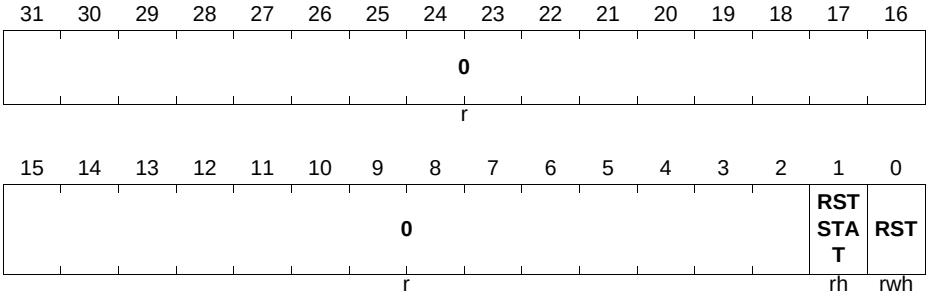
Kernel Reset Register 0 (KRST0)

The Kernel Reset function is used to synchronously reset the AHB module. To activate the kernel reset, it is necessary to set the RST bits by writing with 1_B in both Kernel Reset Registers.The RST bit will be re-set by the adapter with the end of the adapter kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to 1_B in the same clock cycle the RST bit is reset. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, write accesses to the module registers will result in an error acknowledge. Adapter registers can still be accessed.

I2C0_KRST0
Kernel Reset Register 0 **(10014_H)** **Reset Value: 0000 0000$_H$**



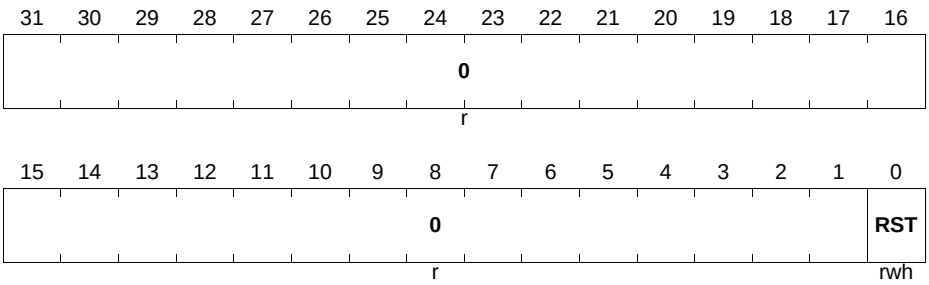
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (reset to 0_B) b after the kernel reset was executed.
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates whether a kernel reset was executed or not. This bit is set after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

I2C0_KRST1

Kernel Reset Register 1 **(10018_H)** **Reset Value: 0000 0000$_H$**



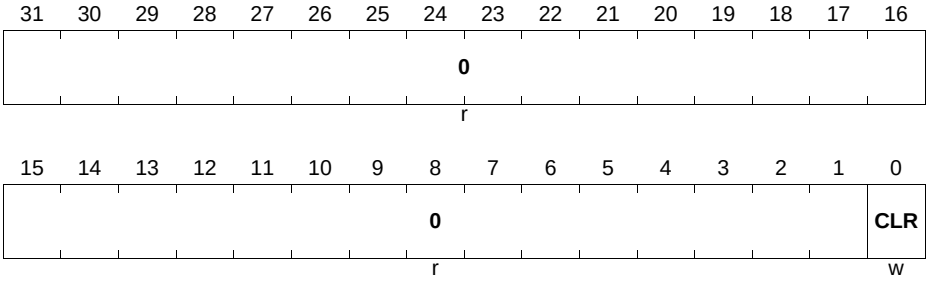
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to 0_B) after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0_B; should be written with 0_B.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

I2C0_KRSTCLR

Kernel Reset Status Clear Register (1001C$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0_B.
0	[31:1]	r	**Reserved** Read as 0_B; should be written with 0_B.

31 Input Output Monitor (IOM)

31.1 Overview

The Input Output Monitor (IOM) module serves as a smart I/O comparison unit, observing and checking for the correct operation of system peripheral outputs that may serve and/or control externally-attached hardware, as well as the correct operation of the hardware itself, including any sensors whose signals may serve as an input to the monitoring function.

The monitoring function may be achieved in a number of configurable ways depending upon the application and the type of safety measure to be deployed. (Examples of such measures are included later-on within this chapter). Triggering via software is also permissible in this manner.

Monitor and reference signals (where needed) are taken from applicable system peripherals (i.e. Capture/Compare Units and General Purpose Timer Units) where they connect to internal padlogic (that feeds/controls I/O Ports), which may or may not be driven to the pads (configuration dependent). In this manner connectivity can be made to a signal that is to be driven externally, and to another signal that may serve as a reference, although may not be driven off-chip. A driven signal may also serve as a reference in order to compare against another that may be provided via a GPIO input, e.g. from a sensor external to the device.

Up to 16 monitoring points can be configured, with the capability to generate a system event that may be driven from one individual, several individual or multiple occurrences of a monitored condition, or a combination of several depending upon configuration.

31.2 Features

- 16 Filter & Prescaler Channels, each connected to a specific pad (Pn_IN), the output of which to serve as a monitor or reference signal.
- 16 Logic Analyzer Modules (LAMs), with each channel comprising a mux to independently select monitor and reference signal inputs, with which to undertake the compare. A local event (i.e. internal to IOM) is generated when parity or disparity occurs between the selected monitor and reference signals. Configurable via register settings.
- 1 EXOR combiner, configurable (via register) to select a range of upto 8 GTM inputs in order to generate a combined signal to serve as a reference.
- Event Combiner Module (ECM), that takes the 16 local event signals (1 from each of the LAM modules) and generates a system event signal (connecting to system Safety Management Unit) from a single, combination or multiple local event(s). Configurable via register settings.

- System Peripheral Bus (SPB) interface for configuration and status register interaction.

31.3 Interfaces

The IOM features the following interfaces:

- System Peripheral Bus (SPB) - for the configuration of constituent parts of the IOM and the interrogation of associated status registers/bitfields.
- Multiple port logic/module connectivity, serving as reference or monitor signals. See SoC Integration section within this chapter for device-specific connections to GTM, GPT12, QSPI, CCU, GPIO (for GTM, etc.).
- Safety Management Unit (SMU) - a single global event signal used inform the SMU of a generated event within the IOM.
- System Signals - FPI Clock, GTM Clock, System Reset.

Note: The functionality of the IOM is independent from system debug, and no connectivity or mode of operation exists for this purpose.

31.4 Kernel Description

In addition to the Logic Analyzer Modules, Filter & Prescaler Blocks and Event Combiner Module, the IOM also features a System Peripheral Bus (SPB) interface for configuration and status register access. Note: All the configuration registers are protected by the register access protection mechanism (global definition).

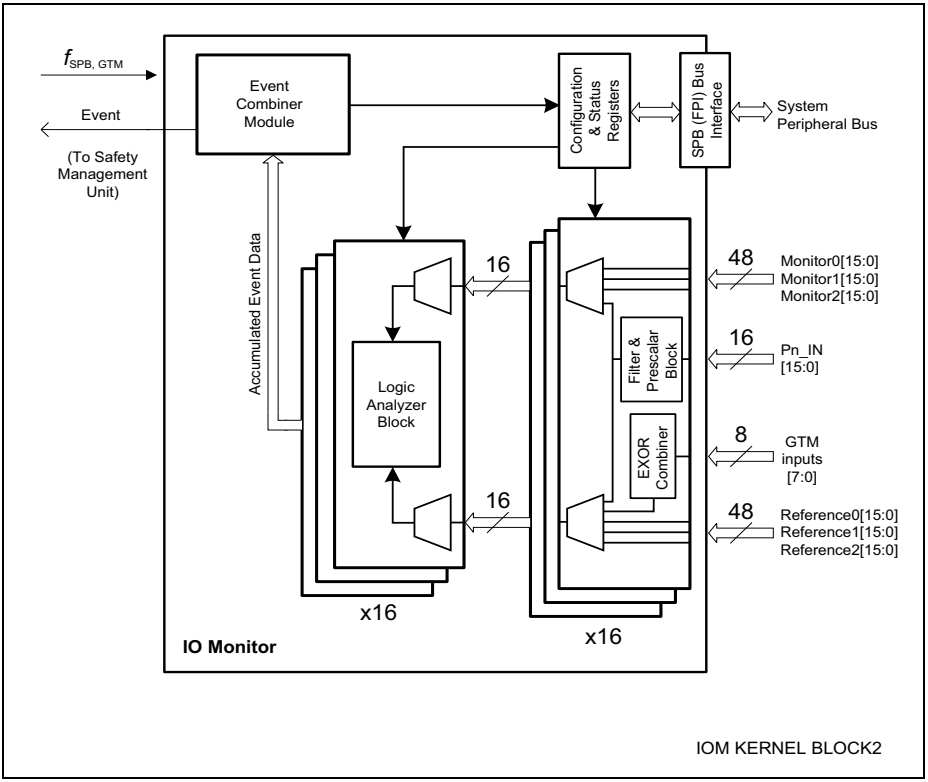


Figure 31-1 IO Monitor Block Diagram

The operational clock for the IOM is derived by combining the SPB and GTM clocks as a logical OR, the resultant frequency of which is therefore determined to be the higher of the two frequencies (assuming a synchronous relationship between the two, both being derived from the same system-level clock). This provides the capability for the IOM to sample GTM-related signals when the SPB (FPI) clock is lower than that of the GTM within the system.

31.5 Filter & Prescaler Channel Description

The IOM instances 16 Filter & Prescaler Channels(FPC's) for the purposes of preconditioning and filtering the signals received from the pads (Pn_IN inputs) that may be used as a reference or monitor.

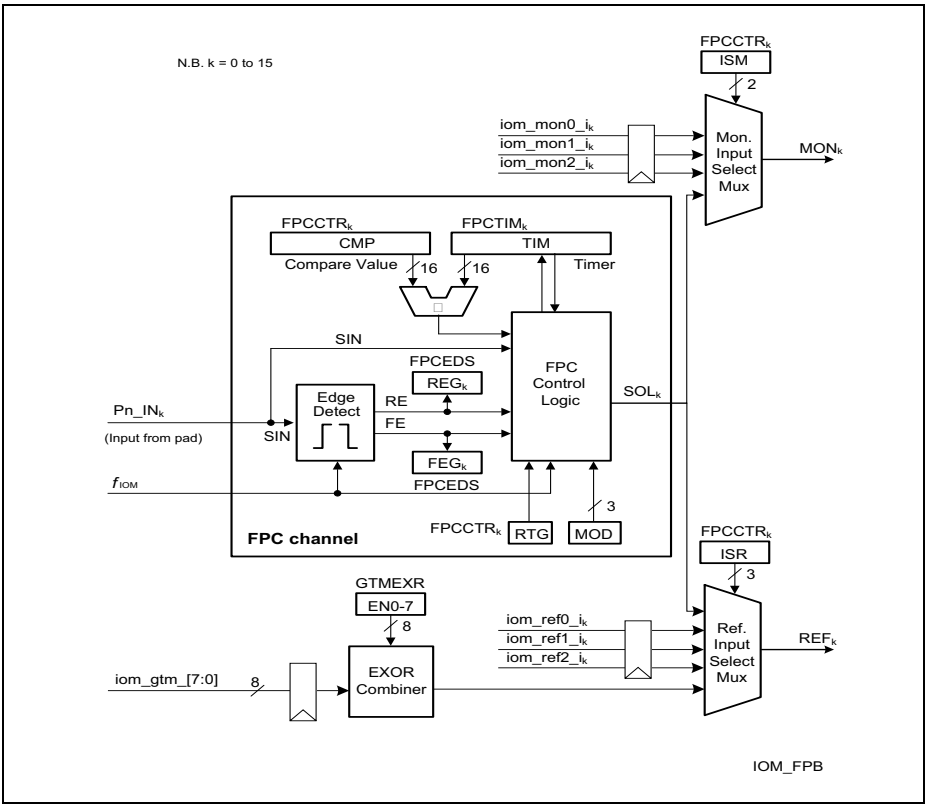

Figure 31-2 Monitor & Reference Selection logic incorporating Filter and Prescaler channel

As shown in **Figure 31-2**, each FPC channel (cell) is equipped with an signal input multiplexer, a clock multiplexer, an edge detection circuitry, a 16-bit timer, a 16-bit compare register, a 16-bit comparator, and a FPC control circuitry. The edge detection circuitry detects respective edges for the prescaler modes and detects glitches in all other modes.

FPC Registers

The following registers are assigned to the Filter and Prescaler Cells FPC_k (k = 0-15):

- FPCESR = Filter and Prescaler Cells Rising and Falling Edge Status Register.
- $FPCCTR_k$ = Filter and Prescaler Cell Control Register k
- $FPCTIM_k$ = Filter and Prescaler Cell Timer Register k

FPC Operating Modes

Each filter and prescaler cell can be individually configured to operate in one of the following operating modes:

- Delayed Debounce Filter Mode on both edges
- Immediate Debounce Filter Mode on both edges
- Rising edge: Immediate Debounce Filter Mode, falling edge: No filtering
- Rising edge: No filtering, falling edge: Immediate Debounce Filter Mode
- Rising edge: Delayed Debounce Filter Mode, falling edge: Immediate Debounce Filter Mode
- Rising edge: Immediate Debounce Filter Mode, falling edge: Delayed Debounce Filter Mode
- Prescaler Mode (triggered by edge detection circuitry on rising edge)
- Prescaler Mode (triggered by edge detection circuitry on falling edge)

The operation mode is selected by bit field $FPCCTR_k$.MOD.

FPC Input Signal notes

The maximum FPC input signal frequency must be less than or equal to the sampling rate ($f_{FPI}/2$).

FPC Output Signal notes

A level output, representative signal SOL_k, indicating the direction of the detected signal transition, that can be configured to connect to the Logic Analyzer $Module_m$.

Delayed Debounce Filter Mode

In Delayed Debounce Filter Mode, the signal input SIN is filtered from all signal transitions and glitches with a width smaller than the selected clock period length multiplied by the compare register value.

The input signal SIN is analyzed at the selected filter clock rate of f_{IOM}. If the state of the input sample differs from the current output signal value, the 16-bit timer is increased by one. When the timer register $FPCTIM_k$ is not in its idle state (0000_H) **and** the state of the input sample matches the current output signal value, the 16-bit timer is decremented by one (see **Figure 31-3**); if bit $FPCCTR_k$.RTG is set, the timer will be set to idle state again (see **Figure 31-4**). A rising or falling edge, occurring on the signal input line SIN when the timer is greater than zero but less than the compare value, sets the corresponding glitch flag FPCRES.REG (on rising edge glitch) or FPCFES.FEG (on falling edge glitch). When the timer matches the 16-bit compare value stored in $FPCCTR_k$.CMP (timer threshold), the level output signal line SOL_k is inverted, and the timer is reset to 0000_H. The rising/falling edge glitch flags must be reset by software.

The filter is by-passed if the compare value $FPCCTR_k$.CMP is programmed to zero (0000_H). In this case, the input signal is directly copied to the output signal.

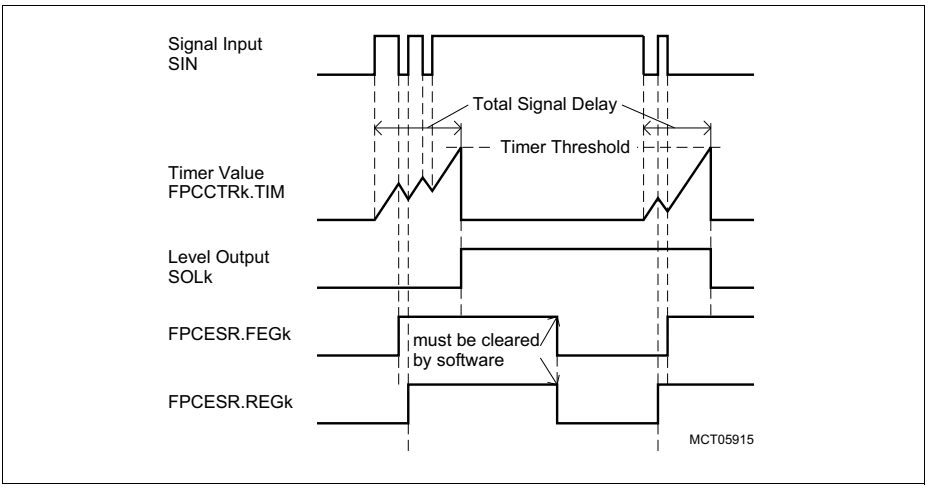

Figure 31-3 FPC Delayed Debounce Filter Algorithm with Timer Decrement

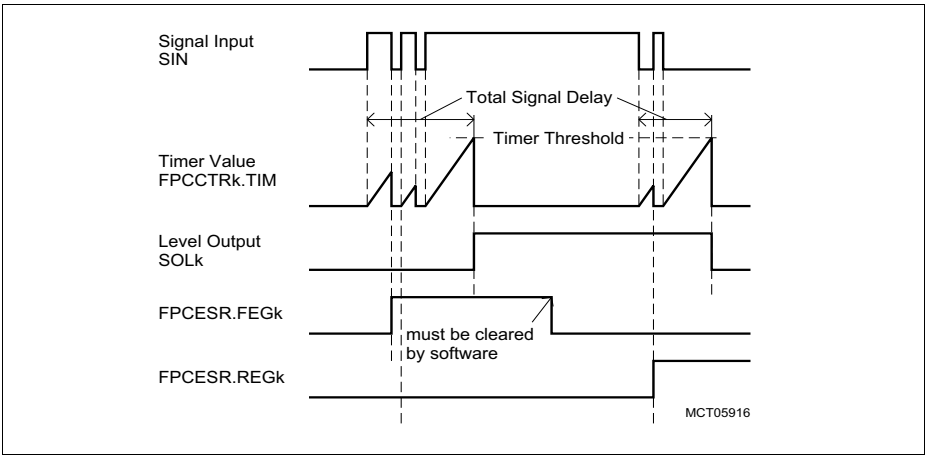

Figure 31-4 FPC Delayed Debounce Filter Algorithm with Timer Reset

The total signal delay from input to output depends on the programmed compare register value, the number of high-frequency pulses (glitches) during the filter operating time, and the timer behaviour in case of a glitch (decrement or reset).

The FPC Delayed Debounce Filter Mode is selected by:

- $FPCCTR_k.MOD = 000_B$

Immediate Debounce Filter Mode

In Immediate Debounce Filter Mode, the input signal is filtered from signal transitions and glitches arriving a programmable time after an input signal edge detection (see **Figure 31-5**).

The input signal SIN is sampled with f_{FPI} and the input signal SIN edge detection is also performed with f_{FPI}. The further analysis (e.g. filter timer increment, glitch detection) is also achieved with f_{FPI}.

As long as the timer is reset, the FPC control circuitry copies the sampled input value directly to the level output signal line SOLk. When a rising or falling edge occurs on the signal input line SIN and the 16-bit compare value $FPCCTR_k$.CMP is not zero, the timer is enabled to be increased by the selected clock and the copy mechanism is disabled. When the timer value $FPCTIM_k$.TIM matches the compare value $FPCCTR_k$.CMP, the timer is reset and the copy mechanism is enabled again. A rising or falling edge, occurring on SIN while the timer is greater than zero but less than the compare value, sets the corresponding glitch flag FPCRES.REG (on rising edge glitch) or FPCFES.FEG (on falling edge glitch). The rising/falling edge glitch flags must be reset by software.

The filter is by-passed if the compare value $FPCCTR_k$.CMP is programmed to zero (0000_H). In this case, the input signal is directly copied to the output signal without any disable periods.

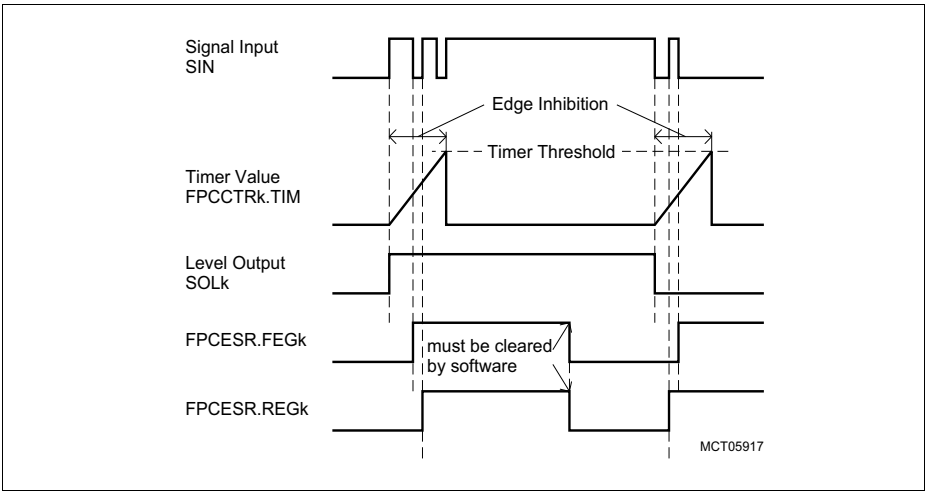

Figure 31-5 FPC Immediate Debounce Filter Algorithm on Both Edges

Note: During the last clock cycle of edge inhibition time (where timer value is equal to the compare value) an input signal glitch will be filtered but the corresponding glitch status flag in register FPCRES/FPCFES is not set.

The Immediate Debounce Filter can be enabled only for one edge, either rising or falling. In this case, the signal output follows the signal input value immediately after the timer threshold of the filtered edge is reached, without re-starting the timer (see **Figure 31-6**).

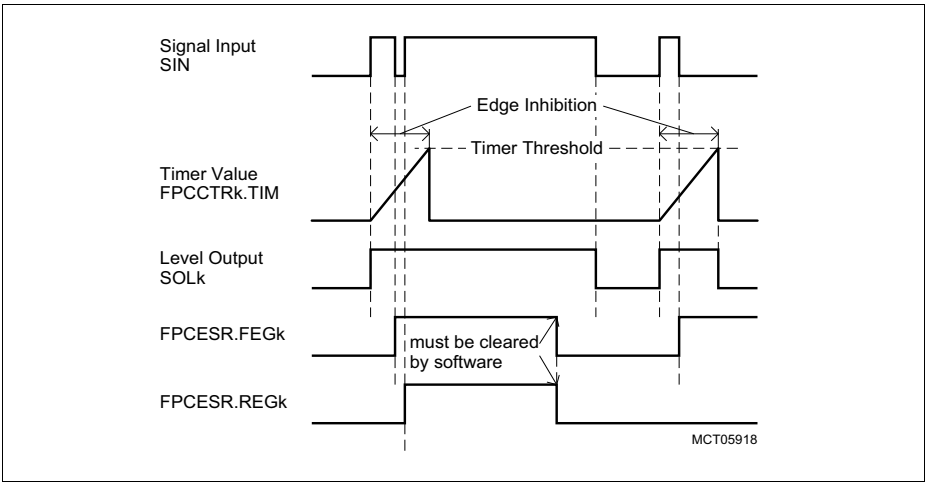

Figure 31-6 FPC Immediate Debounce Filter Algorithm on Rising Edge only

The FPC Immediate Debounce Filter Modes are selected by:

- $FPCCTR_k.MOD = 001_B$: Immediate Debounce Filter Mode on both edges
- $FPCCTR_k.MOD = 010_B$: Immediate Debounce Filter Mode on rising edge only, no filtering on falling edge.
- $FPCCTR_k.MOD = 011_B$: Immediate Debounce Filter Mode on falling edge only, no filtering on rising edge.

Mixed Filter Modes

In the Mixed Filter Modes, one edge of a signal is filtered in the Delayed Debounce Mode, and the other edge is filtered in the Immediate Debounce Mode. The Debounce Mode is switched when the timer threshold is reached. Note that both filter modes use the same timer threshold in this case (see **Figure 31-7**, demonstrating Delayed Debounce Mode with Timer Decrement on Rising Edge and Immediate Debounce of on Falling Edge).

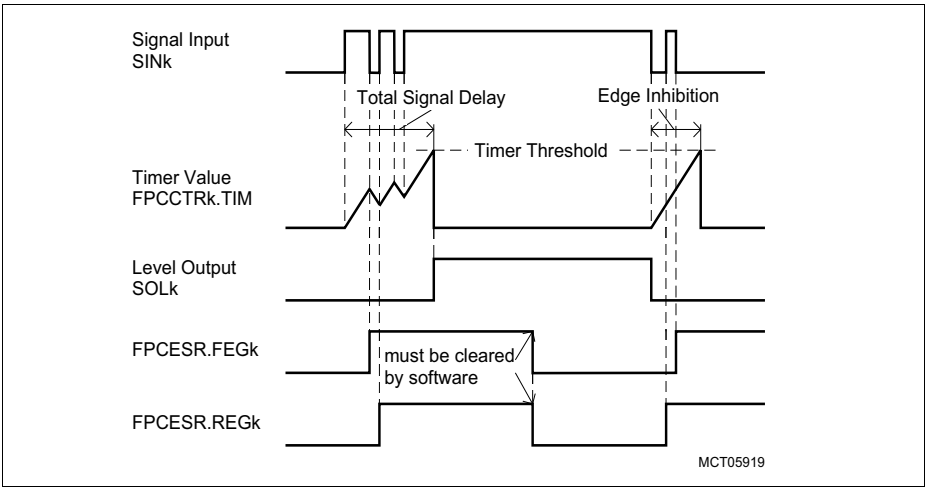

Figure 31-7 FPC Mixed Filter Algorithm

The FPC Mixed Filter Modes are selected by:

- $FPCCTR_k.MOD = 100_B$: Delayed Debounce Filter Mode on rising edge
  Immediate Debounce Filter Mode on falling edge
- $FPCCTR_k.MOD = 101_B$: Immediate Debounce Filter Mode on rising edge
  Delayed Debounce Filter Mode on falling edge

Prescaler Mode

In Prescaler Mode, the input signal is sampled and analyzed with f_{FPI}. The FPC control circuitry counts each rising (or falling) edge of the input signal. When the timer value matches the compare value:

- one IOM module clock pulse is generated at the level output signal SOL_k
- the timer $FPCTIM_k$.TIM is reset to 0000_H

Figure 31-8 shows a divide-by-6 operation using the FPC in Prescaler Mode with trigger on rising edge selected.

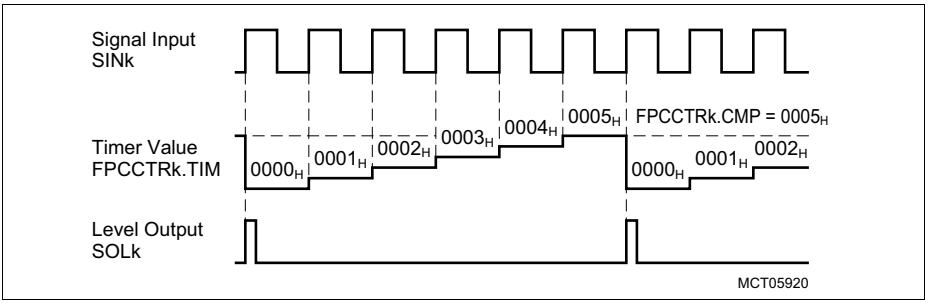

Figure 31-8 FPC Prescaler Mode

For a divide-by-n operation, the compare value $FPCCTR_k$.CMP must be set to n - 1.

The FPC Prescaler Modes are selected by:

- $FPCCTR_k$.MOD = 110_B: Prescaler Mode triggered by edge detection circuitry on rising edge
- $FPCCTR_k$.MOD = 111_B: Prescaler Mode triggered by edge detection circuitry on falling edge

31.6 EXOR Combiner Description

The EXOR Combiner can be configured to accepts upto 8 external inputs from GTMmodule outputs, used for replicate a typical *combined* signal from an automotive multi-phase motor. The output from which can then be used as a reference to monitor such a motor.

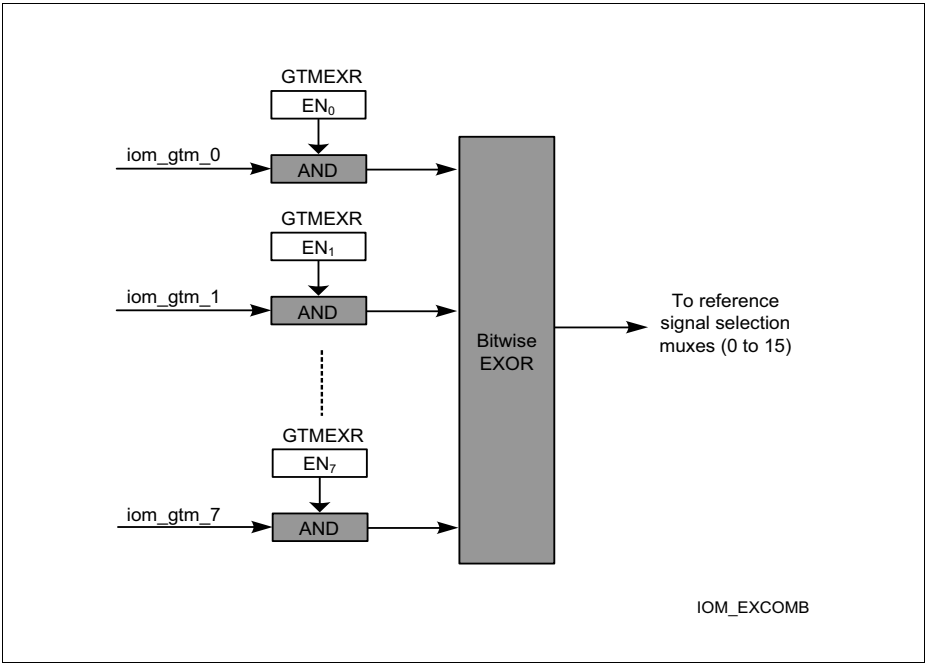

Figure 31-9 EXOR Combiner block diagram

EXOR Combiner Registers

The following registers are assigned to the block:

- GTMEXR = GTM Input EXOR Combiner Selection Configuration Register.

EXOR Combiner Input Signals

- 8 inputs from the GTM module(s).

EXOR Combiner Output Signals

- 1 output signal reflecting the combined logical EXOR function on the associated (and enabled input(s)).

31.7 Logic Analyzer Module (LAM) Description

The IOM instances 16 Logic analyzer Modules (LAM's) for the purposes of monitor and reference signal comparison. Each block accepts one monitor and one reference level signal from the 16 monitor & 16 reference signals available, from the FPC/Input selection block. The behaviour of each LAM is set by configuring the associated register settings.

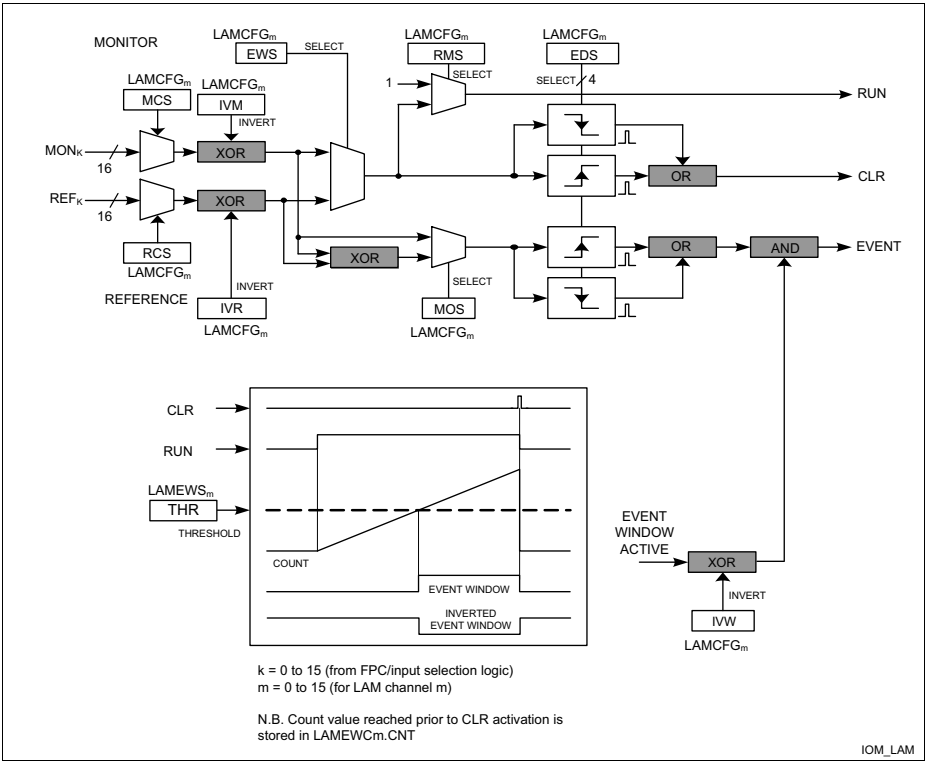

Figure 31-10 Logic Analyzer Module (LAM) block diagram

As shown in **Figure 31-9**, each Logic Analyzer Module features inputs for the Reference & Monitor points, fed from the requisite Filter & Prescaler block. Depending upon the Logic Analyzer Module configuration register (LAMCFG), and the event window settings register (LAMEWS), the block may be configured to monitor a particular type of signal behaviour, input from sensors external to the device in order to monitor, govern and/or control external application behaviour with particular regard to any given safety requirements.

LAM Registers

The following registers are assigned to the Logic Analyzer Module LAM_m (m = 0-15):

- $LAMCFG_m$ = Logic Analyzer Module Configuration Register m
- $LAMEWS_m$ = Logic Analyzer Module Event Window Settings Register m
- $LAMEWC_m$ = Logic Analyzer Module Event Window Count Status Register m

LAM Input Signals

Two inputs exist for each LAM_m:

- Reference signal input, fed from the requisite Filter & Prescaler block.
- Monitor signal input, fed from the requisite Filter & Prescaler block.

Depending upon the required function, both inputs or just the Monitor input may be utilised.

LAM Output Signals

One output is provided by each LAM:

- Event trigger output, configured to be active when a monitored signal falls outside the intended timed and/or periodic behaviour.

31.8 Event Combiner Module (ECM) Description

The IOM instances one Event Combiner Module, which takes the event outputs from each of the 16 Logic Analyzer Modules (LAM's). Some or all of these events can then be combined in a variety of configurable ways in order to generate a single system event.

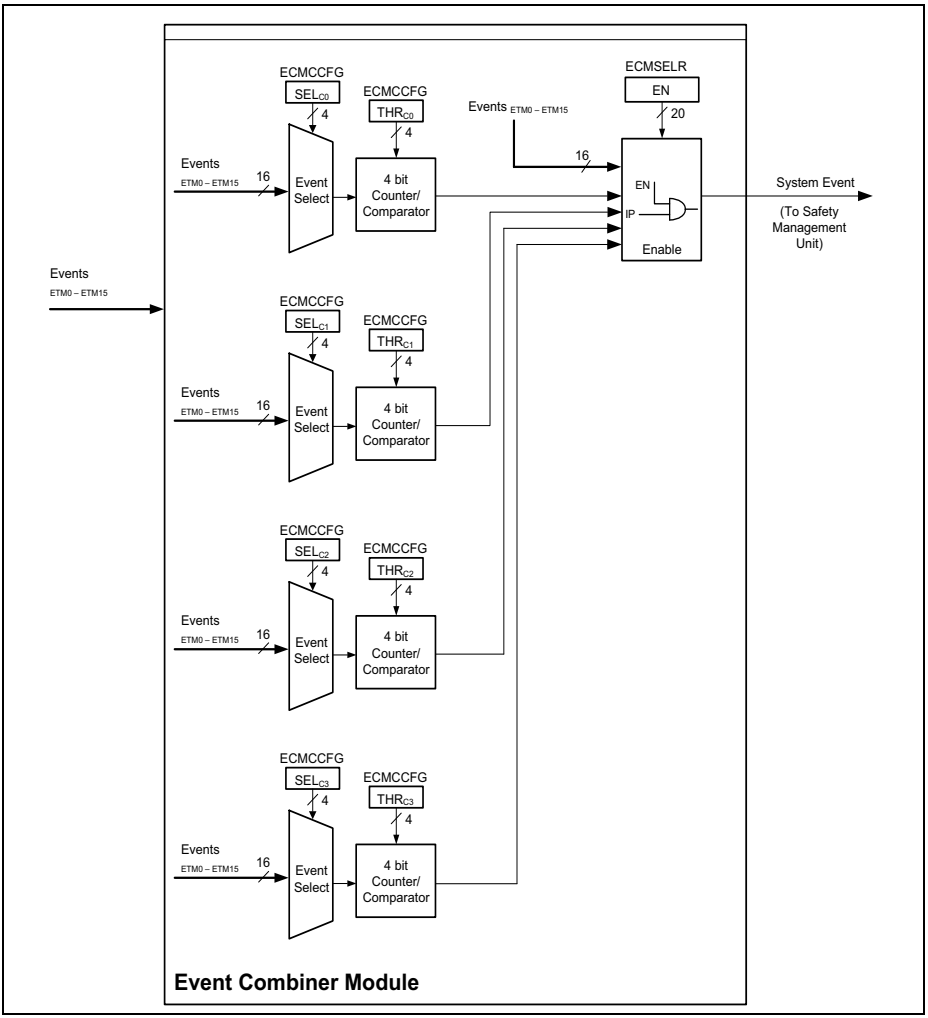

Figure 31-11 Event Combiner Module (ECM) block diagram

Four separate 4bit counters with configurable thresholds are also available to be assigned to count multiple occurring events from any of the 16 available LAM's. The output of these counter units (active once a count threshold has been met/surpassed) can also be included (via configuration) within the generation of the system event. (Note: the alarm output will be connected to the Safety Management Unit, SMU.EMM).

The ECM also includes two Event Trigger History (ETMETH0/1) registers, updated with each system event, used to record the status of the 16 LAM event outputs, thereby identifying which triggers were responsible.

In addition, the ECM incorporates a System Peripheral Bus (SPB) interface for writing configuration and reading status registers appertaining to all subblock within the IOM.

ECM Registers

The following registers are assigned to the ECM:

- ECMCCFG = ECM counter configuration register (for the four 4bit local event counters).
- ECMSELR = ECM global event selection register (for the selection of local events, or multiples thereof, required to generate the global event signal).

ECM Input Signals

- From Logic Analyzer Modules (LAM's)
  - Local event triggers from LAM blocks (0 to 15).
- System Peripheral Bus.

ECM Output Signals

One output is generated by each LAM:

- Global event trigger output, intended to be connected to the Safety Management Unit.
- System Peripheral Bus.

31.9 IOM Registers

This section describes the kernel registers of the IOM unit.

All read and write accesses to an undefined address location within the IOM address space will result in a bus error on the System Peripheral Bus (SPB).

IOM Kernel Register Overview

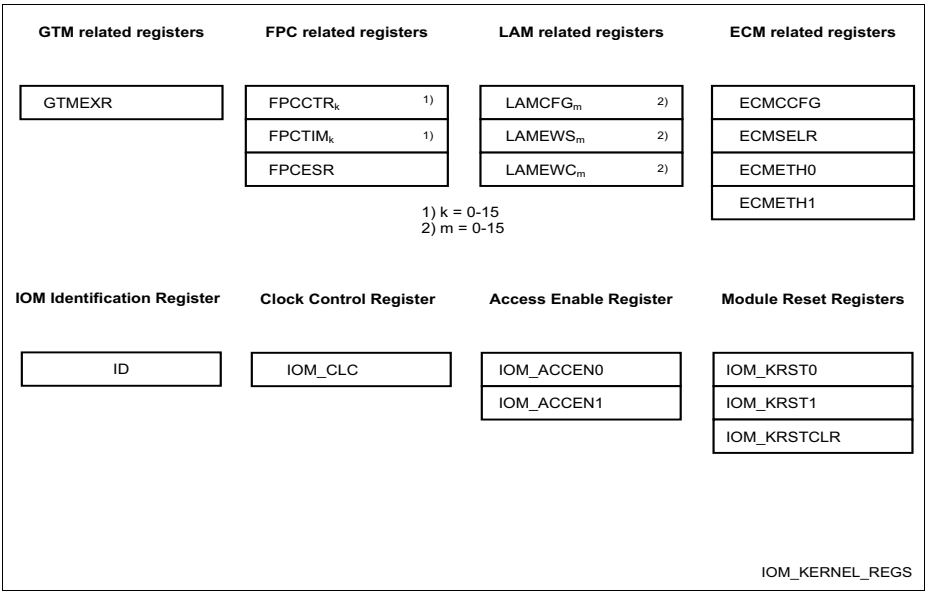

Figure 31-12 IOM Kernel Registers

In the TC27x, the registers of the IOM units are located in the following address ranges.

Table 31-1 Registers Address Space

Module	Base Address	End Address	Note

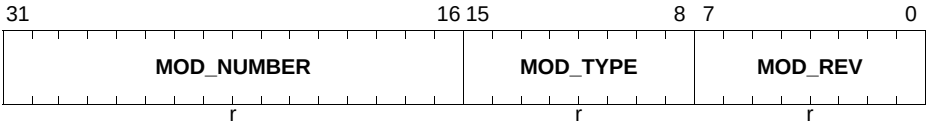
31.9.1 IOM Identification Register (IOM_ID)

The IOM Identification Register ID contains read-only information about the module version.

IOM_ID
IOM Identification Register **(008_H)** **Reset Value: $00CC\ C001_H$**



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the Module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Number Value** This bit field defines the module as a 32 bit module: $C0_H$
MOD_NUM	[31:16]	r	**Module Number Value** This bit field defines the identification number for the IOM.

31.9.2 Filter & Prescaler Cell (FPC) Registers

IOM Filter and Prescaler Cells Rising & Falling Edge Status Register (IOM_FPCESR)

The Filter and Prescaler Edge Status Register stores the state of detected rising and falling edges from each of the FPC cells.

The register can be written to selectively clear individual bits.

Individual bits are also cleared with a write to the control register (FPCCTRk) or timer register (FPCTIMk).

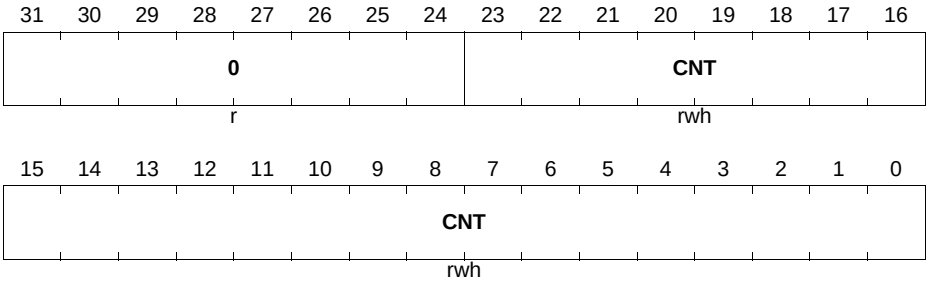
31.9.4 Logic Analyzer Module (LAM) Registers

IOM Logic Analyzer Module Event Window Count Status register (IOM_LAMEWCm)

Used to store the window count value reached prior to being cleared in the LAM block once an event has been generated.

Note: A write to this register will result in a bus error, i.e.existing contents unaffected.

IOM_LAMEWCm (m = 0-15)
IOM Logic Analyzer Module Event Window Count Status Register$_m$
(100_H+m*4_H) **Reset Value: 0000 0000_H**

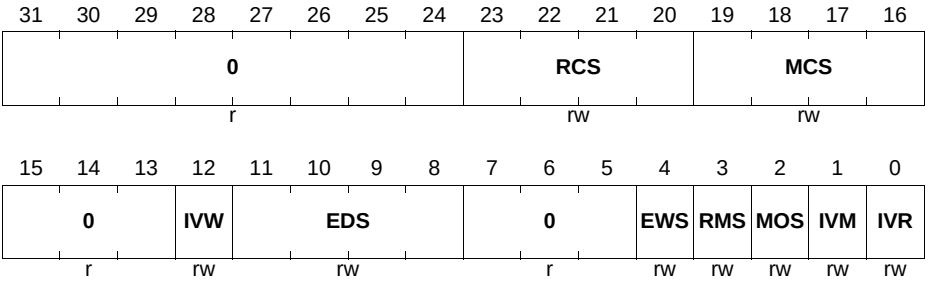


Field	Bits	Type	Description
CNT	[23:0]	r	**Event Window Count Value LAM block m** The count value of the event window attained coincident with an event occuring.
0	[31:24]	r	**Reserved** Read as 0.

IOM Logic Analyzer Module Configuration Register (IOM_LAMCFGm)

Use to configure the application-specific settings for each LAM block, including signal selection muxes at the block inputs.

IOM_LAMCFGm (m = 0-15)
IOM Logic Analyzer Module Configuration Register$_m$
(180_H+m*4_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
IVR	0	rw	**Invert Reference LAM block m** This bit field determines whether the reference signal from the FPCrch is inverted or not. 0_B Don't invert reference signal from FPC. 1_B Invert reference signal from FPC.
IVM	1	rw	**Invert Monitor LAM block m** This bit field determines whether the monitor signal from the FPCmch is inverted or not. 0_B Don't invert monitor signal from FPC. 1_B Invert monitor signal from FPC.
MOS	2	rw	**Monitor Source Select LAM block m** This bit field determines whether the monitor signal from the FPCmch is sourced directly or compared (EXOR'd) with the reference signal from the FPCrch for the event compare. 0_B Monitor signal is sourced directly from FPCmch. 1_B Monitor signal is EXOR'd with FPCrch.

Field	Bits	Type	Description
RMS	3	rw	**Runmode Select LAM block m** This bit field determines whether the event window generation is free-running or gated with the monitor or reference. 0_B Event window generation is free-running. 1_B Event window generation is gated with the monitor or reference signal.
EWS	4	rw	**Event Window Select LAM block m** This bit field determines whether the event window generation is from the monitor or reference signal. 0_B Event window generation is determined from the reference signal. 1_B Event window generation is determined from the monitor signal.
0	[7:5]	r	**Reserved** Read as 0; should be written with 0.
EDS	[11:8]	rw	**Event Window Active Edge Selection LAM block m** This bit field determines which active edges of the monitor and reference signals are used for the event window generation. $xx00_B$ Neither edge used to clear event windowcounter. $xx01_B$ Positive edge used to clear event windowcounter. $xx10_B$ Negative edge used to clear event windowcounter. $xx11_B$ Either edge used to clear event windowcounter. $00xx_B$ Neither edge used to gate event generation. $01xx_B$ Positive edge used to gate event generation. $10xx_B$ Negative edge used to gate event generation. $11xx_B$ Either edge used to gate event generation.
IVW	12	rw	**Invert Event Window LAM block m** This bit field determines whether the event window polarity is inverted or not. 0_B Event window non-inverted. 1_B Event window inverted.
0	[15:13]	r	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
MCS	[19:16]	rw	**Monitor Input Signal Selection LAM block m** This bit field determines which FPC/mux block k monitor output signal is to be used for LAM block m. 0000_B Monitor signal provided by FPC/mux block 0. 0001_B Monitor signal provided by FPC/mux block 1. 0010_B Monitor signal provided by FPC/mux block 2. 0011_B Monitor signal provided by FPC/mux block 3. 0100_B Monitor signal provided by FPC/mux block 4. 0101_B Monitor signal provided by FPC/mux block 5. 0110_B Monitor signal provided by FPC/mux block 6. 0111_B Monitor signal provided by FPC/mux block 7. 1000_B Monitor signal provided by FPC/mux block 8. 1001_B Monitor signal provided by FPC/mux block 9. 1010_B Monitor signal provided by FPC/mux block 10. 1011_B Monitor signal provided by FPC/mux block 11. 1100_B Monitor signal provided by FPC/mux block 12. 1101_B Monitor signal provided by FPC/mux block 13. 1110_B Monitor signal provided by FPC/mux block 14. 1111_B Monitor signal provided by FPC/mux block 15.

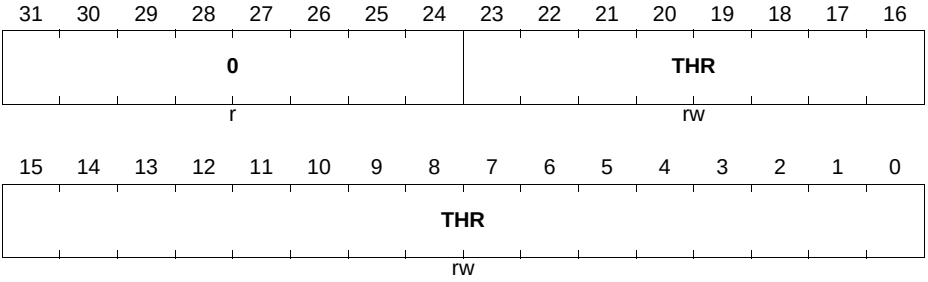
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

IOM Logic Analyzer Module Event Window Configuration Register (IOM_LAMEWSm)

Used to set the threshold value for the event window counter.

IOM_LAMEWSm (m = 0-15)
IOM Logic Analyzer Module Event Window Configuration Register$_m$
($1C0_H$+m*4_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
THR	[23:0]	rw	**Event Window Count Threshold** This bit field determines the threshold value for the event window counter from which an event is generated. Note: if THR has a value of 0 then no event will be generated.
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

31.9.5 Event Combiner Module (ECM) Registers

Event Combiner Module Counter Configuration register (IOM_ECMCCFG)

The Event Combiner Configuration register is used to configure each of the four event counter submodules, enabling multiple events from one selected LAM block (for each event counter submodule) to be counted in the generation of a system event.

IOM_ECMCCFG
IOM Event Combiner Module Counter Configuration Register
(030_H) Reset Value: $0000\ 0000_H$

CTSn (n=0-3)	n+16	rw	**Accumulated (Counted) Event Combiner Selection** The setting of individual bitfields determines the inclusion of the respective channel event counter output (1 of 4) in the generation of the global event (AND function). 0_B Don't include channel event/event counter output within the global event generation. 1_B Include channel event/event counter output within the global event generation.
0	[31:20]	r	**Reserved** Read as 0; should be written with 0.

Event Combiner Module Event Trigger History Register (IOM_ECMETH0)

One of two registers (IOM_ECMETH0 and IOM_ECMETH1) that record the status of LAM's 0 to 15 event outputs for the last 4 generated system events.

The generation of a system event will cause the status of the event outputs from LAM blocks 0 to 15 to be recorded in ETA0-15, respectively. Just prior to this happening, the previous status held in ETA0-15 is moved to ETB0-15. Similarly, the previous contents of ETB0-15 and ETC0-15 are moved to ETC0-15 and ETD15-0, respectively. The old contents of ETD15-0, being lost.

At reset (or a register write to either IOM_ECMETH0 or IOM_ECMETH1), all Event Trigger Active flags (ETA, ETB, ETC, ETD) will be cleared.

31.9.6 System Registers

IOM Clock Control Register (IOM_CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the $f_{<>}$ module clock signal, sleep mode and disable mode for the module.

IOM_CLC
IOM Clock Control Register (000_H) Reset Value: 0000 0003$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RMC								0				EDIS	0	DISS	DISR
rw								r				rw	rw	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
0	2	rw	**Reserved** Read as 0; should be written with 0.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
RMC	[15:8]	rw	**8-bit Clock Divider Value in RUN Mode**
0	[31:16], [7:4]	r	**Reserved** Read as 0; should be written with 0.

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency, which is selected via bit field RMC in the CLC register. Therefore, increasing

CLC.RMC may result in a longer FPI Bus read cycle access time for kernel registers and can also slow down the write throughput to the kernel registers.

IOM Access Enable Register (IOM_ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

IOM_ACCEN0
IOM Access Enable Register 0 ($02C_H$) Reset Value: FFFF FFFF$_H$

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

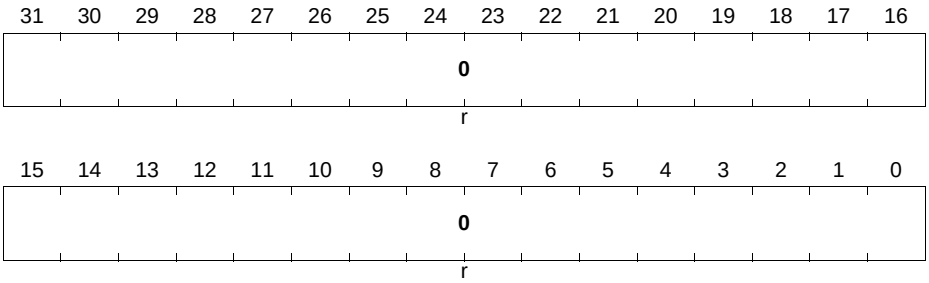
1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

IOM Access Enable Register (IOM_ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

IOM_ACCEN1
IOM Access Enable Register 1 (028_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

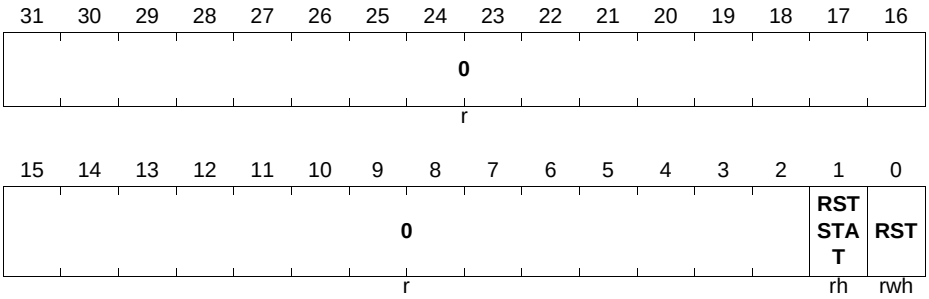
IOM Kernel Reset Register 0 (IOM_KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

IOM_KRST0
IOM Kernel Reset Register 0 (024_H) Reset Value: $0000\ 0000_H$



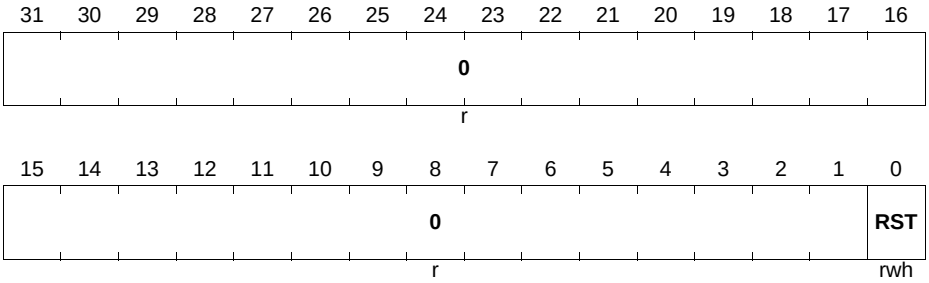
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.

Field	Bits	Type	Description
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

IOM Kernel Reset Register 1 (IOM_KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

IOM_KRST1
IOM Kernel Reset Register 1 (020_H) Reset Value: 0000 0000_H



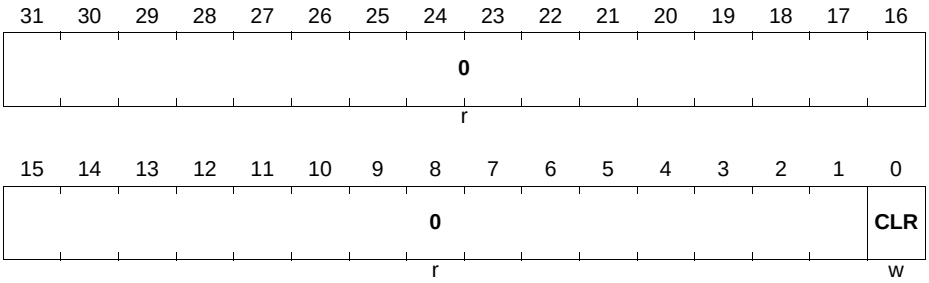
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

IOM Kernel Reset Status Clear Register (IOM_KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

IOM_KRSTCLR

IOM Kernel Reset Status Clear Register($01C_H$) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

31.10 SoC Integration

31.11 Example Monitor/Safety Measures

For each channel the following measurements shall be possible:

- Duty cycle measurement
- Set-up and/or hold time measurement
- Delay window (min,max) with respect to rising or falling edge

The following waveforms provide more examples of typical signal monitoring functionality that could be deployed using the IOM. Some typical configuration settings are also provided on some of the examples.

31.11.1 Example 1 - Pulse or duty cycle too short

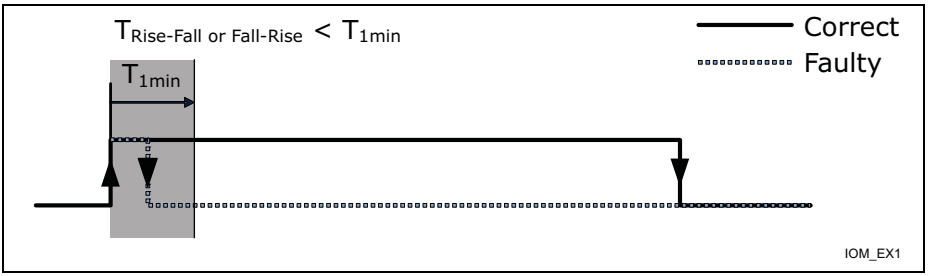

Figure 31-16 example 1 - pulse or duty cycle too short

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't care

LAMCFG.IVM: 0x0 ; don't invert monitor signal (or invert for non-duty part of period)

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x9 ; CLR on positive edge, EVT on negative edge

LAMCFG.IVW : 0x1 ; invert window, capture events under the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (minimum duty cycle length required. If duty cycle is shorter than this value then EVT will trigger)

31.11.2 Example 2 - Pulse or duty cycle too long

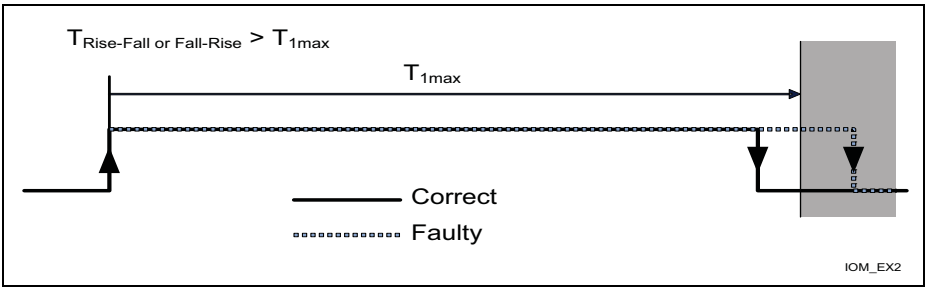

Figure 31-17 example 2 - pulse or duty cycle too long

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't care

LAMCFG.IVM: 0x0 ; don't invert monitor signal (or invert for non-duty part of period)

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x9 ; CLR on positive edge, EVT on negative edge

LAMCFG.IVW : 0x0 ; don't invert window, capture events beyond the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (maximum duty cycle length required. If duty cycle is longer than this value then EVT will trigger)

31.11.3 Example 3 - Period too short

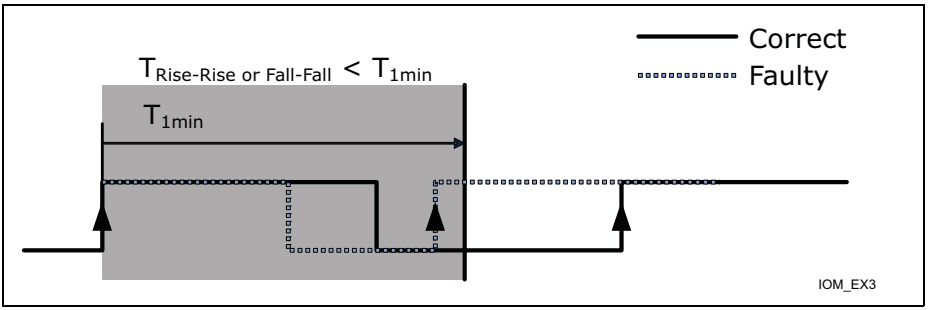

Figure 31-18 example 3 - period too short

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't care

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x5 ; CLR on positive edge, EVT on positive edge

LAMCFG.IVW : 0x1 ; invert window, capture events under the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (minimum period length required. If duty cycle is shorter than this value then EVT will trigger)

31.11.4 Example 4 - Period too long

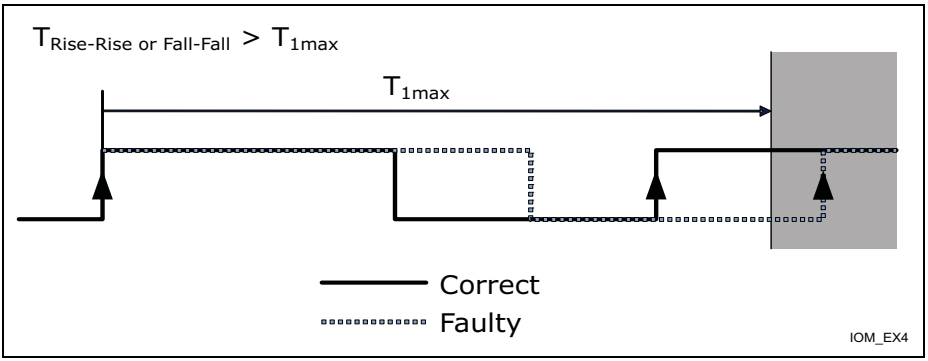

Figure 31-19 example 4 - period too long

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't care

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x5 ; CLR on positive edge, EVT on positive edge

LAMCFG.IVW : 0x0 ; don't invert window, capture events beyond the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (maximum period length required. If duty cycle is longer than this value then EVT will trigger)

31.11.5 Example 5 - Diagnosis of Command and Feedback - acceptable propagation window and/or signal consistency check

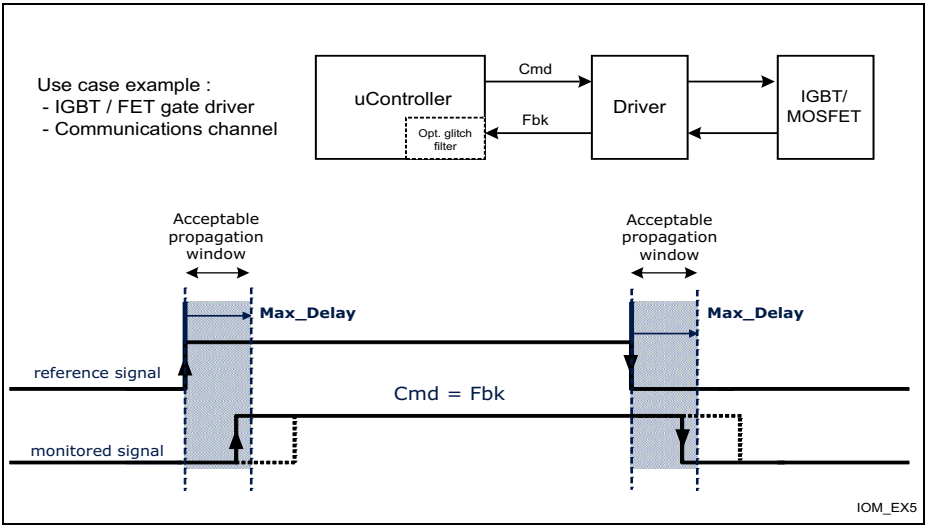

Figure 31-20 example 5 - Diagnosis of Command & Feedback

Using the driven signal (off-chip) as a reference, using a feedback signal (input to device) as the monitor. Checking that the monitored signal shows activity within an acceptable propagation window, and/or that the feedback signal shows the same behaviour as the reference (Command = Feedback).

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't invert reference signal

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x1 ; (MON xor REF) signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x0 ; select reference signal for event window

LAMCFG.EDS: 0xB ; CLR on both edges of REF, EVT on falling edge (of xor'd signal)

LAMCFG.IVW : 0x0 ; don't invert window, capture events beyond the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; set to max delay allowed

31.11.6 Example 6 - Diagnosis of Set-up and Hold times

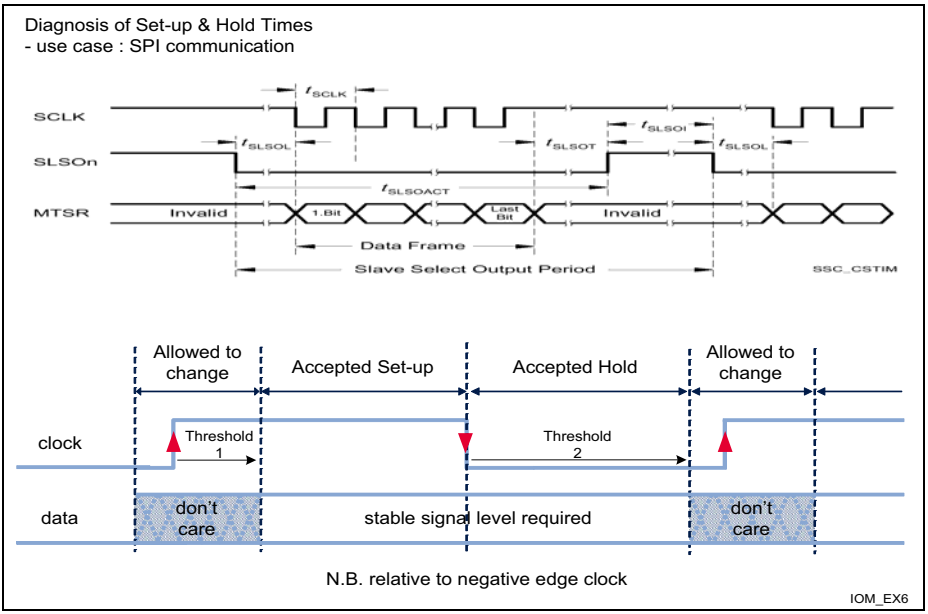

Figure 31-21 example 6 - Diagnosis of Set-up & Hold times

Ensuring that data remains stable within the Set-up and Hold windows, generating an event otherwise, and/or ensuring that data only changes within the specified windows.

Note that 2 LAM channels will be required for this purpose, one for set-up, one for hold.

Example settings for LAM block registers for Set-up :

LAMCFG.IVR: 0x0 ; don't invert reference signal

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x1 ; run is gated

LAMCFG.EWS: 0x0 ; select reference signal for event window

LAMCFG.EDS: 0xF ; CLR on both edges, EVT on both edges

LAMCFG.IVW : 0x0 ; don't invert window, capture events beyond the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; Acceptable Set-up (ref Threshold 1 on waveforms shown)

Example settings for LAM block registers for Hold:

LAMCFG.IVR: 0x0 ; invert reference signal (use for gating)

LAMCFG.IVM: 0x0 ; don’t invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x1 ; event window is gated

LAMCFG.EWS: 0x0 ; select reference signal for event window

LAMCFG.EDS: 0xD ; CLR on positive edge (inverted neg. edge), EVT on both edges

LAMCFG.IVW : 0x1 ; invert window, capture events below the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; Acceptable Hold (ref Threshold 2 on waveforms shown)

32 Peripheral Sensor Interface (PSI5)

This chapter describes the PSI5 Interface of the TC27x. It contains the following sections:

- Functional description of the PSI5 kernel (see **"Overview" on Page 32-2**)
- PSI5 kernel register descriptions (see **"PSI5 Kernel Registers" on Page 32-22**)
- TC27x implementation-specific details and registers of the PSI5 module (port connections and control, interrupt control, address decoding, and clock control) see **"PSI5 Module Implementation" on Page 32-141**

32.1 PSI5 Kernel Description

Figure 32-1 shows a global view of the PSI5 interface.

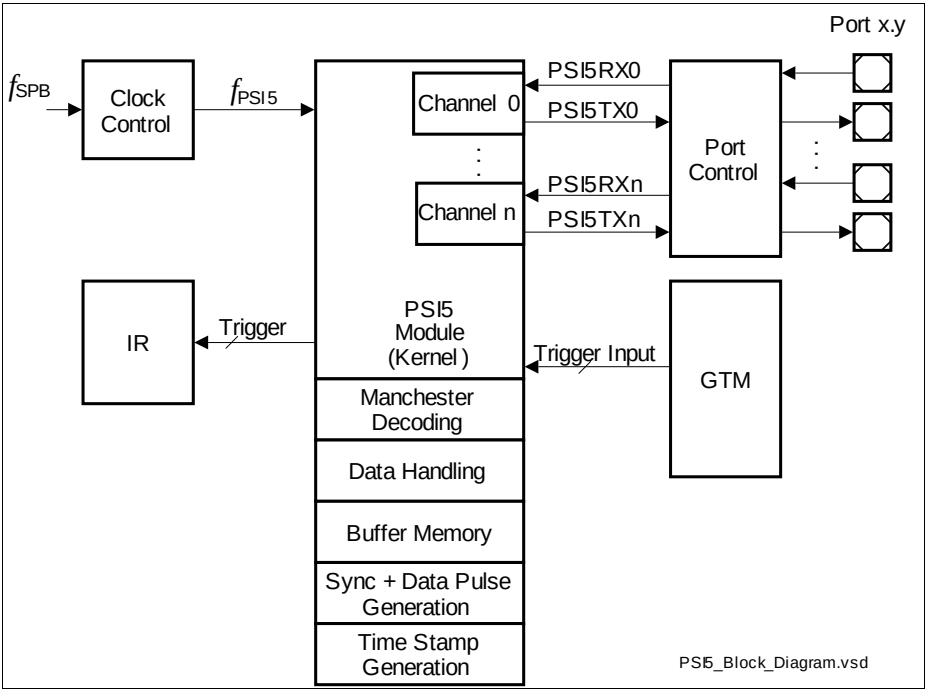

Figure 32-1 General Block Diagram of the PSI5 Interface

The PSI5 module communicates with the external world via one I/O line for each channel. The PSI5RXx lines are the receive data input signals. If the optional unidirectional mode is used, the signals PSI5TXx are transmitted on separate GPIO ports. Receive and transmit path are always routed to two different ports.

32.1.1 Overview

The PSI5 IP-module performs communication according to the PSI5 specification V1.3.

The Peripheral Sensor Interface is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of airbag systems.

This module supports many additional features as discussed today in the standard organization.

The PSI5 interface provides a current loop based serial communication link typically used to connect airbag sensors or other peripheral devices.

While the physical layer is done externally, this module manages protocol handling and data representation to the application. Note that there is no on chip phy, i.e. the current to voltage and voltage to sync pulse translation is done externally.

Receive data on a PSI5 channel can be set up according to the underlying application. In particular the number of bits forming one value is configured.

The message storage consists of a 32-bit buffer register for each channel and an additional 32-bit register containing the 24-bit time stamp and additional status bits. These 64 bits per frame are additionally stored in a buffer of 32 lines per channel.

In Host to sensor communication mode, the module can provide regular sync pulses and select between internal and external timer/trigger resources. It supports as well CPU to sensor communication, e.g. for setting up the sensor and retrieving sensor status information.

The register set of the PSI5 module can be accessed directly by the CPU for configuration, data read out and status query.

The PSI5 module supports the following features:

Features

- Conformance with PSI5 protocol specification V1.3
- Data rates of 125 kbit/s and 189 kbit/s supported
- 3 PSI5 channels working independently in parallel
- Supports 6 sensor slots per channel
- Asynchronous and synchronous data transmission modes (control by micro controller in synchronous mode)
- Decoding manchester protocol
- Error recognition in manchester code
- Configurable data word length 8, 10, 16, 20, 24 bit according to standard (PSI5 V1.3)
- Support of non standard V1.3 frame length: 11… 33 bit
- CRC check of received sensor data implemented but CRC code transparent
- Support of extended serial data messaging according to SENT SAE J2716 JAN 2010

- 24-Bit time stamp (resolution: 1µs)
- Storage of up to 32 frames per channel with time stamp
- FIFO access and management
- Buffer overrun detection
- Buffer Memory Status Overview Registers
- Support of ECU to Sensor communication
- Three 64-bit downstream data registers for data input, data preparation and data output
- Downstream data transmission by variation of pulse length (2.0)
- Downstream data transmission by leaving out sync pulses (V1.3)
- Staggering Sync Pulses of all channels to avoid too many channels sending sync pulses in parallel
- Generation of 3 or 6 bit CRC for downstream data
- Start sequence and CRC generator for downstream data
- One sum interrupt for general events
- One sum interrupt on selectable errors
- Sticky interrupt flags, error interrupt optional (default disabled)
- Optional output inversion for use of external open drain transistor
- Optional input inversion for use of external open transistor for level shifting

Configurability

- Number of PSI5 channels working independently in parallel (1 - 5)
- Storage of up to 32 frames per channel with time stamp (w/wo)
  - FIFO access and management
  - Buffer overrun detection
  - Buffer Memory Status Overview, Set and Clear Registers

32.2 General Operation

PSI5 is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/D converters and PWM and as a simpler low cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

Figure 32-2 shows a typical TC27x application in which a PSI5 interface reads a sensor device.

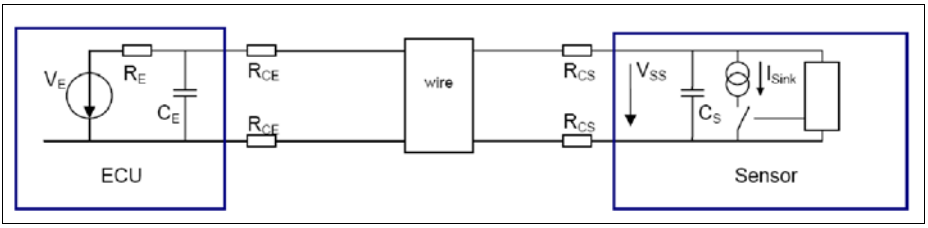

Figure 32-2 PSI5 to External Device Connection

PSI5 communication is

- asynchronous, unidirectional from sensor to controller without any synchronization
- synchronous, bidirectional with a sync pulse from the ECU triggering messages
- synchronous, bidirectional, sync pulses additionally coding data from ECU to sensor

The sensor signal is transmitted as a series of current pulses in Manchester coding.

The sync pulses are transmitted by increasing the voltage.

Figure 32-3 shows a typical TC27x application in which a PSI5 ECU reads multiple PSI5 sensor devices on a bus.

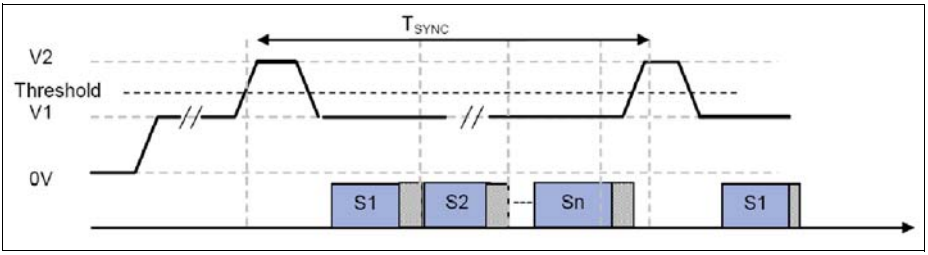

Figure 32-3 PSI5 Frames with Sync pulses

32.3 Definitions

SENT: Single Edge Nibble Transmission

Nibble: Four Bit value between 0 and 15 = half a Byte = one character in hex (0 to F)

ASIC: Application Specific Integrated Circuit

CAN: Controller Area Network

LIN: Local Interconnect Network

ISO: International Organization for Standardization

ECU: Electronic Control Unit

FSM: Finite State Machine

SOF: Start of Frame

EOF: End of Frame

STS: Start Sequence

AD: Address Data (e.g. of ECU to Sensor Frame)

SD: Send Data (Payload of ECU to Sensor Frame)

CRC: Cyclic Redundancy Check

32.4 PSI5 Operation

The Module supports two modes:

Standard PSI5 Mode supports communication fully compliant to V1.3

Extended PSI5 Mode supporting additional bit fields and longer frames. (See below)

In standard V1.3 mode, a specific start condition and a start sequence switch the sensor in ECU to Sensor communication mode. In this mode, the sync pulses are no longer used as triggers for data frames but are interpreted as data. A pulse represents a 1 and a missing pulse represents a 0. This requires isochronous pulses.

In extended Mode (Power Train sub standard), the pulse width is modulated. A standard pulse represents a 0, a longer pulse a 1. This way continuos data transmission can be achieved.

32.5 Frame Formats and Definitions

This section describes the frame formats and definitions of the PSI5 protocol.

32.5.1 PSI5 V1.3 Frame

Figure 32-4 shows the layout and definitions of a standard PSI5 frame. Note that the PSI5 standard specifies that the least significant bit is sent out first. See standard for CRC and Parity definition.

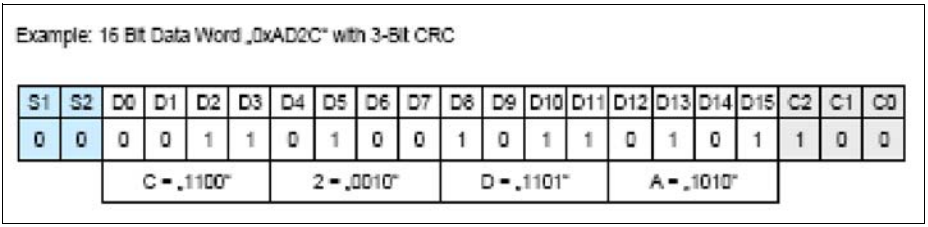

Figure 32-4 Standard PSI5 Frame

32.5.2 Extended PSI5 Frame (non standard)

Figure 32-5 shows the layout and definitions of an extended PSI5 frame as defined in V2.0 for automotive power train application. Note that the PSI5 standard specifies that the least significant bit is sent out first.

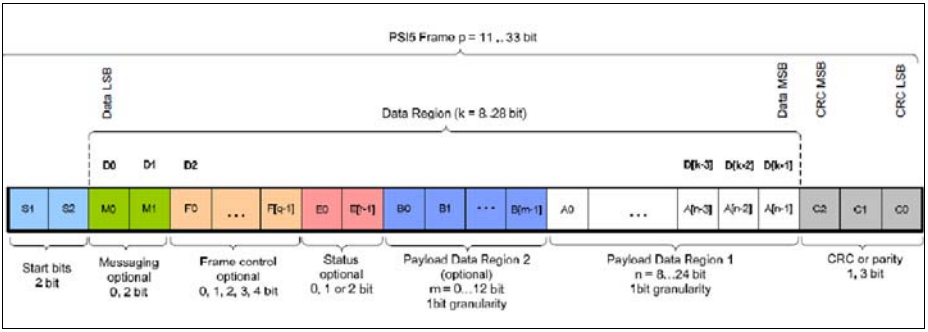

Figure 32-5 Extended PSI5 Frame

Enhanced PSI5 Sensor to ECU Message CRC

The transmission of PSI5 data is checked by the following protection modes. The transmission error detection must be selectable:

1) 1-bit even parity

2) 3-bit CRC

The applied generator polynomial of the CRC is g(x) = 1 + x + x3 with a binary start value (seed) “111”. The transmitter shall extend the data bits by three zeros (as MSBs). This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits shall be ignored in this check. When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum. These three check bits shall be transmitted in reverse order (MSB first: C2, C1, C0)

In this implementation the number of elements is configurable and thus longer or shorter than 8 .. 28 bits!

32.5.3 Extended Serial Data Encoding (“Slow Channel”)

The serial data is transmitted bit wise per frame in bits [1:0] of the Messaging bit field of 18 consecutive messages from the transmitter.

32.5.4 Extended Serial Data Frame

Serial data (“Slow Channel”) is communicated in a 18-bit sequence as shown in **Figure 32-6**. The frame start of a serial message is indicated by the unique pattern “01111110” in bit M1. The first “1” in a series of six ones (after a “0”) indicates the first set of a Messaging bits (M1 and M0) of a serial frame. Messaging bit M1 of serial data frames 1 - 6 are set to “1”. Messaging bit M1 of serial communication nibbles 7, 13 and 18 are set to “0”. 18 consecutive PSI5 messages must be successfully transmitted (no errors) for the serial value to be received. The CRC generation is different from the CRC generation on the data nibbles. (See SENT Standard SAE_J2716_201001)

The serial message frame contains 21 bits of message data and a 6-bit frame-check sequence. Two different configurations can be chosen:

- 12-bit data and 8-bit message ID
- 16-bit data and 4-bit message ID

A configuration bit (serial data bit M1, serial communication Messaging bits of frame No. 8) determines the configuration of the enhanced serial message frame. It determines how the PSI5 module automatically interprets the serial data.

- Configuration bit = 0: 12-bit data and 8-bit message ID
- Configuration bit = 1: 16-bit data and 4-bit message ID

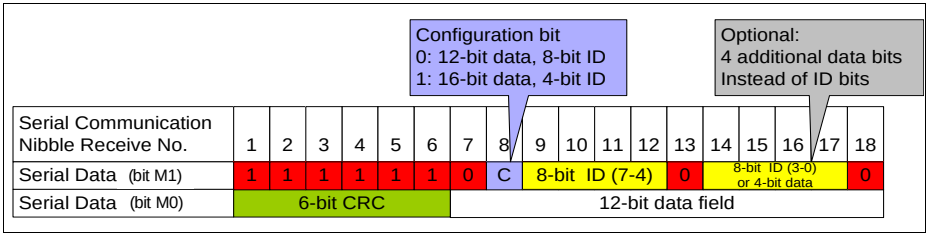

Figure 32-6 Extended Serial Data Frame

Figure 32-7 shows in detail the frame structure for Extended Serial Data Frames with Configuration Bit = 0.

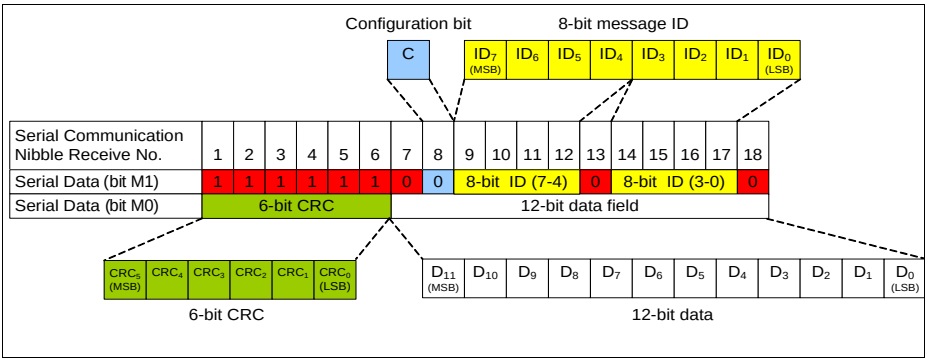

Figure 32-7 Configuration Bit = 0

Figure 32-8 shows in detail the frame structure for Extended Serial Data Frames with Configuration Bit = 1.

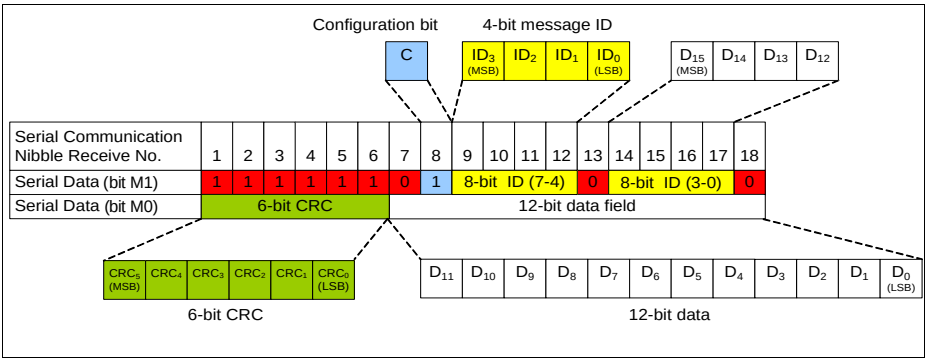

Figure 32-8 Configuration Bit = 1

32.6 Sync Pulses

Sync Pulses are used for two different purposes:

- Triggering a data frame for data acquisition from a sensor or
- ECU to sensor communication.

32.6.1 Synchronous Transmission

In the “synchronous” mode, the sensor (slave) starts to transfer a complete data frame only after a sync pulse is forced by the master on the OUT pin. An external phy translates this pulse into a voltage increase. The sensor then initiates a measurement and starts to calculate the new output data value. The data follows in a standard PSI5 frame, starting

with the 2 start bits, data and Parity or CRC . The timing diagram in **Figure 32-9** visualizes a synchronous transmission

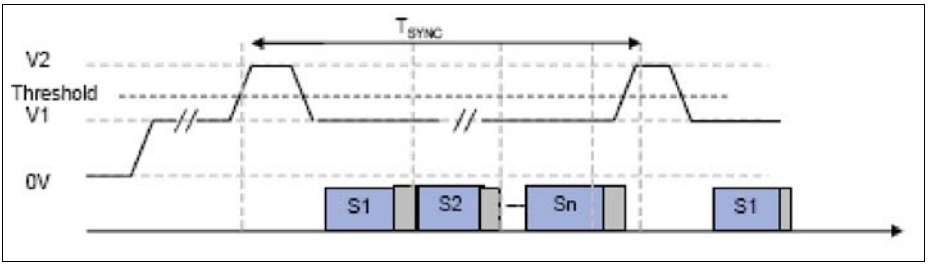

Figure 32-9 Synchronous Transmission

32.6.2 ECU to Sensor Communication

Two versions are supported:
legacy PSI5 V1.3 (see **Figure 32-10**) and
revised version (see **Figure 32-11** and **Figure 32-12**) .

The legacy version

uses sync pulses as start condition and start bits to signal the start of the ECU to Sensor Communication. From this start on, the sync pulses are interpreted by the sensor as data. See standard for CRC and Parity definition.

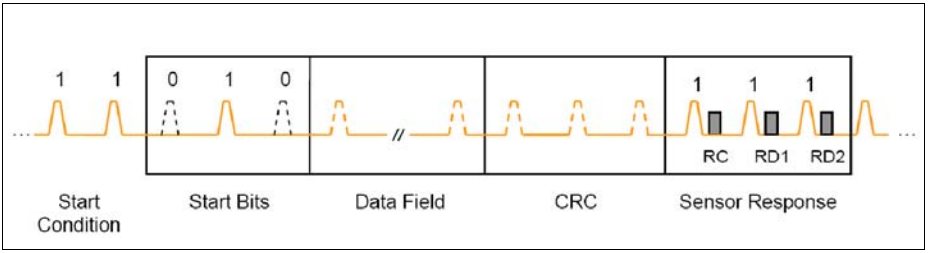

Figure 32-10 ECU to Sensor (legacy)

The revised version

allows for modulation of the sync pulse duration. This way bidirectional communication is possible continuously. Every ECU-to-Sensor frame starts with a nine-bit frame-start-sequence [0 1 1 1 1 1 1 1 0]. Synchronization is possible at the beginning of each frame.

Sync Bits

A consecutive train of seven ones within the transmitted data could be misinterpreted as a frame start condition. Therefore a “sync bit” (logical 0) is inserted at every seventh bit position (after every six bits of the sensor address and the payload data). With respect

to the data transmission, these sync bits are treated like stuffing bits, which are removed at the receiver side.

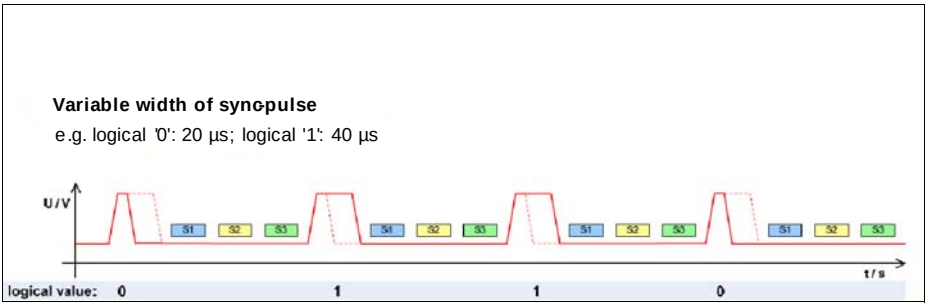

Figure 32-11 ECU to Sensor, Bit transmission (revised)

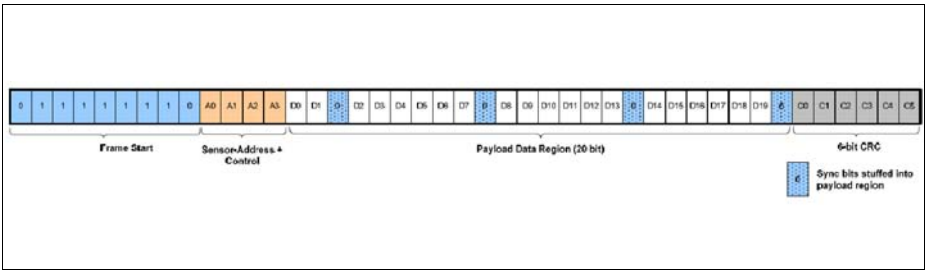

Figure 32-12 ECU to Sensor, Frame format (revised)

Enhanced ECU to Sensor Message CRC

The ECU-to-Sensor Frame has a 6-bit CRC.
The generator polynomial of the CRC is
g(x)=x6 + x4 +x3 +1
with a binary CRC initialization value “010101”.
The transmitter extends the data bits by six zeros (as MSBs).
This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits and sync bits are ignored in this check.

When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum.

These six check bits shall be transmitted LSB first [C0, C1 .. C5].

In this implementation the number of elements is configurable and thus longer or shorter than 24 bits (standard is 4 address and 20 data bits)!

32.7 Manchester Decoding

Decoding of the Manchester protocol:

- The Manchester decoder uses a nominal 4 MHz / 6.048 MHz sampling clock (32 samples per bit).
- A sampling counter, running at the sampling clock rate controls the sampling of the incoming Manchester encoded data.
- The Manchester signal transition occurring in the middle of the bit time resets the counter, making the counter count from 0-31 (nominally) between successive mid-bit times.
- Detection of the mid-bit transitions uses three consecutive samples (011 = rising edge, 100 = falling edge).
- The maximum value of the 6 bit counter shall be 41, at which point a Manchester error is detected due to lack of a transition, and the counter rolls over to 0. (“Idle Time”)
- The value of a Manchester encoded input data bit is determined by proper logic levels before and after a transition and proper timing of the transition.
- Bit-value determination nominally takes place at the 1/4 and 3/4 bit times, with the mid-bit transition occurring at the 1/2 bit time. This is nominally at sampling counter values of 8 (1/4 bit time) and 24 (3/4 bit time).
- Logic levels are determined using a 2 of 3 majority vote of consecutive samples (samples 23, 24, 25 and 7, 8, 9)
  - The combinations 111, 011, 101, 110 indicate a 1
  - The combinations 000, 001, 010, 100 indicate a 0

Manchester-2 is used by standard PSI5 V1.3:

- Start bits = ‘00’
- Falling edge corresponds to logical ‘1’
- Rising edge corresponds to logical ‘0’
- Least significant bit (LSB) is sent out first

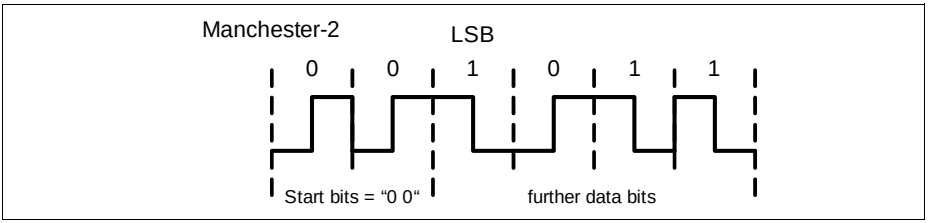

Figure 32-13 Manchester-2

Sampling Details

- Recognition of Frame Start
  - Manchester Code requires a deterministic Start of Frame
  - Frame Separation: An “Idle Time” of at least one Bit time is required

  - "Idle Time" is the time without edges on the line that is required to safely determine that no frame is being transceived (1 Bit time + tolerance = > 41 samples)
    The Idle Counter starts counting
    - on a falling edge, after sync pulse or after BOT, if the channel is switched on
    - if the line is low
    - up to 41 and stops and
    - activates the idle flag
    - until the line shows a rising edge, this clears the idle counter
  - After this idle time, a determined start bit sequence is required for synchronization of the phase of receiver and transmitter ('0 0' in case of the „Manchester 2"-code employed)
  - If no idle time occurs at the end of a frame, bits after the configured length are dropped.
  - If a 2nd frame comes too early (collision = no idle time) the 2nd frame is dropped. The decoder waits for an "Idle Time" for re synchronization.
  - Idle time is particularly required in case of Manchester Errors and frame collisions for a save re synchronization. Otherwise, two successive zeros in a damaged frame / a second colliding frame could lead to reception of wrong data. Note that back to back transfers of correct frames are forbidden by standard (T_gap required).
  - This idle time is required as well after a regular End Of Frame, Sync Pulse or a Blank Out Time to avoid inadvertent synchronization inside frames under transmission.
- Bit sampling
  - After the start of the protocol is detected and an edge on the line signal is detected and the counter is greater 25 the counter is set to '0'
  - If the counter is 41 the counter is set to '0' and stops
  - The counter will be incremented each clock cycle
  - When the sample counter has the value 9, the level is stored in register cnt9_val
  - When the sample counter has the value 25, the level is stored in register cnt25_val
  - This register is reset if no frame is detected. Otherwise a wrong start bit detection could occur.
- Bit evaluation
  - When the sample counter value is 16, the decision is done for the new sample value:
  - Check if the last edge was detected correctly i.e.: edge detected between sample counter value 25 and sample counter value 41
  - If true:
  - Cnt_25_lev = 0 & cnt_9_lev = 1 => new sample = '0'
  - Cnt_25_lev = 1 & cnt_9_lev = 0 => new sample = '1'
  - If the edge check fails or cnt_25_lev = cnt_9_lev, Manchester Error is assumed.

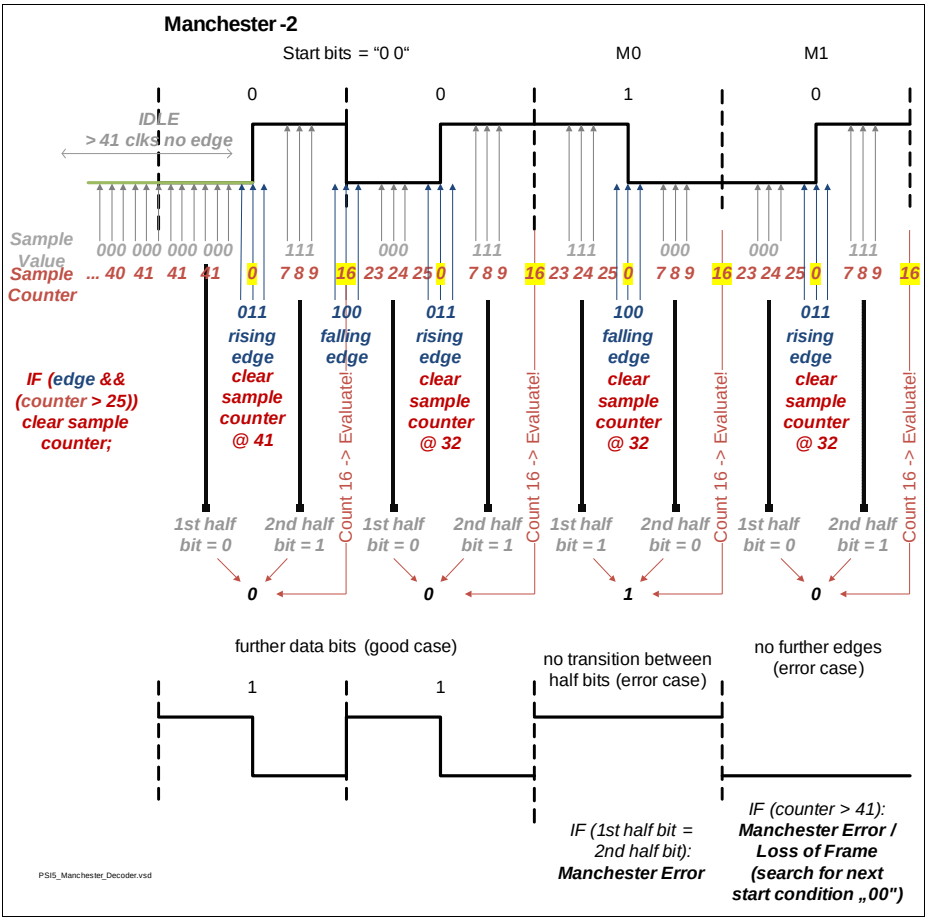

Figure 32-14 Manchester Decoder

Definition of Manchester Error (ME)

- Two half bits have the same value => ME, the decoder waits for an "Idle Time"
- > 41 sample times no edge => ME
- The ME is no dedicated interrupt but will lead to various error responses depending on where it occurs. See **Table 32-1**.

Table 32-1 Error Responses due to ME

Manchester Error (ME) Case	Response	Comment
First ME in start bits	Discard frame	NFI (if FEC is set) and empty frame stored (if FEC and VBS is set), Time Stamp = end of slot where SOF happened. This is true even if these start bits should start before WDL and end after WDL
Start bits cut off by BOT or Sync Pulse (frame starts without leading idle time)	Discard frame	NFI (if FEC is set) and empty frame stored (if FEC and VBS is set)
First ME in Messaging bits	If MSG is set: MEI	Frame is stored, bits after error are lost (“0”)
	If MSG cleared: NBI	
First ME in data, parity or CRC / Frame ends too early	NBI	Frame is stored, bits after error are lost (“0”)
Frame ends too late (longer than PDL)	no NBI	Bits after PDL are cut off and EOF is detected. Frame is stored.
Collision (Idle Time missing)	Discard 2nd frame	If the 1st frame was too late and running over WDL or If the 2nd frame was too early and running over WDL then for 2nd frame, NFI (if FEC is set) and empty frame stored (if FEC and VBS is set), Time Stamp = end of 2nd slot
In all cases, the receiver waits for an idle time followed by the start bits “00” before a new frame is detected.		

32.8 Bit Rate Generation

The bit rate of each channel is individually selectable from the 2 standard bit rates 125 kHz and 189 kHz. The two referring over sampling frequencies are generated centrally.

This chapter shows in detail how the bit rate for each channel is adjusted.

In the first stage, a global fractional divider serves as pre divider. Its intermediate frequency $f_{fracdiv}$ can be set up so that it is handy as input frequency for the different PSI5 channels. Usually this can be left unused.

For each of the two bit rates there is an own fractional divider. Each channel can select one out of the two clock signals f_{125} and f_{189}.

For details on the principles of a fractional divider, please refer to the SCU chapter of TC27x section “Clock Control”.

The PSI5 module provides 5 clock signals centrally (**Figure 32-15**):

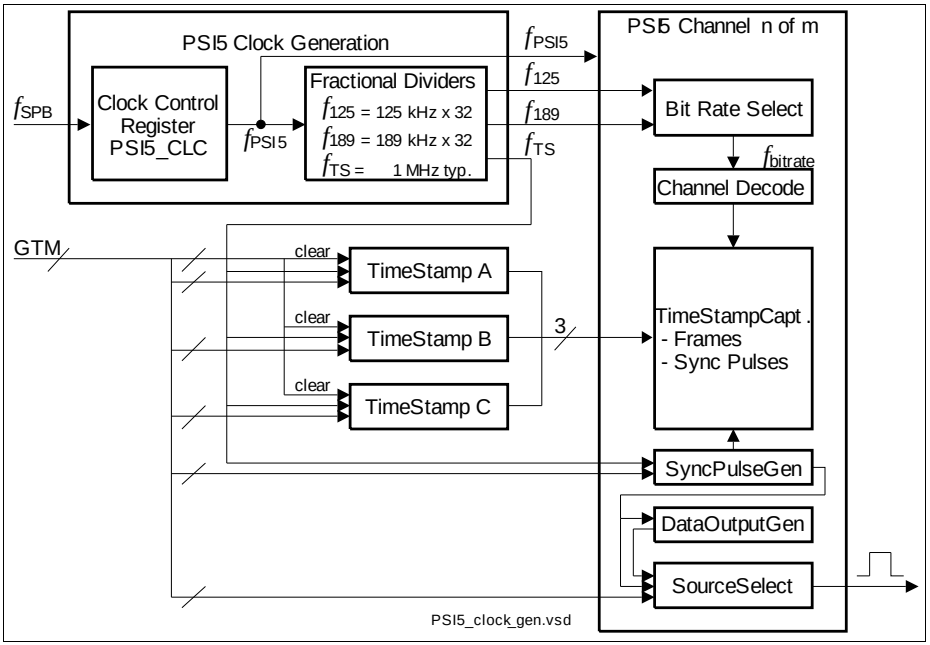

Figure 32-15 PSI5 Module Clock Generation

- f_{PSI5}
  This is the module clock that is used inside the PSI5 kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{PSI5} is always identical to the system clock frequency f_{SPB}. The clock control register PSI5_CLC makes it possible to enable/disable f_{PSI5} under certain conditions.
- $f_{fracdiv}$
  This clock is the module clock that is used inside the PSI5 kernel for bit rate generation of the serial channels. The fractional divider register PSI5_FDR controls the frequency of $f_{fracdiv}$. Usually not required and set to 1.

- f_{125}
  This clock is the over sampling clock that can be selected for use inside a PSI5 channel as the bit rate frequency. The fractional divider register PSI5_FDRL controls the frequency of f_{125}.The clock drives the manchester decoder and needs to be 32 times faster than the nominal bus frequency
- f_{189}
  This clock is the over sampling clock that can be selected for use inside a PSI5 channel as the bit rate frequency. The fractional divider register PSI5_FDRH controls the frequency of f_{189}.The clock drives the manchester decoder and needs to be 32 times faster than the nominal bus frequency.
- f_{TS}
  This clock is used to drive the central time stamp counter.
  It can be selected to drive the global sync pulse time base and
  inside the PSI5 channels to drive the local watch dog timers. The fractional divider register PSI5_FDRT controls the frequency of f_{TS}.This is usually adjusted to 1 MHz / 1 µs period time.

The following two formulas define the frequency of $f_{fracdiv}$:

$f_{fracdiv} = f_{PSI5}$ / (1024 - PSI5_FDR.STEP); FDR.DM = 01B (32.1)

$f_{fracdiv} = f_{PSI5}$ x PSI5_FDR.STEP / 1024 with STEP = 0 … 1023; FDR.DM = 10B (32.2)

The following two formulas define the frequency of f_{125}.

$f_{125} = f_{fracdiv}$ / (1024 - PSI5_FDRL.STEP); FDRL.DM = 01B (32.3)

$f_{125} = f_{fracdiv}$ x PSI5_FDRL.STEP / 1024 with STEP = 0 … 1023; FDRL.DM = 10B (32.4)

The following two formulas define the frequency of f_{189}.

$f_{189} = f_{fracdiv}$ / (1024 - PSI5_FDRH.STEP); FDRH.DM = 01B (32.5)

$f_{189} = f_{fracdiv}$ x PSI5_FDRH.STEP / 1024 with STEP = 0 … 1023; FDRH.DM = 10B (32.6)

The following two formulas define the frequency of f_{TS}:

$f_{TS} = f_{PSI5}$ / (1024 - PSI5_FDRT.STEP); FDRT.DM = 01B (32.7)

$f_{TS} = f_{PSI5}$ x PSI5_FDRT.STEP / 1024 with STEP = 0 … 1023; FDRT.DM = 10B (32.8)

32.9 Digital Glitch Filter

Very slow slopes and signal noise can lead to fast transitions of the input signal. These unwanted transitions are suppressed by a digital glitch filter similar to a Filter and Prescaler Cell (FPC) of Infineons GPTA® in Delayed De-bounce Filter Mode with up and down (no reset).

It is built for filtering very fast transitions only. The filter calculates the integral of the signal. If the integral reaches a programmable saturation point, the signal change is notified to the pulse measurement unit. Thus it helps to find the exact pulse length for said slow slopes in noisy environment.

The glitch filter is clocked with f_{PSI5}. If the state of the input sample differs from the current output signal value, the internal counter is incremented by one. When the state of the input sample matches the current output signal value and the timer is not in idle, the timer is decremented by one. When the timer matches the compare value stored in IOCRx.DEPTH, the level of the output signal line is inverted. The timer will be reset and set to idle state again.

The depth of the filter can be programmed to a value between 1 and 15. Typically a depth of 3 to 5 T_{PSI5} is sufficient. By default it is cleared. If IOCRx.DEPTH is cleared the filter is inactive/bypassed. Nevertheless, the input signal is sampled with f_{PSI5}.

The internal signal after the filter will change value not before the new value was sampled DEPTH times. If during this period a spike occurs, it takes 2 x T_{PSI5} times longer for the internal signal to change value. The filters principal implies a delay of the signal by (DEPTH x T_{PSI5}).

Upon detection of glitch during rising or falling edge, IOCRx.REG or IOCRx.FEG is set. The rising / falling edge glitch flags must be reset by software.

Figure 32-16 shows the digital glitch filter:

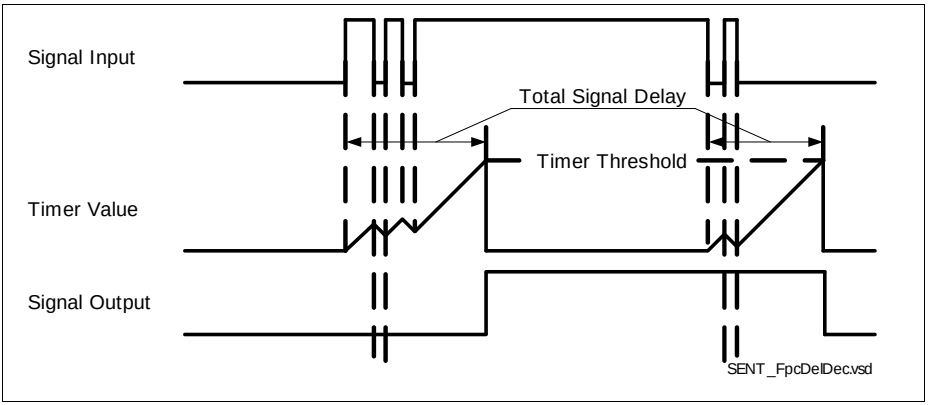

Figure 32-16 Digital Glitch Filter

32.10 Time Stamp Generation

Three time bases can be selected for Time Stamping:

Any of TSRA, TSRB and TSRC provide one time stamp counter. Each of them can be configured to be driven by either f_{TS} or by an external timer, i.e. one of the GTM inputs. The frequency of f_{TS} is controllable by the fractional divider in register FDRT.

All of them can be cleared by a selectable GTM signal or by SW, single or synchronously.

Two times are captured for each channel:

The last sync pulse sent on this channel is stored in the sync pulse time stamp capture register SPTSCx.

The last start of frame (SOF) on this channel is stored in the SOF capture register SFTSCx.

For each channel the capture time (SPTSC or SFTSC) can be selected, that will be stored in the Receive Data Register and the Receive Data Memory.

Figure 32-17 shows the time stamp generation:

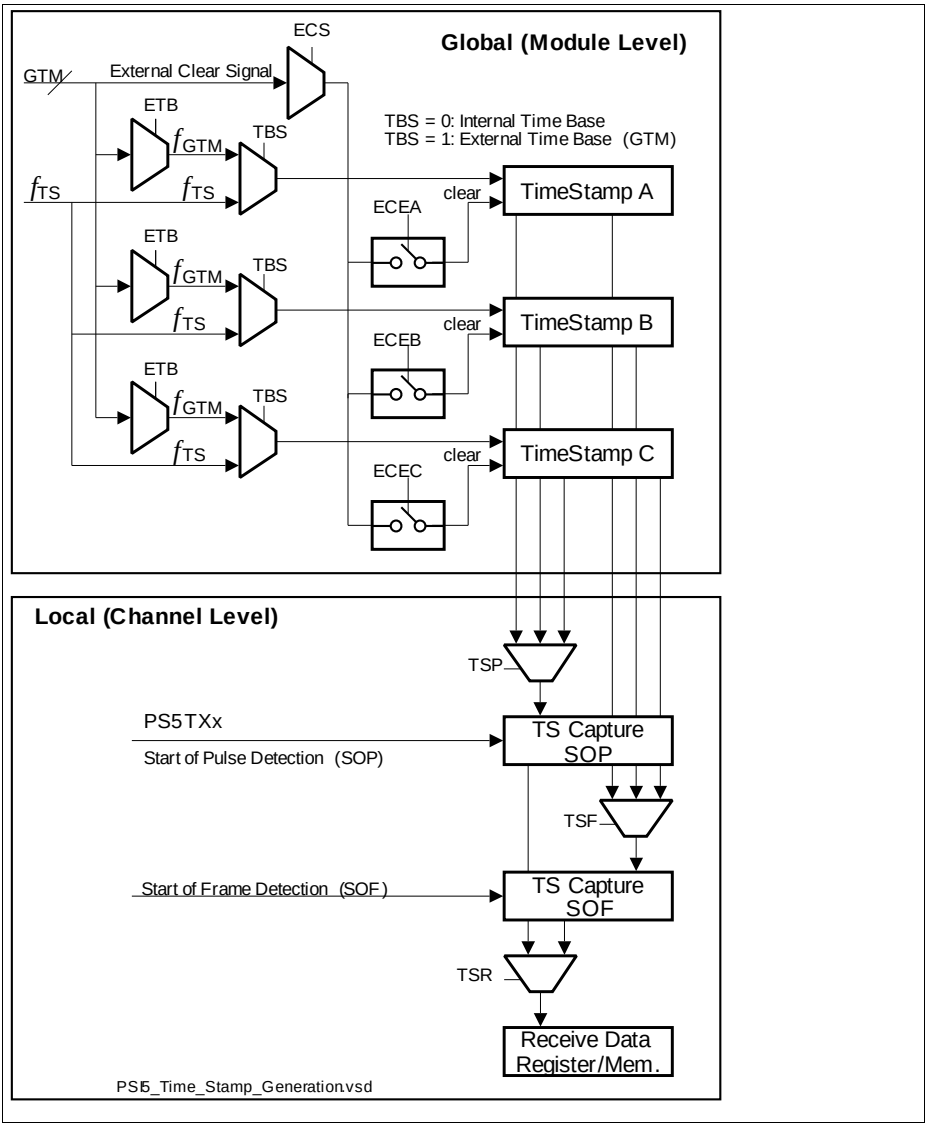

Figure 32-17 Time Stamp Generation

32.11 Error Detection Capabilities

Each PSI5 channel can detect and signal the following error conditions:

Protocol Level:

- No frame received / Manchester coding error in start bits (NFI)
- Messaging Bits with Manchester coding Error (MEI)
- Number of bits too small / Manchester coding error but messaging bits ok (NBI)
- Checksum error (CRCI)
- Frame not sent in expected time slot (TEI)
- Serial Communication: Wrong Status and Communication bit field (WSI)
- Serial Communication: CRC error (SCRI)

Transfer Management Level:

- Receive Data Buffer Overrun (RBI)
- Receive Data Memory Overrun (RMI)
- FIFO Warning Level (FWI)
- Receive Memory Underrun (RUI)
- ECU to Sensor Data Buffer Underrun (TBI)

32.12 Interrupts

8 Interrupt sources are available for the PSI5 module. For each trigger source of a channel x one interrupt can be selected in register INPx.

RDI indicates a receive data interrupt. It is activated when a received frame is moved to a Receive Data Register RDR. This happens always if at least the start bits were received without Manchester coding error.

RSI indicates a receive frame success interrupt, i.e. non of the interrupts NFI, MEI, NBI, CRCI, TEI, RBI, RMI was detected. The referring interrupt must be enabled in GCR to be considered for RSI. This allows e.g. to use only the Receive data register RDRL/Hx and ignore the Receive Data Memory RDML/Hx. Both RDI and RSI will be issued together in normal use cases where reception is correct.

RBI indicates a receive buffer overrun interrupt. It is activated when a new frame is transferred to a Receive Data Register RDR while the old value was still not read by the host (“overwrite”), i.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set.

RMI is issued if no memory buffer is available. RMI is set after a frame has been received or a No Frame Received (NFI) message is to be stored while RDIOVx.RDI[RFCx.WRP] is set. I.e. the kernel wants to set flag RDIxWRP and finds any of these two flags already set. The old data is overwritten by the new data in the buffer memory.

FWI is set if the configured warning level of the FIFOx was reached. (See RFCx)

TPI, TSI and TOI indicate a transmit interrupt. They are activated when data is moved from a SDR to SSR (TPI), from SSR to SOR (TSI) and from SOR to the pulse generator (TOI).

TPOI, TSOI and TOOI indicate a transfer (send) register overrun interrupt. They are set if data is written to one of the registers in the transmission chain while the referring register is locked (occupied). The data written is ignored in this case.

In addition the protocol error interrupts are available:

TEI, NBI, MEI, CRCI. If one of the protocol interrupts is activated, data is to be treated as invalid according to standard V1.3. Note that the wrong data is still available in all buffers. In particular, on MEI the wrong data is still fed into the SENT serial data analyzer (slow channel).

NFI is set, if a frame is missing in a slot configured by the watch dog timer. The module can be configured to store a complete message anyhow with flag NFI set. The slot count and the time stamp can be helpful for debugging. This provides a method for easy data handling, e.g. by using DMA transfers only without checking single interrupt bits.

WSI, SDI, SCRI treat the interrupts referring to the Status and Communication nibble.

For acceleration of the interrupt service routine, a Register INTOV is implemented that shows if an interrupt class (RSI, RDI, RBI, TDI, TBI, ERRI, SDI, FWI) is active on any of the channels. It holds a flag for each class which ORs the states from all channels of each node pointer in interrupt node pointer registers INPx. This flag is automatically set if there is an interrupt pending for the node pointer which is enabled. It is automatically reset, if no more enabled interrupt is pending for interrupt class.

In addition, there are 8 overview registers per channel holding the flags NBI, CRCI, TEI, RMI, RSI, RDI, NFI, MEI for each buffer line: NBIOVx, CRCIOVx, TEIOVx, RMIOVx, RSIOVx; RDIOVx, NFIOVx, MEIOVx; x = [2 .. 0]. E.g. NBIOV0 holds 32 bits, one for each buffer line of channel 0 reflecting if NBI is set in this buffer line.

The interrupt request or the corresponding interrupt set bit (in register INTSETA/B) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in register INTSTATA/Bx. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLRA/B.
If more than one interrupt source is connected to the same interrupt node (in register INPx), the requests are combined to one common line.

32.13 Trigger Outputs

Any interrupt source can be used as trigger output TRIGO outside the module. Each TRIGO is connected to the interrupt router. See **Table 32-4 “Service Request Lines of PSI5” on Page 32-142**.

32.14 PSI5 Kernel Registers

This section describes the kernel registers of the PSI5 module. All PSI5 kernel register names described in this section will be referenced in other parts of the TC27x User's Manual by the module name prefix "PSI5_" for the PSI5 interface.

All registers in the PSI5 address spaces are reset with the application reset (definition see SCU section "Reset Operation").

The complete and detailed address map of the PSI5 module is described in **Table 32-2** on **Page 32-22**.

w can take the values 0 … 6 (watch dog limit values)

x can take the values 0 … 2 (PSI5 channels)

y can take the values 0 … 31

z can take the values 0 … 5

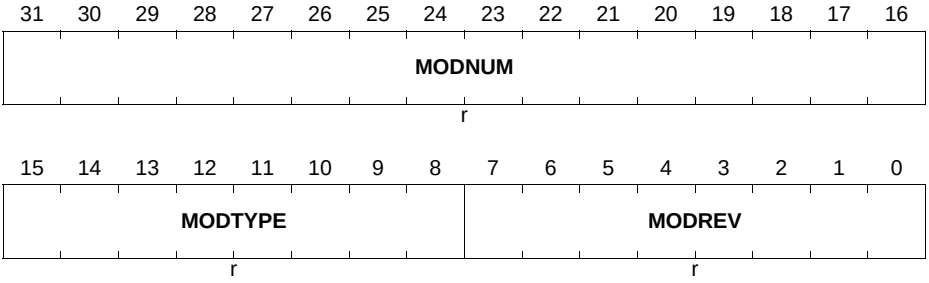
1) The absolute register address is calculated as follows:
Module Base Address (Table 32-2) + Offset Address (shown in this column)

32.14.1 Module Control

Module Identification Register

The PSI5 Module Identification Register ID contains read-only information about the module version.

PSI5_ID
Module Identification Register (008$_H$) Reset Value: 00C3 C0XX$_H$

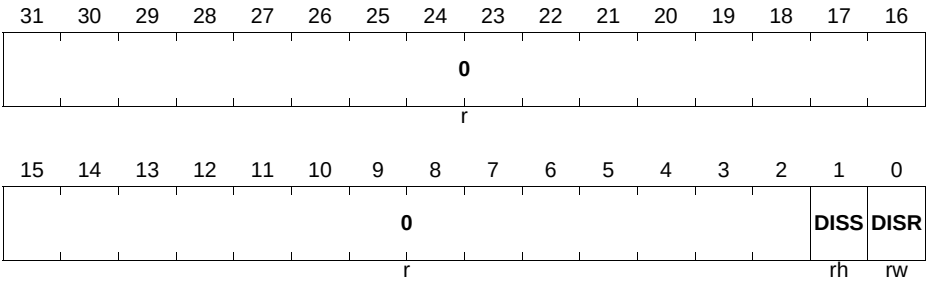


Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field defines the module as a 32-bit module: C0$_H$
MODNUM	[31:16]	r	**Module Number Value** This bit field defines the module identification number for the PSI5: 00C3$_H$

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock, sleep mode and disable mode for the module.

PSI5_CLC
Clock Control Register **(000_H)** **Reset Value: 0000 0003$_H$**



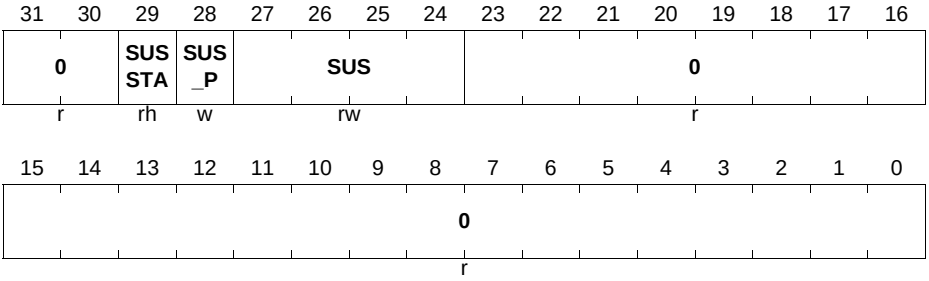
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset operation, the f_{PSI5} clock is switched off and the PSI5 module is disabled (DISS set).

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode.

PSI5_OCS
OCDS Control and Status **(3CC$_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. The kernel continues when hard suspend is left. 2_H Soft suspend option A (Suspends after end of current send or receive transfers, if any are ongoing) **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... , EN31 -> TAG ID 011111B.

PSI5_ACCEN0
Access Enable Register 0 ($3D0_H$) Reset Value: FFFF FFFF$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

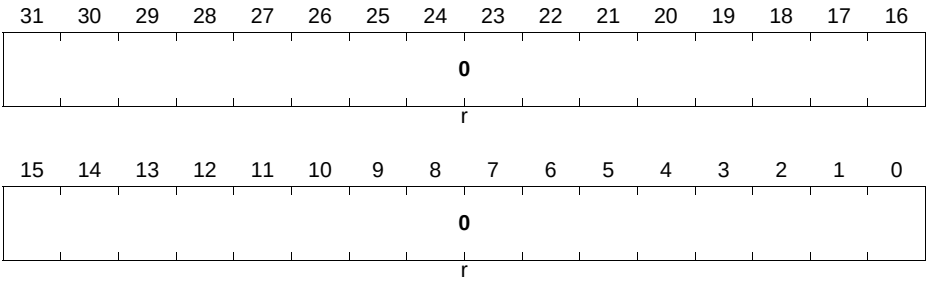
Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... , EN31 -> TAG ID 111111B.

PSI5_ACCEN1
Access Enable Register 1 **($3D4_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

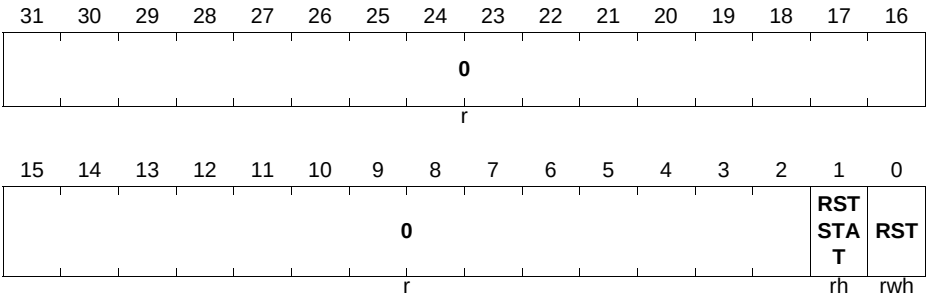
Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

PSI5_KRST0
Kernel Reset Register 0 **(3D8$_H$)** **Reset Value: 0000 0000$_H$**



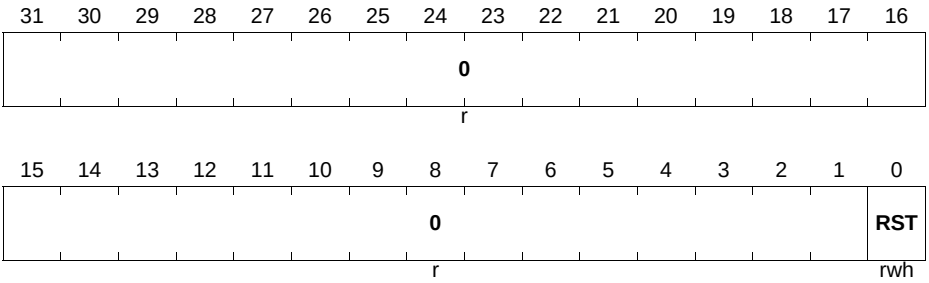
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

PSI5_KRST1

Kernel Reset Register 1 **(3DC$_H$)** **Reset Value: 0000 0000$_H$**



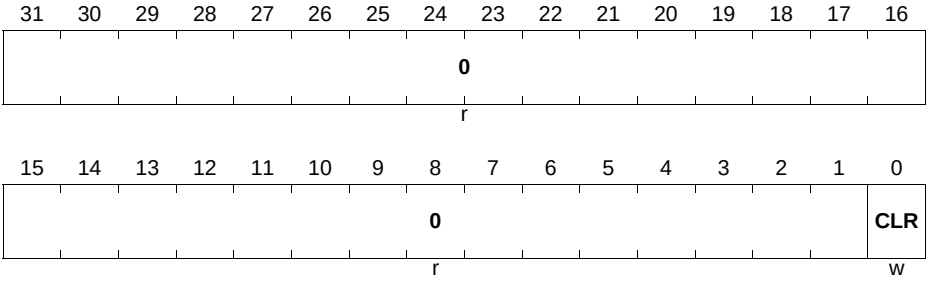
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

PSI5_KRSTCLR

Kernel Reset Status Clear Register (3E0$_H$) **Reset Value: 0000 0000$_H$**



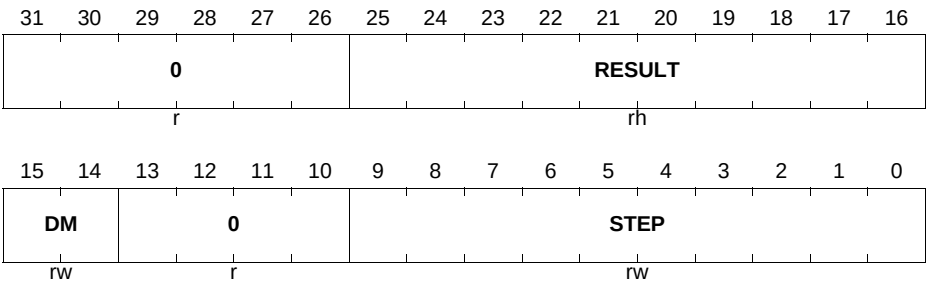
Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider Register

The Fractional Divider Register controls the input clock $f_{fracdiv}$.

PSI5_FDR

PSI5 Fractional Divider Register (00C$_H$) **Reset Value: 0000 0000$_H$**



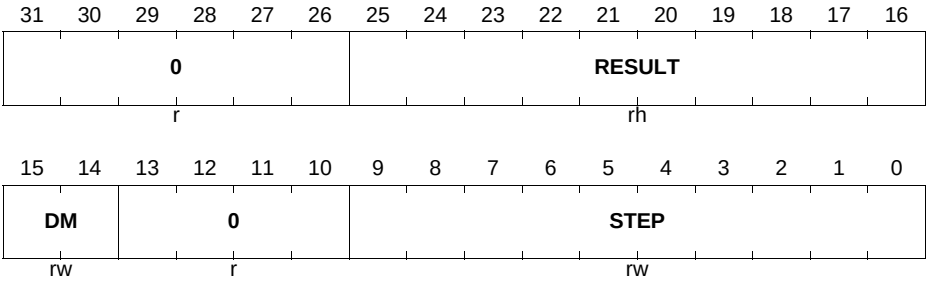
Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
DM	[15:14]	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.
0	[13:10], [31:26]	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider Register for Lower Bit Rate

The Fractional Divider Register for lower Bit Rate contains the pre divider that defines the time resolution of the f_{125}. It divides $f_{fracdiv}$ by a factor as given in **Equation (32.3)** and **Equation (32.4)** and provides f_{125} to all channels.

FDRL

Fractional Divider Register for Lower Bit Rate (010_H) **Reset Value: $0000\ 0000_H$**



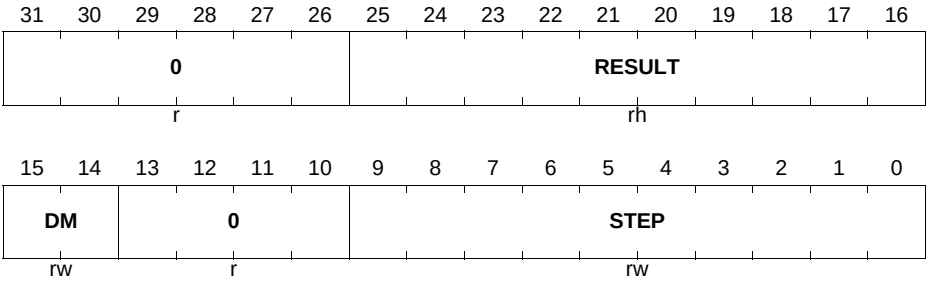
Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
DM	[15:14]	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.
0	[13:10], [31:26]	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider Register for Higher Bit Rate

The Fractional Divider Register for Higher Bit Rate contains the pre divider that defines the time resolution of f_{189}. It divides $f_{fracdiv}$ by a factor as given in **Equation (32.5)** and **Equation (32.6)** and provides f_{189} to all channels.

FDRH

Fractional Divider Register for Higher Bit Rate (014_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
DM	[15:14]	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.
0	[13:10], [31:26]	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider Register for Time Stamp

The PSI5 Module Time Stamp Predivider Register contains the pre divider that defines the time resolution of the Time Stamp Registers TSRA/B/C and the Sync Pulse Time Base Counter SBC. It divides f_{PSI5} by a factor as given in **Equation (32.7)** and **Equation (32.8)**. It contains as well the bits for reset control of the time stamp counters.

FDRT

Fractional Divider Register for Time Stamp (018_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECEC	ECEB	ECEA	ECS			RESULT									
rw	rw	rw	rw			rh									

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DM		0				STEP									
rw		r				rw									

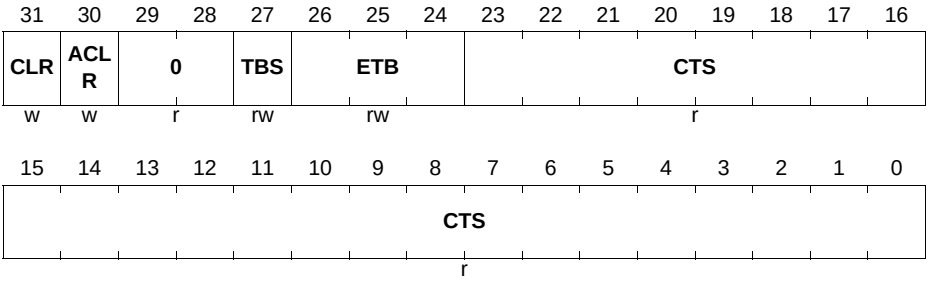
Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
DM	[15:14]	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.

Field	Bits	Type	Description
ECS	[28:26]	rw	**External Time Stamp Clear Source Select** Selects the external trigger line that clears the global time stamp counters TSRA/B/C.CTS if this is enabled by ECEA/ECEB/ECEC. Channel must be disabled if changed (GCR.CEN = 0). 000_B TRIG0 001_B TRIG1 $\ldots_B$ … 101_B TRIG5 110_B reserved, no trigger selected 111_B reserved, no trigger selected
ECEA	29	rw	**External Time Stamp Clear Enable A** Enables the external trigger line selected by ECS to clear the global time stamp counter TSRA.CTS on rising edge of the external trigger. 0_B disabled 1_B enabled
ECEB	30	rw	**External Time Stamp Clear Enable B** Enables the external trigger line selected by ECS to clear the global time stamp counter TSRB.CTS on rising edge of the external trigger. 0_B disabled 1_B enabled
ECEC	31	rw	**External Time Stamp Clear Enable C** Enables the external trigger line selected by ECS to clear the global time stamp counter TSRC.CTS on rising edge of the external trigger. 0_B disabled 1_B enabled
0	[13:10]	r	**Reserved** Read as 0; should be written with 0.

Module Time Stamp Register A

This PSI5 Module Time Stamp Register contains read-only information about the current time given in clock cycles of f_{TS} or f_{GTM} since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSRA
Time Stamp Register A **($01C_H$)** **Reset Value: $0000\ 0000_H$**



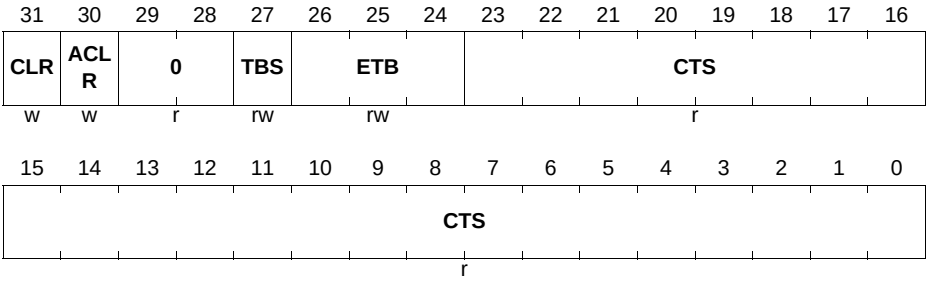
Field	Bits	Type	Description
CTS	[23:0]	r	**Current Time Stamp for the Module** This bit field shows the current time stamp.
ETB	[26:24]	rw	**External Time Base Select** Selects the external clock line for counter CTS. Channel must be disabled if changed (GCR.CEN = 0). 000_B TRIG0 001_B TRIG1 $\ldots_B$ … 101_B TRIG5 110_B reserved, no trigger selected 111_B reserved, no trigger selected
TBS	27	rw	**Time Base Select** This bit selects the clock source for CTS 0_B Internal, CTS counts in clock cycles of f_{TS} 1_B External, CTS counts in clock cycles of f_{GTM}
ACLR	30	w	**Clear All Current Time Stamp Counters** If set, this bit clears TSRA/B/C.CTS. TSRA/B/C.CTS count on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.

Field	Bits	Type	Description
CLR	31	w	**Clear Current Time Stamp for the Module** If set, this bit clears CTS. CTS counts on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
0	[29:28]	r	**Reserved** Read as 0; should be written with 0.

Module Time Stamp Register B

This PSI5 Module Time Stamp Register contains read-only information about the current time given in clock cycles of f_{TS} or f_{GTM} since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSRB
Time Stamp Register B **(020_H)** **Reset Value: 0000 0000_H**



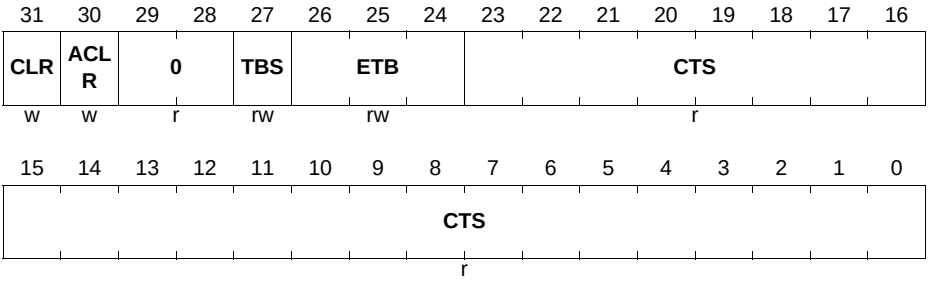
Field	Bits	Type	Description
CTS	[23:0]	r	**Current Time Stamp for the Module** This bit field shows the current time stamp.
ETB	[26:24]	rw	**External Time Base Select** Selects the external clock line for counter CTS. Channel must be disabled if changed (GCR.CEN = 0). 000_B TRIG0 001_B TRIG1 $\ldots_B$ … 101_B TRIG5 110_B reserved, no trigger selected 111_B reserved, no trigger selected
TBS	27	rw	**Time Base Select** This bit selects the clock source for CTS 0_B Internal, CTS counts in clock cycles of f_{TS} 1_B External, CTS counts in clock cycles of f_{GTM}
ACLR	30	w	**Clear All Current Time Stamp Counters** If set, this bit clears TSRA/B/C.CTS. TSRA/B/C.CTS count on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.

Field	Bits	Type	Description
CLR	31	w	**Clear Current Time Stamp for the Module** If set, this bit clears CTS. CTS counts on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
0	[29:28]	r	**Reserved** Read as 0; should be written with 0.

Module Time Stamp Register C

This PSI5 Module Time Stamp Register contains read-only information about the current time given in clock cycles of f_{TS} or f_{GTM} since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSRC
Time Stamp Register C **(024_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CTS	[23:0]	r	**Current Time Stamp for the Module** This bit field shows the current time stamp.
ETB	[26:24]	rw	**External Time Base Select** Selects the external clock line for counter CTS. Channel must be disabled if changed (GCR.CEN = 0). 000_B TRIG0 001_B TRIG1 $\ldots_B$ … 101_B TRIG5 110_B reserved, no trigger selected 111_B reserved, no trigger selected
TBS	27	rw	**Time Base Select** This bit selects the clock source for CTS 0_B Internal, CTS counts in clock cycles of f_{TS} 1_B External, CTS counts in clock cycles of f_{GTM}
ACLR	30	w	**Clear All Current Time Stamp Counters** If set, this bit clears TSRA/B/C.CTS. TSRA/B/C.CTS count on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.

Field	Bits	Type	Description
CLR	31	w	**Clear Current Time Stamp for the Module** If set, this bit clears CTS. CTS counts on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
0	[29:28]	r	**Reserved** Read as 0; should be written with 0.

Global Control Register

The Global Control Register defines module wide settings.

The first 5 bits define, which error flags are regarded at RSI. RSI indicates that the referring frame is free of the selected errors. Each of these errors can be selected: NFI, TEI, NBI, MEI, CRCI.

GCR
Global Control Register **(02C$_H$)** **Reset Value: 0000 001F$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0											CEN 4	CEN 3	CEN 2	CEN 1	CEN 0
r											rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0			ETC 4	ETC 3	ETC 2	ETC 1	ETC 0	0			TEI	NFI	MEI	NBI	CRCI
r			rw	rw	rw	rw	rw	r			rw	rw	rw	rw	rw

Field	Bits	Type	Description
CRCI	0	rw	**CRCI** is selected if bit is set.
NBI	1	rw	**NBI** is selected if bit is set.
MEI	2	rw	**MEI** is selected if bit is set.
NFI	3	rw	**NFI** is selected if bit is set.
TEI	4	rw	**TEI** is selected if bit is set.

Field	Bits	Type	Description
ETCx (x = 0-4)	8+x	rw	**Enable Channel Trigger Counter CTVx.CTC** This bit enables CTVx.CTC. The bits ETC0 ..x can be set with one write access to synchronously start all counters. This is required for proper sync pulse staggering. If set, CTCx counts on, starting from its current value. CTCx can be written only if ETCx is cleared (stopped). In TC27x only ETC0 .. 2 are available. All other must be written with 0, and always read 0.
CENx (x = 0-4)	16+x	rw	**Enable Channel** This bit enables PSI5 Channel x. If cleared, all internal state machines of the receiver and the sender are forced to default idle state while all registers can be read and written. Used for configuration of a channel.
0	[31:21], [15:13], [7:5]	r	**Reserved** Read as 0; should be written with 0.

32.14.2 Input and Output Control

Input and Output Control Register Functions

The Input and Output Control Register IOCRx determines for the PSI5 channel x:

for the receiver:

- the alternate input
- the filter depth
- the input signal polarity

for the transmitter

- the output signal polarity

IOCRx (x = 0-2)
Input and Output Control Register x(030_H+x*36*4) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TXM	RXM	0													
rh	rh	r

CFEG	CREG	FEG	REG	0		IIE	OIE	DEPTH				0		ALTI	
w	w	rh	rh	r		rw	rw	rw				r		rw	

Field	Bits	Type	Description
ALTI	[1:0]	rw	**Alternate Input Select** Selects the alternate input for channel x: 00_B Alternate Input 0 selected 01_B Alternate Input 1 selected 10_B Alternate Input 2 selected 11_B Alternate Input 3 selected

Field	Bits	Type	Description
DEPTH	[7:4]	rw	**Digital Glitch Filter Depth** DEPTH determines the number of port input samples clocked with *f*PSI5 that are taken into account for the calculation of the floating average. The higher DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 0000_B off, default 0001_B 1 T_{PSI5} 0010_B 2 0011_B 3 $\cdots_B$ … 1111_B 15
OIE	8	rw	**Output Inverter Enable Channel x** Selects the Pulse Polarity of the output of channel x 0_B Pulse polarity is not inverted 1_B Pulse polarity is inverted
IIE	9	rw	**Input Inverter Enable Channel x** Selects the Pulse Polarity of the input of channel x 0_B Pulse polarity is not inverted 1_B Pulse polarity is inverted
REG	12	rh	**Rising Edge Glitch Flag for Channel x** Shows the status of the glitch detection of channel x 0_B No Glitch detected on rising edge 1_B Glitch detected on rising edge REG is cleared by setting CREG.
FEG	13	rh	**Falling Edge Glitch Flag for Channel x** Shows the status of the glitch detection of channel x 0_B No Glitch detected on falling edge 1_B Glitch detected on falling edge FEG is cleared by setting CFEG.
CREG	14	w	**Clear Rising Edge Glitch Flag for Channel x** Clears the status flag REG 0_B REG is not cleared 1_B REG is cleared CREG always read zero.

Field	Bits	Type	Description
CFEG	15	w	**Clear Falling Edge Glitch Flag for Channel x** Clears the status flag FEG 0_B FEG is not cleared 1_B FEG is cleared CFEG always read zero.
RXM	30	rh	**Receive Monitor for Channel x** Shows the status of the receive signal of channel x after glitch filtering and inverted as specified by IIE. 0_B Current signal is low. 1_B Current signal is high.
TXM	31	rh	**Transmit Monitor for Channel x** Shows the status of the transmit signal of channel x inverted as specified by OIE. 0_B Current signal is low. 1_B Current signal is high.
0	[3:2], [11:10], [29:16]	r	**Reserved** Read as 0; should be written with 0.

32.14.3 Receiver Control Registers

Receiver Control Register A

The Receiver Control Registers RCRA contains control bits/bit fields that are related to the PSI5 receiver operation. It configures the payload length of the up to 6 frames in the up to 6 slots.

RCRAx (x = 0-2)
Receiver Control Register A x (034$_H$+x*36*4) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
AVBS	ASYN	PDL5					PDL4					PDL3			
rw	rw	rw					rw					rw			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PDL3	PDL2					PDL1					PDL0				
rw	rw					rw					rw				

Field	Bits	Type	Description
PDLy (y = 0-5)	[5*y+4: 5*y]	rw	**Payload Data Length** PDL determines the number of data bits per frame that the PSI5 channel x is setup for in slot y. PDL does not include the start bits and the Parity/CRC bits. PDL incudes the Messaging bits, the Frame Control bits and the Status bits. 00000_B 0 bit data 00001_B 1 bit data 00010_B 2 bit data 00011_B 3 bit data ... ... 11100_B 28 bit data 11101_B 0 bit data ... ... 11111_B 0 bit data

Field	Bits	Type	Description
ASYN	30	rw	**Asynchronous Mode** If set, • the watch dog timers for the PSI5 channel x, slot WDL1 .. 6 are disabled • If WDL0 is not cleared TEI is issued if the distance between two frames is longer than specified in WDL0 • Slot Counter SC is incremented with each received frame (works as frame counter) with roll over after 6. • No Sync Pulses generated, TX path is inactive 0_B off (default) 1_B on
AVBS	31	rw	**Verbose Mode for Asynchronous Mode** If set, and ASYN is set and WDL0 is > 0 an empty frame is stored in RDRL/Hx and the referring RDML/H each time, the watch dog timer for the PSI5 channel x without reception of a frame. 0_B off (default) 1_B on

Receiver Control Register B

The Receiver Control Registers RCRBx contains control bits/bit fields that are related to the PSI5 receiver operation. It configures up to 6 frame types in the up to 6 slots.

RCRBx (x = 0-2)
Receiver Control Register B x **(038_H+x*36*4)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								VBS 5	FEC 5	CRC 5	MSG 5	VBS 4	FEC 4	CRC 4	MSG 4
r								rw	rw	rw	rw	rw	rw	rw	rw

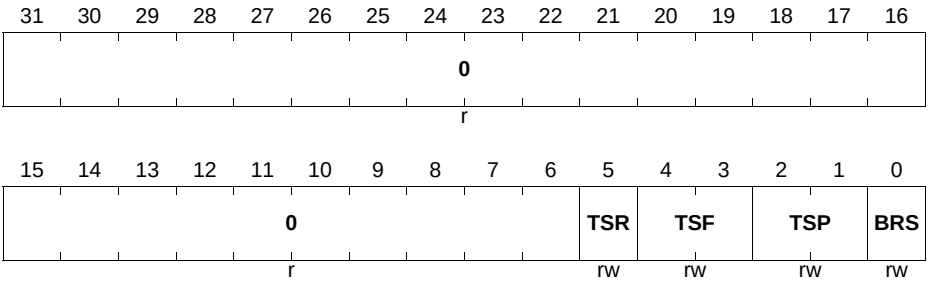
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VBS 3	FEC 3	CRC 3	MSG 3	VBS 2	FEC 2	CRC 2	MSG 2	VBS 1	FEC 1	CRC 1	MSG 1	VBS 0	FEC 0	CRC 0	MSG 0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
MSGy (y = 0-5)	4*y	rw	**Messaging Bits** If set, the 2 Messaging bits are configured for the PSI5 channel x in slot y. If set, Extended Serial Message processing on bits D[1:0] is activated. (18 frames, 4 or 8 bit ID, 12 or 16 bit data, 6 bit CRC) If Messaging bits are transmitted they are always presented in RDRx independently from status of MSGy. I.e. RDRx always stores exactly the data that was received. 0_B No Messaging bits (default) 1_B 2 Messaging bits
CRCy (y = 0-5)	4*y+1	rw	**CRC or Parity Selection** If set, a 3 bit CRC checksum is expected for the PSI5 channel x in slot y. Else, 1 bit Parity is assumed. 0_B 1 Parity Bit is configured (default) 1_B 3 CRC bits are configured
FECy (y = 0-5)	4*y+2	rw	**Frame Expectation Control** If set, a frame is expected for the PSI5 channel x in slot y. A No Frame Received error interrupt NFI is issued each time, the watch dog timer for the PSI5 channel x, slot y expires without reception of a SOF or EOF. 0_B No Message expected (default) 1_B A Message is expected, SC is checked
VBSy (y = 0-5)	4*y+3	rw	**Verbose Mode** If set, and a message is expected for the PSI5 channel x in slot y (FECy) an empty frame is stored in RDRL/Hx and the referring RDML/H each time, the watch dog timer for the PSI5 channel x, slot y expires without reception of a frame. 0_B off (default) 1_B on
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

Receiver Control Register C

The Receiver Control Registers RCRCx contains control bits/bit fields that are related to the PSI5 receiver operation. Bit Rate and Time Stamp Sources are configured here.

RCRCx (x = 0-2)
Receiver Control Register C x (03C$_H$+x*36*4) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
BRS	0	rw	**Baud Rate Select** 0_B f_{125} selected for channel x 1_B f_{189} selected for channel x
TSP	[2:1]	rw	**Time Stamp Select for Pulses** 00_B TSRA.CTS is captured in SPTSC 01_B TSRB.CTS is captured in SPTSC 10_B TSRC.CTS is captured in SPTSC 11_B not defined. Do not use
TSF	[4:3]	rw	**Time Stamp Select for Start of Frame (SOF)** 00_B TSRA.CTS is captured in SFTSC 01_B TSRB.CTS is captured in SFTSC 10_B TSRC.CTS is captured in SFTSC 11_B not defined. Do not use
TSR	5	rw	**Time Stamp Select for Receive Data Registers** 0_B SPTSC is stored in RDRHx 1_B SFTSC is stored in RDRHx
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

Watch Dog Timer Register

Synchronous Mode

Selected with RCRAx.ASYN = 0.
The Watch Dog Timer Registers WDTxy contain 7 time limits defining 6 frame slots.

The internal Watch Dog timer is started automatically at the start of a sync pulse. The value entered here defines the time in multiples of TTS (defined in FDRT) from the last start of a sync pulse on channel x.

The internal Watch Dog Timer is compared to WDLxy. A match triggers:

- the automatic incrementing of slot counter RDRH.SCx
- starting from WDLx1 on: check if a frame with the corresponding SC y has been received or if such a frame is still being received since last WDLxy expired. If this is not the case but a frame was expected in this slot y (configured so in RCRBx.FECy) “No Frame Received” Interrupt NFI is issued. If configured so (in RCRBx.VBSy), an empty frame (all data fields are ‘0’) is stored in RDRL/Hx and the referring RDML/H.
- Frames that start before a slot boundary and end after this boundary but are too short and thus discarded will result in an NFI / empty frame as well (if configured).
  - If no frame was received before the SOF in this slot,
    SC = slot where SOF happened.
    Time Stamp = end of slot where SOF happened.
  - If a good frame was received in this slot before a second SOF crosses WDL, the parameters for the next slot are taken over already and
    if no good frame is received in this next slot:
    SC = next slot (SC where SOF happened + 1)
    Time Stamp = end of next slot (SC where SOF happened + 1).
  - If a good frame was received in this slot before a second SOF crosses WDL, the parameters for the next slot are taken over already and
    if a good frame is received in this next slot: no NFI is issued.
- (The remarks about the Time Stamps assume that RCRCx.TSR selects SFTSCx.)
- A frame starting before a slot y and ending in slot y will not prevent NFI for slot y.

Detection of Frame Boundaries:

- SOF is the first rising edge of the first start bit after an “Idle Time”, a time stamp is triggered and SC is captured for the frame at this point in time
- EOF is determined based on the configured frame length (RCRAx.PDLy and RCRCx.CRCy). An unexpected “Idle Time” or Manchester Error will result in earlier EOF detection.
- For each frame, the receiver checks if slot counter SC at SOF is equal to SC at EOF. If not, the interrupt TEI is issued. FEC is not relevant for TEI.

If WDLxy is cleared no check is performed but RDRH.SC is still incremented when it is its turn in the sequence of the WDLs. Thus such unconfigured WDLxy must appear only at the end. If an unconfigured WDLxy appears between configured WDLxy, the slot count will be confused.

If a frame is received in a slot where no frame is expected, no dedicated flag is set but the frame is received with the parameters (PDL, SC and on) given for this slot. SW will detect this as SC for this frame is wrong.

Asynchronous Mode

Selected with RCRAx.ASYN = 1.
The watch dog timers for the PSI5 channel x, slot WDL1 .. 6 are disabled. If WDL0 is not cleared TEI is issued if the distance between two frames is longer than specified in WDL0. Slot Counter SC is incremented with each received frame (works as frame counter) with roll over after 6. If AVBS (verbose mode) is set too, an empty frame is stored in RDRL/Hx and the referring RDML/H.

Channel Configuration at Slot Boundaries / Take over of Slot Parameters

The receiver takes over the parameters for a frame at the beginning of a slot
- with 3 exceptions:

Exception 1)

During SLOT0 (this is the slot after the last configured slot), after the sync pulse, the configuration of SLOT1 is already used. An internal shadow slot count value makes sure, the messaging bits are routed to slow channel for SLOT1. This way, a frame for SLOT1 that is too early will be received correctly, the messaging bits are sorted correctly. The time violation is still visible by TEI = 1 as such a frame would still start in a different slot (SLOT0) than it ends (SLOT1). SC = 1 will be stored in the receive buffer/memory.

Exception 2)

Frames that come too early could destroy the slow channel of the preceding slot. To prevent this, during SLOT1 .. SLOT5, the configuration of the next slot is loaded immediately after EOF was received. Note that an SOF must be seen first in the same slot before an EOF is looked for. This way, the HW prevents the destruction of a good frame by a preceding frame that is too late. An internal shadow slot count value makes sure, the messaging bits are routed to the slow channel for the following SLOT. This way, a frame for e.g. SLOT3 that is too early will be received correctly, the messaging bits are sorted correctly in SLOT3 and not in SLOT2 where the SOF of this frame is. The time violation is still visible by TEI = 1 as such a frame would still start in a different slot (SLOT2) than it ends (SLOT3). SC = 3 will be stored in the receive buffer/memory.

Exception 3)

If a frame does not end at the configured end of a slot, the new parameters of the following slot are taken over by the receiver only after the EOF was detected. This allows to receive a frame properly that is too late.

Note that orphan frames, i.e. frames that come with a timely shift of of one ore more slots can not be detected as such. Thus they will be stored with the SC as they appear.

Notes on Frames coming too early

A frame may come too early and thus start in a slot that is configured for no frame (FEC = 0).

If the user wants to make sure that this frame is stored in RDR/RDM, the slot with FEC = 0 must be configured in the same way as its follower.

At least, the length field PDL must be set to its maximum value (28) to allow for reception of all frame lengths. This allows to capture such a frame with referring error bits. (TEI, NBI, CRC in most cases)

If this is not done and PDL is (by default) = 0 the following happens:

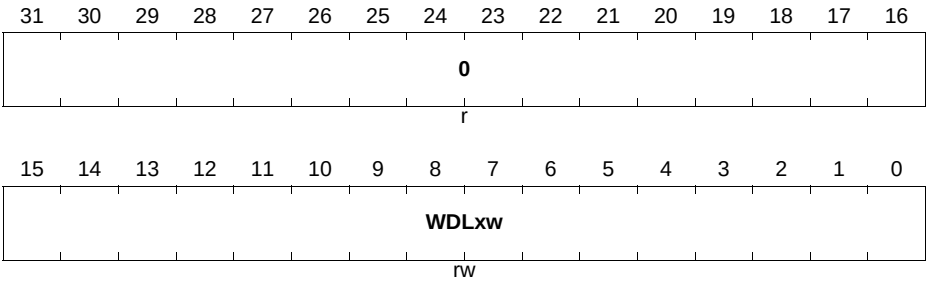
CASE1: SOF is too early and thus in the slot with FEC = 0, due to PDL = 0 also EOF is detected in the slot with FEC = 0.

The Frame is stored in RDR/RDM with Time Stamp, 0 bits of data (as configured in PDL), Slot Count of the too early slot (with FEC =0), CRCI is generated as the FSM assumes that no CRC can be checked ok on no data, NBI is issued.

CASE2: SOF is too early and thus in the slot with FEC = 0, although PDL = 0 EOF is detected in the slot FOLLOWING the slot with FEC = 0 (because CRC transmission end here, i.e. the SOF was very close to the end of the slot)

The Frame is stored in RDR/RDM with Time Stamp, 0 bits of data (as configured in PDL), Slot Count of the too early slot (with FEC =0), CRCI is generated as the FSM assumes that no CRC can be checked ok on no data, NBI and TEI bits are set.

WDT0w (w = 0-6)
Watch Dog Timer Register 0w **(040_H+w*4)** **Reset Value: 0000 0000_H**
WDT1w (w = 0-6)
Watch Dog Timer Register 1w **($0D0_H$+w*4)** **Reset Value: 0000 0000_H**
WDT2w (w = 0-6)
Watch Dog Timer Register 2w **(160_H+w*4)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
WDLxw	[15:0]	rw	**Watch Dog Timer Limit** for channel x limit w.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

Usage of the Watch Dog Timer Limits:

The example below shows some use cases.

F1: “Frame too early”: Slot Count SC at SOF is 0 and 1 at EOF. Timing Error is issued (TEI). F1 is stored with configuration of Slot 1 and SC = 1.

WDL2: Slot Count SC incremented by HW, no “No Receive Frame” Interrupt as no frame expected (FEC=0)

F3: “Frame too late”: Slot Count SC at SOF is 3 and 4 at EOF. Timing Error is issued (TEI). The configuration for Slot 3 is kept until the end of F3 so that it is not destroyed. Note that the EOF of Frame 3 does not lead to take over the configuration of Slot 5! But the EOF of F4 does. This way a F5 coming too early would be received correctly.

WDL5: “Frame missing”: No SOF or EOF received since WDL4. A frame was expected (FEC=1), No Receive Frame Interrupt is issued.

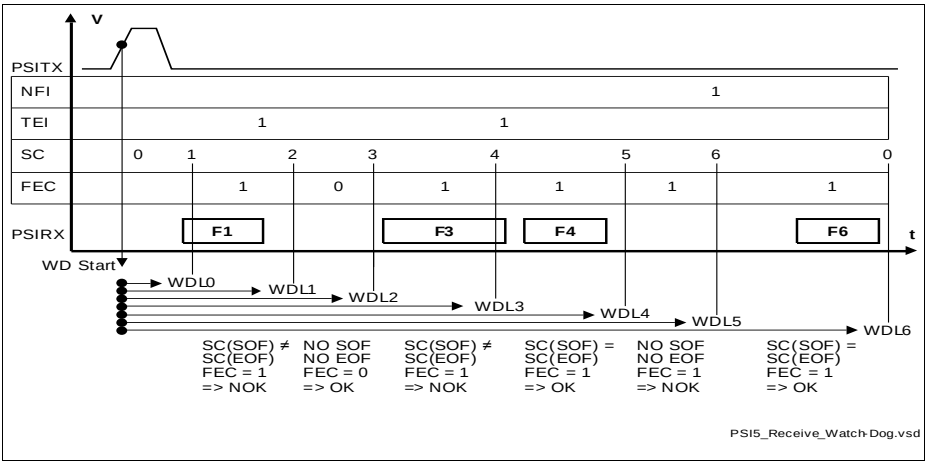


Figure 32-18 Watch Dog Timer Limits

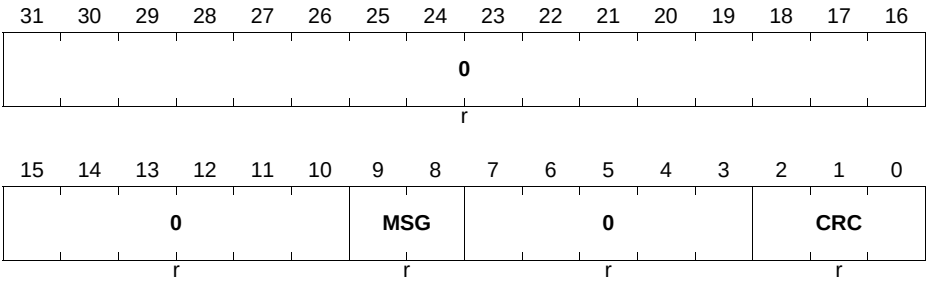
32.14.4 Receive Data and Status Registers

Receiver Status Register

The Receive Status Register provides the status information of channel x.

RSRx (x = 0-2)
Receive Status Register x **($05C_H$+x*36*4)** **Reset Value: 0000 0000_H**

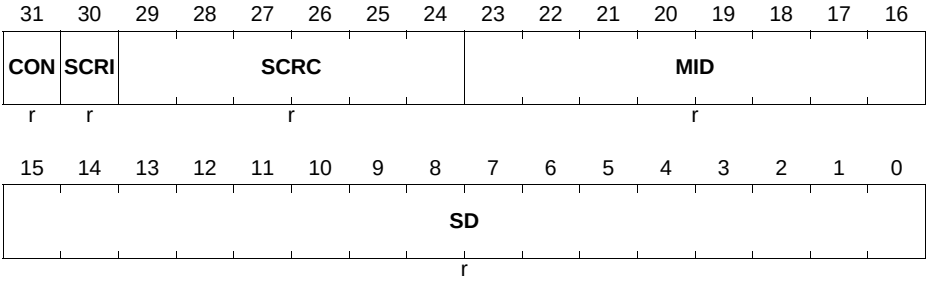


Field	Bits	Type	Description
CRC	[2:0]	r	**CRC** of last frame. CRC0 is on bit position 0.
MSG	[9:8]	r	**Messaging Bits** of last frame. MSG0 is on bit position 8.
0	[7:3], [31:10]	r	**Reserved** Read as 0; should be written with 0.

Serial Data and Status Register (“Slow Channel”)

The Serial (Receive) Data and Status Register provides the data and status information of channel x slot y. The data is presented in bit field SD independent from the SCRC check result in SCRI.

SDS0z (z = 0-5)
Serial Data and Status Register 0z (060H+z*4) **Reset Value: 0000 0000$_H$**
SDS1z (z = 0-5)
Serial Data and Status Register 1z (0F0H+z*4) **Reset Value: 0000 0000$_H$**
SDS2z (z = 0-5)
Serial Data and Status Register 2z (180H+z*4) **Reset Value: 0000 0000$_H$**

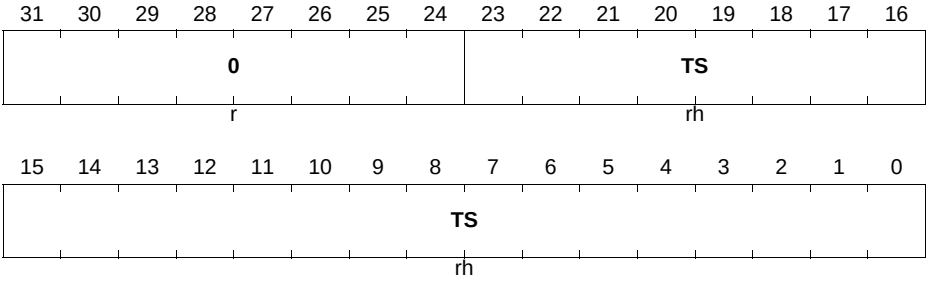


Field	Bits	Type	Description
SD	[15:0]	r	**Serial Data** of last serial data frame on channel x slot y. SD0 is on bit position 0. If SDS.CON is not set, bits [15:12] are zero.
MID	[23:16]	r	**Message ID** of last serial data frame. ID0 is on bit position 16. If SDS.CON is set, bits [23:20] are zero.
SCRC	[29:24]	r	**SCRC** CRC of last serial data frame. CRC0 is on position 24.
SCRI	30	r	**CRC of Serial Message failed Interrupt Flag.** This bit is set if the CRC of the serial message fails. This includes a check of the Messaging bit field for correct 0 values of bit 1 in frames 7, 13 and 18. See INTSTATx.
CON	31	r	**Configuration bit** of last serial frame. 0_B 12-bit data and 8-bit message ID 1_B 16-bit data and 4-bit message ID

Start of Pulse Time Stamp Capture Register SPTSCx

Each time a sync pulse is sent on channel x, the time stamp is captured in this register. RCRC.TSP selects, if TSRA, B or C is used. RCRC.TSR determines if SPTSCx or SFTSCx is stored in RDRHx.

SPTSCx (x = 0-2)
SOP TS Capture Register SPTSCx(078_H+x*36*4) **Reset Value: 0000 0000_H**

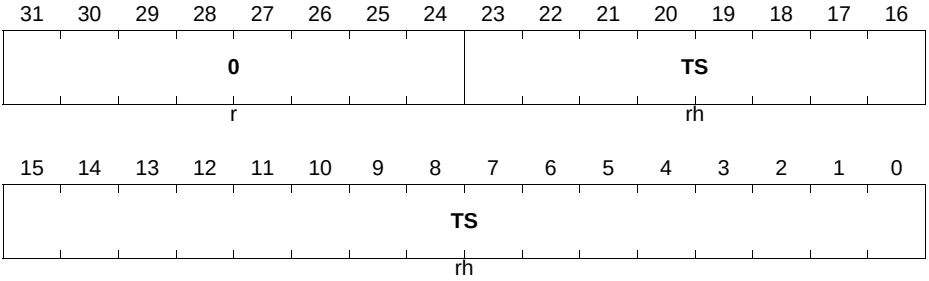


Field	Bits	Type	Description
TS	[23:0]	rh	**Time Stamp** of the last sync pulse sent on channel x. The Time Stamp is taken at the rising edge of the pulse.
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

Start of Frame Time Stamp Capture Register SFTSCx

Each time a start of frame is received on channel x, the time stamp is captured in this register. The first rising edge of the first start bit is captured. Note that a preceding “Idle Time” is required for start bit detection. In case the two start bits should not be received successfully (i.e. without manchester coding errors) the frame is completely dropped and the latest captured value is overwritten with the next SOF or at the referring WDLy for “empty messages” if configured in RCRBx.VBSy. RCRC.TSF selects, if TSRA, B or C is used. RCRCx.TSR determines if SPTSCx or SFTSCx is stored in RDRHx.

SFTSCx (x = 0-2)
SOF TS Capture Register SFTSCx($07C_H$+x*36*4) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TS	[23:0]	rh	**Time Stamp** of the last frame received on channel x. The Time Stamp is taken at the rising edge of the first start bit S1 that was qualified by the receiver.
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

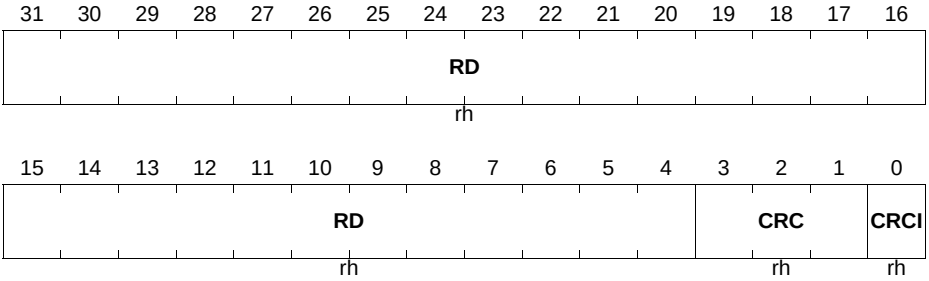
Receive Data Registers RDRLx

The Receive Data Register RDRLx for channel x shows the data content of a received data frame.

The internal receive buffer is always cleared ($0x0000\ 0000_H$) at each frame start. Thus unused nibbles are always read as zero.

The bit CRCI reflect, wether the conditions are met to issue an interrupt signal and set the referring interrupt status bit in INTSTATA for the latest frame. Thus it is independent from the old status of the referring sticky bit in INTSTATA before latest frame reception.

RDRLx (x = 0-2)
Receive Data Register Low x (080H+x*36*4) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
CRCI	0	rh	**CRC Error Flag** This bit is set if the CRC or Parity check fails. Set as well if CRC can not be calculated: PDL = 0, CRC cut off by Manchester Error, too few bits, BOT, Sync Pulse) 0_B correct CRC/Parity 1_B wrong CRC/Parity
CRC	[3:1]	rh	**CRC** CRC/parity bit of last PSI5 frame. CRC0 or Parity bit is on bit position 1. In case of NFI, this field is cleared.
RD	[31:4]	rh	**RD** Receive data of last PSI5 frame. D0 is on bit position 4. In case of NFI, this field is cleared.

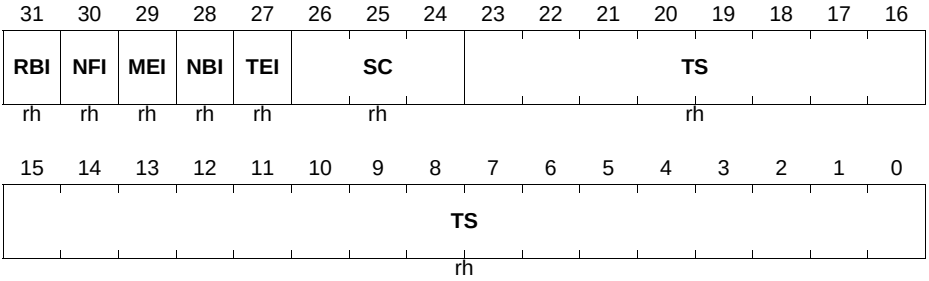
Receive Data Registers RDRHx

The Receive Data Register RDRHx for channel x shows the data content of a received data frame.

The internal receive buffer is always cleared (0x0000 0000$_H$) at each frame start. Thus unused bits are always read as zero.

The bits RBI, RMI, RSI, NBI and TEI reflect, wether the conditions are met to issue an interrupt signal and set the referring interrupt status bit in INTSTATA for the latest frame. Thus it is independent from the the old status of the referring sticky bit in INTSTATA before latest frame reception.

RDRHx (x = 0-2)
Receive Data Register High x (084H+x*36*4) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
TS	[23:0]	rh	**Time Stamp** of the last received PSI5 frame. RCRC.TSR determines if SPTSCx or SFTSCx is stored in RDRHx. (It can be selected if the time stamp of the last sync pulse is stored or the time stamp for the start of frame).
SC	[26:24]	rh	**Slot Counter** In Synchronous Mode (RCRAx.ASYN=0): Number of the slot the SOF of the frame was received in. In Asynchronous Mode (RCRAx.ASYN=1): revolving frame number between 1 and 6. 000_B not valid (SOF too early) 001_B Slot 1 $\ldots_B$ … 110_B Slot 6 111_B not valid
TEI	27	rh	**Time Slot Error Flag** In Synchronous Mode (RCRAx.ASYN = 0), this bit is set if the SOF and the EOF of a frame are received in different time slots. The slots are constraint by the watch dog timer (see WDTxy). In Asynchronous Mode (RCRAx.ASYN = 1), this bit is set if the distance between two frames is longer than specified in WDL0. 0_B no error 1_B error

Field	Bits	Type	Description
NBI	28	rh	**Number of bits Error Flag** This bit is set if the last frame received less bits than expected but no manchester coding error occurred until S1, S2, M0 and M1 where received. Note that the frame after the error might be completely wrong. 0_B all bits received 1_B not all bits received
MEI	29	rh	**Error in Message Bits Flag** This bit is set if a manchester error occurred in Bit M0 or M1. (Only if configured in RCRBx.MSG) Note that the frame after the error might be completely wrong. 0_B frame is correct 1_B frame is not correct
NFI	30	rh	**No Frame Received Flag** This bit is set at the end of a slot if neither an SOF nor an EOF was received in this slot. If only the two start bits are received and no further data, this “SOF” is discarded completely and treated like no frame received as well. If RCRBx.VBS is set, an empty frame is stored anyhow and RDIx is issued as well. The content of RDRL/Hx / RDML/Hx is valid for SC, TS (captured at the end of the slot) and for this bit (NFI). Bit fields RD and CRC are cleared (all zero). 0_B no error 1_B error
RBI	31	rh	**Receive Buffer Overflow Flag** This bit is set after a frame has been received while the old one was not read from RDRHx. I.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set. The old data is overwritten by the new data. 0_B No overflow 1_B Overflow

32.14.5 Receive Data Memory

The module design allows for usage in 2 ways without mode selection:

Ring Buffer Usage

The Receive Data Memory x is built as a ring buffer. I.e. the first frame is stored in RDML/Hx0, the next in RDML/Hx1 and so on. At buffer 31 a wrap around is performed automatically. I.e. the next frame is stored in buffer 0. RFCx.WRP is showing the last location written and automatically incremented after write.

Receive Buffer Overrun Interrupt Flag RBI is set, if a buffer is written before the SW cleared Receive Data Interrupt Overview Flag RDIOVx (unchecked or erroneous frame received or No Frame Received (NFI) message to be stored).

FIFO Usage

Writing to the Receive Data Memory by the module moves the write pointer after writing. Reading from RDFx 2 times with a 32 bit word access moves the read pointer to the next younger buffer automatically after the read access. It clears as well all interrupt overview bits for this buffer line in NBIOVx, CRCIOVx, TEIOVx, RMIOVx, RSIOVx; RDIOVx, NFIOVx, MEIOVx. This allows for fully automatic DMA transfers without CPU intervention. The DMA simply needs to be set up in a way that it reads exactly the number of buffers configured with the FIFO warning level FWL. The application SW configures “FIFO Warning Level Request Interrupt” FWI so that it is routed to the referring DMA channel as trigger source. Note that FWI does not need to be cleared to repetitively trigger the DMA.

If RFCx.WRAP is cleared and the read pointer (after the auto increment said above) equals the write pointer while reading from RDFx, a Receive Memory Underrun Interrupt RUIx is flagged and the read pointer is not moved on automatically even if RDFx is read.

IF RFCx.FRQ is set, the FIFO needs to be flushed by RFCx.FLU.

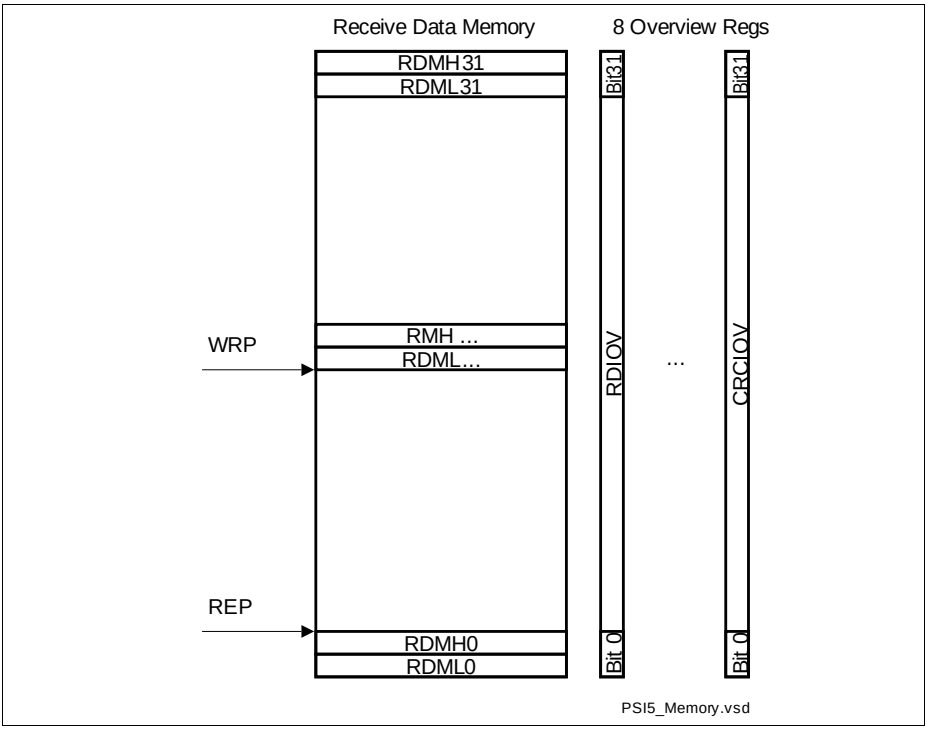


Figure 32-19 Receive Data Memory

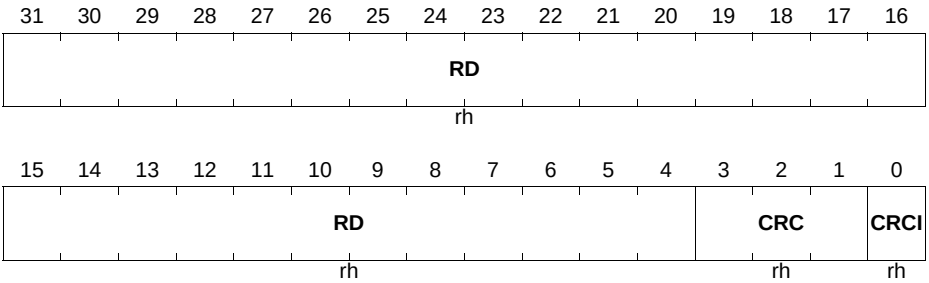
Receive Data Memory RDMLxy

The Receive Data Memory RDMLx for channel x shows the data content of up to 32 received data frames.

The internal receive buffer is always cleared (0x0000 0000_H) at each frame start. Thus unused nibbles are always read as zero.

RDML0y (y = 0-31)
Receive Data Memory Low 0y (600H+y*8) Reset Value: 0000 0000$_H$
RDML1y (y = 0-31)
Receive Data Memory Low 1y (700H+y*8) Reset Value: 0000 0000$_H$
RDML2y (y = 0-31)
Receive Data Memory Low 2y (800H+y*8) Reset Value: 0000 0000$_H$



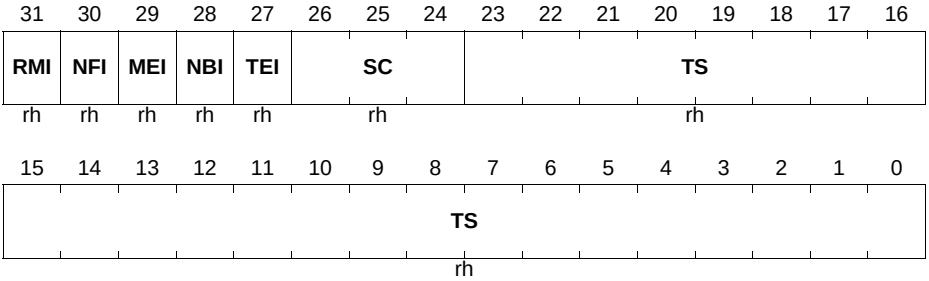
Field	Bits	Type	Description
CRCI	0	rh	**CRC Error Flag** Copied from RDRLx at frame end.
CRC	[3:1]	rh	**CRC** Copied from RDRLx at frame end.
RD	[31:4]	rh	**RD** Copied from RDRLx at frame end.

Receive Data Memory RDMHxy

The Receive Data Memory RDMHx for channel x shows the data content of up to 32 received data frames.

The internal receive buffer is always cleared (0x0000 0000$_H$) at each frame start. Thus unused nibbles are always read as zero.

RDMH0y (y = 0-31)
Receive Data Memory High 0y (604H+y*8) Reset Value: 0000 0000$_H$
RDMH1y (y = 0-31)
Receive Data Memory High 1y (704H+y*8) Reset Value: 0000 0000$_H$
RDMH2y (y = 0-31)
Receive Data Memory High 2y (804H+y*8) Reset Value: 0000 0000$_H$

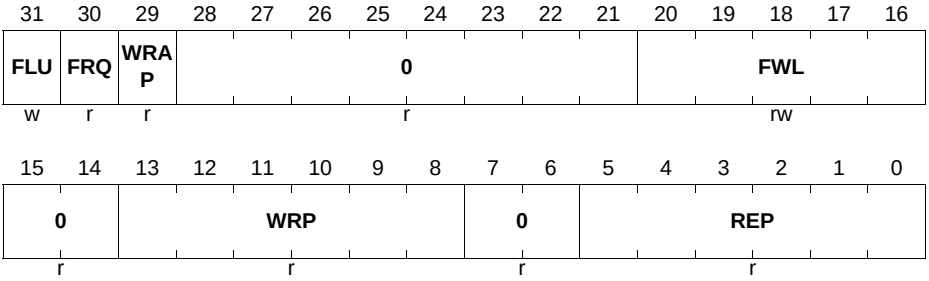


Field	Bits	Type	Description
TS	[23:0]	rh	**Time Stamp** Copied from RDRHx at frame end.
SC	[26:24]	rh	**Slot Counter** Copied from RDRHx at frame end.
TEI	27	rh	**Time Slot Error Flag** Copied from RDRHx at frame end.
NBI	28	rh	**Number of bits Error Flag** Copied from RDRHx at frame end.
MEI	29	rh	**Error in Messaging Bits Flag** Copied from RDRHx at frame end.
NFI	30	rh	**No Frame Received Flag** Copied from RDRHx at frame end.
RMI	31	rh	**Receive Memory Overflow Flag** Copied from INTSTATAx at frame end.

Receive FIFO Control Register RFCx

RFCx contains control bits for the FIFO and Ring Buffer operation.

RFCx (x = 0-2)
Receive FIFO Control Register x (3E4$_H$+x*4) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
REP	[5:0]	r	**FIFO Read Pointer** points to the buffer to be read next. Incremented after read. The last bit bit indicates if RDMxH or RDMxL is read. This LSB is ignored for FWL comparison WRP - REP collision (RBI, RUI)
WRP	[13:8]	r	**FIFO/Ring Buffer Write Pointer** points to the buffer written last. Incremented before write. The last bit indicates if RDMxH or RDMxL is written. This LSB is ignored for FWL comparison WRP - REP collision (RBI, RUI).
FWL	[20:16]	rw	**FIFO Warning Level** Number of new entries at which the FIFO Warning Interrupt FWIx is set automatically. For calculation WRP and REP are used. I.e. only if the memory is read via RDFx, this works properly.
WRAP	29	r	**Write Pointer WRAP Indicator** If set, the Write Pointer is one wrap around ahead of the Read Pointer. It is cleared, if the the Read Pointer wraps around too or when FLU is set by SW.

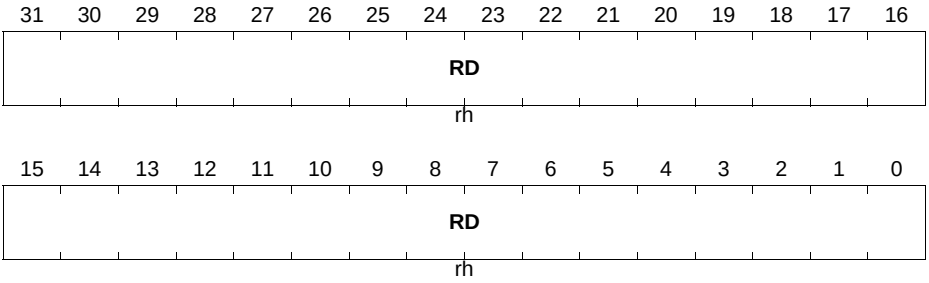
Field	Bits	Type	Description
FRQ	30	r	**Flush Request** if set, FIFO read and write pointers are not incremented any more due to excessive RMI. (Too many overrun conditions). This bit is cleared when FLU is set.
FLU	31	w	**Flush** if set, FIFO read and write pointers are cleared. Bits and WRAP are cleared. SW needs to clear interrupts as needed. This bit can only be set and is cleared by HW. Always read as 0.
0	[28:21], [15:14], [7:6]	r	**Reserved** Read as 0; should be written with 0.

Receive Data FIFO RDFx

The Receive Data FIFO RDFx for channel x shows the oldest data content of up to 32 received data frames. I.e. RFCx.REP is pointing at the buffer presented.

Do not set a debugger watch point on this register as any read access will issue a hard ware request for new data (move read pointer REP and present referring memory content in RDFx). A debugger watch point can be set on the RDML/Hx and RFCx to monitor the FIFO behavior.

RDFx (x = 0-2)
Receive Data FIFO x **(3F8H+x*4)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RD	[31:0]	rh	**RD** Shows the content of RDML/Hxy; y = RFCx.REP[5:1]; L/H = RFCx.REP[0]. Reading this register triggers incrementation of REP and presentation of next FIFO value at next read access! Once a complete buffer is read (64 bit, 2 accesses to RDF) all overview flags for this very buffer are cleared automatically.

RSI Overview Register

The RSI Overview Register RSIOVx contains flags to manage the receive memory of PSI5 channel x.

RSIOVx (x = 0-2)
RSI Overview Register **($40C_H$+x*4)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSI31	**RSI30**	**RSI29**	**RSI28**	**RSI27**	**RSI26**	**RSI25**	**RSI24**	**RSI23**	**RSI22**	**RSI21**	**RSI20**	**RSI19**	**RSI18**	**RSI17**	**RSI16**

32.14.6 Sync Pulse Control

The sync pulse generation provides the following functionality:

- periodic sync pulses, driven by a common module time base (PTE is set)
- angle synchronous sync pulses, driven by GTM (ETE is set)
- sync pulses for ECU to Sensor communication (PSI5 V1.3) (EPS is cleared)
- sync pulses for ECU to Sensor communication (PSI5 enhanced) (EPS is set)
- sync pulses provided by GTM (Bypass BYP set)
- Blank Out (switch off receiver during and after the Sync Pulse)

It is possible to switch on and off the periodic trigger or the angle synchronous trigger at any time. If data is available (TOF is set) the pulses will be modulated according to the selected standard. EPS selects between extended standard with pulse length modulation and legacy mode according to PSI5 standard V1.3 with pulse dropping. The minimum pulse length is defined by PGC.PLEN for both standards. For the extended standard, the pulses are prolonged by PGC.DEL if a one is coded. Exception is the bypass path (BYP is set). These pulses are transmitted without any modulation.

Any combination of PTE, ETE and BYP can produce too long pulses!

An ECU to Sensor communication can be stopped at any point in time by setting the flush bit. This will clear the send register and flag TOF.

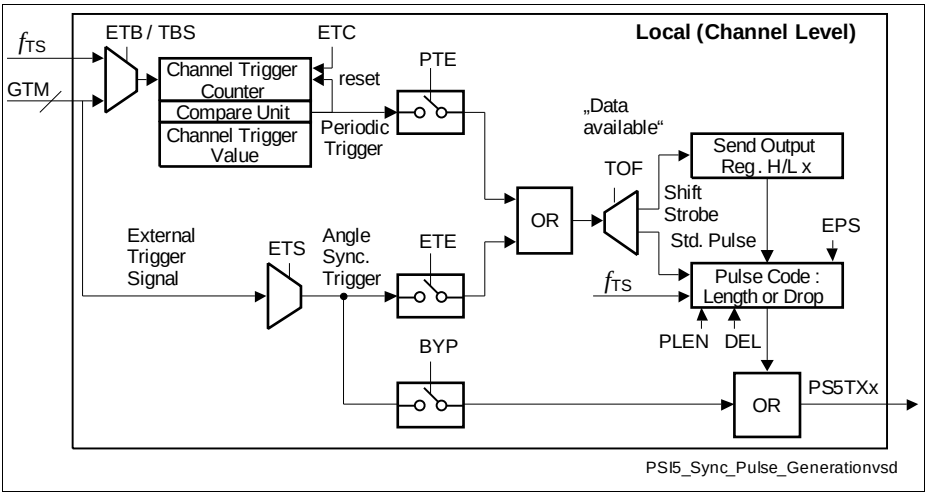

Figure 32-20 PSI5 Sync Pulse Generation

Blank Out Time

BOT defines the length of the blank out time in TTS times (defined by FDRT) starting from the end of a Sync Pulse. The receiver is always switched off starting from the beginning of a Sync Pulse. BOT keeps the receiver switched off additionally after the Sync Pulse. This suppresses potential noise on the receive line after the pulse and thus eases the design of the transceiver.

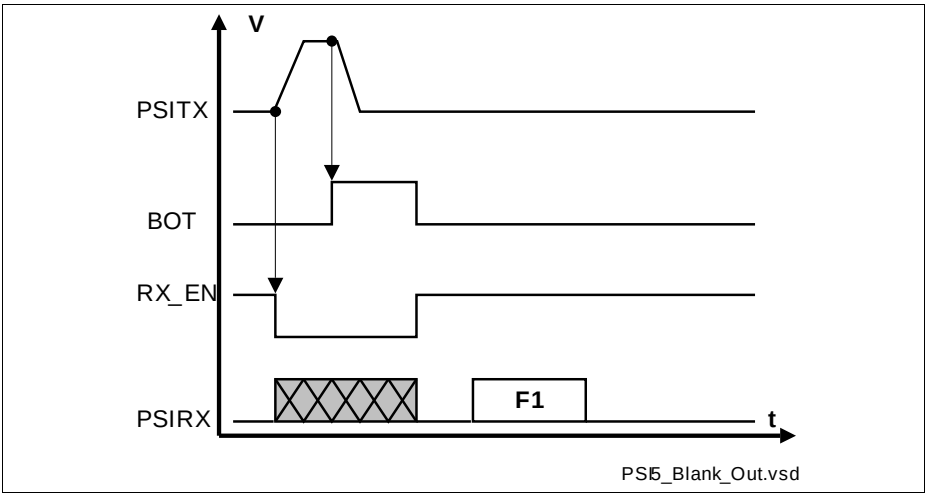

Figure 32-21 PSI5 Blank Out Time

Pulse Generation Control Registers PGCx

The Pulse Generation Control Register PGC contains control data for the sync pulse generation. It contains as well the trigger control bits required for sending data from the PSI5 module to the sensor / external PSI5 device.

PGCx (x = 0-2)

Pulse Generation Control Register x(088_H+x*36*4) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TBS	0	DEL						0		PLEN					
rw	r	rw						r		rw					

Field	Bits	Type	Description
PLEN	[5:0]	rw	**Pulse Length** Defines the length of the pulse in TTS times (defined by FDRT). This is the standard pulse width without data coding into the pulse width or for coding a ‘0’. 000000_B Pulse length is 0 TTS 000001_B Pulse length is 1 TTS ... ... 111111_B Pulse length is 63 TTS
DEL	[13:8]	rw	**Delay Length** In case data is coded into the pulse length, this defines the ADDITONAL length of the pulse in TTS times. The resulting sum length is the pulse width for coding a ‘1’ into the pulse width. 000000_B Pulse length is 0 TTS 000001_B Pulse length is 1 TTS ... ... 111111_B Pulse length is 63 TTS
TBS	15	rw	**Time Base Select** This bit selects the clock source for CTVx 0_B Internal, CTV counts in clock cycles of f_{TS} 1_B External, CTV counts in clock cycles of f_{GTM}
ETB	[18:16]	rw	**External Time Base Select** Selects the external clock line for counter CTVx. 000_B TRIG0 001_B TRIG1 $\cdots_B$ … 101_B TRIG5 110_B reserved, no trigger selected 111_B reserved, no trigger selected
PTE	19	rw	**Periodic Trigger Enable** Periodic trigger is defined by CTVx. Should be 0 if ETE or BYP is set. 0_B disabled 1_B enabled

Field	Bits	Type	Description
ETS	[22:20]	rw	**External Trigger Select** Selects the external trigger line for pulse generation (e.g. angle synchronous). 000_B TRIG0 001_B TRIG1 $\ldots_B$ … 101_B TRIG5 110_B reserved, no trigger selected 111_B reserved, no trigger selected
ETE	23	rw	**External Trigger Enable** “Angle sync. trigger”, external line is selected by ETS. Should be 0 if PTE or BYP is set. 0_B disabled 1_B enabled
BYP	24	rw	**Bypass Enable** An external signal, selected by ETS directly drives the output of channel x. Should be 0 if PTE or ETE is set. 0_B disabled 1_B enabled
BOT	[31:25]	rw	**Blank Out Time** BOT defines the length of the blank out time in TTS times (defined by FDRT) starting from the end of a Sync Pulse. The receiver is always switched off starting from the beginning of a Sync Pulse. BOT keeps the receiver switched off additionally after the Sync Pulse. This suppresses potential noise on the receive line after the pulse and thus eases the design of the transceiver. 0000000_B Blank Out Time is 0 TTS 0000001_B Blank Out Time is 1 TTS ... ... 1111111_B Blank Out Time is 127 TTS
0	14, [7:6]	r	**Reserved** Read as 0; should be written with 0.

Channel Trigger Value Register x CTVx

The Channel Trigger Value Register x contains a two cell reset counter. It allows for setting up periodic sync pulses for channel x.
The Channel Trigger Value CTV is the compare value which clears the counter CTC on

equality and only on equality. At exactly this time, a sync pulse is triggered.
The compare on equality allows to preset CTC and thus configure an offset between the CTVx.CTCs. This allows for staggering periodic sync pulses that must have frequencies with common multiples (e.g. same frequency, double etc.).

In this document OFFSET = 65535 - “CTC preset value”

I.e. CTC preset is > CTV so that the the time to to roll over is the offset.
Of course CTC preset can be < CTV so that this CTC has some advance.
Note that CTC can be written only if it is disabled by clearing GCR.ETCx.

Staggering the pulses might be required if the current source for the external phys can provide only limited current so that not all channels can be provided with the additional current that is required to apply the voltage increase representing a proper sync pulse.
For a synchronization of all counters CTVx.CTC, bits GCR.ETC0 .. 2 can be used.

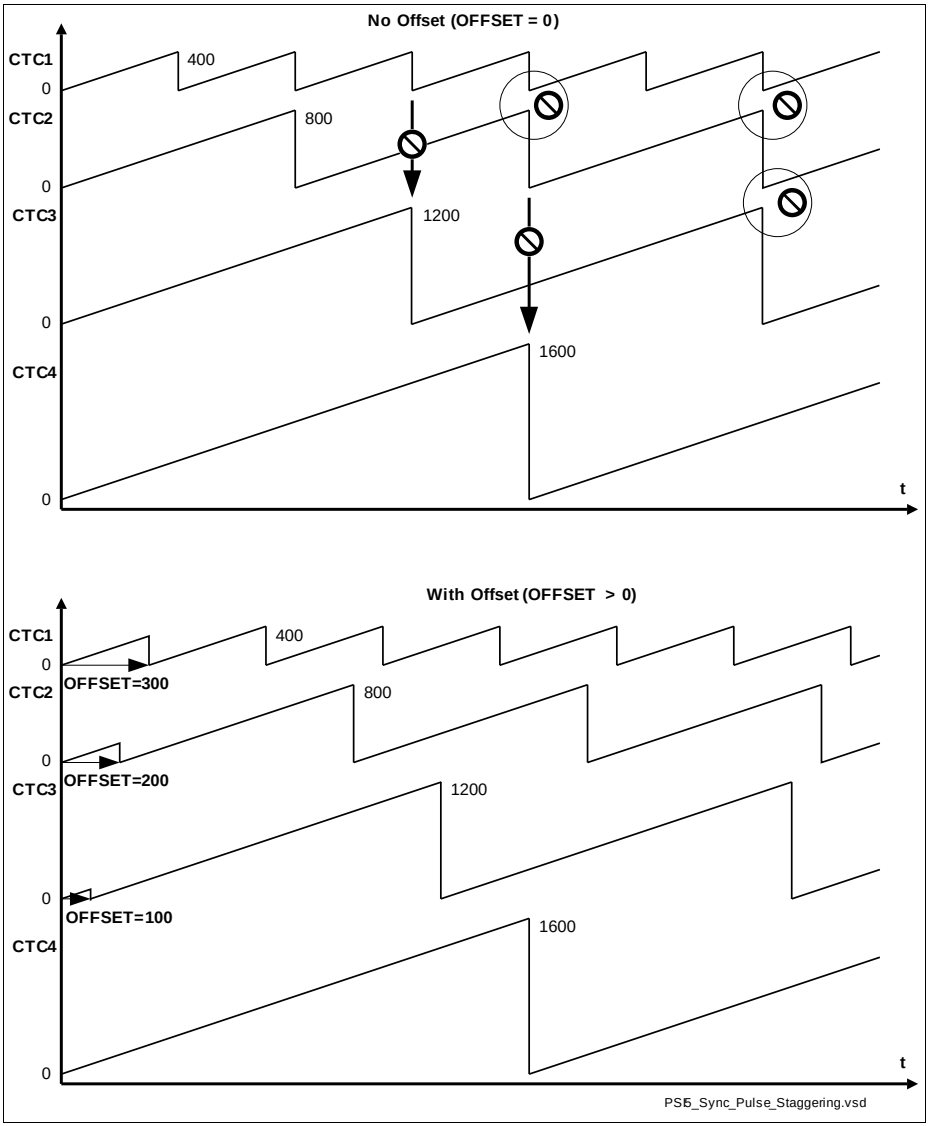

Figure 32-22 PSI5 Pulse Staggering

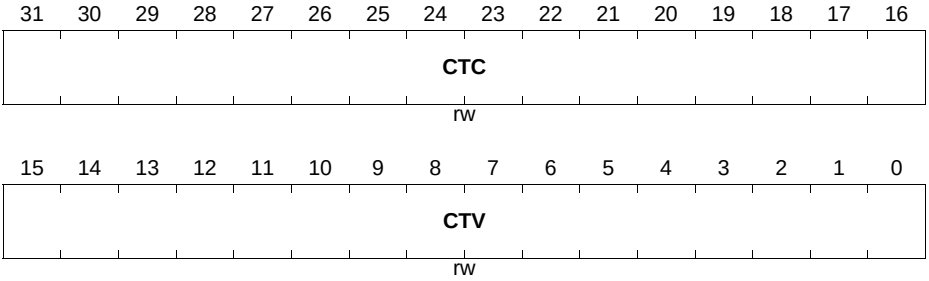
CTVx (x = 0-2)

Channel Trigger Value Register x (08C$_H$+x*36*4) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CTV	[15:0]	rw	**Channel Trigger Value CTV** Contains the compare value (exact match) of Channel Trigger CTC at which a sync pulse is triggered for channel x and the counter CTC is cleared. If cleared, CTC is stopped and no pulse is generated.
CTC	[31:16]	rw	**Channel Trigger Counter** This bit field allows to read the current counter value of the reset timer cell CTVx. If GCR.ETCx is cleared, CTC can be written.

Send Data Preparation

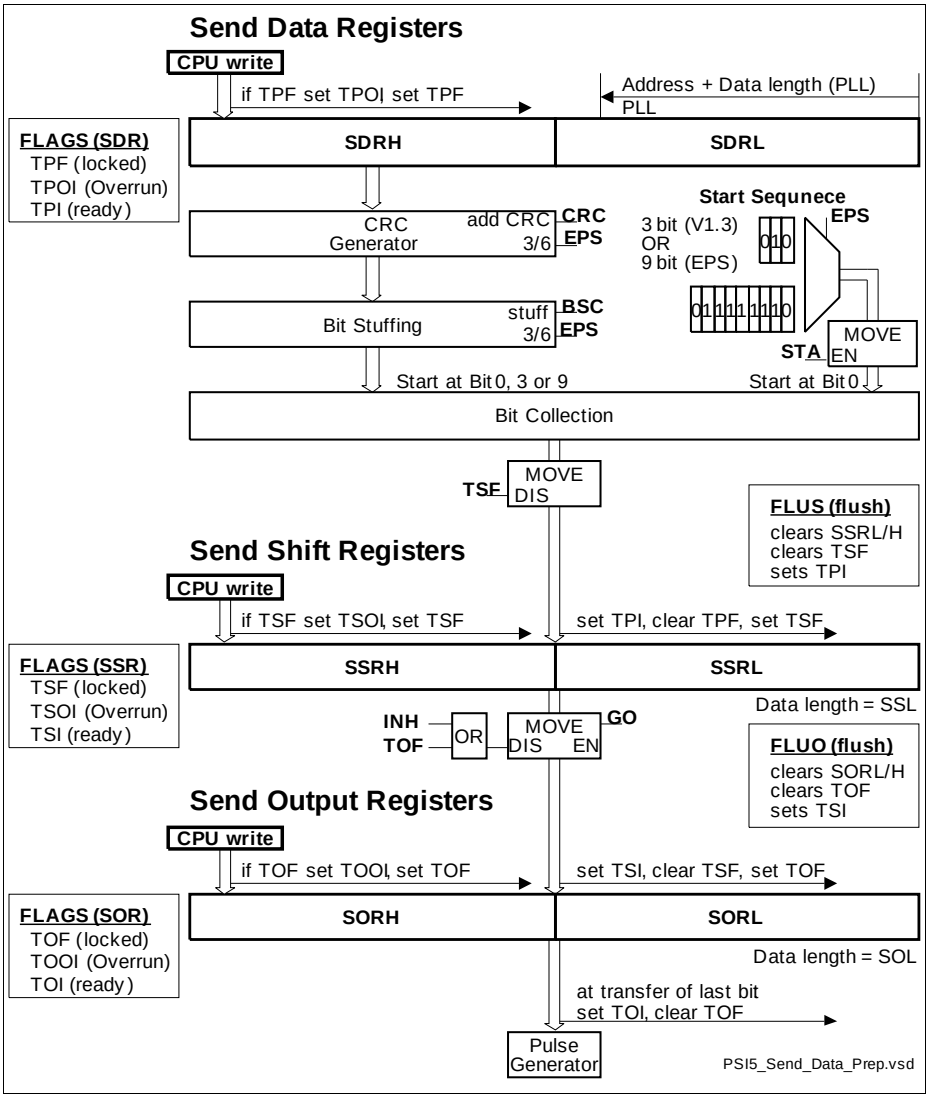


Figure 32-23 PSI5 Send Data Preparation

Send Control Registers SCRx

The Send Control Register SCR contains control data bits required for sending data from the PSI5 module to the sensor / external PSI5 device.

Data is collected in SDRL/Hx and the control bits are collected in SCRx.

The send control unit is build to transmit complete ECU to sensor frames.

SCRx (x = 0-2)
Send Control Register x **(090_H+x*36*4)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TRQ	0		TOF	TSF	TPF	GO	INH	STA	CRC	SOL					
r	r		r	r	r	w	rw	rw	rw	rw					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLUO	FLUS	SSL						BSC	EPS	PLL					
w	w	rw						rw	rw	rw					

Field	Bits	Type	Description
PLL	[5:0]	rw	**Pay Load Length of Registers SDRL/H** Defines the length that is taken into account: 000000_B length is 1 000001_B length is 2 ... ... 111111_B length is 64 If PLL > 31, SDRH needs to be written to trigger the HW for automatic STA, BSC or CRC generation or just moving data to SSRL/H. Else writing to SDRL is sufficient. PLL needs to written before SDRL/H is used for proper operation. If insertion of STA, BSC and CRC results in more than 64 bits, the MSBs are truncated in SSR.
EPS	6	rw	**Enhanced Protocol Selection** 0_B PSI5 V1.3. No Pulse length extension 1_B Enhanced Protocol with Pulse length extension.

Field	Bits	Type	Description
BSC	7	rw	**Bit Stuffing Control** 0_B No automatic bit stuffing 1_B Automatic bit stuffing is enabled. Depending from bit EPS after 3 bits a '1' is inserted (V1.3) or after 6 bits a '0' is inserted (enhanced Power Train Mode) Note that this makes the frame longer.
SSL	[13:8]	rw	**Pay Load Length of Registers SSRL/H** Defines the length that is taken into account. Start Sequence, BSC and CRC need to be added to PLL by SW if SSL is calculated based on PLL. 000000_B length is 1 000001_B length is 2 ... ... 111111_B length is 64 If SSL > 31, SSRH needs to be written to trigger the HW for automatic moving data to SORL/H. Else writing to SSRL is sufficient. SSL needs to be written before SSRL/H is used for proper operation.
FLUS	14	w	**Flush SSRH/Lx** Setting this bit stops the shifting process and flushes (clears) SSRH/Lx and TSF. TPIx is issued at the end of successful flushing. Reads always as zero.
FLUO	15	w	**Flush SORH/Lx** Setting this bit stops the sending process and flushes (clears) SORH/Lx and TOF. TSIx is issued at the end of successful flushing. Reads always as zero.

Field	Bits	Type	Description
SOL	[21:16]	rw	**Pay Load Length of Registers SORL/H** Defines the length that is taken into account. Start Sequence, CRC and Stuffing needs to be added by SW to PLL if SOL is calculated based on PLL. 000000_B length is 1 000001_B length is 2 ... ... 111111_B length is 64 If SOL > 31, SORH needs to be written to trigger the HW for automatic moving data to the pulse generator. Else writing to SORL is sufficient. SOL needs to written before SORL/H is used for proper operation.
CRC	22	rw	**CRC Generation Control** 0_B CRC is not generated automatically. 1_B CRC is automatically generated and added to the frame by HW (according to EPS). Note that this makes the frame longer. CRC calculation is not performed, if at least 1 CRC bit does not fit into 64 bit, e.g. due to STA or BSC. In this case, one or two zero bits are inserted.
STA	23	rw	**Start Sequence Generation Control** 0_B no start sequence generated, payload starts at bit 0! 1_B automatically generated and added to the frame by HW (according to EPS) payload starts at bit 3/9 (EPS = 0/1). Note that this makes the frame longer.

Field	Bits	Type	Description
INH	24	rw	**Inhibit Transfer** This inhibits the automatic transfer from the shift registers SSRL/H to SORL/H after the preparation of all automatic bit fields (STA, BSC, CRC). After a write access to SDRL/Hx, the automatic preparation is done by HW if selected. If automatic preparation of the start sequence is not selected, data is moved by HW without change to SSRL/H. When the HW is done with the transfer to the internal shift registers, interrupt TPI is activated, flag TSF is set and flag TPF is cleared automatically. Depending on INH, GO must be set after TPI before transfer to SORL/H takes place: After the transfer to SORL/H, TSI is activated, TOF is set and and TSF is cleared automatically. . INH defines the start mode: 0_B automatic transfer 1_B GO bit must be set before transfer
GO	25	w	**Release prepared Send data** This is only relevant if INH is set It allows for manual control of the transfer from SSRH/L to SORL/H. It is always read as zero and is automatically cleared. 0_B no transfer 1_B start transfer
TPF	26	r	**Transmit Preparation Flag** If set, preparation is in progress: start sequence and/ or CRC and/or stuffing and/or at least copying data from SDRL/H. If set, write access to SDRL/H will not change any data and issue TPOI. It is cleared automatically after preparation is finished.

Field	Bits	Type	Description
TSF	27	r	**Transmit Shift Flag** If set, data in SSRL/H is waiting to be shifted to SORL/H. This can be caused by an automatic transfer from SDRL/H or from a CPU write access to SSRL/H. If SSL < 32 it is sufficient to write SSRL. Else, only writing SSRH will set TSF. If set, write access to SSRL/H will not change any data and issue TSOI. It is cleared automatically after data was shifted to SORL/H or after flushing the register by setting bit FLUS.
TOF	28	r	**Transmit Output Flag** If set, data in SORL/H is waiting to be transmitted to the sensor. This can be caused by an automatic transfer from SSRL/H or from a CPU write access to SORL/H. If SOL < 32 it is sufficient to write SORL. Else, only writing SDRH will set TSF. If set, write access to SORL/H will not change any data and issue TOOI. It is cleared automatically after data was transmitted to the sensor or after flushing the register by setting bit FLUO.
TRQ	31	r	**Transfer Request in Progress** While a transfer is being sent this bit is set. Write access is ignored.
0	[30:29]	r	**Reserved** Read as 0; should be written with 0.

Send Data Registers SDRLx

The Send Data Register SDRLx for channel x shows the data content of a data frame to be sent.

Data to be sent must be written while the channel is enabled (GCR.CEN is set). While CEN is cleared the HW can not detect the write access as all state machines are stopped.

SDRLx (x = 0-2)
Send Data Register Low x **(094_H+x*36*4)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
SDy (y = 63-32)	y-32	rw	**SDy** Send data of next ECU to Sensor frame. The unused MSBs (bit position SCRx.PLL and higher) must be written with '0'. If PLL is < 32, SDRHx must not be written.

Send Shift Registers SSRLx

The Send Shift Register SSRLx for channel x shows the data that will be shifted to the Send Output Register SORL. It contains as well the stuff bits as specified in PSI5 V1.3 or in the enhancement proposal of PSI5 standard as of July 2010. During transmission, all bits are shifted to LSB with each sync pulse. MSB is filled up with zero.

SSRLx (x = 0-2)
Send Shift Register Low x **($09C_H$+x*36*4)** **Reset Value: 0000 0000_H**

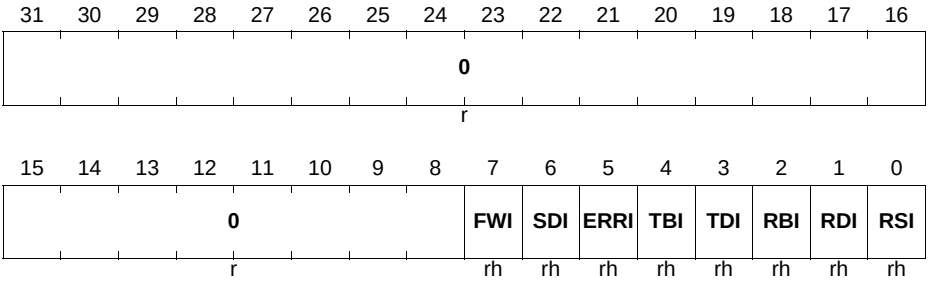
32.14.7 Interrupt Control Registers

INTOV
Interrupt Overview Register **($2F8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RSI	0	rh	**Interrupt Pending on any Node Pointer RSI** If any interrupt requested flag is set for any Node Pointer RSI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.RSI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
RDI	1	rh	**Interrupt Pending on any Node Pointer RDI** If any interrupt requested flag is set for any Node Pointer RDI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.RDI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
RBI	2	rh	**Interrupt Pending on any Node Pointer RBI** If any interrupt requested flag is set for any Node Pointer RBI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.RBI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.

Field	Bits	Type	Description
TDI	3	rh	**Interrupt Pending on any Node Pointer TDI** If any interrupt requested flag is set for any Node Pointer TDI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.TDI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
TBI	4	rh	**Interrupt Pending on any Node Pointer TBI** If any interrupt requested flag is set for any Node Pointer TBI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.TBI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
ERRI	5	rh	**Interrupt Pending on any Node Pointer ERRI** If any interrupt requested flag is set for any Node Pointer ERRI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.ERRI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
SDI	6	rh	**Interrupt Pending on any Node Pointer SDI** If any interrupt requested flag is set for any Node Pointer SDI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.SDI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
FWI	7	rh	**Interrupt Pending on any Node Pointer FWI** If any interrupt requested flag is set for any Node Pointer FWI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.FWI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
0	[31:8]	r	**Reserved** Read as 0.

Interrupt Status Registers

The Interrupt Status Registers INTSTATA/Bx contains status bits that show the status of any interrupt of PSI5 channel x.

The bits are set independently from the referring Interrupt Enable in Register INTENx. Thus they can be used as status bits as well e.g. by a SW based on polling.

INTSTATAx (x = 0-2)
Interrupt Status Register A x **(310_H+x*4)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
							0								**NFI**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TOOI	**TOI**	**TSOI**	**TSI**	**TPOI**	**TPI**	**RMI**	**RUI**	**FWI**	**CRCI**	**MEI**	**NBI**	**TEI**	**RBI**	**RDI**	**RSI**
rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RSI	0	rh	**Receive Success Interrupt Request Flag** This bit is set at the successfully received end of a frame. It indicates that this frame is free of the errors NFI, TEI, NBI, MEI, CRCI if selected to be taken into account in register GCR. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRAx.RSI. This bit can be set by bit INTSETAx.RSI. This bit is set independently from INTENAx.

Field	Bits	Type	Description
RDI	1	rh	**Receive Data Interrupt Request Flag** RDI is activated when a received frame is moved to a Receive Data Register RDRL/Hx. Both RDI and RSI will be issued together at correct reception. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRAx.RDI. This bit can be set by bit INTSETAx.RDI. This bit is set independently from INTENAx.
RBI	2	rh	**Receive Buffer Overflow Interrupt Request Flag** This bit is set after a frame has been received while the old one was not read from RDRHx. I.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set. The old data is overwritten by the new data. Thus, RBI can be ignored if the receive memory is used. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is NOT cleared by reading RDRx. This bit can be cleared by bit INTCLRAx.RBI. This bit can be set by bit INTSETAx.RBI. This bit is set independently from INTENAx.

Field	Bits	Type	Description
TEI	3	rh	**Time Slot Error Interrupt Request Flag** In Synchronous Mode (RCRAx.ASYN = 0), this bit is set if the SOF and the EOF of a frame are received in different time slots. The slots are constraint by the watch dog timer (see WDTxy). In Asynchronous Mode (RCRAx.ASYN = 1), this bit is set if the distance between two frames is longer than specified in WDL0. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRAx.TEI. This bit can be set by bit INTSETAx.TEI. This bit is set independently from INTENAx.
NBI	4	rh	**Number of Bits Wrong Request Flag** This bit is set if the last frame received less bits than expected but no Manchester coding error occurred until S1, S2, M0 and M1 where received. Note that the frame after the error might be completely wrong. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRAx.NBI. This bit can be set by bit INTSETAx.NBI. This bit is set independently from INTENAx.
MEI	5	rh	**Error in Message Bits Flag** This bit is set if a manchester error occurred in Bit M0 or M1. (Only if configured in RCRBx.MSG) Note that the frame after the error might be completely wrong. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRAx.MEI. This bit can be set by bit INTSETAx.MEI. This bit is set independently from INTENAx.

Field	Bits	Type	Description
CRCI	6	rh	**CRC Error Request Flag** This bit is set if the CRC fails. Set as well if CRC can not be calculated: PDL = 0, CRC cut off by Manchester Error, too few bits, BOT, Sync Pulse) 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRAx.CRCI. This bit can be set by bit INTSETAx.CRCI. This bit is set independently from INTENAx.
FWI	7	rh	**FIFO Warning Level Request Flag** This bit is set after if the configured warning level of the FIFOx was reached. (See RFCx) 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRAx.FWI. This bit can be set by bit INTSETAx.FWI. This bit is set independently from INTENAx.
RUI	8	rh	**Receive Memory Underrun Interrupt Request Flag** This bit is set after a SPB master reads from FIFO while no new data was available. (See RFCx) 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRAx.RUI. This bit can be set by bit INTSETAx.RUI. This bit is set independently from INTENAx.

Field	Bits	Type	Description
RMI	9	rh	**Receive Memory Overflow Flag** This bit is set after a frame has been received while RDIOVx.RDI[RFCx.WRP] is set. I.e. the kernel wants to set flag RDIxWRP and finds this flag already set. The old data is overwritten by the new data in the buffer memory. 0_B No overflow 1_B Overflow This bit can be cleared by bit INTCLRAx.RMIx. This bit can be set by bit INTSETAx.RMIx. This bit is set independently from INTENAx.
TPI	10	rh	**Transfer Preparation Interrupt Request Flag** This bit is set after data to be transferred has been moved from SDRL/H to SSRL/H. Thus a new value can be written to SDRL/Hx and the prepared data can be checked and modified by SW. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is automatically cleared by writing SDRx. This is an exception! It allows for DMA transfers without CPU activity. This bit can be cleared by bit INTCLRAx.TDI. This bit can be set by bit INTSETAx.TDI. This bit is set independently from INTENAx.
TPOI	11	rh	**Transmit Preparation Overflow Interrupt Request Flag** This bit is set after if SDRL/H is written while TPF is set. The old data is NOT overwritten. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRAx.TPOI. This bit can be set by bit INTSETAx.TPOI. This bit is set independently from INTENAx.

Field	Bits	Type	Description
TSI	12	rh	**Transfer Shift Interrupt Request Flag** This bit is set after data to be transferred has been moved from SSRL/H to SORL/H. Thus a new value can be written to SSRL/Hx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is NOT cleared by writing SSRL/Hx. This bit can be cleared by bit INTCLRAx.TSI. This bit can be set by bit INTSETAx.TSI. This bit is set independently from INTENAx.
TSOI	13	rh	**Transmit Shift Overflow Interrupt Request Flag** This bit is set after if SSRL/H is written while TSF is set. The old data is NOT overwritten. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRAx.TSOI. This bit can be set by bit INTSETAx.TSOI. This bit is set independently from INTENAx.
TOI	14	rh	**Transfer Output Interrupt Request Flag** This bit is set after last bit to be transferred has been moved from SORL/H to the pulse generator. Thus a new value can be written to SORL/Hx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is NOT cleared by writing SORL/Hx. This bit can be cleared by bit INTCLRAx.TOI. This bit can be set by bit INTSETAx.TOI. This bit is set independently from INTENAx.

Field	Bits	Type	Description
TOOI	15	rh	**Transmit Shift Overflow Interrupt Request Flag** This bit is set after if SORL/H is written while TOF is set. The old data is NOT overwritten. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRAx.TOOI. This bit can be set by bit INTSETAx.TOOI. This bit is set independently from INTENAx.
NFI	16	rh	**No Frame Received Interrupt Flag** This bit is set at the end of a slot if neither an SOF nor an EOF was received in this slot. If only the two start bits are received and no further data, this “SOF” is discarded completely and treated like no frame received as well. If the “SOF only frame” crosses the WDL, NFI occurs after WDL and EOF detection. If RCRBx.VBS is set, an empty frame is stored anyhow. In this case RDIx is issued as well. The only valid information is SC, TS (captured at the end of the slot) and this bit (NFI). 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRAx.NFI. This bit can be set by bit INTSETAx.NFI. This bit is set independently from INTENAx.
0	[31:17]	r	**Reserved** Read as 0.

INTSTATBx (x = 0-2)
Interrupt Status Register B x **(324_H+x*4)** **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
WSIy (y = 0-5)	y	rh	**Wrong Serial Protocol Error Request Flag** This bit is set if the Messaging bits are configured and do not show a start sequence for more than 18 frames of slot y. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRBx.WSIy. This bit can be set by bit INTSETBx.WSIy. This bit is set independently from INTENBx.
SDIy (y = 0-5)	y+6	rh	**Serial Data Receive Interrupt Request Flag** This bit is set after all serial data bits have been received via the Messaging bit field of slot y. This does NOT indicates a successful check of the CRC. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRBx.SDIy. This bit can be set by bit INTSETBx.SDIy. This bit is set independently from INTENBx.

Field	Bits	Type	Description
SOIy (y = 0-5)	y+12	rh	**Serial Data Buffer Overrun Interrupt Request Flag** This bit is set if the HW wants to set SDIy while SDIy is still set. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRBx.SOIy. This bit can be set by bit INTSETBx.SOIy. This bit is set independently from INTENBx.
SCRIy (y = 0-5)	y+18	rh	**Serial Data CRC Error Request Flag** This bit is set if the CRC of the serial message fails. This includes a check of the Messaging bit field for correct 0 values of bit 1 in frames 7, 13 and 18. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRBx.SCRIy. This bit can be set by bit INTSETx.SCRIy. This bit is set independently from INTENBx.
0	[31:24]	r	**Reserved** Read as 0.

Interrupt Set Registers

The Interrupt Set Register INTSETA/Bx contain control bits that trigger an interrupt pulse for any interrupt of PSI5 channel x.

INTSETAx (x = 0-2)
Interrupt Set Register A x **(338_H+x*4)** **Reset Value: 0000 0000_H**

Interrupt Node Pointer Register

The Interrupt Node Pointer Register INPx contains the node pointers of PSI5 channel x.

Node Pointer ERRI is one single node pointer for the following interrupts:

- TEI
- NFI
- NBI
- MEI
- CRCI
- RUI
- RMI
- WSIy
- SOIy
- SCRIy

Node Pointer TBI is one single node pointer for the following interrupts:

- TPOI
- TSOI
- TOOI

Node Pointer TDI is one single node pointer for the following interrupts:

- TPI
- TSI
- TOI

INPx (x = 0-2)

Field	Bits	Type	Description
RSI	[3:0]	rw	**Interrupt Node Pointer for Interrupt RSI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.RSI (if enabled by bit INTENAx.RSI). 0000_B Trigger Output TRIGO 0 is selected 0001_B Trigger Output TRIGO 1 is selected ... ... 0111_B Trigger Output TRIGO 7 is selected 1000_B reserved ... ... 1111_B reserved
RDI	[7:4]	rw	**Interrupt Node Pointer for Interrupt RDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.RDI (if enabled by bit INTENAx.RDI). For bit field definition, see RSI.
RBI	[11:8]	rw	**Interrupt Node Pointer for Interrupt RBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.RBI (if enabled by bit INTENAx.RBI). For bit field definition, see RSI.
TDI	[15:12]	rw	**Interrupt Node Pointer for Interrupt TDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.TPI, TSI, TOI (if enabled by bit INTENAx.TPI, TSI, TOI). For bit field definition, see RSI.
TBI	[19:16]	rw	**Interrupt Node Pointer for Interrupt TBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.TPOI, TSOI, TOOI (if enabled by bit INTENAx.TPOI, TSOI, TOOI). For bit field definition, see RSI.

Field	Bits	Type	Description
ERRI	[23:20]	rw	**Interrupt Node Pointer for Interrupt ERRI** This bit field defines the interrupt node, that is requested due to the set condition for bit TEI, NFI, NBI, MEI, CRCI, RUI, RMI, CRCIy, WSIy, SOIy, SCRIy. For bit field definition, see RSI.
SDI	[27:24]	rw	**Interrupt Node Pointer for Interrupt SDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.SDI (if enabled by bit INTENx.SDI). For bit field definition, see RSI.
FWI	[31:28]	rw	**Interrupt Node Pointer for FWI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.FWI. For bit field definition, see RSI.

32.15 PSI5 Module Implementation

This section describes the PSI5 module interface as it is implemented in the TC27x. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

32.15.1 Interface Connections of the PSI5 Module

Figure 32-24 shows the TC27x-specific implementation details and interconnections of the PSI5 module.

The PSI5 module is supplied with a separate clock control, address decoding, and interrupt control logic. The 8 modules' service request outputs are connected with the interrupt router. Outputs of the GTM module are connected to the timer inputs: 6 configured.

The serial data inputs PSIRXn of the receive channels of the PSI5 module as well as the sender outputs PSITXn are connected to GPIO lines. If the outputs are used, they are mapped to a different port pin than the referring PSI5 data input line as most phys will use separate TX and RX lines.

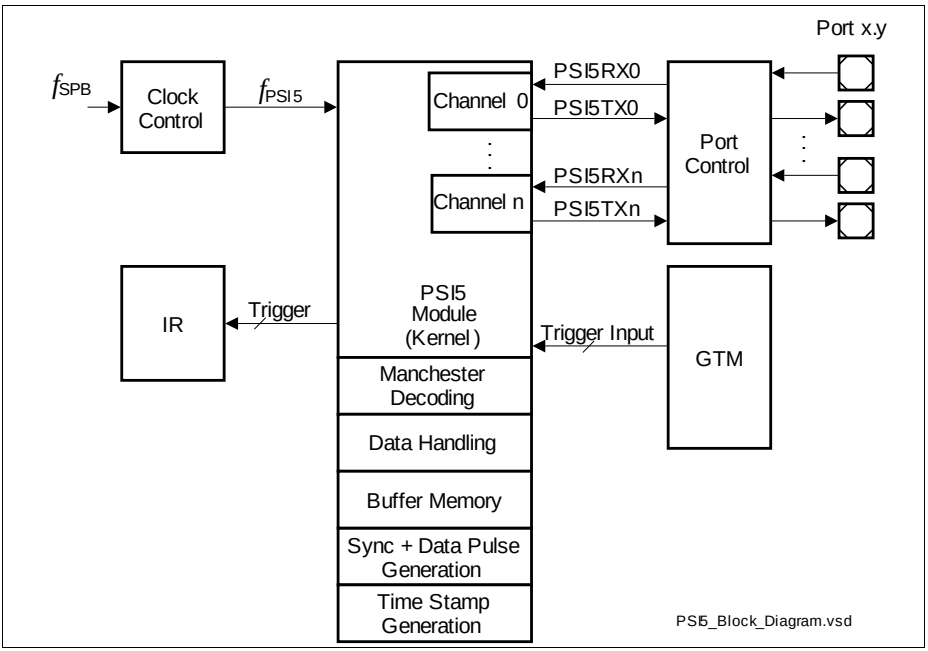

Figure 32-24 PSI5 Module Implementation and Interconnections

32.15.1.1 On-Chip Connections

This section describes the on-chip connections of the PSI5 module.

Interrupt Router Service Requests

The module has 8 Request Trigger outputs connecting it to the interrupt router. The request lines are connected to the IR controller as shown in **Table 32-4**.

Table 32-4 Service Request Lines of PSI5

INP value	Request Line	Connected to	Description
0000b	TRIGO0	PSI5_SRC0	PSI5 Service Request Node 0
0001b	TRIGO1	PSI5_SRC1	PSI5 Service Request Node 1
0010b	TRIGO2	PSI5_SRC2	PSI5 Service Request Node 2
0011b	TRIGO3	PSI5_SRC3	PSI5 Service Request Node 3
0100b	TRIGO4	PSI5_SRC4	PSI5 Service Request Node 4
0101b	TRIGO5	PSI5_SRC5	PSI5 Service Request Node 5
0110b	TRIGO6	PSI5_SRC6	PSI5 Service Request Node 6
0111b	TRIGO7	PSI5_SRC7	PSI5 Service Request Node 7

Trigger Inputs

The module has 6 trigger inputs which can be randomly chosen by programming IOCRx.ETS, ECS or ETB. The trigger inputs (TRIG[5:0]) of the PSI5 module are connected to the GTM as shown in **Table 32-5**.

Table 32-5 Trigger Input Lines of PSI5

Request Line	Connected to	Description
TRIG0	gtm.psi5_0_trig_0_o	GTM Trigger Line TRIG0
TRIG1	gtm.psi5_1_trig_0_o	GTM Trigger Line TRIG1
TRIG2	gtm.psi5_2_trig_0_o	GTM Trigger Line TRIG2
TRIG3	gtm.psi5_3_trig_0_o	GTM Trigger Line TRIG3
TRIG4	gtm.psi5_4_trig_0_o	GTM Trigger Line TRIG4
TRIG5	gtm.psi5_5_trig_0_o	GTM Trigger Line TRIG5

32.15.2 PSI5 Module-Related External Registers

The registers listed in **Figure 32-25** are not included in the PSI5 module kernel but must be programmed for proper operation of the PSI5 module.

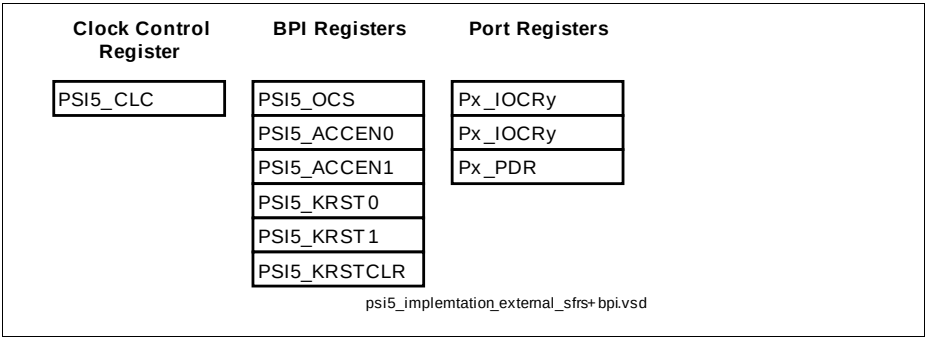

Figure 32-25 PSI5 Implementation-specific Special Function Registers

32.15.2.1 Port Control

The Port Control Registers contain:

- Input/output function selection (Port IOCR registers)
- Pad driver characteristics selection for the outputs (Port PDR registers)

Input/Output Function Selection

Table 32-6 shows an overview how bits and bit fields must be programmed for the required I/O functionality of the PSI5 I/O lines.
The PSI5 interface input shares its input pins with digital ports.

For one channel the PSI5 output pins and PSI5 input pins are next to each other.

Table 32-6 PSI5 I/O Control Selection and Setup

PSI5 Channel	Port Lines	Input Select Register	Input/Output Control Register Bits	I/O
0	P00.1/ PSIRX0A	PSI5_IOCR0.ALTI = 00_B	P00_IOCR0.PC1 = $0XXXX_B$	I

2	P00.5/ PSIRX2A	PSI5_IOCR2.ALTI = 00_B	P00_IOCR4.PC5 = $0XXXX_B$	I
	P00.6/ PSITX2	not applicable	P00_IOCR4.PC6 = $1X100_B$	O
	P02.7/ PSIRX2B	PSI5_IOCR2.ALTI = 01_B	P02_IOCR4.PC7 = $0XXXX_B$	I
	P02.8/ PSITX2	not applicable	P02_IOCR8.PC8 = $1X100_B$	O
	P33.5/ PSIRX2C	PSI5_IOCR2.ALTI = 10_B	P33_IOCR4.PC5 = $0XXXX_B$	I
	P33.6/ PSITX2	not applicable	P33_IOCR4.PC6 = $1X100_B$	O

32.15.2.2 Timing Constraints

Delays and jitter inside the module:

- The time from the detection of the last bit of a frame at the input pin of the controller, to the presentation of the data to the software (including CRC calculation) is ≤ 3 µs.
- The time from the sync pulse trigger output of the Sync Pulse Generator, to the output of the sync pulse trigger at the data output pin of the controller is ≤ 2 µs.
- Latency between first high slope of first start bit / sync pulse and time stamp generation will be defined after design started, target is a few module clock cycles
- Jitter between first high slope of first start bit / sync pulse and time stamp generation is calculated in the following way:
  - each timer in the chain adds its jitter given by the time resolution:
  - the TS counter itself has a resolution of nominally 1 µs
  - the FDRT driving it has a jitter of one input clock phase (this can be avoided by using normal divider mode which should be default)
  - The PLL driving FDRT has a jitter of one input clock phase due to FM PLL clock clipping, this happens at nominally 600 MHz
  - The PLL driving FDRT has an accumulated jitter of +- 5 ns (as of today, subject to change after characterization)
  - Thus, the jitter is at least 1µ + 5 ns

32.16 Revision History

This Internal Target Specification is based on: “PSI5 Specification **V1.3**”.

Table 32-7 Revision History

Version Number	Changes to Previous Version
Rev_0.1D	First Draft (Bullet Points ++)
Rev_0.5D	First Draft with content, Pulse Generation tbd, Implementation details tbd Interrupt Flag Overview Registers for Memory Buffers tbd
Rev_0.9	First version for review Addresses, some implementation details and pictures tbd.
Rev_0.10	Updated Sync Pulse Generator block, added figure Updated ECU to Sensor Communication block, now containing 3 stages, added detailed figure Updated Serial Data (slow data) , added receive registers and memory for raw data Updated Manchester decoder and added figure Updated Watch Dog timer block, added 7th timer, added figure Added Time Stamp Generation and selection logic, added figure Cleaned up Interrupts and Triggers Added Port Mapping (full filling the requirements) Addresses, some implementation details and pictures tbd.
Rev_0.11	Added GTM input to Sync Pulse Generator block, updated figure Added Time Stamp configuration logic to support 3 Timers Updated Watch Dog timer block, added capability to check time windows instead of time outs only, updated figure Updated Time Stamp Generation and selection logic, to contain 3 counters (was 2) with individual selection of input clock (GTM or F_ts), was 2 counters with fixed inputs, updated figure Added interrupt “No Frame Received” and the possibility to store this event in the Receive Memory Added RDIOV, NFIOV and MEIOV and the referring set and clear regs. Added Picture of Receive Data Memory INTOV now shows pending interrupts per Node Pointer Addresses, some implementation details and pictures tbd.

Table 32-7 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.00	Added GCR.ETC0..5 to start/stop sync pulse counters synchronously. Added capability to set an OFFSET between sync pulse counters (CTCs are writable) including figure Removed PGCx.CLRA and CLR for clearing CTCs. Syncing of Trigger Counters CTCs is now done in GCR.ETC0 .. 5. Added Blank Out Time BOT Defined data value for not received frames (NFI) Added note not to set debugger Watch Point to FIFO read register Added capability to select sources to be regarded for RSI (see GCR) Enlarged Watch Dog Counters from 11 to 16 bits Added Asynchronous mode support RCRAx.ASYN Corrected Typos Implemented Address Map
Rev_1.1	Added hint on TPI Added description to RCRA.ASYN: in Asynchronous Mode no Sync Pulses are generated Added description of treatment of frames coming too early (see WDT) Added note that the unused bits in SDRL/H must be written with '0'
Rev_1.2	corrected formulas for f_{125} and f_{189} Added description to FDRT.ECEA/BC: rising edge clears Added description to FDRT.ECS, TSRA/B/C.ETB: "Channel must be disabled if changed (GCR.CEN = 0)." Added clarification to RCRBx.MSGy Kernel Reset Registers are bus master tag protected Note inserted on pulse length (default PLEN for both standards) Note inserted not to use PTE, ETE and BYP together. Changed wording of OIE and IIE Added note to SDR.PLL: If insertion of STA, BSC and CRC results in more than 64 bits, the MSBs are truncated in SSR Changed Bit Filed Name of SDSxz.SCRI Register Overview Table: the Kernel Registers are Master Tag protected ("P"). Changed bit order in INTSTATA to match INTSET/CLRA
Rev_1.3	Detailed bit description of CTS.ACLR and CLR Added CLC.RMC Detailed description of NFI
Rev_1.4	Added 3rd alternate port mapping

Table 32-7 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.5	Changed to 5 channels for TC29x
Rev_1.6	Added remarks (to CRC, SCRI, MEI, NBI) for clarity, no functional changes. Changed names of bits in INTOV according to their interrupt class representation (for more clarity) into: RSI, RDI, RBI, TDI, TBI, ERRI, SDI, FWI instead of INP[7:0]. Changed access restrictions of IOCR.CFEG/CREG from rw to w.
Rev_1.7	Removed CLC.RMC
Rev_1.8	Updated BE behavior
Rev_1.9	Added RFCx.FRQ and WRAP Note on hard suspend
Rev_1.10	Updated description of OCS
Rev_1.11	Updated description (typo) of SFTSCx Updated Port Chapter
Rev_1.12	Idle time mandatory before looking for start bits, also after BOT and Sync Pulse EOF of a dropped frame will not prevent NFI any more Added Manchester Decoder description from Concept Engineering Slide Set. NBI will be issued not only on too short frames but on too long frames as well for safer detection of wrong sensor assembly.
Rev_1.13	Changed Manchester Decoder sample counter max value from 39 to 41 Removed CR: "NBI will be issued not only on too short frames but on too long frames as well for safer detection of wrong sensor assembly."
Rev_1.14	Support for 2 channels implemented
Rev_1.15	Added pin out description to channel 3 and 4

33 Peripheral Sensor Interface with Serial PHY Connection (PSI5-S)

This document contains the following sections:

- Functional description of the PSI5-S kernel (see **Page 33-2**)
- PSI5-S kernel register descriptions (see **Page 33-58**)
- TC27x implementation details (see **Page 33-139**

33.1 PSI5-S Description

Figure 33-1 shows a global view of the PSI5-S interface.

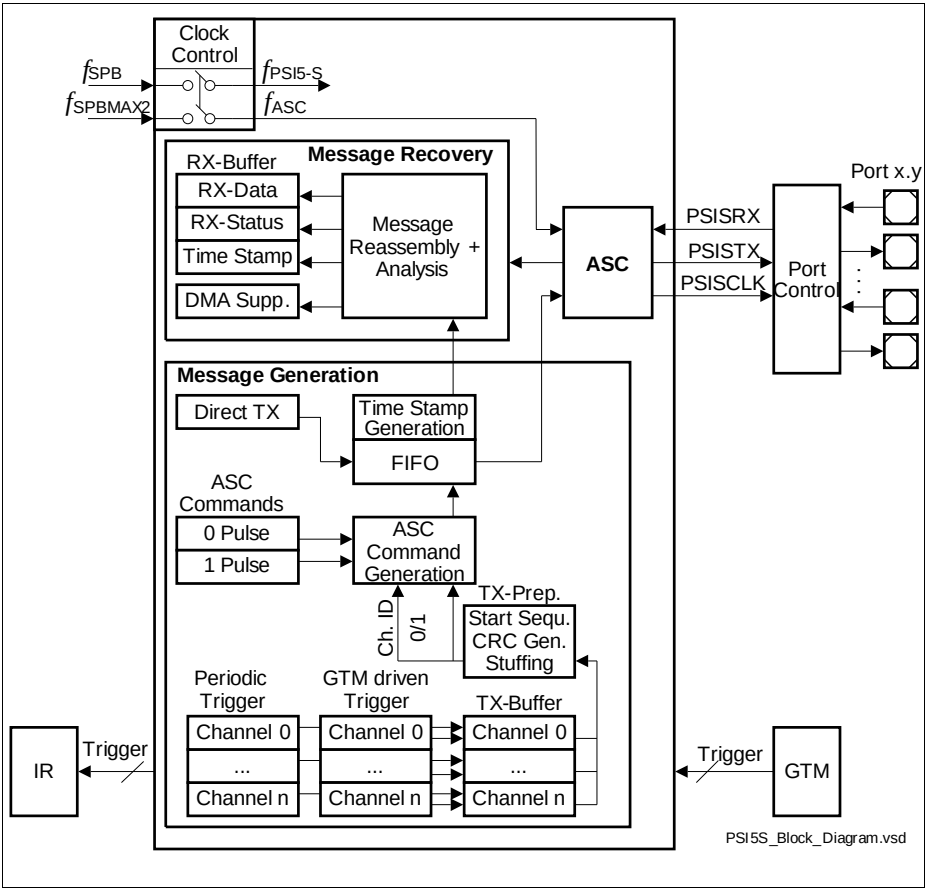

Figure 33-1 General Block Diagram of the PSI5-S Interface

The PSI5-S module communicates with the external world via one ASC interface for all channels. This ASC is built into the PSI5-S module. If the optional bidirectional mode is used, the commands to the external Physical Layer Interface (PHY) are transmitted via this ASC.

33.1.1 Overview

The Peripheral Sensor Interface is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of airbag systems.

The PSI5-S IP-module performs communication according to the PSI5 specification V2.0 2011-6.

PSI5 defines a current loop based serial communication link typically used to connect airbag sensors or other peripheral devices.

While the physical layer is done externally, this module manages communication with this PHY and the presentation of the data to the application. Note that there is no on chip PHY, i.e. the current to voltage and voltage to sync pulse translation is done externally.

Receive data on a PSI5-S channel can be set up according to the underlying application. In particular the number of bits forming one value is configured.

The message storage consists of a set of 3 32-bit registers for all channels: one PSI5-S Message Receive Data Register containing the received sensor data, one time stamp register containing the 24-bit value and one additional register containing status bits.

For synchronous communication mode, the module can consume sync pulses from the external GTM or generate periodic sync pulses by itself. It supports as well ECU to sensor communication by offering a 32-bit register, where messages can be set up by the CPU. All kinds of sync pulses are translated into a referring, programmable Byte to be sent via ASC.

The register set of the PSI5-S module can be accessed directly by the CPU for configuration, data read out and status query.

The PSI5-S module supports the following features:

General Features

- ASC based communication with compatible PSI5-S PHY
- Baud rate Generator (up to 12,5) MHz (@ 200 MHz ASC Sub Module Clock)
- Clock out generator to supply external PHY
- Conformance with PSI5 protocol specification V2.0 2011-6
- Data rates of 125 kbit/s and 189 kbit/s supported (by external PHY already)
- 8 PSI5-S channels sharing one common ASC (incl. channel 0 frame 1 special use)
- Supports 6 sensor slots per channel
- Asynchronous and synchronous PSI5 data transmission modes

- 8 Interrupt or DMA triggers

Features of Message Recovery Block

- ASC format 10 Bit: 1 Start Bit, 8 Data bits, 1 Stop Bit (Up Stream)
- Each PSI5 Frame is transported in a Packet Frame consisting of 3 to 6 UART Frames transmitted back to back, i.e. with exactly one stop bit - no additional delay.
- Packet Frames are separated by a programmable idle time (1 .. 16 idle bits)
- Assembly and decoding of Packet frames (envelope)
- Routing of PSI5 Frames to their referring channel receive buffer in system memory by hardware DMA support
- Checking CRC of Packet Frames (XCRC)
- Frames with XCRC NOK will be routed to channel 0 frame 1
- The external PHY sends all Frames of an Asynchronous Channel with FID = 1, all frames of this channel have the same length and structure as defined for FID 1. Thus it is sufficient to configure frame 1 for asynchronous channels.
- Configurable data length 8 .. 28 bit + 3 bit PSI5 CRC or 1 bit PSI5 Parity
- CRC check of received PSI5 sensor data, CRC code still transparent
- NO HW Support of extended serial data messaging according to SENT SAE J2716 JAN 2010. Messaging bits are transported fully transparent for SW decoding
- 24-Bit time stamp on sync pulse request via ASC (resolution: 1µs)
- Two independent time bases for Time Stamp: clocked by GTM (1 out of n GTM signals is selectable) or internal periodic trigger generator
- PHY answers to CPU commands with standard frames of fixed predefined length in channel 0 frame 0.
- Error bits in Packet Frame are presented fully transparent and an interrupt is issued.
- One Interrupt for error free Packet Frame, relevant errors are selectable
- One Interrupt for Packet Frame reception disregarding any error.

Features of Message Generation Block

- Support of ECU to Sensor communication
- One 32-bit send data register per channel for downstream data input
- Data is shifted out LSB first, MSB is filled with ‘0’ or ‘1’ with each shift (depending on bit coding method: Tooth Gap or Pulse Width)
- ASC format 11 Bit: 1 Start Bit, 8 Data bits, 1 Parity, 1 Stop Bit (Down Stream)
- Downstream commands of fixed format (3 MSB = Channel ID, 5 LSB = Command)
- All commands are randomly programmable and thus not interpreted by PSI5-S
- Downstream data transmission by 2 different ASC commands (short/no and long pulse)
- 8 common lines of FIFO for all channels, writable by
- PSI5 Message Generation
- Sync Pulse Generation (pre programmed Bytes for ‘0’ and ‘1’)
- CPU Commands

- Direct CPU Write Registers allow for insertion of commands into the FIFO for configuration and debugging
- 8 GTM inputs for Sync Pulse Triggering
- SW configurable staggering of Sync Pulse generation
- Generation of 3 or 6 bit CRC for downstream data
- Start sequence generator for downstream data (can be switched off)
- Bit stuffing generator for downstream data (can be switched off)
- CRC generator for downstream data (can be switched off)
- Internal Loop Back mode for check of CRC generator and SW development

Configurability

- No configuration options planned.

33.2 Definitions

SENT: Single Edge Nibble Transmission

CAN: Controller Area Network

LIN: Local Interconnect Network

ISO: International Organization for Standardization

PHY: Physical Layer Interface

ECU: Electronic Control Unit

FSM: Finite State Machine

ASIC: Application Specific Integrated Circuit

Nibble: Four Bit value between 0 and 15 = half a Byte = one character in hex (0 to F)

SOF: Start of Frame

EOF: End of Frame

STS: Start Sequence

AD: Address Data (e.g. of ECU to Sensor Frame)

SD: Send Data (Payload of ECU to Sensor Frame)

CRC: Cyclic Redundancy Check

UART: Universal Asynchronous Receiver Transmitter

33.3 General Operation

PSI5-S is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/D converters and PWM and as a simpler low cost alternative to CAN or LIN. The implementation assumes that the

sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

Figure 33-2 shows a typical TC27x application in which a PSI5-S interface reads a sensor device.

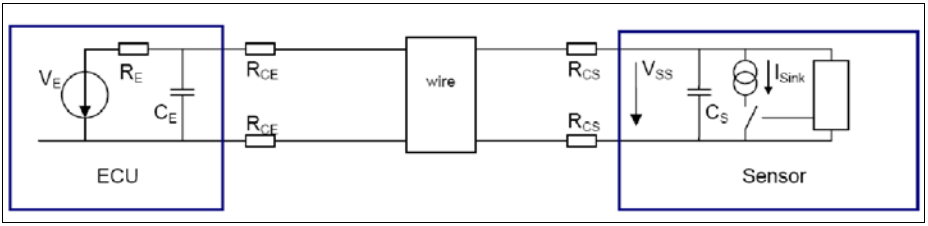

Figure 33-2 PSI5 to External Device Connection

PSI5-S communication is

- asynchronous, unidirectional from sensor to controller without any synchronization
- synchronous, bidirectional with a sync pulse from the ECU triggering messages
- synchronous, bidirectional, sync pulses additionally coding data from ECU to sensor

The sensor signal is transmitted as a series of current pulses in Manchester coding.

The sync pulses are transmitted by increasing the voltage of the current loop.

Figure 33-3 shows a typical TC27x application in which a PSI5 ECU reads multiple PSI sensor devices on a bus.

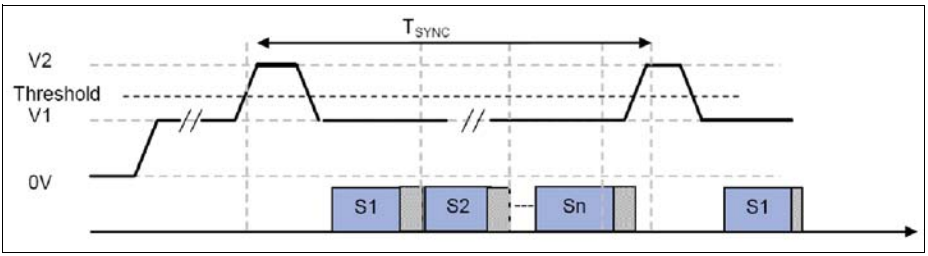

Figure 33-3 PSI5 Frames with Sync pulses

33.4 PSI5 ECU to Sensor Operation

ECU to Sensor communication is defined in PSI5 V2.0 2011-06. Data transmission and configuration of the sensor can be done by modulation of the Sync Pulses.

The Module supports two modes:

- Tooth Gap Method
- Pulse Width Method

With the Tooth Gap Method, a specific start condition and a start sequence switch the sensor in ECU to Sensor communication mode. In this mode, the sync pulses are no longer used as triggers for PSI5 Frames but are interpreted as data for the sensor. A pulse represents a 1 and a missing pulse represents a 0. This requires isochronous pulses.

With the Pulse Width Method a standard length pulse represents a 0, a longer pulse a 1. This way continuos data transmission can be achieved. The pulses can be non isochronous, e.g. dependent from the angle position of a rotating axis.

33.5 Frame Formats and Definitions

This section describes the frame formats and definitions of the PSI5-S protocol.

33.5.1 Communication between PSI5-S and PHY via UART

This chapter treats the communication on the UART connection.

33.5.1.1 “Packet Frames” received from PHY

Figure 33-4 and **Figure 33-5** show the layout and definitions of the “Packet Frames”. Packet Frames are 3 to 6 “UART Frames” carrying one “PSI5 Frame”. The format accepted by PSI5-S is explained here. A UART frame is one transmission unit on the ASC. On the receive path it consists of one Start Bit, 8 Data Bits and one Stop bit. Parity can be chosen optionally, e.g. for loop back tests.The figures show the minimum and maximum Packet Frame population with data. Where the figures show ‘Res0’ bits, these bits can be crowded by more data bits if configured so.

Detection of Frame Boundaries and Packet Frame Processing

- SOF (Start of Frame) is defined by a start bit detected after idle on ASC.
- Idle equals at least 2 Stop Bits.
  - The required idle time can be configured between 1 and 16 additional Stop Bits.
  - An idle state signal is provided internally by the ASC to the reassembly unit.
  - The idle signal starts on detection of the first stop bit and ends when the first slope of the next start bit has passed the 2 out of 3 majority vote input filter.
- If idle is detected before the minimum of 3 UART Frames was received, these UART Frames are copied to channel 0 frame 1 (non recoverable frames).
- Based on the ChID and FID received in the first UART frame, the module checks
  - If the referring channel is enabled and
  - If the FID is valid and configured (PDL > 0) and
  - What the number is of expected UART frames configured in UFC
  - If at least this number of UART frames is received without idle and
  - If the XCRC is correct
- If these checks pass
  - EOF is detected after the correct number of UART frames

  - Data is copied to RDR, interrupts, and the status are updated in RDS. In particular CRC/P check is executed. Time Stamp (TSM) and Target address (TAR) are updated. Depending from bit RCRAx.FIDS the FID might be manipulated.
  - The message recovery unit does not wait for idle to execute the steps above.
- If these checks fail (“non recoverable frames”)
  - EOF is detected after idle or a maximum of 6 UART Frames
  - The 1 to 6 UART Frames are stored in channel 0 frame 1.
- If more UART frames follow a passing or failing Packet Frame without idle,
  - EOF is detected after idle or a maximum of 6 UART Frames
  - The 1 to 6 UART Frames are stored in channel 0 frame 1
  - Reception is stopped
  - The next UART Frames following without idle time are ignored
  - Reception starts only after the idle time programmed in GCR.IDT is detected (“bubbling idiot” protection)

Non Recoverable Frame Presentation in RDR and RDS

- RDS.FID and ChID are derived from the first UART Frame received.
- RDR.RD[27:0] contains all bits of each UART Frame received after the header. I.e.
  0 bits for 1 UART Frame,
  8 bits for 2 UART Frames,
  16 bits for 3 UART Frames,
  24 bits for 4 UART Frames,
  28 bits for 5 and 6 UART Frames.
- RDS.CRC is determined as follows:
  - If 6 UART Frames were received: bits [6:4] of the 5th UART Frame.
  - If 1 .. 5 UART Frames where received: determined by PDL
  - PDL may not be reliable, but this way all data is covered either in the data field or in the XCRC field. In case PDL was correct, CRC is shown correctly.
- RDS.XCRC contains always the bits [7:2] of the last UART Frame received. Also if only 1 UART Frame was received.
- Note that XCRCI is always set as either XCRC was wrong or the number of UART frames received was wrong or it could not be determined.

Loop Back support

- Parity and number of stop bits need to be configured the same for sender and receiver in loop back mode. Parity control and polarity of parity can be configured separately each for TX and RX. This can be done before switching on loop back mode. Alternatively the parity control can be adjusted as well in one single register access together with switching the ASC part to loop back mode.
- Both ways are supported: add Parity bit to the receiver or use the transmitter without parity. (Standard use case is to use transmitter with parity)
- Data to be transmitted can be written directly to register CDW
- This way a synthetic Packet Frame can be sent to the reassembly unit for test purposes.

- The received loop back data is treated in the same way as the normal receive data. Good frames are received in their referring channel and slot. Frames with wrong XCRC, idle time or UFC are stored in channel 0 frame 1.

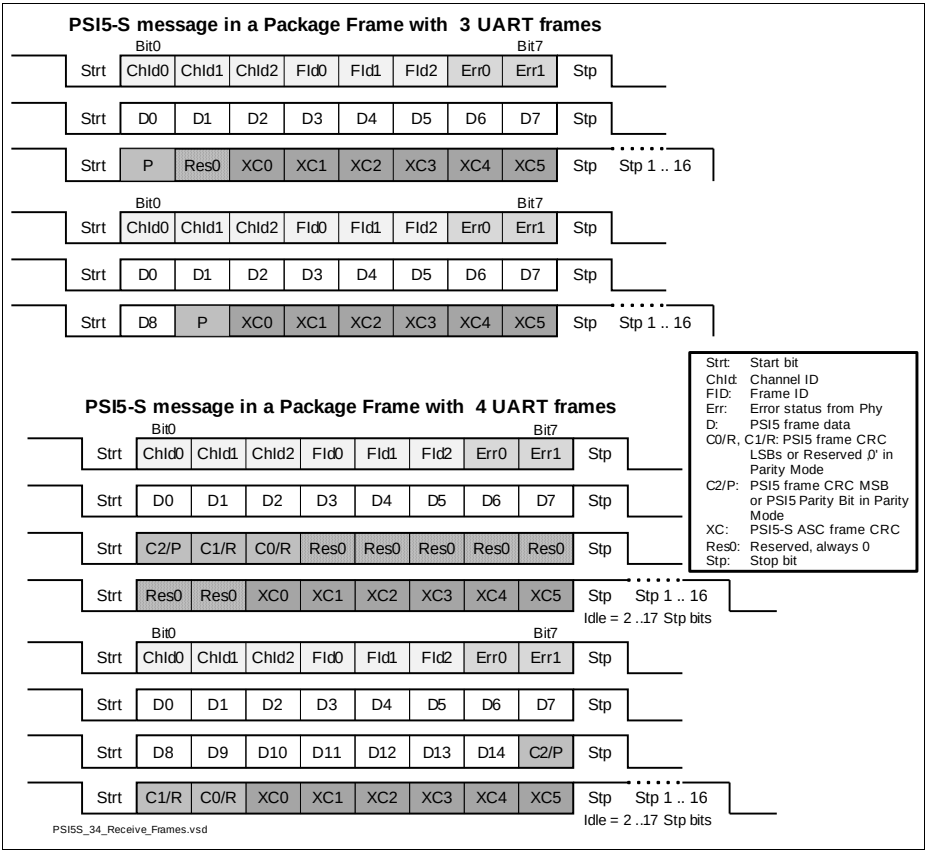

Figure 33-4 PSI5-S 3 + 4 UART Frames per Package Frame received from PHY

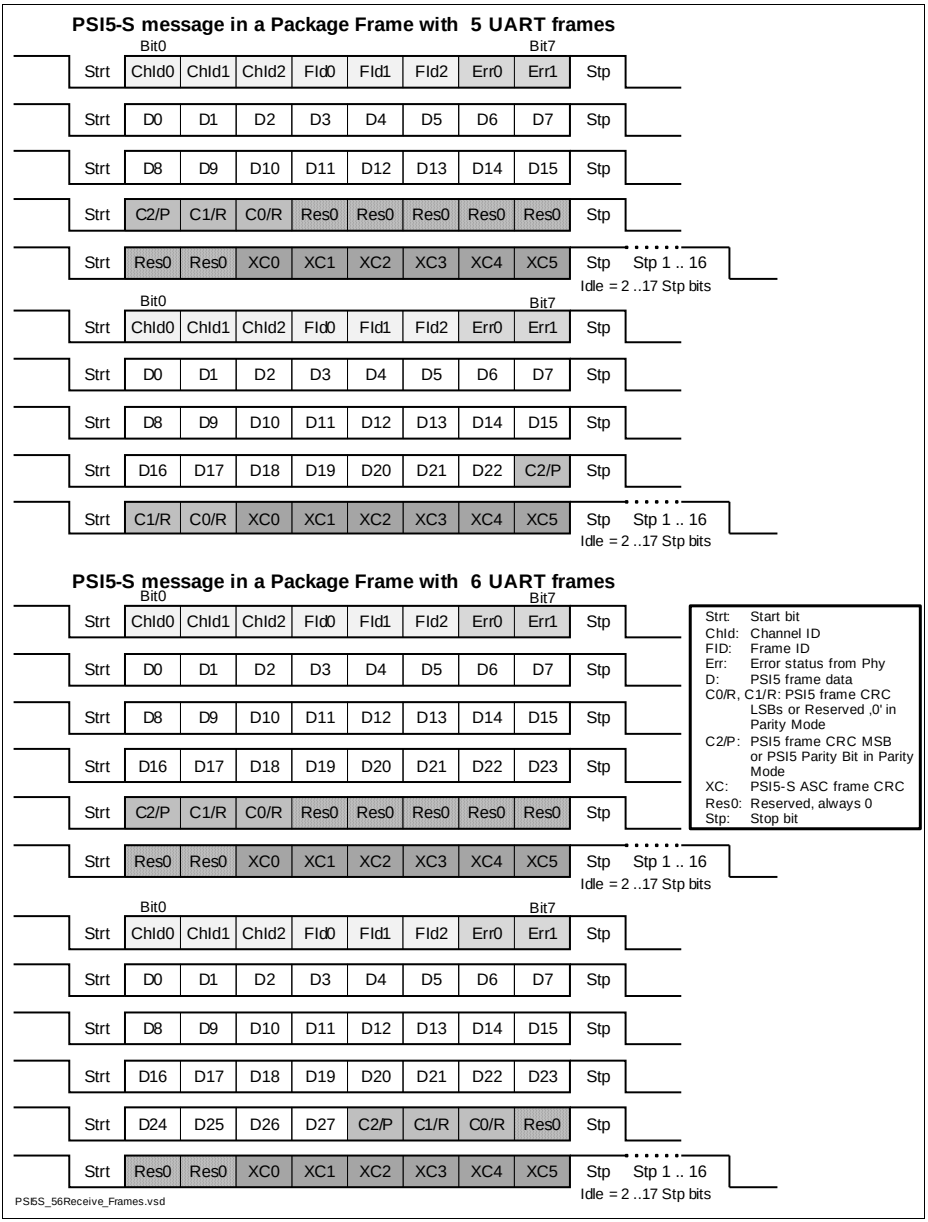

Figure 33-5 PSI5-S 5 + 6 UART Frames per Package Frame received from PHY

XCRC Content

XCRC is always sent at the end of the last UART Packet. For XCRC calculation, all bits of the preceding UART Frames that belong to the Packet Frame are relevant including potential stuffing bits (Res0). UART Start / Stop bits are excluded.

In detail the XCRC shall contain the header (ChID, FID, Err0, Err1), PSI5 frame data (D0 .. Dx, PSI5 frame Parity Bit or CRC bits) and potential stuffing bits (Res0) between P/CRC and XCRC. Not included are start and stop bits of the UART packets and the 2 start bits (S0, S1) of the PSI5 frame.

The LSB of the first byte (ChId0) is fed first into the XCRC polynomial.

XCRC Calculation Method

XCRC equals the CRC defined in PSI5 Standard 2.0 “Frame format 4 ECU to Sensor Message CRC”, see **“ECU to Sensor Communication” on Page 33-12**.

33.5.1.2 PSI5-S UART Frames transmitted to PHY

Figure 33-6 shows the layout and definitions of the UART Frames sent by PSI5-S.

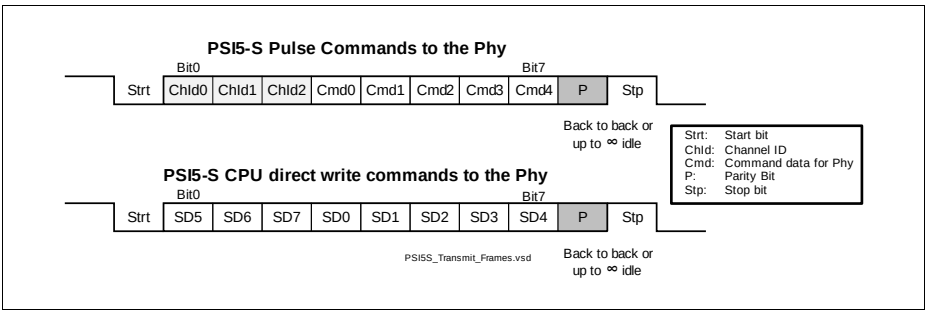

Figure 33-6 PSI5-S UART Frames transmitted to the PHY

33.5.2 Communication between PHY and Sensor (PSI5 Standard)

This chapter treats the frame formats on the PSI5 bus as short reference.

33.5.2.1 PSI5 Standard Frame Format

Figure 33-7 shows the principal layout and definitions of a PSI5 Frame. Note that the PSI5 standard specifies that the least significant bit is sent out first. See standard for CRC and Parity definition.

Example: 16 Bit Data Word „0xAD2C" with 3-Bit CRC

S1	S2	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	D10	D11	D12	D13	D14	D15	C2	C1	C0
0	0	0	0	1	1	0	1	0	0	1	0	1	1	0	1	0	1	1	0	0
		C = „1100"				2 = „0010"				D = „1101"				A = „1010"						

Figure 33-7 Standard PSI5 Frame Format

33.5.2.2 PSI5 Extended Frame Format

Figure 33-8 shows the layout and definitions of an Extended PSI5 Frame. Note that the PSI5 standard specifies that the least significant bit is sent out first.

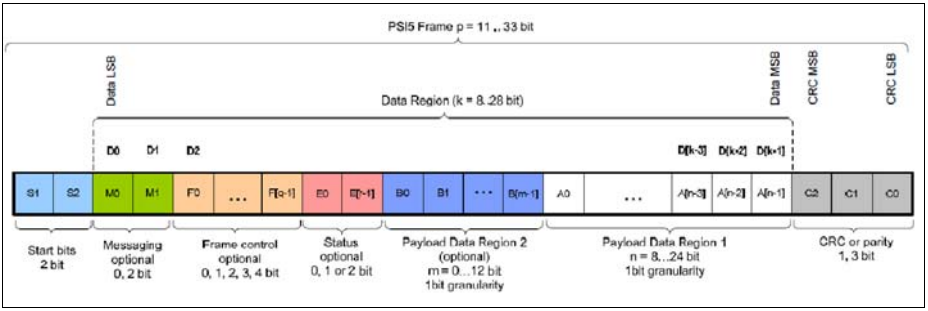

Figure 33-8 PSI5 Extended Frame Format

PSI5 Sensor to ECU Message CRC

The transmission of PSI5 data is checked by the following protection modes. The transmission error detection must be selectable:

1) 1-bit even parity

2) 3-bit CRC

The applied generator polynomial of the CRC is g(x) = 1 + x + x3 with a binary start value (seed) “111”. The transmitter shall extend the data bits by three zeros (as MSBs). This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits shall be ignored in this check. When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum. These three check bits shall be transmitted in reverse order (MSB first: C2, C1, C0)

33.5.2.3 Sync Pulses

Sync Pulses are used for two different purposes:

- Triggering a data frame for data acquisition from a sensor or
- ECU to sensor communication.

Synchronous Transmission

In the “synchronous” mode, the sensor (slave) starts to transfer a complete data frame only after a sync pulse is transmitted via ASC to the external PHY. The external PHY translates this ASC command into a voltage increase. The sensor then initiates a measurement and starts to calculate the new output data value. The data follows in a standard PSI5 Frame, starting with the 2 start bits, data and Parity or CRC. The timing diagram in **Figure 33-9** visualizes a synchronous transmission

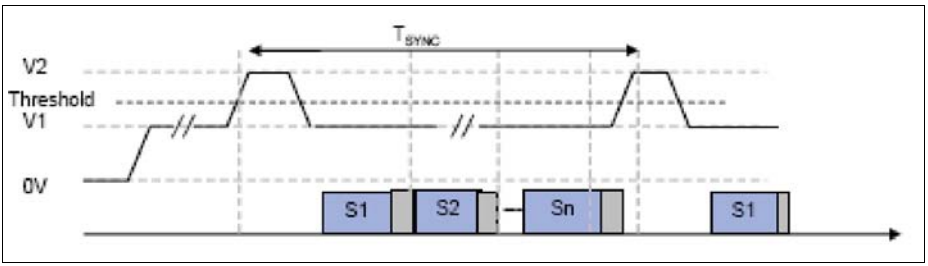

Figure 33-9 Synchronous Transmission

ECU to Sensor Communication

PSI5 V2.0 2011-06 defines 4 principle frame formats. Please refer to this standard document for more details. As the main target application is power train, only frame format 4 is cited here. This is the format for the power train sub standard.

Two methods for the ECU to Sensor Communication are supported:
Tooth Gap Method (see **Figure 33-10**) and
Pulse Width Method (see **Figure 33-11** and **Figure 33-12**) .

Tooth Gap Method

uses usually 31 sync pulses as start condition and start bits (0 1 0) to signal the start of the ECU to Sensor Communication. From this start on, the sync pulses are interpreted by the sensor as data. See standard for CRC and Parity definition.

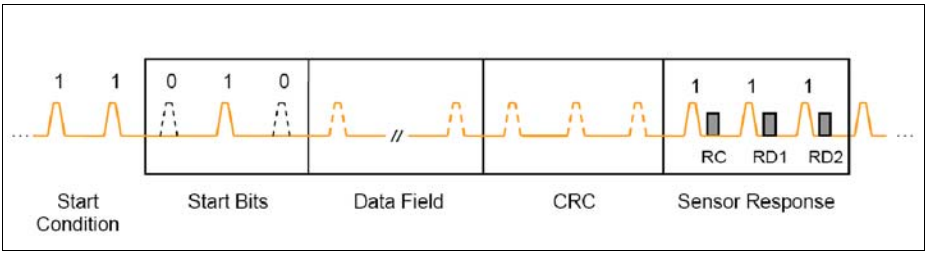

Figure 33-10 ECU to Sensor (Tooth Gap Method)

Pulse Width Method

allows for modulation of the sync pulse duration. This way bidirectional communication is possible continuously.

Sync Bits of frame format 4

A consecutive train of seven ones within the transmitted data could be misinterpreted as a frame start condition. Therefore a “sync bit” (logical 0) is inserted after every six bits of the sensor address and the payload data. With respect to the data transmission, these sync bits are treated like stuffing bits, which are removed at the receiver side.

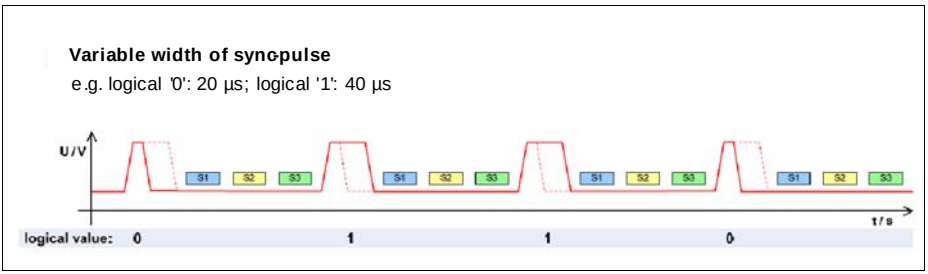

Figure 33-11 ECU to Sensor, Bit transmission (Pulse Width Method)

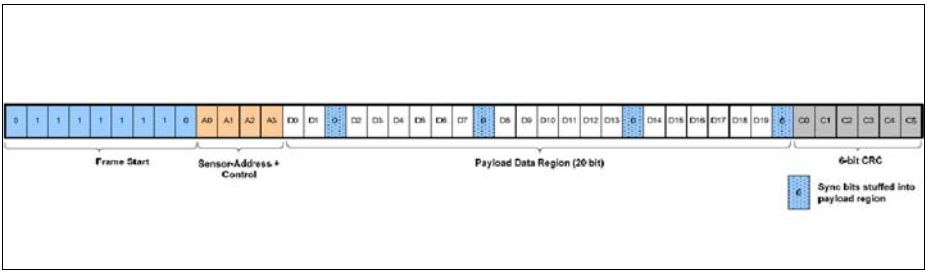

Figure 33-12 ECU to Sensor, Frame format 4 (power train)

Frame format 4 ECU to Sensor Message CRC

The ECU-to-Sensor Frame has a 6-bit CRC.
The generator polynomial of the CRC is
g(x)=x6 + x4 +x3 +1
with a binary CRC initialization value “010101”.
The transmitter extends the data bits by six zeros (as MSBs).
This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits and sync bits are ignored in this check.

When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum.

These six check bits shall be transmitted LSB first [C0, C1 .. C5].This CRC value is computed as a function of the contents of all address and data bits and Sync bits (“0” bits). For purposes of the CRC calculation, the bits shall be ordered: m = [A0 A1 .. A3 D0 D1 0 D2 .. D19 0].

In this implementation the number of elements is configurable. While the standard is 4 address and 20 data bits, the module allows longer or shorter messages too.

33.6 Clock Generation

The PSI5-S module provides 2 central Time Stamp Counters and the central Time Stamp Clock f_{TS} to each channel. See **Figure 33-13**. The clock of each Time Stamp Counter is individually selectable: either f_{TS} or any of the GTM inputs can be selected to drive them.

This chapter shows in detail how f_{TS} is adjusted.

For details on the principles of a fractional divider, please refer to the SCU chapter of TC27x section “Clock Control”.

The PSI5-S module provides 2 internal clock signals centrally

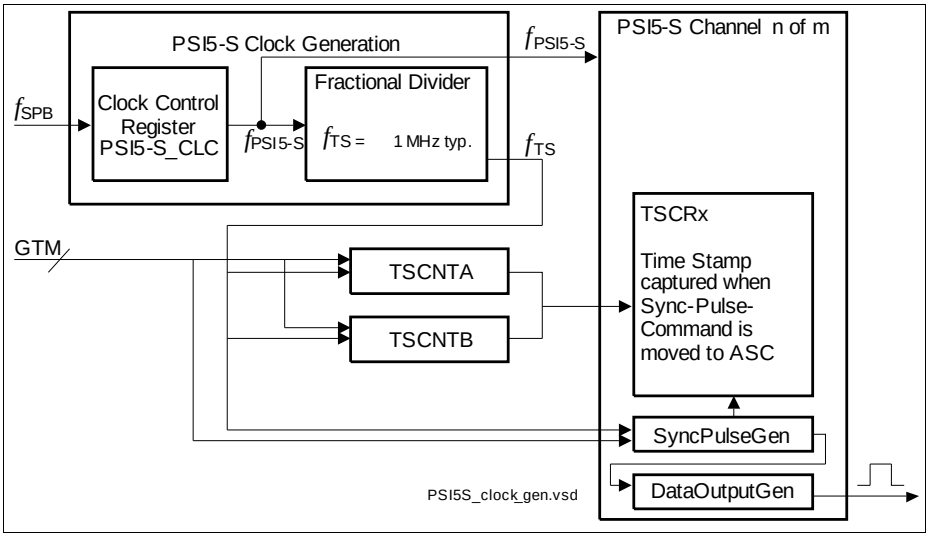

Figure 33-13 PSI5-S Module Clock Generation

- f_{PSI5-S}
  This is the module clock that is used inside the PSI5-S kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{PSI5-S} is controlled by register FDR and derived from the system clock frequency f_{SPB}. The clock control register CLC makes it possible to enable/disable f_{PSI5-S} under certain conditions.
- f_{TS}
  This clock is usually used to drive the central Time Stamp Counters.
  It can be selected to drive the global sync pulse time base and
  inside the PSI5-S channels to drive the local sync pulse generators and watch dog timers. The fractional divider register FDRT controls the frequency of f_{TS}.This is usually adjusted to 1 MHz / 1 µs period time.

The following two formulas define the frequency of f_{TS}:

$f_{TS} = f_{PSI5-S}$ / (1024 - PSI5-S_FDRT.STEP); FDRT.DM = 01B (33.1)

$f_{TS} = f_{PSI5-S}$ x PSI5-S_FDRT.STEP / 1024 with STEP = 0 … 1023; FDRT.DM = 10B (33.2)

33.6.1 Overview on Clocks in the System

To reduce system cost, the external PHY can be supplied with a clock from TC27x. EXTCLK1/2 (SCU), CMU_ECK (GTM) or by PSISCLK (PSI5-S). The range is limited to

20 .. 25 MHz maximum for proper clock transmission. The PHY needs to provide 3 clocks from this: Sample clock for 189 kHz, and 125 kHz and the ASC oversampling clock.

A divider by 2 is added between the actual fractional divider block and the output signal $f_{PSISCLK}$ in order to achieve a duty cycle of 50% (plus tolerances due to fractional divider jitter)! This is why the formulas contain the division by 2 at the end.

- $f_{PSISCLK}$
  This clock is used to drive the external PHY.
  The fractional divider register **FDO** controls the frequency of $f_{PSISCLK}$.

The following formula defines the frequency of $f_{PSISCLK}$:

$$f_{PSISCLK} = f_{BAUD2} / (2048 - PSI5\text{-}S\_FDO.STEP) / 2;\ DM = 01B \quad (33.3)$$

$$f_{PSISCLK} = f_{BAUD2} \times PSI5\text{-}S\_FDO.STEP / 2048 / 2 \text{ with } STEP = 0 \ldots 2047;\ DM = 10B \quad (33.4)$$

In order to relax the requirements with respect to ASC communication with TC27x while allowing for high bit rates, some additional provisions have been made. The ASC Sub Module is supplied with a higher frequency (f_{BAUD2}) to allow for very high precision at high baud rates (4 - 12,5 MBaud). As a second measure to achieve this, the fractional divider in ASC is longer than in the standard module. **Figure 33-14** illustrates the situation on PCB. Refer to the ASC sub chapter for baud rate calculations.

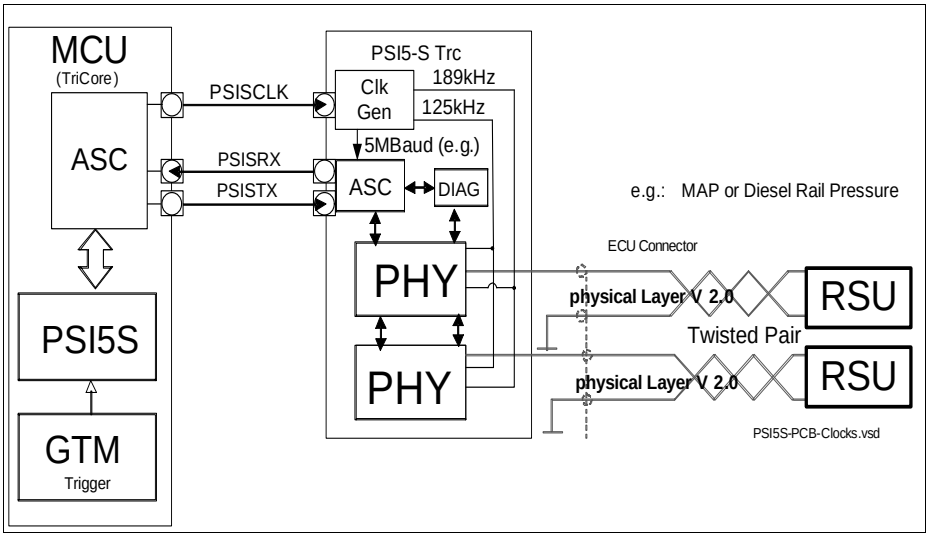

Figure 33-14 PSI5-S Clock Requirements of PHY

33.7 Time Stamp Generation

Two time bases can be selected for Time Stamping:

Any of TSCNTA and TSCNTB provide one Time Stamp Counter. Each of them can be configured to be driven by either f_{TS} or by an external timer, i.e. one of the GTM inputs. The frequency of f_{TS} is controllable by the fractional divider in register FDRT.

All of them can be cleared by SW single or synchronously.

The last sync pulse sent on a channel is stored in the sync pulse time stamp capture register TSCRx. Note that if RCRAx.TSTS is set, the Sync Pulses do not trigger the Time stamp capture. In this case, the Packet Frame reception triggers the capture. Non recoverable Packet Frames will be stored with the current value of TSCNTA/B directly copied to TSM. See RCRAx on **Page 33-83** and on for more details.

For each channel the capture time (TSCRx) is stored.

Figure 33-15 shows the time stamp generation:

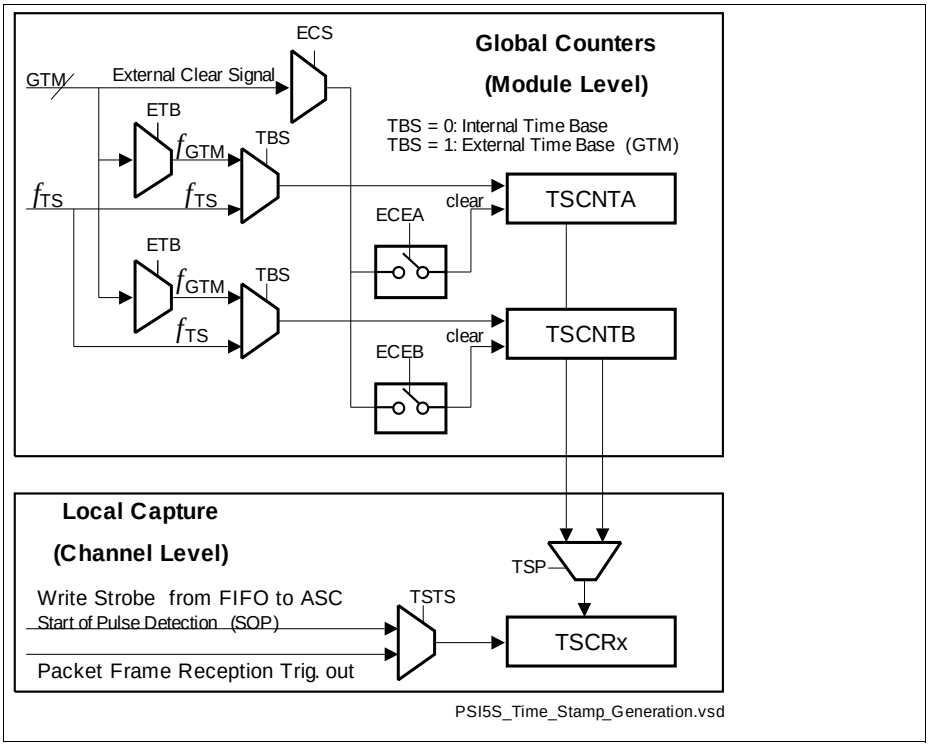

Figure 33-15 Time Stamp Generation

33.8 Watch Dog Timers

The value entered in WDTx.WDL defines the time in multiples of TTS (defined in FDRT) until expiry of the watch dog.

There are two modes of operation that can be selected with bit RCRAx.WDMS.

In normal operation an interrupt (TEI) is issued if the distance between two RDIs is longer than specified in WDL. In this mode, The internal watch dog timer is started automatically when the channel is enabled.

In synchronous mode, TEI is issued if the watch dog timer expires without reception of CHCI in time. I.e. the time from issuing the sync pulse to reception of the last expected frame configured in NFC.NFx was too long.

In both modes, only completely and correctly received Packet Frames on channel x can qualify, i.e. Packet Frames with XCRC checked ok. Otherwise the channel number can not be determined - the referring WDLx not be selected.

The internal watch dog timer is compared to WDL. A match

- triggers a TEI.
- restarts the watch dog timer. I.e. it clears the internal watch dog timer and it counts on from zero. TEI is repeated if no recoverable frames are received.

If no watch dog is needed, WDL is cleared, the internal watch dog timer is stopped and no check is performed.

Asynchronous mode of the Watch Dog Timers:

If RCRAx.WDMS is cleared the internal watch dog timer y is restarted on reception of a new recoverable frame (RDIx) for the referring channel. It is not restarted by a sync pulse and not stopped by a certain number of received Packet Frames.

The example below shows the use of the watch dog. The sync pulse is completely ignored by the watch dog system.

F2 is the only frame coming too late. All others start before the expiry of the watch dog.

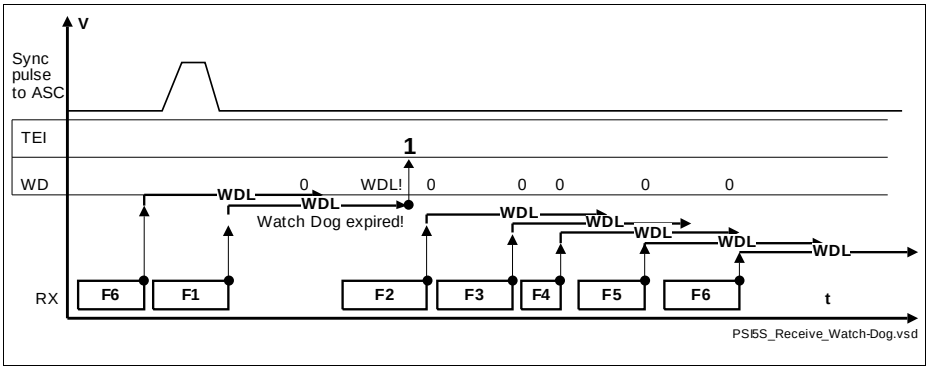

Figure 33-16 Watch Dog Timers

Synchronous mode of the Watch Dog Timers:

If RCRAx.WDMS is set the WDT is restarted on sync pulse and stopped at reception of the last frame configured in NFx. Register NFCx contains the bit fields NFx which configure the number of Packet Frames expected after the sync pulse. FCNT.FCx is the counter that is compared with NFx.

The Watch Dog Timer is restarted (cleared and set to run), each time a Sync Pulse is transferred for the referring channel from FIFO to ASC. The Watch Dog Timer of this channel is forced to stop if the number of a received Packet Frames (counted in FCNT.FCx matches the number configured in NFC.NFx. This supports in particular angle synchronous channels where the distance of packets can vary strongly with e.g. the roundings per minute of an axis.

The WDT can not stop in time if a non recoverable (and thus not countable) Packet Frame is received! If more than the configured number of Packet Frames are received, no dedicated interrupt is issued for this but the frame is still received correctly.

RCRAx.WDMS should be 0 on asynchronous channels. Otherwise, the internal Watch Dog Timer will be stopped after reception of the number of configured frames but never be restarted due to the lack of a Sync Pulse!

If a sensor is not present in a special configuration, NFx must be reduced accordingly! E.g. if out of F1 .. F6 the F2 is missing, only 5 frames are configured.

Please refer to register **“NFC” on Page 33-79** for detailed description.

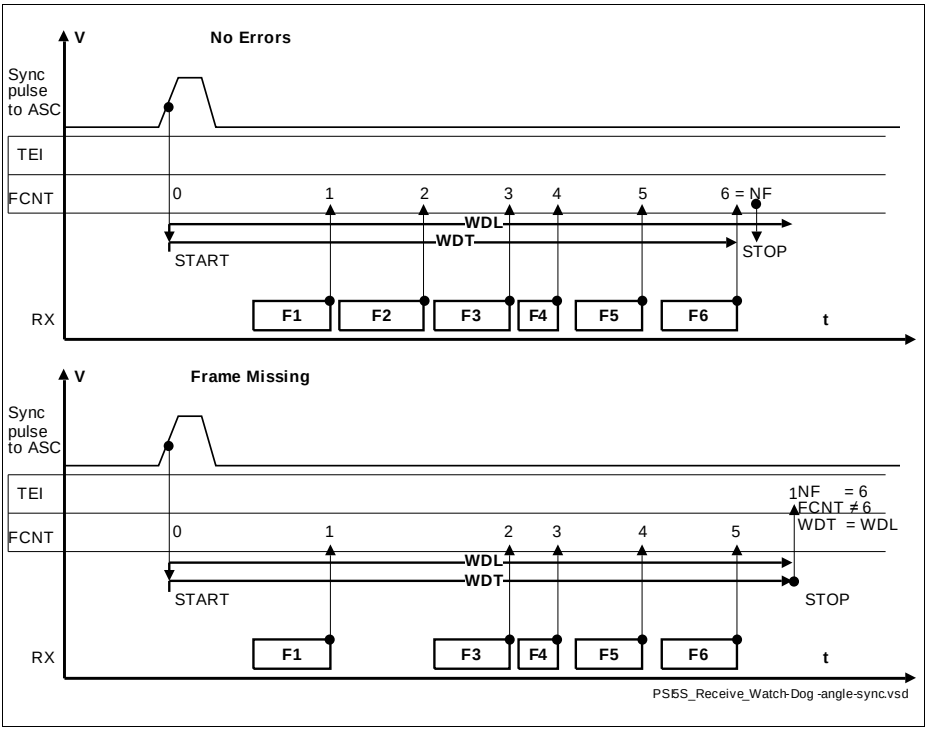

Figure 33-17 Watch Dog Timers in synchronous mode

33.9 Send Data

This chapter contains the details of how data to be sent is prepared. The scope extends to:

- Periodic Triggers
- Angle Synchronous Triggers
- ECU to Sensor communication

33.9.1 Channel Trigger

The Channel Trigger Value Register CTVx contains a two cell reset counter. It allows for setting up periodic sync pulses for channel x.
The Channel Trigger Value CTV is the compare value which restarts the counter CTC on equality and only on equality. At exactly this time, a sync pulse is triggered.
The compare on equality allows to preset CTC and thus configure an offset between the CTVx.CTCs. This allows for staggering periodic sync pulses that must have frequencies with common multiples (e.g. same frequency, double etc.).

In this document OFFSET = 65535 - “CTC preset value”

I.e. CTC preset is > CTV so that the the time to to roll over is the offset.
Of course CTC preset can be < CTV so that this CTC has some advance.
Note that CTC can be written only if it is disabled by clearing GCR.ETCx.

Staggering the pulses might be required if the current source for the external PHYs can provide only limited current so that not all channels can be provided with the additional current that is required to apply the voltage increase representing a proper sync pulse.
For a synchronization of all counters CTVx.CTC, bits GCR.ETC0 .. 7 can be used.

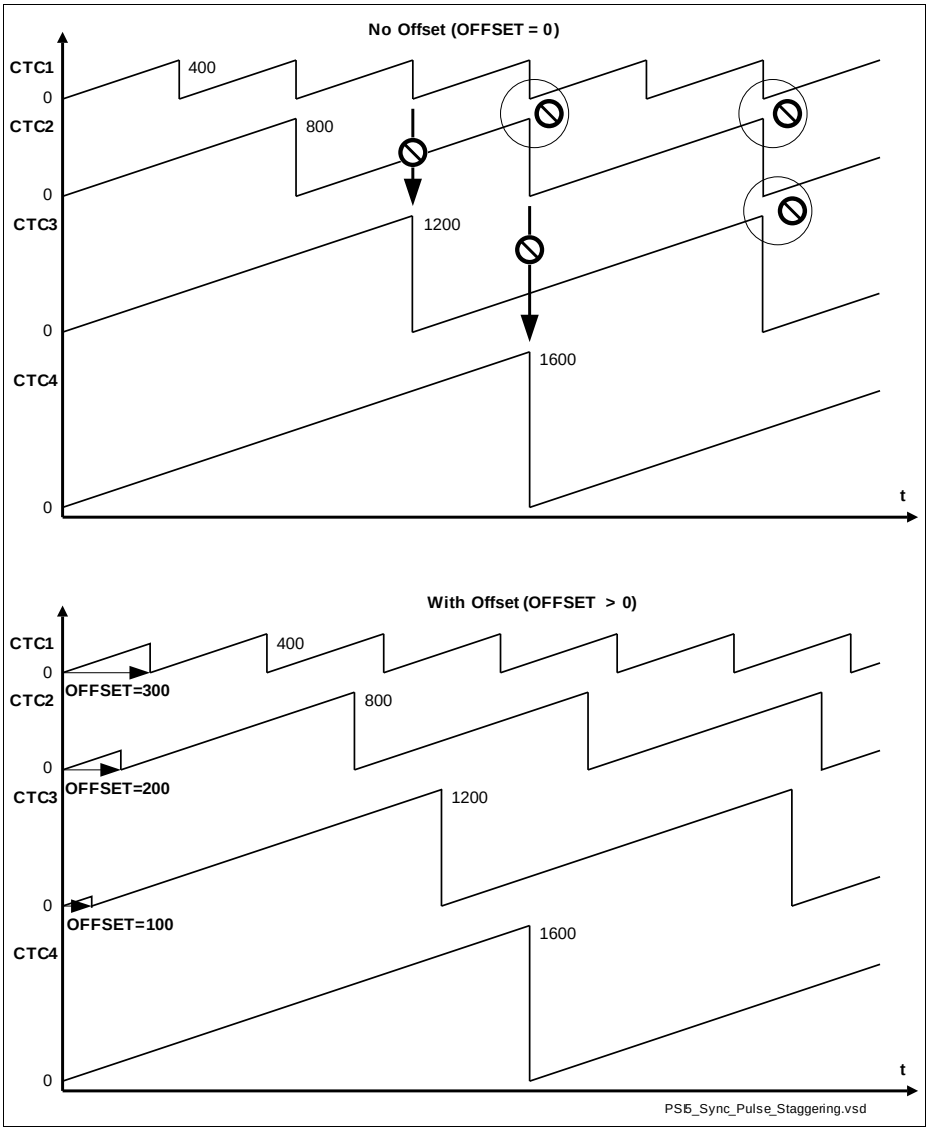

Figure 33-18 PSI5-S Pulse Staggering

33.9.2 Sync Pulse Control

The sync pulse generation provides the following functionality:

- periodic sync pulses, driven by a common module time base (PTE is set)
- angle synchronous sync pulses, driven by GTM (ETE is set)
- sync pulses for ECU to Sensor communication (Tooth Gap Method, EPS[0]=0)
- sync pulses for ECU to Sensor communication (PWM Method, EPS[0]=1)

It is possible to switch on and off the periodic trigger or the angle synchronous trigger at any time. The pulses will be modulated according to the selected standard. EPS selects between PWM method and Tooth Gap Method with pulse dropping.

An ECU to Sensor communication can be stopped at any point in time by setting the flush bit. This will clear the send register and flag TPF.

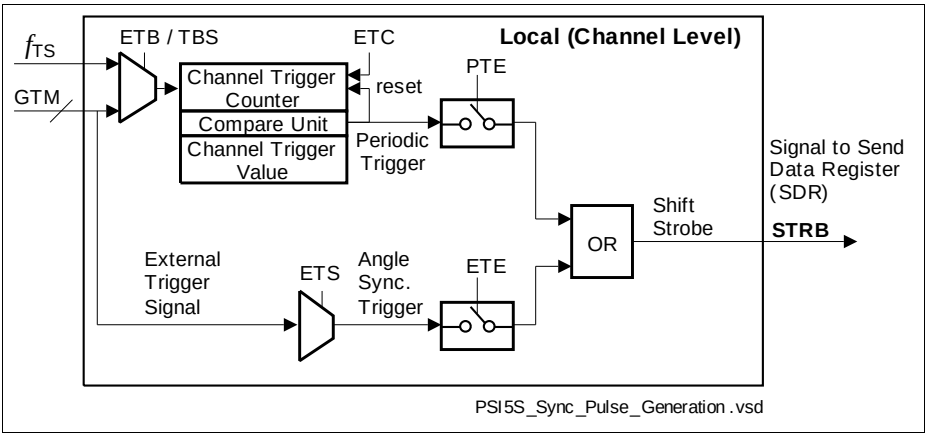

Figure 33-19 PSI5-S Sync Pulse Generation

33.9.3 Send Data Preparation

Figure 33-20 shows the mechanisms how ECU to sensor communication data is treated:

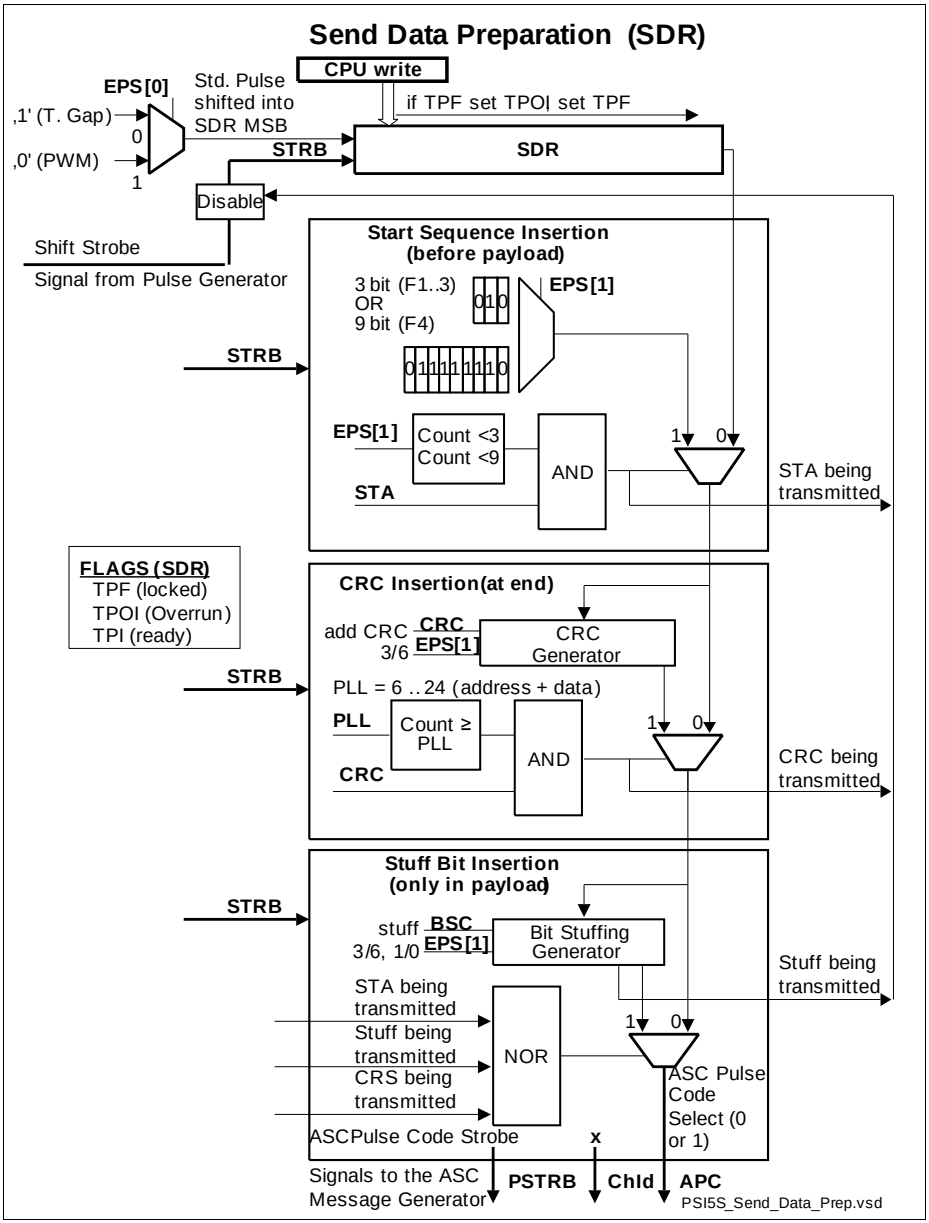

Figure 33-20 PSI5-S Send Data Preparation

33.10 Message Generation

Figure 33-21 shows the message generation logic. The generated ASC commands are sorted into an internal FIFO of 8 entries of 9 bits width. The MSB stores the information, if a command is generated from the sync pulse generation (ASC Pulse Code Strobe issued the write into FIFO) or if the CPU wrote a command. This is important for the Time Stamp generation. Usually the Time Stamp is captured when a Sync Pulse Command leaves the FIFO i.e. is copied to the ASC TX buffer. Commands stored in the FIFO can only trigger a Time Stamp capture if they are marked as Sync Pulse in bit 8. Nevertheless, the CPU can set MSB (bit 8) in Register CDW if the command is to be treated like a Sync Pulse Command and a Time Stamp should be captured. Note that if RCRAx.TSTS is set, the Sync Pulses do not trigger the Time stamp capture. In this case, the Packet Frame reception triggers the capture and bit 9 is ignored.
There is no further arbitration of the CPU and Message Generation Unit. The PHY answers CPU commands with standard frames of fixed predefined length in channel 0 frame 0.

Interrupt FOI is issued if a transfer to the FIFO was generated by the message generation unit or by CDW (CPU direct write register) while the FIFO was full. In a correct setup, this will never be the case as the bandwidth of the ASC is assumed to be by far higher than the write bandwidth in order to have short delays. In most cases too many write accesses to CDW will be the root cause. This exceptional condition can be handled either by waiting until the FIFO has transferred at least one command or by a module reset by SW. It should not occur in the application but FOI should help SW generation and debugging.

The transfer path of a command to the ASC could add jitter to sync pulses.

In case several channels request a pulse at exactly the same time, the channel with the lower channel number is served first and CDW has highest priority.

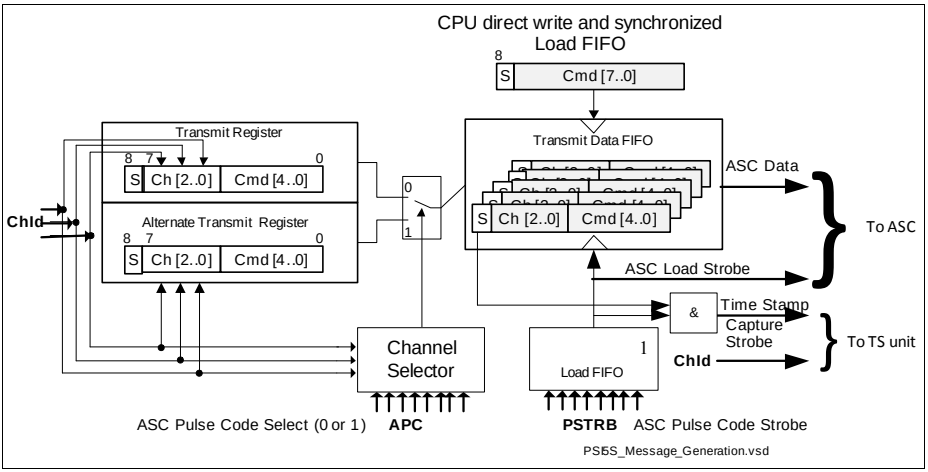

Figure 33-21 PSI5-S Message Generation Logic

33.11 DMA Support

The received frames come in sequentially and are XCRC checked. The complete reassembled frame including Channel Id (ChId), Frame ID (FId) and status are available at RDR and RDS. TSM shows the latest time stamp of the currently received channel.

RDR, RDS and TSM are located in 3 sequentially addressed registers. This way, they are easily readable by DMA. See **Figure 33-22**.

33.11.1 Single DMA, 8 dedicated DMAs

With one single DMA channel, one common frame buffer in the system memory can be build up. All frames can be collected from RDR, RDS and TSM. The DMA source address is programmed to be always RDS, block transfer is set to 3 words with auto address increment. The target is set to be automatically incremented. This results in one buffer in system memory with all frames from all channels.

Individual buffers for each channel can be build up if more DMA channels are used. Each channel can generate its own receive triggers RDI and RSI. Thus individual DMAs can be set up for each channel similarly to the single DMA use case but with individual target addresses for each channel.

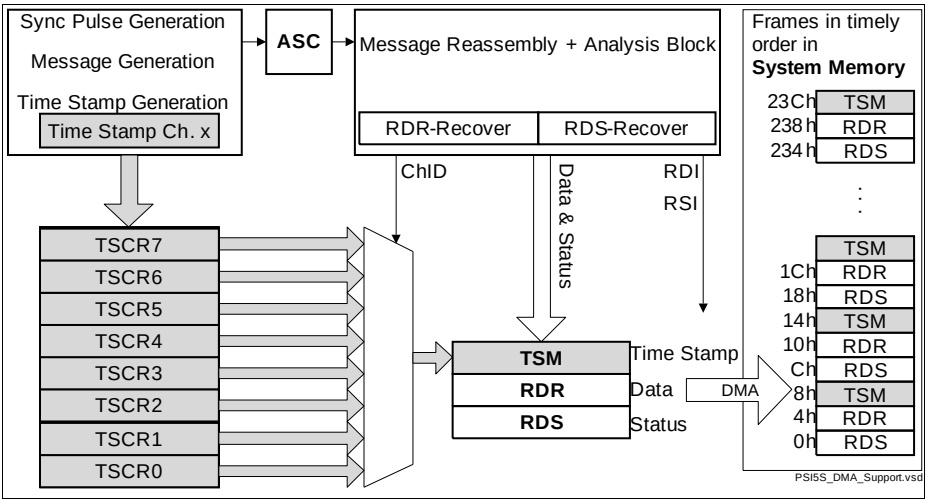

Figure 33-22 PSI5-S Single DMA Support

33.11.2 Two daisy chained DMAs

The PSI5-S supports sorting by channel with only two DMA channels. Register TAR contains the target address that is to be copied by the first DMA into the target address register of the second DMA. Source and target of the first DMA are fixed (DMA register SADR and DADR). The target address offered in TAR is calculated by PSI5-S by adding an offset value to the programmable base address defined in BAR. This allows for locating the channel buffers at any location in system memory.

The resulting base + offset is presented in TAR. The target address depends on:

- BAR (base address)
- ChID: offset of channel number currently received (channel number x 6 (buffer lines) x 3 (words per frame) x 4 Bytes per word = 72 Bytes x channel number. This allows to receive 6 frames per channel which equals the maximum number of PSI5 Frames per Sync Pulse.
- FID: offset of frame ID currently received. (3 words i.e. 12 Bytes per frame)
  Note that the frame ID used for this sorting depends from RCRAx.FIDS! In particular in asynchronous mode, FIDS needs to be set so that the FID from the Packet Frame is replaced by a rolling number.
- Note that the message reassembly unit forces non recoverable messages to be stored at the address for ChID = 0, FID = 1 but with original ChID and FID! I.e. RDS contains the CHID and FID as received in the first UART Frame for better debugging!
- The source address of the second DMA needs to be programmed to be fixed to the address of RDS. Use shadow control to “wrap around” the source address.

(DMA_MExADICR.SHCT must be set to 0x0101b).
Block transfer with address auto incrementing must be selected and the number of transactions programmed to 3 (see DMA chapter, DMA_MExCHCR.BLKM) 32 bit (the data width is defined in DMA_MExCHCR.CHDW) accesses.
Use shadow control to “wrap around” the source address. (DMA_MExADICR.SHCT must be set to 0x0101b).

The source address of the second DMA needs to be programmed to be fixed (see DMA chapter, register ADRCRxz) to the address of RDS.
Block transfer with address auto incrementing must be selected and the number of transactions programmed to 3 (see DMA chapter, DMA_MExCHCR.BLKM) 32 bit (the data width is defined in DMA_MExCHCR.CHDW) accesses.
Use shadow control to “wrap around” the source address. (DMA_MExADICR.SHCT must be set to 0x0101b).

The second DMA must be of the next lower priority than the first. Selecting hardware request input via CHCRxz.PRSEL allows for daisy chaining the two DMA channels. See **Figure 33-23**.

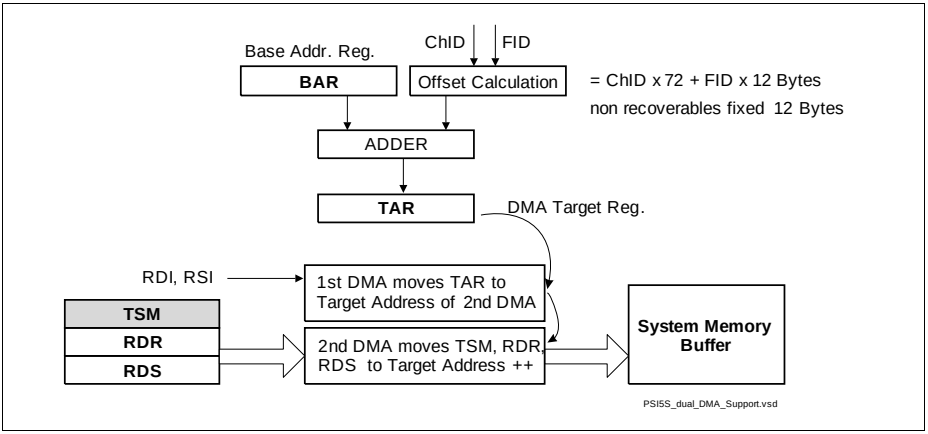

Figure 33-23 PSI5-S Dual DMA Support (daisy chained)

Table 33-1 shows the detailed mapping of the received frames resulting from the described calculation rules:

33.11.3 Interrupts for DMA support

Interrupts for Single DMA usage

Interrupts RDI or RSI can be used as trigger for the DMA transfer from TSM/RDS/RDR.

Interrupts for two daisy chained DMA usage

If one of the buffers is full, this is signalled to SW by interrupt CHCI. The “status buffer full” is defined as follows: current number of received frames counted in FCNT.FCx equals the number of expected frames configured in NFC.NFx. In synchronous mode this is the case, if all expected PSI5 frames after a Sync Pulse are received by PSI5-S. The number of expected frames is looked up in register NFC.NFx for channel x. In Asynchronous mode, NFC.NFx should be programmed to 6 while RCRAx.FIDS is set. This way the FID for an asynchronous channel is a rolling number 0 .. 5 and the 6 buffer locations are used completely before CHCI is issued. See **Figure 33-24**.

There is a delay between CHCI and the completion of the DMA transfer of the last set of RDS, RDR and TSM to the system memory! SW needs special checks to grant data consistency, e.g. evaluating the DMA interrupts or comparison of the Time Stamps in the System Memory!

CHCI is not granting that all data is completely moved to system memory by DMA!

Improved Data Consistency with Packet Frame Count (PFC)

For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.

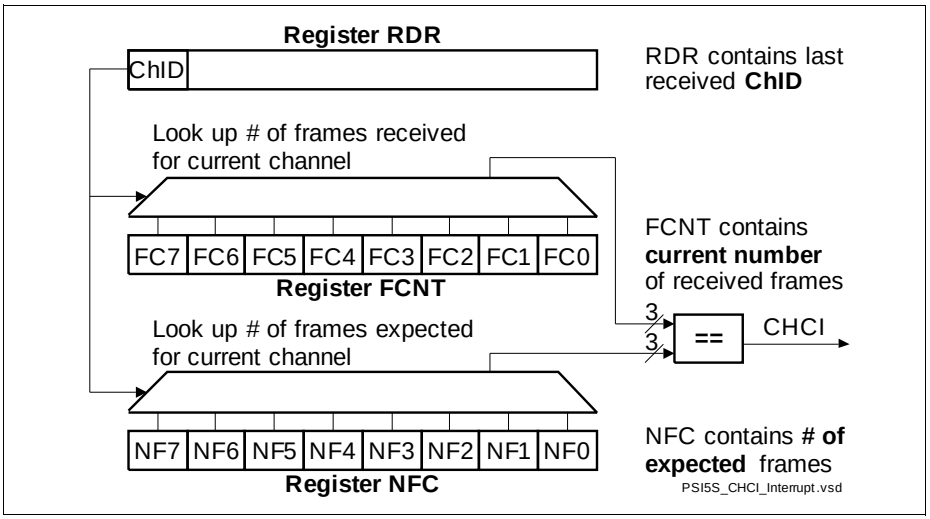

Figure 33-24 PSI5-S Generation of Interrupt CHCI

33.12 Error Detection Capabilities

Each PSI5-S channel can detect and signal the following error conditions:

Protocol Level:

- Packet Frame CRC Error (XCRC)
- PSI5 Frame Checksum error (CRCI)
- Frame not sent in time / UART Frames missing (TEI)
- Error Bits Set in Packet Frame (HDI)
- Errors Signalled by ASC Sub Module (i.e. PE, FE, OE)

Transfer Management Level:

- Receive Data Buffer Overrun (RBI)
- ECU to Sensor Data Buffer Underrun (TBI)

33.13 Special use of Channel 0

Note that data that is received in incomplete or too long Packet Frames is always copied - as is - to Channel 0 Frame ID 1. This can happen, if UART Frames are lost, the PHY sends non allowed data or idle before the actual end of the Packet Frame. See **""Packet Frames" received from PHY" on Page 33-6**.

This is the only actual reservation / limitation in functionality of Channel 0. I.e. all frames can be received and sorted correctly in Channel 0 as long as the Packet Frame is configured with: ChID = 0. It is recommended not to use ChID = 0 AND FID = 1 for normal sensor frames but to keep FID = {2, 3 ,4 ,5}.

The target application assumes, that the PHY sends messages for its own house keeping with ChID = 0, FID = 0. This is assumed in this document and e.g. shown in **Table 33-1 "Frame Mapping" on Page 33-31**. Nevertheless, a different application may not have this functionality or may use a different ChID / FID configuration.

33.14 ASC Kernel Description

Figure 33-25 shows a global view of the ASC interface. The ASC is fully integrated into the PSI5-S module. It can be switched to dedicated internal use of the PSI5-S module or to ASC only mode where all PSI5 functionality is disabled. In the last case, the whole PSI5-S module represents one additional ASC in the system.

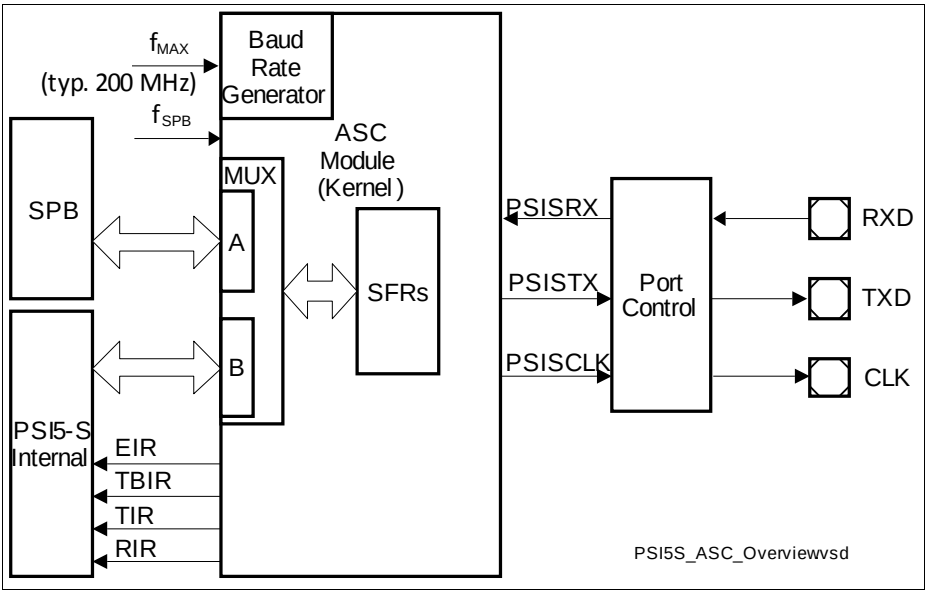

Figure 33-25 General Block Diagram of the ASC Interface

The ASC module communicates with the external world via two I/O lines. The RXD line is the receive data input signal (and also output signal in Synchronous Mode), and TXD is the transmit output signal.

Clock control, address decoding, and interrupt service request control are managed outside the ASC module kernel.

33.14.1 Overview

The ASC provides serial communication between the TC27x and other micro controllers, microprocessors, or external peripherals.

The ASC supports full-duplex asynchronous communication and half-duplex synchronous communication. In Synchronous Mode, data is transmitted or received synchronous to a shift clock that is generated by the ASC internally. In Asynchronous Mode, 8-bit or 9-bit data transfer, parity generation, and the number of stop bits can be selected. Parity, framing, and overrun error detection are provided to increase the reliability of data transfers. Transmission and reception of data is double-buffered in ASC only mode. During internal PSI5-S mode, double-buffering is switched off for the transmitter. The receiver stays double buffered. For multiprocessor communication, a mechanism is included to distinguish address Bytes from data Bytes. Testing is supported by a loop-back option. A 13-bit baud rate generator provides the ASC with a

separate serial clock signal, which can be accurately adjusted by a prescaler implemented as fractional divider.

Features

- Full-duplex asynchronous operating modes
  - 8-bit or 9-bit data frames, LSB first
  - Parity-bit generation/checking
  - Separate Parity control for receive and transmit
  - One or two stop bits
  - Baud rate from 12,5 Mbit/s to 3 bit/s (@ 200 MHz module clock)
  - Multiprocessor mode for automatic address/data Byte detection
  - Loop-back capability
- Half-duplex 8-bit synchronous operating mode
  - Baud rate from 25 Mbit/s to 2034,5 bit/s (@ 200 MHz module clock)
- Double-buffered transmitter (in ASC-only mode)/receiver
- Interrupt generation
  - On a transmit buffer empty condition
  - On a transmit last bit of a frame condition
  - On a receive buffer full condition
  - On an error condition (frame, parity, overrun error)
- Implementation features
  - Connections to DMA Controller
  - Connections of receiver input to GTM for baud rate detection and LIN break signal measuring

33.14.2 General Operation

The ASC supports full-duplex asynchronous communication and half-duplex synchronous communication. In Synchronous Mode, data is transmitted or received synchronously to a shift clock generated by the microcontroller. In Asynchronous Mode, 8-bit or 9-bit data transfer, parity generation, and the number of stop bits can be selected. Parity, framing, and overrun error detection are provided to increase the reliability of data transfers. Transmission and reception of data are double-buffered. For multiprocessor communication, a mechanism is included to distinguish address Bytes from data Bytes. Testing is supported by a loop-back option. A 13-bit baud rate generator provides the ASC with a separate serial clock signal, which can be accurately adjusted by a prescaler implemented as fractional divider.

A transmission is started by writing to the Transmit Buffer Register, TBUF. Only the number of data bits determined by the selected operating mode will actually be transmitted; that is, bits written to positions 9 through 15 of register TBUF are always insignificant. Data transmission is double-buffered, so a new character may be written to TBUF before the transmission of the previous character is complete. This allows a back-to-back transmission of characters to take place without gaps.

Data reception is enabled by the receiver enable bit CON.REN. After a reception has been completed, the received data and, if provided by the selected operating mode, the received parity bit can be read from the (read-only) receive buffer register RBUF. Unused bits in the upper half of RBUF that are not required in the selected operating mode will be read as zeros.

Data reception is double-buffered, so that reception of a second character may already begin before the previously received character has been read out of the receive buffer register. During the exclusive use by the PSI5-S, double buffering is switched off. The PSI5-S internal output FIFO is used instead. As commands for sync pulses are time stamped inside PSI5-S as they leave the internal FIFO, the double buffering would add unwanted jitter. In all modes, receive buffer overrun error detection can be selected through bit CON.OEN. When enabled, the overrun error status flag CON.OE and the error interrupt request line EIR will be activated when the receive buffer register has not been read by the time reception of a second character is complete. In this case, the previously received character in the receive buffer is overwritten.

The loop-back option (selected by bit CON.LB) allows the data currently being transmitted to be received simultaneously in the receive buffer. This may be used to test serial communication routines at an early stage without having to provide an external network. In loop-back mode, the alternate input/output function of port pins is not required.

33.14.3 Asynchronous Operation

Asynchronous Mode supports full-duplex communication, in which both transmitter and receiver use the same data frame format and have the same baud rate. Data is transmitted on pin TXD and received on pin RXD. **Figure 33-26** shows the block diagram of the ASC when operating in Asynchronous Mode.

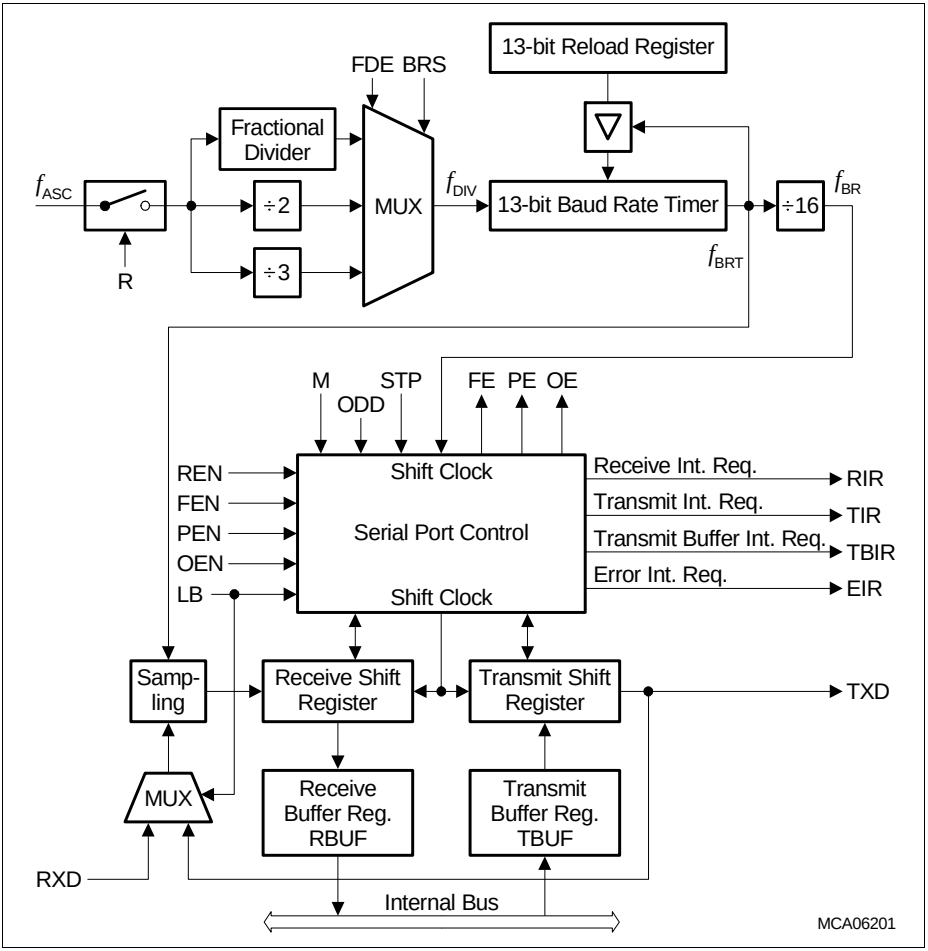

Figure 33-26 Asynchronous Mode of the ASC

33.14.3.1 Asynchronous Data Frames

Asynchronous data frames can consist of 8-bit or 9-bit data frames.

8-bit Data Frames

The 8-bit data frames consist of either eight data bits D7 … D0 (CON.M = 001_B), or of seven data bits D6 … D0 plus an automatically generated parity bit (CON.M = 011_B). Parity may be odd or even, depending on bit CON.ODD. An even parity bit will be set if the modulo-2 sum of the seven data bits is 1. An odd parity bit will be cleared in this case. Parity checking is enabled via bit CON.PEN (always OFF in 8-bit data mode). The parity error flag CON.PE will be set, along with the error interrupt request flag, if a wrong parity bit is received. The received parity bit itself will be stored in RBUF too.

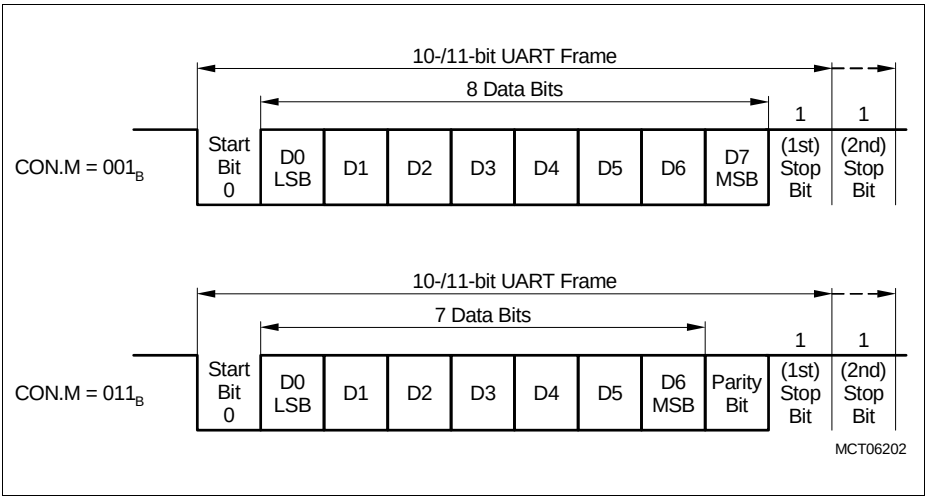

Figure 33-27 Asynchronous 8-bit Frames

9-bit Data Frames

The 9-bit data frames consist of nine data bits D8 … D0 (CON.M = 100_B), or of eight data bits D7 … D0 plus an automatically generated parity bit (CON.M = 111_B) or of eight data bits D7 … D0 plus wake-up bit (CON.M = 101_B). Parity may be odd or even, depending on bit CON.ODD. An even parity bit will be set if the modulo-2-sum of the eight data bits is 1. An odd parity bit will be cleared in this case. Parity checking is enabled via bit CON.PEN (always OFF in 9-bit data and wake-up mode). The parity error flag CON.PE will be set along with the error interrupt request flag if a wrong parity bit is received. The received parity bit itself will be stored in RBUF too.

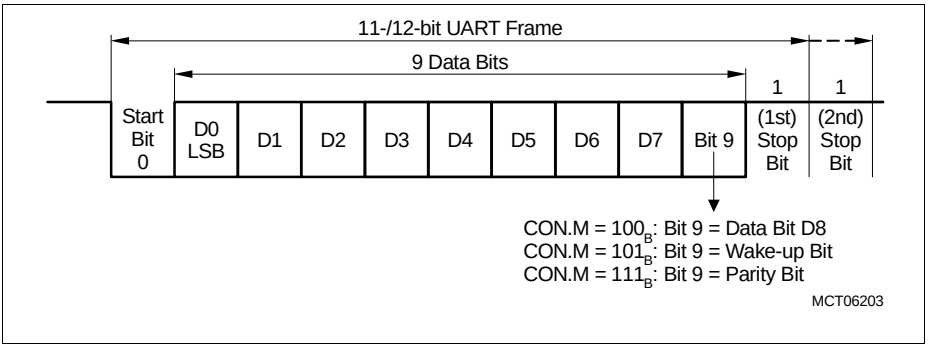

Figure 33-28 Asynchronous 9-bit Frames

In Wake-up Mode (CON.M = 101_B), received frames are transferred to the receive buffer register only if the 9^{th} bit (the wake-up bit) of the frame is 1. If this bit is 0, no receive interrupt request will be activated and no data will be transferred.

This feature can be used to control communication in multi-processor systems, for example:
When the master processor aims to transmit a block of data to one of several slaves, it first sends out an address ‘Byte’ (in this case, a ‘Byte’ consists of nine bits) that identifies the target slave. An address ‘Byte’ differs from a data ‘Byte’ in that the additional 9^{th} bit is a 1 for an address ‘Byte’ but is a 0 for a data ‘Byte’, so, no slave will be interrupted by a data ‘Byte’. An address ‘Byte’ will interrupt all slaves (operating in 8-bit data + wake-up bit mode), so each slave can examine the eight LSBs of the received character (the address). The addressed slave will switch to 9-bit data mode (for example, by clearing bit CON.M[0]), which enables it to also receive the data Bytes that will be coming (having the wake-up bit cleared). The slaves that were not being addressed remain in 8-bit data + wake-up bit mode, ignoring the following data ‘Bytes’.

33.14.3.2 Asynchronous Transmission

Asynchronous transmission begins when the next overflow of the divide-by-16 baud rate timer (transition of the baud rate clock f_{BR}) occurs, if bit CON.R is set and data has been loaded into TBUF. The transmitted data frame consists of three elements:

1. The start bit
2. The data field (8 or 9 bits, LSB first, including a parity bit, if selected)
3. The delimiter (1 or 2 stop bits)

Data transmission is double-buffered. When the transmitter is idle, the transmit data loaded into TBUF is immediately moved to the transmit shift register; thus, freeing TBUF for the next transmit data to be loaded. This is indicated by the transmit buffer interrupt request line TBIR being activated. TBUF may then be loaded with the next transmit data while transmission of the previous one continues.

The Transmit Interrupt Request line TIR will be activated before the last bit of a frame is transmitted, that is, before the first or the second stop bit is shifted out of the transmit shift register.

Note: A dedicated GPIO device pin which is connected to the module output pin TXD must be configured by software as alternate data output for asynchronous transmission.

33.14.3.3 Asynchronous Reception

Asynchronous reception is initiated by a falling edge (1-to-0 transition) on pin RXD, on the condition that bits CON.R and CON.REN are set. The receive data input pin RXD is sampled at sixteen times the rate of the selected baud rate. A majority decision of the 7^{th}, 8^{th} and 9^{th} sample determines the effective sampled bit value. This avoids erroneous results that may be caused by noise.

If the detected value is not a 0 when the start bit is sampled, the receive circuit is reset and waits for the next 1-to-0 transition at pin RXD. If the start bit proves valid, the receive circuit continues sampling and shifts the incoming data frame into the receive shift register.

When the last stop bit has been received, the contents of the receive shift register are transferred to the Receive Data Buffer Register RBUF. Simultaneously, the receive interrupt request line RIR is activated after the 9^{th} sample in the last stop bit time-slot (as programmed), regardless whether valid stop bits have been received or not. The receive circuit then waits for the next start bit (1-to-0 transition) at the receive data input line.

Note: A dedicated GPIO pin that is connected to the module input pin RXD must be configured by software as input for asynchronous reception.

Asynchronous reception is stopped by clearing bit CON.REN. A currently received frame is completed including generation of the receive interrupt request and an error interrupt request, if appropriate. Start bits that follow this frame will not be recognized.

Note: In wake-up mode, received frames are transferred to the receive buffer register only if the 9th bit (the wake-up bit) is 1. If this bit is 0, no receive interrupt request will be activated and no data will be transferred.

33.14.3.4 RXD/TXD Data Path Selection in Asynchronous Modes

The data paths for the serial input and output data in Asynchronous Modes are affected by control bit CON.LB (loop-back) as shown in **Figure 33-29**.

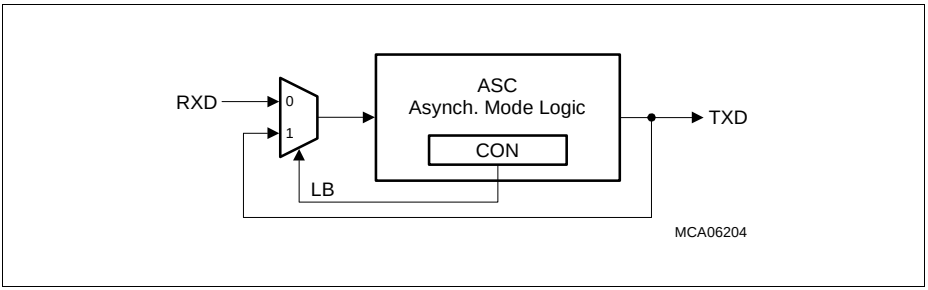

Figure 33-29 RXD/TXD Data Path Selection in Asynchronous Modes

33.14.4 Synchronous Operation

Synchronous Mode supports half-duplex communication, usable for simple I/O expansion via shift registers. Data is transmitted and received via pin RXD while pin TXD outputs the shift clock. These signals are typically connected as alternate functions with GPIO port pins. Synchronous Mode is selected with CON.M = 000_B.

Eight data bits are transmitted or received synchronous to a shift clock generated by the internal baud rate generator. The shift clock is active only as long as data bits are transmitted or received.

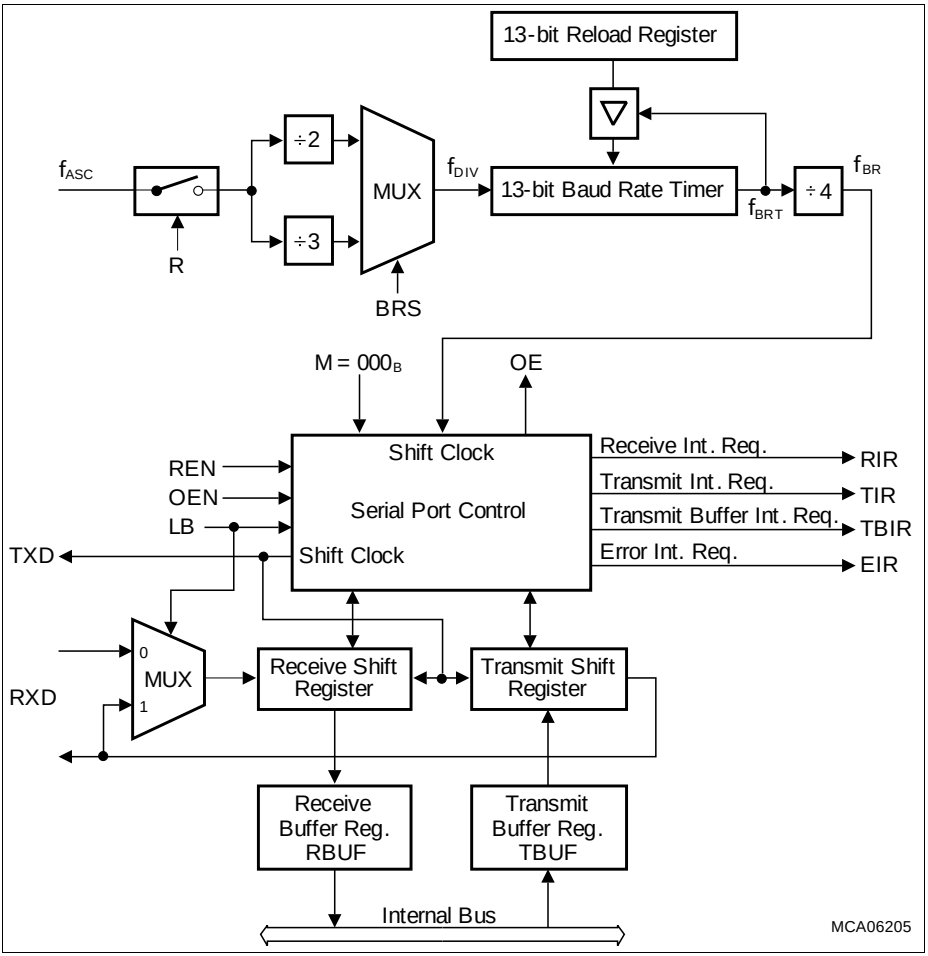

Figure 33-30 Synchronous Mode of Serial Channel ASC

33.14.4.1 Synchronous Transmission

Synchronous transmission begins after data has been loaded into TBUF, provided that CON.R is set and CON.REN = 0 (half-duplex, no reception), with one exception: in asynchronous Loop-back Mode (bit CON.LB set), CON.REN must be set for reception of the transmitted Byte. In synchronous Loop-back Mode, the transmitted Byte can still be received if CON.REN=0. Data transmission is double-buffered. When the transmitter is idle, the transmit data loaded into TBUF is immediately moved to the transmit shift register, thus freeing TBUF for the next data to be sent. This is indicated by the transmit buffer interrupt request line TBIR being activated. TBUF may now be loaded with the next data, while transmission of the previous one continues. The data bits are transmitted synchronously with the shift clock. After the bit time for the 8^{th} data bit, both TXD and RXD will be set to high level, the transmit interrupt request line TIR is activated, and serial data transmission stops.

Note: The dedicated GPIO device pins that are connected to TXD and RXD must be configured by software as alternate data outputs in order to provide the shift clock and the output data during synchronous transmission.

33.14.4.2 Synchronous Reception

Synchronous reception is initiated by setting bit CON.REN = 1. If bit CON.R = 1, the data applied at RXD is clocked into the receive shift register synchronously to the clock which is output at TXD. After the 8^{th} bit has been shifted in, the contents of the receive shift register are transferred to the receive data buffer RBUF, the receive interrupt request line RIR is activated, the receiver enable bit CON.REN is reset, and serial data reception stops.

Synchronous reception is stopped by clearing bit CON.REN. Any Byte that is currently being received is completed, including the generation of the receive interrupt request and an error interrupt request, if appropriate. Writing to the transmit buffer register while a reception is in progress has no effect on reception and will not start a transmission.

If a previously received Byte has not been read out of the receive buffer register by the time the reception of the next Byte is complete, both the error interrupt request line EIR and the overrun error status flag CON.OE will be activated/set, provided that the overrun check has been enabled by bit CON.OEN.

Note: The dedicated GPIO device pin that is connected to TXD must be configured by software as alternate data output in order to provide the shift clock. The dedicated GPIO device pin that is connected to RXD must be configured by software as input during synchronous reception.

33.14.4.3 Synchronous Timing

Figure 33-31 shows timing diagrams of the ASC Synchronous Mode data reception and data transmission. In idle state, the shift clock is at high level. With the beginning of a synchronous transmission of a data Byte, the data is shifted out at RXD with the falling edge of the shift clock. If a data Byte is received through RXD, data is latched with the rising edge of the shift clock.

One shift clock cycle (f_{BR}) delay is inserted between two consecutive receive or transmit data Bytes.

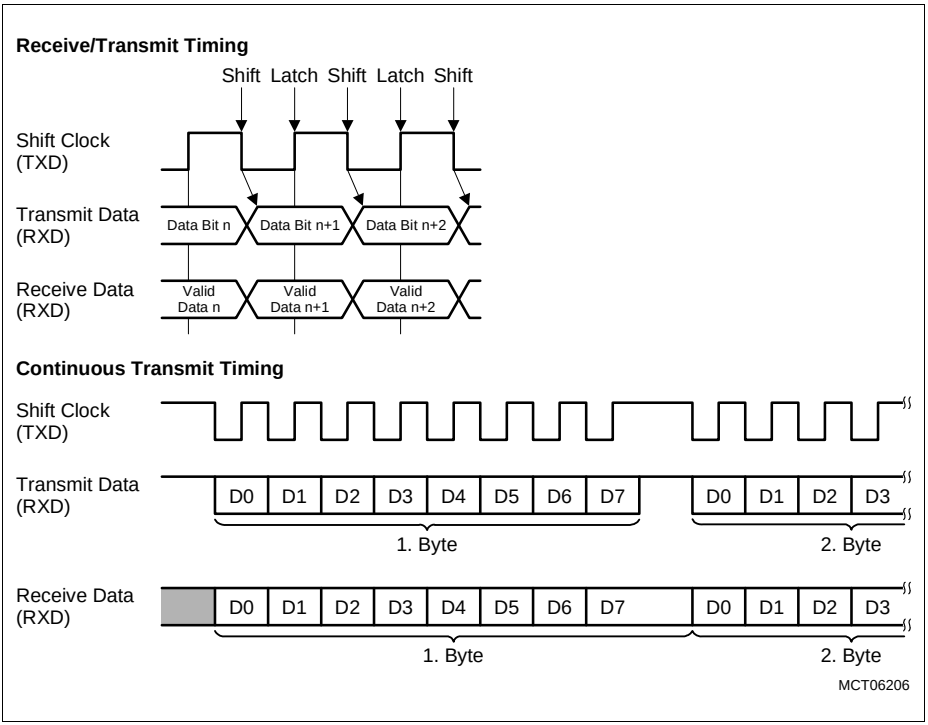

Figure 33-31 ASC Synchronous Mode Waveforms

33.14.5 Baud Rate Generation

The ASC has its own dedicated 13-bit baud rate generator with 13-bit reload capability, allowing baud rate generation independent of other timers.

The baud rate generator is clocked with a clock (f_{DIV}) which is derived via a prescaler from the ASC module clock f_{ASC}. The baud rate timer is counting downwards and can be started or stopped through the baud rate generator run bit CON.R. Each underflow of the timer generates one clock pulse to the serial channel. The timer is reloaded with the value stored in its 13-bit reload register at each underflow. The resulting clock f_{BRT} is again divided by a factor for the baud rate clock (÷ 16 in asynchronous operating modes and ÷ 4 in synchronous operating mode). The prescaler is selected by the bits CON.BRS and CON.FDE. In the asynchronous operating modes, a fractional divider prescaler unit is available (in addition to the two fixed dividers) that allows selection of prescaler divider ratios of n/2048 with n = 0-2047. Therefore, the baud rate of ASC is determined by the module clock, the content of register FDV, the reload value in register BG, and the operating mode (asynchronous or synchronous).

Register BG is the dual-function baud rate generator/reload register. Reading BG returns the contents of the timer in bit field BR_VALUE (bits 31:13 return zero), while writing to BG always updates the reload register (bits 31:13 are insignificant).

An auto-reload of the timer with the contents of the reload register is performed each time BG is written to. However, if CON.R = 0 at the time the write operation to BG is performed, the timer will not be reloaded until the first instruction cycle after CON.R = 1. For a clean baud rate initialization, BG should only be written if CON.R = 0. If BG is written with CON.R = 1, an unpredictable behavior of the ASC may occur during running transmit or receive operations.

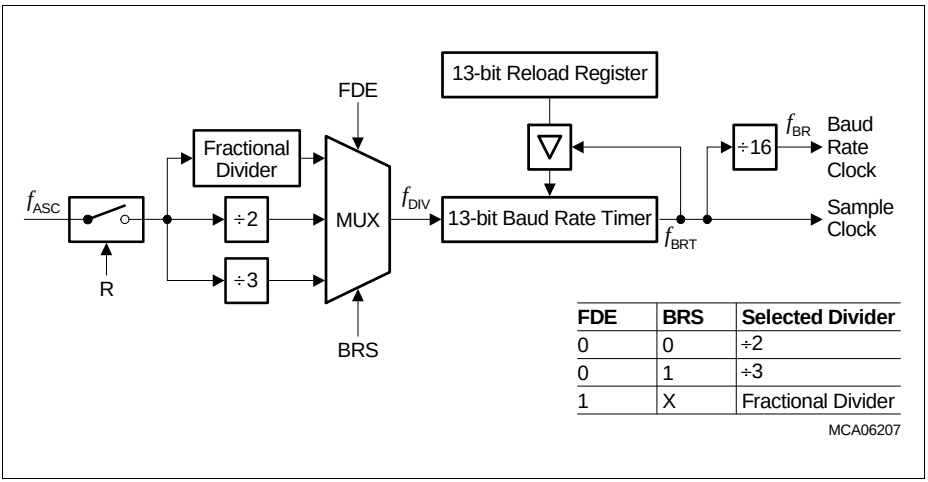
33.14.5.1 Baud Rates in Asynchronous Mode

For asynchronous operation, the baud rate generator provides a clock f_{BRT} with sixteen times the rate of the established baud rate. Every received bit is sampled on the 7th, 8th and 9th cycle of this clock. The clock divider circuitry, which generates the input clock f_{DIV} for the 13-bit baud rate timer, is extended by a fractional divider circuitry that allows the adjustment of more accurate baud rates and the extension of the baud rate range.

The baud rate of the baud rate generator depends on the settings of the following bits and register values:

- Input clock f_{ASC}
- Selection of the baud rate timer input clock f_{DIV} by bits CON.FDE and CON.BRS
- If bit CON.FDE = 1 (fractional divider): value of register FDV
- Value of the 13-bit reload register BG

The output clock of the baud rate timer with the reload register is the sample clock in the asynchronous operating modes of the ASC. For baud rate calculations, this baud rate clock f_{BR} is derived from the sample clock f_{BRT} by a division of sixteen.



FDE	BRS	Selected Divider
0	0	÷2
0	1	÷3
1	X	Fractional Divider

Figure 33-32 ASC Baud Rate Generator Circuitry in Asynchronous Modes

Using the Fixed Input Clock Divider

The baud rate for asynchronous operation of the serial channel ASC when using the fixed input clock divider ratios (CON.FDE = 0) and the required BG reload value for a given baud rate can be determined by the following formulas:

Table 33-2 Asynchronous Baud Rate Formulas using the Fixed Input Clock Dividers

FDE	BRS	BG	Formula
0	0	0 … 8191	Baud rate = f_{ASC} / (32 x (BG + 1)) BG = f_{ASC} / (32 x Baud rate) - 1
	1		Baud rate = f_{ASC} / (48 x (BG + 1)) BG = f_{ASC} / (48 x Baud rate) - 1

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer.

The maximum baud rate that can be achieved for the asynchronous operating modes when using the two fixed clock dividers and a module clock of 200 MHz is 6.25 Mbit/s.

Using the Fractional Divider

When the fractional divider is selected, the input clock f_{DIV} for the baud rate timer is derived from the module clock f_{ASC} by a programmable fractional divider. If CON.FDE = 1, the fractional divider is activated. It divides f_{ASC} by a fraction of n/2048 for any value of n from 0 to 2047. If n = 0, the divider ratio is 1, which means that $f_{DIV} = f_{ASC}$. In general, the fractional divider allows the baud rate to be programmed with much better accuracy than with the two fixed prescaler divider stages.

Note: In fractional divider mode, the clock f_{DIV} can have a maximum period jitter of one f_{ASC} clock period.

Table 33-3 Asynchronous Baud Rate Formulas using the Fractional Input Clock Divider

FDE	BRS	BG	FDV	Formula
1	–	0 … 8191	1 … 2047	Baud rate = (FDV / 2048) x (f_{ASC} / (16 x (BG + 1)))
			0	Baud rate = f_{ASC} / (16 x (BG + 1))

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer. FDV represents the contents of the fractional divider register bit field FDV.FD_VALUE, taken as an unsigned 11-bit integer.

33.14.5.2 Baud Rates in Synchronous Mode

For synchronous operation, the baud rate generator provides a clock f_{BRT} that runs with four times the established baud rate (see **Figure 33-33**).

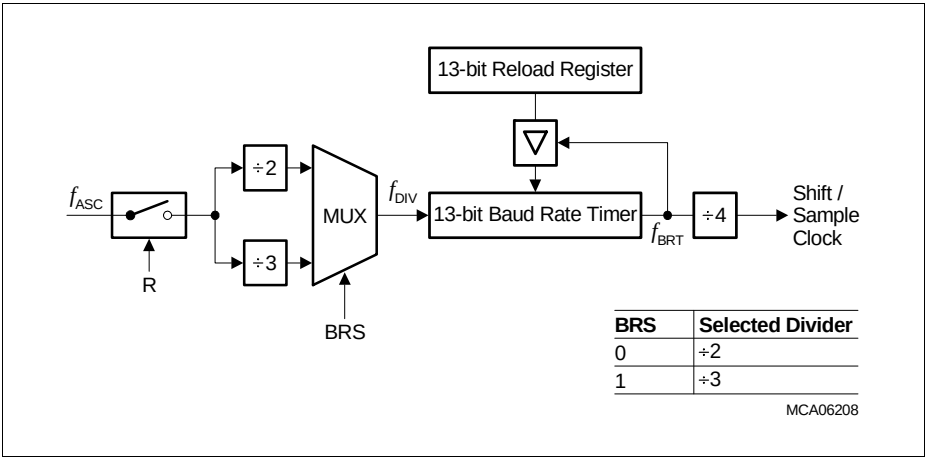


Figure 33-33 ASC Baud Rate Generator Circuitry in Synchronous Mode

The baud rate for synchronous operation of the serial channel ASC can be determined by the formulas as shown in **Table 33-4**.

Table 33-4 Synchronous Baud Rate Formulas

BRS	BG	Formula
0	0 … 8191	Baud rate = f_{ASC} / (8 x (BG + 1)) BG = f_{ASC} / (8 x Baud rate) - 1
1		Baud rate = f_{ASC} / (12 x (BG + 1)) BG = f_{ASC} / (12 x Baud rate) - 1

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer.

33.14.6 Hardware Error Detection Capabilities

To improve the reliability of serial data exchange, the serial channel ASC provides an error interrupt request flag that indicates the presence of an error and three (selectable) error status flags in register CON that indicate which error has been detected during reception. Upon completion of a reception, the error interrupt request line EIR will be activated simultaneously with the receive interrupt request line RIR, if one or more of the following conditions are met:

- If the framing error detection enable bit CON.FEN is set and any of the expected stop bits is not high, the framing error flag CON.FE is set, indicating that the error interrupt request is due to a framing error (asynchronous operating modes only).
- If the parity error detection enable bit CON.PEN is set in the modes where a parity bit is received and the parity check on the received data bits proves false, the parity error flag CON.PE is set, indicating that the error interrupt request is due to a parity error (asynchronous operating modes only).
- If the overrun error detection enable bit CON.OEN is set and the last character received was not read out of the receive buffer by software or DMA transfer at the time the reception of a new frame is complete, the overrun error flag CON.OE is set indicating that the error interrupt request is due to an overrun error (Asynchronous and Synchronous Modes).

33.14.7 Interrupts

Four interrupt sources are provided for serial channel ASC. Line TIR indicates a transmit interrupt, TBIR indicates a transmit buffer interrupt, RIR indicates a receive interrupt, and EIR indicates an error interrupt of the serial channel. The interrupt output lines TBIR, TIR, RIR, and EIR are synchronized to the PSI5-S kernel and routed by the INPs to the trigger output lines.

The cause of an error interrupt request EIR (framing, parity, overrun error) can be identified by the error status flags CON.FE, CON.PE, and CON.OE.

Note: By contrast to the error interrupt request line EIR, the error status flags CON.FE/CON.PE/CON.OE are not reset automatically but must be cleared by software.

For normal operation (that is, other than error interrupt), the ASC provides three interrupt requests to control data exchange via this serial channel:

- TBIR is activated when data is moved from TBUF to the transmit shift register.
- TIR is activated before the last bit of an asynchronous frame is transmitted, or after the last bit of a synchronous frame has been transmitted.
- RIR is activated when the received frame is moved to RBUF.

While the task of the receive interrupt handler is quite clear, the transmitter is serviced by two interrupt handlers. This provides advantages for the servicing software.

For single transfers, it is sufficient to use the transmitter interrupt (TIR), which indicates that the previously loaded data has been transmitted, except for the last bit of an asynchronous frame.

For multiple back-to-back transfers, it is necessary to load the following piece of data at least before the last bit of the previous frame has been transmitted. In Asynchronous Mode, this leaves just one bit-time for the handler to respond to the transmitter interrupt request; in Synchronous Mode, it is entirely impossible.

Using the Transmit Buffer Interrupt (TBIR) to reload transmit data provides the time necessary to transmit a complete frame for the service routine, as TBUF may be reloaded while the previous data is still being transmitted.

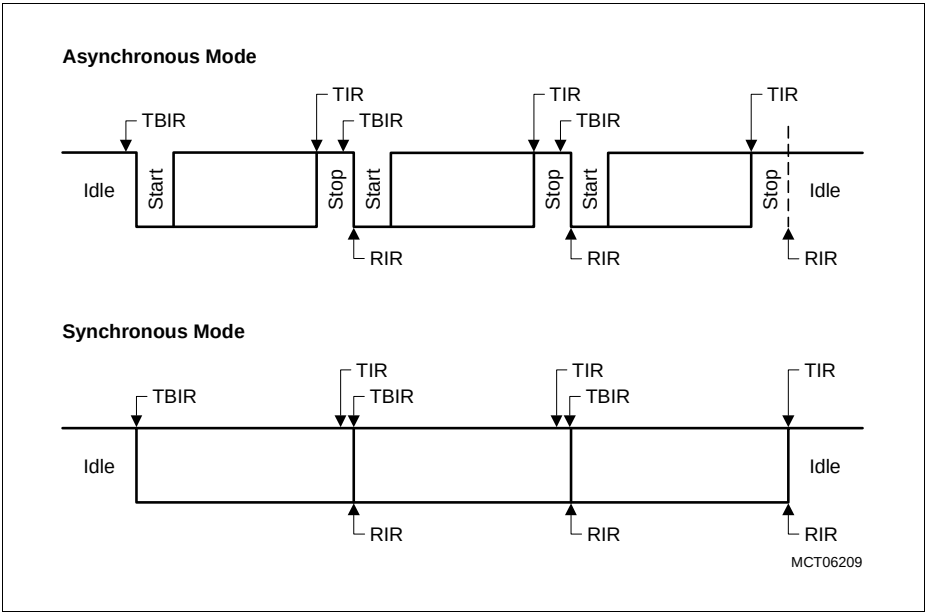

Figure 33-34 ASC Interrupt Generation

As shown in **Figure 33-34**, TBIR is an early trigger for the reload routine, while TIR indicates the completed transmission. Software using handshake should, therefore, rely on TIR at the end of a data block to ensure that all data has been transmitted.

33.15 Interrupts

8 Interrupt sources are available for the PSI5-S module. For each trigger source of a channel x one interrupt can be selected in register INPx.

RDI indicates a receive data interrupt. It is activated when a received frame is moved to Receive Data Register RDR.

RSI indicates a receive frame success interrupt, i.e. non of the interrupts/errors XCRCI, CRCI, TEI, PE, FE, OE, RBI or HDI was detected. The referring interrupt must be enabled in GCR to be considered for RSI. Both RDI and RSI will be issued together in normal use cases where reception is correct.

RBI indicates a receive buffer overrun interrupt. It is activated when a new frame is transferred to a Receive Data Register RDR while the old value was still not read by the host (“overwrite”), i.e. the kernel wants to set interrupt RDI and finds RDI already set.

TPI indicates a transmit interrupt. It is activated when data is completely moved from a SDR to ASC (TPI). Thus it can be used to trigger the next write access to SDR.

TPOI indicates a transfer (send) register (SDR) overrun interrupt. It is set if data is written to SDR while the referring register is locked (occupied), signalled by TPF. The data written is ignored in this case. FOI indicates that the output FIFO was overrun.

In addition the protocol error interrupts are available:

CRCI, XCRC. If CRC interrupt is activated, data is to be treated as invalid according to standard V2.0 2011-06. Note that the wrong data is still available in all buffers. For XCRCI, these frames are always stored in Channel 0 Frame 1.

TEI is issued by the watch dog timer if the timely distance between two frames is too long.

CHCI indicates that the last frame expected for a channel is received.

The interrupt request or the corresponding interrupt set bit (in register INTSET) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in register INTSTATx. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLR.
If more than one interrupt source is connected to the same interrupt node pointer (in register INPx all node pointer point to the same line), the requests are combined to one common line.

33.16 Trigger Outputs

Any interrupt source can be used as trigger output TRIGO outside the module. Each TRIGO is connected to the interrupt router. See **Table 33-7 “Service Request Lines of PSI5-S” on Page 33-140**.

33.17 PSI5-S Kernel Registers

This section describes the kernel registers of the PSI5-S module. All PSI5-S kernel register names described in this section will be referenced in other parts of the TC27x User's Manual by the module name prefix "PSI5S_" for the PSI5-S interface.

All registers in the PSI5-S address spaces are reset with the application reset (definition see SCU section "Reset Operation").

The complete and detailed address map of the PSI5-S module is described in **Table 33-5** on **Page 33-58**.

x can take the values 0 … 7 (PSI5-S channels)

List of Access Protection Abbreviations

U - User Mode

SV - Supervisor Mode

BE - Bus Error

nBE - no Bus Error

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

SE - Safety ENDINIT

Reset Classes

All registers belong to reset class 3 except OCS, which belongs to reset class 1.

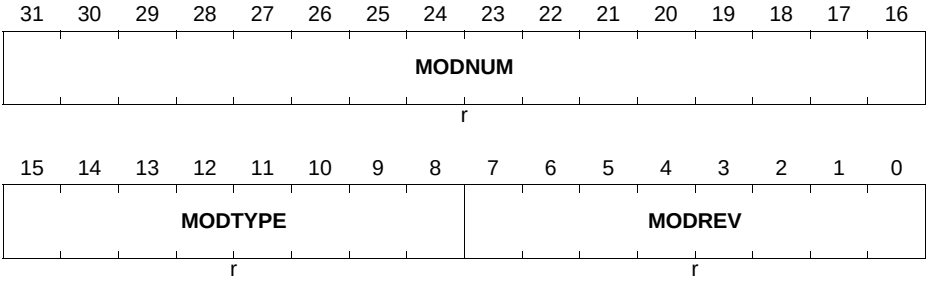
1) The absolute register address is calculated as follows:
Module Base Address (**Table 33-5**) + Offset Address (shown in this column)

33.17.1 Module Control

Module Identification Register

The PSI5-S Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register (008$_H$) Reset Value: 00D3 C0XX$_H$



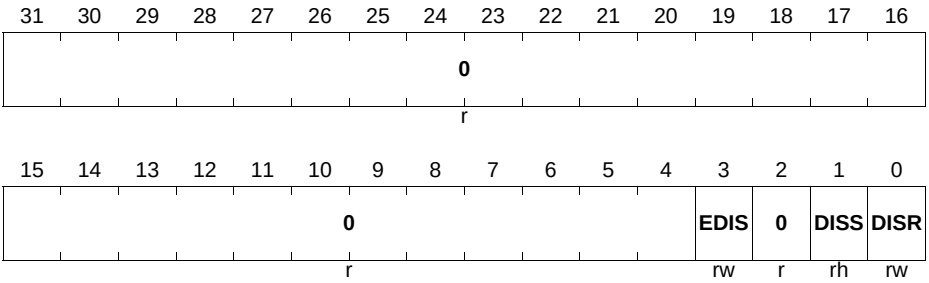
Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field defines the module as a 32-bit module: C0$_H$
MODNUM	[31:16]	r	**Module Number Value** This bit field defines the module identification number for the PSI5-S: 00D3$_H$

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock, sleep mode and disable mode for the module.

CLC

Clock Control Register **(000_H)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. *Note: This bit disables the kernel clocks $f_{CLC\_PSI5\text{-}S}$ and the ASC clock f_{BAUD2}.*
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**External Sleep Mode Request Disable Bit** Used to control module's sleep mode. *Note: If this bit is cleared the kernel clock $f_{CLC\_PSI5\text{-}S}$ and the ASC clock f_{BAUD2} are disabled during System Sleep Mode.*
0	[31:4], 2	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset operation, the clocks $f_{PSI5\text{-}S}$ and f_{BAUD2} are switched off and the PSI5-S module and the included ASC module are disabled (DISS set).

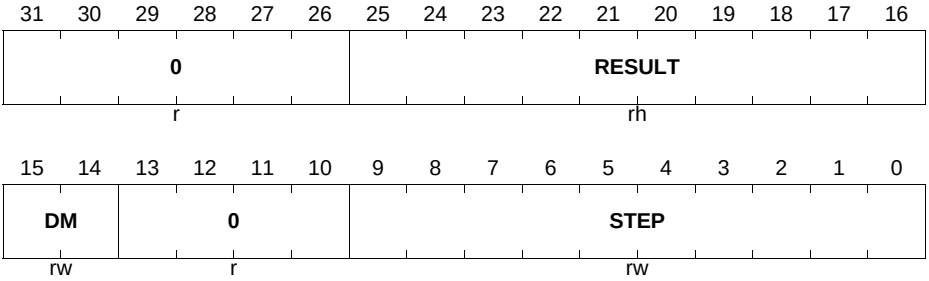
Fractional Divider Register

The Fractional Divider Register controls the clock $f_{PS5\text{-}S}$.

This bit field only controls the kernel clock $f_{PSI5\text{-}S}$ and not the sampling clock f_{BAUD2}.

FDR

PSI5-S Fractional Divider Register ($00C_H$) **Reset Value: $0000\ 0000_H$**



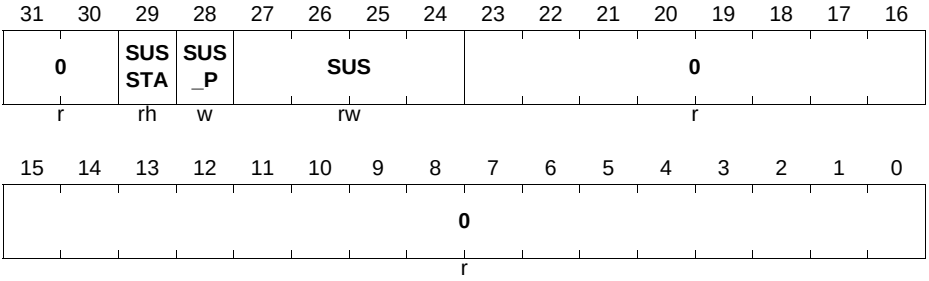
Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
DM	[15:14]	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.
0	[13:10], [31:26]	r	**Reserved** Read as 0; should be written with 0.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode.

OCS

OCDS Control and Status (3CC$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
SUS	[27:24]	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. 2_H Soft suspend option A (Suspends after end of current send or receive transfers, if any are ongoing) **others**, reserved *Note: Suspend disables the kernel clocks $f_{CLC\_PSI5\text{-}S}$ and the ASC clock f_{BAUD2}.*
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	[23:0], [31:30]	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... , EN31 -> TAG ID 011111B.

ACCEN0
Access Enable Register 0 **($3D0_H$)** **Reset Value: FFFF FFFF$_H$**

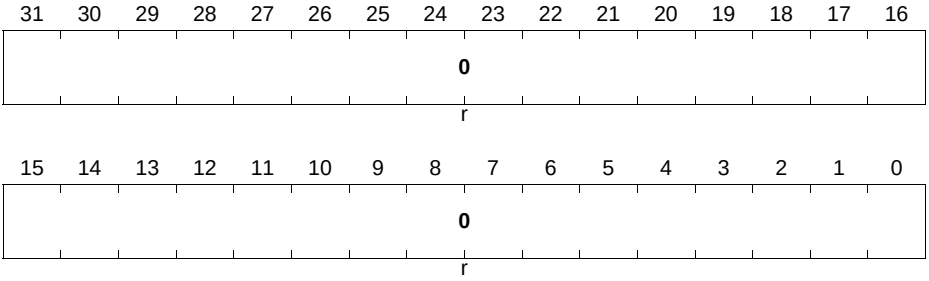
Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... , EN31 -> TAG ID 111111B.

ACCEN1
Access Enable Register 1 **($3D4_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

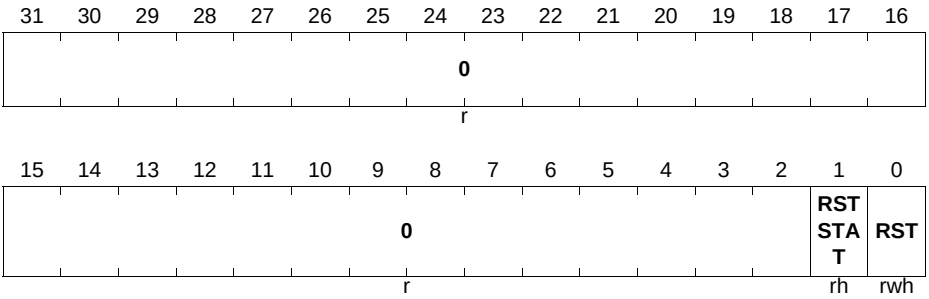
Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **(3D8$_H$)** **Reset Value: 0000 0000$_H$**

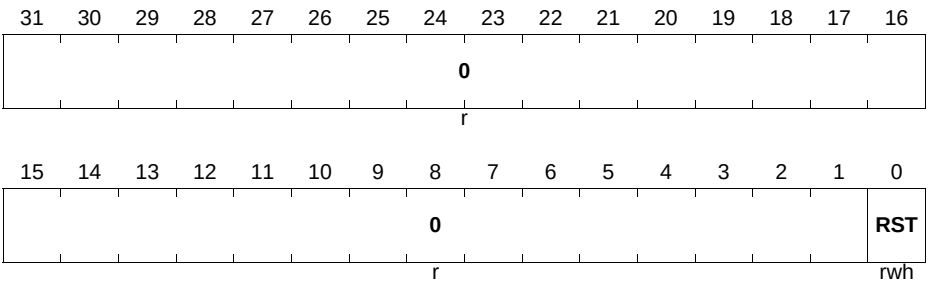


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **(3DC$_H$)** **Reset Value: 0000 0000$_H$**



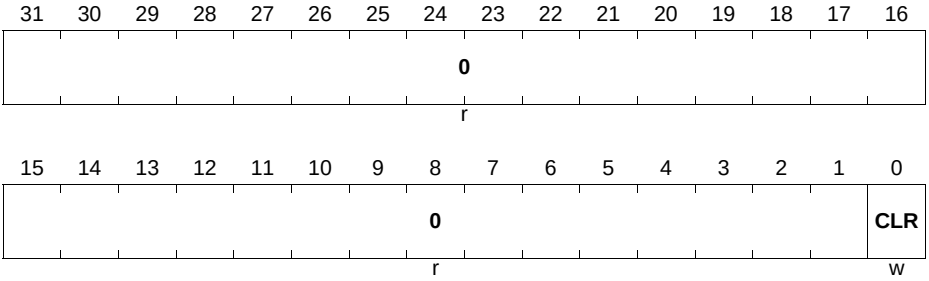
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register ($3E0_H$) **Reset Value: $0000\ 0000_H$**



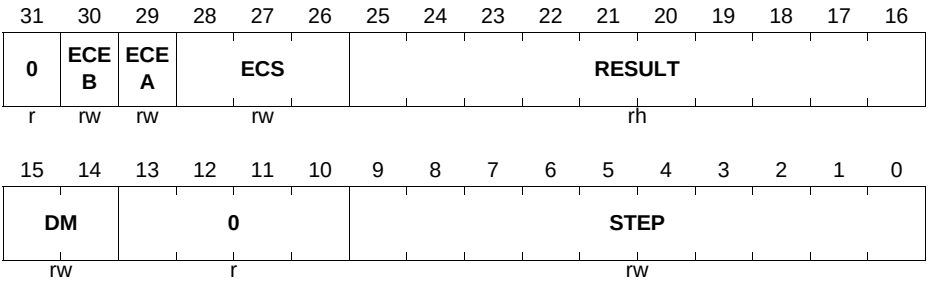
Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider Register for Time Stamp

The PSI5-S Module Time Stamp Predivider Register contains the pre divider that defines the time resolution of the Time Stamp Registers TSCNTA/B and the Sync Pulse Time Base Counter SBC. It divides $f_{PSI5\text{-}S}$ by a factor as given in **Equation (33.1)** and **Equation (33.2)**. It contains as well the bits for reset control of the Time Stamp Counters.

FDRT

Fractional Divider Register for Time Stamp (010_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
DM	[15:14]	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.
ECS	[28:26]	rw	**External Time Stamp Clear Source Select** Selects the external trigger line that clears the global Time Stamp Counters TSCNTA/B.CTS if this is enabled by ECEA/ECEB. 000_B TRIG0 001_B TRIG1 $\ldots_B$ … 111_B TRIG7

Field	Bits	Type	Description
ECEA	29	rw	**External Time Stamp Clear Enable A** Enables the external trigger line selected by ECS to clear the global Time Stamp Counter TSCNTA.CTS on rising edge of the external trigger. 0_B disabled 1_B enabled
ECEB	30	rw	**External Time Stamp Clear Enable B** Enables the external trigger line selected by ECS to clear the global Time Stamp Counter TSCNTB.CTS on rising edge of the external trigger. 0_B disabled 1_B enabled
0	31,[13:10]	r	**Reserved** Read as 0; should be written with 0.

Module Time Stamp Count Register A

This PSI5-S Module Time Stamp Counter Register contains read-only information about the current time given in clock cycles of f_{TS} or f_{TRIGx} since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSCNTA

Time Stamp Count Register A (014_H) Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
CTS	[23:0]	r	**Current Time Stamp for the Module** This bit field shows the current time stamp.
ETB	[26:24]	rw	**External Time Base Select** Selects the external clock line for counter CTS if TBS is set. 000_B TRIG0 001_B TRIG1 $\ldots_B$ … 111_B TRIG7
TBS	27	rw	**Time Base Select** This bit selects the clock source for CTS 0_B Internal, CTS counts in clock cycles of f_{TS} 1_B External, CTS counts in clock cycles received on external clock line selected by ETB
TBEA	28	rw	**Time Base Enable TSCNTA** This bit starts/stops TSCNTA.CTS 0_B CTS stopped (w/o clear of CTS) 1_B CTS started (w/o clear of CTS)

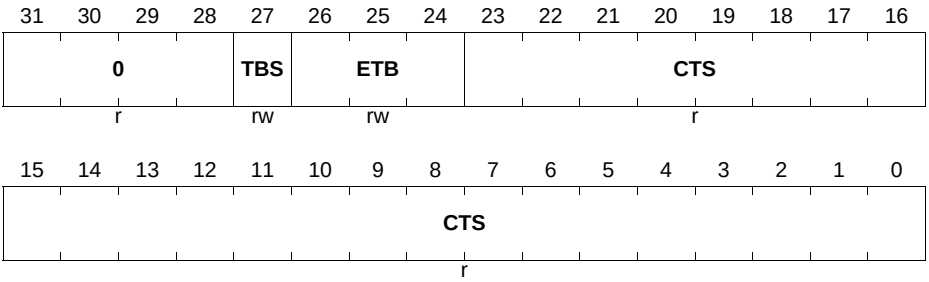
Field	Bits	Type	Description
TBEB	29	rw	**Time Base Enable TSCNTB** This bit starts/stops TSCNTB.CTS 0_B CTS stopped (w/o clear of CTS) 1_B CTS started (w/o clear of CTS)
CLRA	30	w	**Clear Time Stamp Counter A** This bit clears TSCNTA.CTS. TSCNTA.CTS counts on, starting from 0.
CLRB	31	w	**Clear Time Stamp Counter B** This bit clears TSCNTB.CTS. TSCNTB.CTS counts on, starting from 0.

Module Time Stamp Count Register B

This PSI5-S Module Time Stamp Counter Register contains read-only information about the current time given in clock cycles of f_{TS} or f_{TRIGx} since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSCNTB

Time Stamp Count Register B (018_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
CTS	[23:0]	r	**Current Time Stamp for the Module** This bit field shows the current time stamp.
ETB	[26:24]	rw	**External Time Base Select** Selects the external clock line for counter CTS. 000_B TRIG0 001_B TRIG1 $\ldots_B$ … 111_B TRIG7
TBS	27	rw	**Time Base Select** This bit selects the clock source for CTS 0_B Internal, CTS counts in clock cycles of f_{TS} 1_B External, CTS counts in clock cycles received on external clock line selected by ETB
0	[31:28]	r	**Reserved** Read as 0; should be written with 0.

Global Control Register

The Global Control Register defines module wide settings.

The first 8 bits define, which error flags are regarded at RSI. RSI indicates that the referring frame is free of the selected errors. Each of these errors can be selected: CRCI, XCRCI, TEI, PE, FE, OE, RBI, HDI.

GCR
Global Control Register **($01C_H$)** **Reset Value: 0000 001F$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

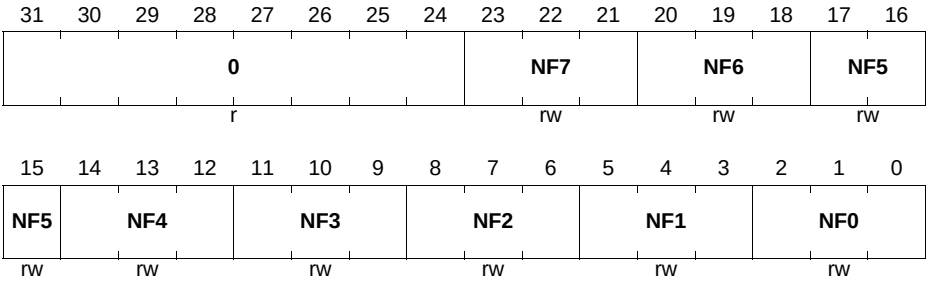
Field	Bits	Type	Description
CRCI	0	rw	**CRCI** is selected if bit is set.
XCRCI	1	rw	**XCRCI** is selected if bit is set.
TEI	2	rw	**TEI** is selected if bit is set.
PE	3	rw	**PE** is selected if bit is set.
FE	4	rw	**FE** is selected if bit is set.
OE	5	rw	**OE** is selected if bit is set.
RBI	6	rw	**RBI** is selected if bit is set.
HDI	7	rw	**HDI** is selected if bit is set.

Field	Bits	Type	Description
ETCx (x = 0-7)	8+x	rw	**Enable Channel Trigger Counter CTVx.CTC** This bit enables CTVx.CTC. The bits ETC0 ..x can be set with one write access to synchronously start all counters. This is required for proper sync pulse staggering. If set, CTCx counts on, starting from its current value. CTCx can be written only if ETCx is cleared (stopped).
CENx (x = 0-7)	16+x	rw	**Enable Channel x** This bit enables PSI5-S Channel x. If cleared, all internal state machines of the receiver and the sender are forced to default idle state while all registers can be read and written. Used for configuration of a channel. Frames received for a disabled channel are copied to ChID 0, FID 1 with original IDs.
IDT	[27:24]	rw	**Idle Time (GLOBAL VALUE FOR ALL CHANNELS)** determines the number of stop bits in addition to the stop bit of the last UART Frame that is required for SOF detection. (IDT-1) idle bit times are allowed/tolerated within one Packet Frame. Default is IDT = 0, i.e. back to back transfer. 0000_B 1 bit time idle 0001_B 2 bit times idle ... ... 1111_B 16 bit times idle
ASC	31	rw	**ASC only Mode** is selected if bit is set. The ASC registers are fully controllable by SW via SPB. If cleared, the ASC is controlled by the message reassembly unit and the message generation unit. RBUF and TBUF are no longer writable by SW and interrupts are handled by the message reassembly block automatically.
0	[30:28]	r	**Reserved** Read as 0; should be written with 0.

Number of Frames Control Register

This register contains the number of Packet Frames expected after a Sync Pulse.
It stores the compare values for the counters in register FCNT.
See **“FCNT” on Page 33-80**.

NFC
Number of Frames Control Register (020_H) **Reset Value: $0024\ 9249_H$**



Field	Bits	Type	Description
NFx (x = 0-7)	[3*x+2: 3*x]	rw	**Number of expected Frames on Channel x** 000_B reserved, do not use! Reads back 1. 001_B 1 $…_B$ … 110_B 6 111_B reserved, do not use! Reads back 6.
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

Number of Frames Count Register

This register contains the number of Packet Frames actually received after the last Sync Pulse. A Sync Pulse on channel x will clear FCx.

If FCNT.FCx equals NFC.NFx interrupt CHCI is issued and FCNT.FCx will roll over to '1' with the reception of the next recoverable message on channel x. The roll over happens in any case, even if no Sync Pulse clears FCx after CHCI.

If RCRAx.WDMS is set, NFC and FCNT affect the operation of the watch dog timer. See **"Watch Dog Timers" on Page 33-18**.

NFC and FCNT also affect the generation of interrupt CHCI. See **"Interrupts for DMA support" on Page 33-36**.

FCNT
Frame Counter Register **(024_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

FC5	FC4			FC3				FC2			FC1			FC0	
r	r			r				r			r			r	

Field	Bits	Type	Description
FCx (x = 0-7)	[3*x+2: 3*x]	r	**Frame Counter for Channel x** Contains the number of received frames on Channel x. Copied to RDR.FID if RCRAx.FIDS is set. 000_B 0 (after reset, Sync (if WDMS is set only) or setting NFCLRx) 001_B 1 $…_B$ … 110_B 6 111_B not valid
NFCLRx (x = 0-7)	x+24	w	**Clear Number of Frame Counter for Channel x** Clears the referring counter FCNT.FCx. Intended for use during recovery from TEI. If set while a frame is being received, this action results in FCx = '1'. Thus FCx will never be '0' when RDI/RSI signal a new receive frame. Use with care!

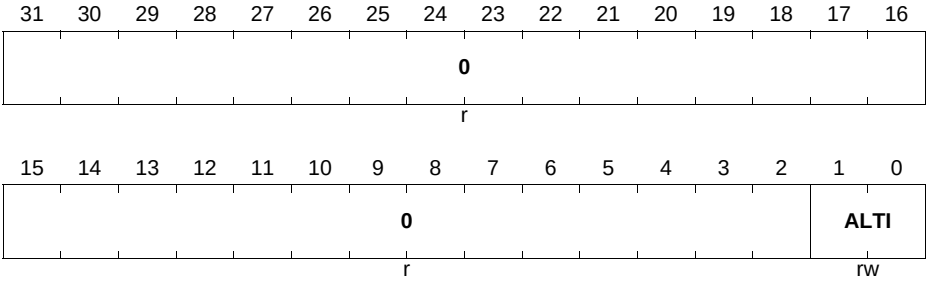
33.17.2 Input and Output Control

Input and Output Control Register Functions

The Input and Output Control Register IOCRx determines for the PSI5-S channel x:

- the alternate input for the receiver

IOCR
Input and Output Control Register (028_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
ALTI	[1:0]	rw	**Alternate Input Select** Selects the alternate input for RX of the ASC: 00_B Alternate Input 0 selected 01_B Alternate Input 1 selected …$_B$ … 11_B Alternate Input 3 selected
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

33.17.3 Receiver Control Registers

Receiver Control Register Ax

The Receiver Control Registers RCRAx contain control bits/bit fields that are related to the PSI5-S receiver operation. It enables the channel and determines the use of CRC or parity. CENx must be clear for write access.

RCRAx (x = 0-7)
Receiver Control Register Ax **(030_H+x*4)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				UFC5		UFC4		UFC3		UFC2		UFC1		UFC0	
r				rw		rw		rw		rw		rw		rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					WDMS	FIDS	TSTS	TSP	TSEN	CRC5	CRC4	CRC3	CRC2	CRC1	CRC0
r					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
CRCy (y = 0-5)	y	rw	**CRC or Parity Selection** If set, a 3 bit CRC checksum is expected for the PSI5-S channel x in slot y. Else, 1 bit Parity is assumed. This bit field is looked up before potential modification of FID according to FIDS. 0_B 1 Parity Bit is configured (default) 1_B 3 CRC bits are configured
TSEN	6	rw	**Time Stamp Enable** Enables the time stamping for channel x 0_B off (default) TSCRx and thus TSM are forced to 0x0000 0000! 1_B on, see TSP and TSTS
TSP	7	rw	**Time Stamp Select** For non recoverable Packets (stored in ChID ‘0’, FID ’1’ with original IDs); TSCNTA is captured in TSM and not in TSCR0 (independent from TSP). 0_B TSCNTA.CTS is captured in TSCRx 1_B TSCNTB.CTS is captured in TSCRx

Field	Bits	Type	Description
TSTS	8	rw	**Time Stamp Trigger Select** 0_B On Sync Pulse. TSCRx is updated on Sync Pulse. TSM is updated from TSCRx on Packet Frame reception after ChID extraction. For non recoverable Packets (stored in ChID ‘0’, FID ’1’ with original IDs); TSCR0 is not updated and TSM is updated with the current value of TSCNTA (independent from TSP). This happens at the time the FSM assumes the Packet Frame to be non recoverable. This allows following good packets to be time stamped correctly. 1_B On any Frame. TSCRx and TSM are updated simultaneously with the current value of TSCNTA/B depending from RCRAx.TSP on Packet Frame reception after ChID extraction. (RDI) This allows SW to read the time of reception on the referring channel from TSCRx. For non recoverable Packets (stored in ChID ‘0’, FID ’1’ with original IDs), TSM is updated with the current value of TSCNTA (independent from TSP and TSEN). This happens at the time the FSM assumes the Packet Frame to be non recoverable. TSCR0 is updated only if RCRA0.TSTS is set (‘1’)
FIDS	9	rw	**Frame ID Select** 0_B Frame ID is updated from Packet Frame Header (sync mode). Channel 0 should have FIDS cleared. This avoids that the module overwrites non recoverable messages with Transceiver Messages. Note that non recoverable messages are always stored in ChID ‘0’, FID ’1’ with original IDs. 1_B Frame ID is a rolling number 0 .. 5 copied from FCNT.(FCx-1) (async mode) Non recoverable messages are still stored in ChID ‘0’, FID ’1’ with original IDs.

Field	Bits	Type	Description
WDMS	10	rw	**Watch Dog Timer Mode Select** 0_B Watch Dog Timer is restarted on reception of each recoverable frame on Channel x (async mode). 1_B Watch Dog Timer is restarted on Sync Pulse and stopped at reception of the last frame configured in NFC.NFx.(sync mode)
UFCy (y = 0-5)	[2*y+17 :2*y+16]	rw	**UART Frame Count per Packet Frame in Slot y** This bit field defines the number of UART Frames per Packet Frame that are expected for Slot y. This bit field is looked up before potential modification of FID according to FIDS. 00_B 3 UART Frames 01_B 4 UART Frames 10_B 5 UART Frames 11_B 6 UART Frames
0	[31:28], [15:11]	r	**Reserved** Read as 0; should be written with 0.

Receiver Control Register Bx

The Receiver Control Registers RCRBx configures the number of payload bits and implicitly the number of UART Frames (Bytes) each of the up to 6 slots in channel x. CENx must be clear for write access.

RCRBx (x = 0-7)
Receiver Control Register Bx **(050_H+x*4)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

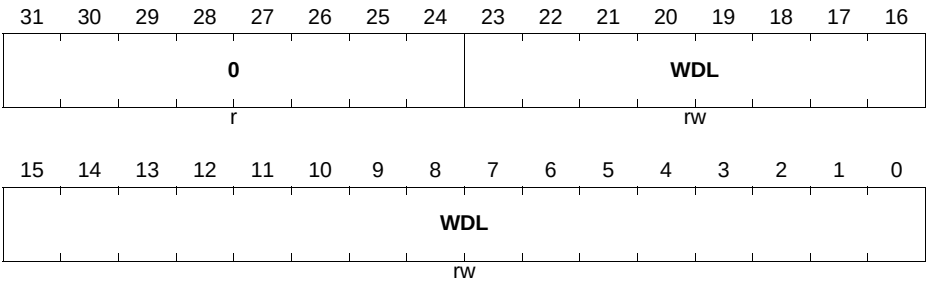
PDL 3		**PDL2**				**PDL1**					**PDL0**				
rw		rw				rw					rw				

Field	Bits	Type	Description
PDLy (y = 0-5)	[5*y+4: 5*y]	rw	**Payload Data Length** PDL determines the number of bits in a Packet Frame frame for Slot y. It also determines the position of the CRC/Parity bit. E.g. 8 defines 8 data bits on position [7:0]. On bit position 8 the CRC/Parity is located. See **Figure 33-4**. If PDLy is cleared (‘0’) no frame is expected for this slot. Packet Frames received for a slot with PDL = ‘0’ are copied to ChID 0, FID 1 with original IDs without further processing. This bit field is looked up before potential modification of FID according to RCRAx.FIDS. 00000_B No Frame expected! 00001_B 8 bits ... ... 01000_B 8 bits 01001_B 9 bits ... ... 11100_B 28 bits ... ... 11111_B 28 bits
0	[31:30]	r	**Reserved** Read as 0; should be written with 0.

Watch Dog Timer Register

WDTx (x = 0-7)
Watch Dog Timer Register x **(070_H+x*4)** **Reset Value: 0000 0000_H**



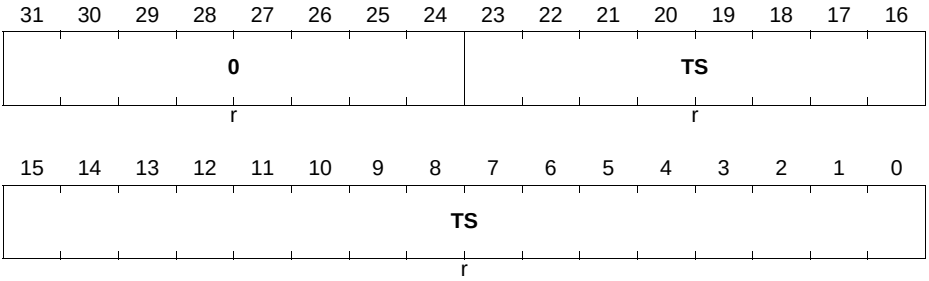
Field	Bits	Type	Description
WDL	[23:0]	rw	**Watch Dog Timer Limit** for channel x. If no watch dog is needed, WDL is cleared, the internal watch dog timer is stopped and no check is performed. CENx must be clear for write access.
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

33.17.4 Receive Data and Status Registers

Start of Pulse Time Stamp Capture Register TSCRx

If RCRAx.TSEN is set, the time stamp is captured in this register each time a sync pulse is sent from the ASC FIFO to the ASC TX buffer for channel x. RCRAx.TSP selects, if TSCNTA or B is used.

TSCRx (x = 0-7)
Capture Register TSCRx **(090_H+x*4)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TS	[23:0]	r	**Time Stamp** of the last sync pulse sent for channel x.
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

Receive Status Registers RDS

The Receive Status Register RDS shows the status of a received data frame.

The internal receive buffer is always cleared (0x0000 0000$_H$) at each frame start. Thus unused bits are always read as zero.

The bits CRCI, XCRCI, HDI, PE, FE, OE, TEI and RBI reflect, wether the conditions are met to issue an interrupt signal and set the referring interrupt status bit in INTSTAT or CON (ASC sub module) for the latest frame. Thus it is independent from the old status of the referring sticky bit in INTSTAT or CON before latest frame reception.

RDS
Receive Status Register (0B0H) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Field	Bits	Type	Description
XCRCy (y = 0-5)	y	r	**XCRC** CRC of last Packet Frame. XCRC0 is on bit position 0.
XCRCI	6	r	**XCRC Error Flag** This bit is set if the CRC check on the enveloping Packet Frame fails including the case where XCRC check can not be performed (non recoverable frames) see **Chapter 33.5.1.1**. 0_B correct XCRC 1_B wrong XCRC
CRCy (y = 0-2)	7+y	r	**CRC** of last frame. CRC0 / Parity is on bit position 7. If Parity is used, CRC1/2 are always 0.

Field	Bits	Type	Description
CRCI	10	r	**CRC Error Flag** This bit is set if the CRC or Parity check on the transported PSI5 frame fails. 0_B correct CRC/Parity 1_B wrong CRC/Parity
ERR0	11	r	**Error signalling Flag 0** This bit represents the status of the error signalling flag Err0 in the enveloping Packet Frame.
ERR1	12	r	**Error signalling Flag 1** This bit represents the status of the error signalling flag Err1 in the enveloping Packet Frame.
HDI	13	r	**Header Error Signalled Flag** This bit is set if at least one of the error signalling flags in the enveloping Packet Frame Err0 and Err1 is set. 0_B (Err0 OR Err1) = false (0) 1_B (Err0 OR Err1) = true (1)
PE	14	r	**ASC Parity Error Flag** This bit is set if the error flag signalling a parity error was set during reception of one of the ASC Bytes transporting this PSI5 frame.
FE	15	r	**ASC Framing Error Flag** This bit is set if the error flag signaling a framing error was set during reception of one of the ASC Bytes transporting this PSI5 frame.
OE	16	r	**ASC Overrun Error Flag** This bit is set if the error flag signaling an overrun error was set during reception of one of the ASC Bytes transporting this PSI5 frame.

Field	Bits	Type	Description
TEI	17	r	**Time Error Flag** This bit is set if the watch dog timer expired. Depending from RCRAx.WDMS either the distance between two RDIs is longer than specified in WDL or it expired without reception of CHCI in time. I.e. the time from issuing the sync pulse to reception of the last expected frame configured in NFC.NFx was too long. If WDMS is in synchronous mode, all frames after TEI have TEI set in RDS until either CHCI is issued or INSTATx.TEI is cleared by SW. RDS.TEI flag is independently from INTENx.TEI. 0_B no error 1_B error
RBI	18	r	**Receive Buffer Overflow Flag** This bit is set after a frame has been received while the old one was not read from RDR. I.e. the kernel wants to set interrupt RDI and finds RDI already set. The old data is overwritten by the new data. 0_B No overflow 1_B Overflow
FID	[21:19]	r	**Frame ID (Frame Number)** See bit RCRAx.FIDS for actual content. 000_B Slot 0 001_B Slot 1 $\ldots_B$ … 101_B Slot 5 110_B not valid, frame is copied to ChID 0, FID 1 with original IDs 111_B not valid, frame is copied to ChID 0, FID 1 with original IDs
CID	[24:22]	r	**Channel ID (Channel Number)** 000_B channel 0 001_B channel 1 $\ldots_B$ … 110_B channel 6 111_B channel 7
AFC	[27:25]	r	**Actual UART Frame Count** This bit field shows the number of UART frames actually received. This is used to further analyze non recoverable frames by SW or during debugging.

Field	Bits	Type	Description
PFC	[31:28]	r	**Packet Frame Count** For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.

Receive Data Registers RDR

The Receive Data Register RDR shows the data content of a received data frame. If Messaging bits are used, they are located on bit position [1:0].

The internal receive buffer is always cleared (0x0000 0000$_H$) at each frame start. Thus unused bits are always read as zero.

RDR
Receive Data Register (0B4H) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PFC				RD27	RD26	RD25	RD24	RD23	RD22	RD21	RD20	RD19	RD18	RD17	RD16
r				r	r	r	r	r	r	r	r	r	r	r	r

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

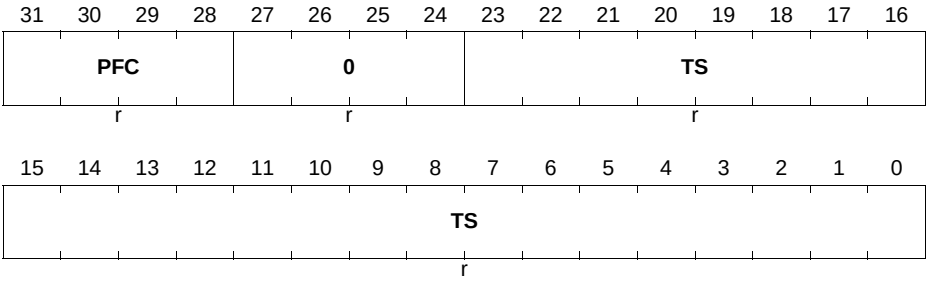
Field	Bits	Type	Description
RDy (y = 0-27)	y	r	**PSI5 Receive Data** of last frame. D0 is on bit position 0.
PFC	[31:28]	r	**Packet Frame Count** For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.

Time Stamp Mirror Register TSM

Each time a new frame is received, the value from TSCRx for the referring channel is mirrored here. This register is updated, after XCRC was checked ok, as the referring channel number can not be securely determined before.

TSM

Time Stamp Mirror Register TSM ($0B8_H$) Reset Value: $0000\ 0000_H$

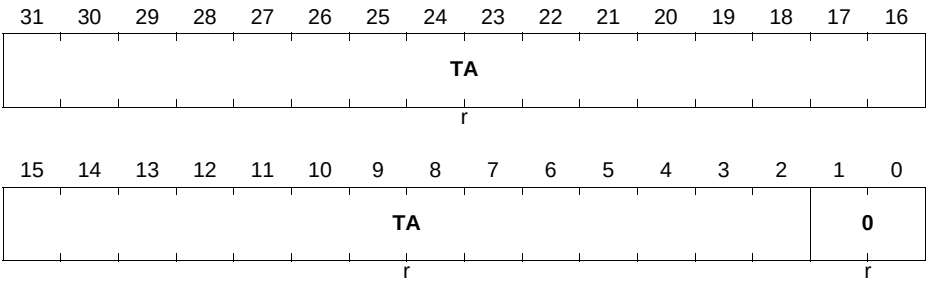


Field	Bits	Type	Description
TS	[23:0]	r	**Time Stamp** of the last sync pulse sent on channel x.
PFC	[31:28]	r	**Packet Frame Count** For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.
0	[27:24]	r	**Reserved** Read as 0; should be written with 0.

Target Address Registers TAR

TAR contains the address that is to be copied by the first DMA into the target address register of the second DMA. This is required for the use case with 2 DMAs. See **“DMA Support” on Page 33-27**

TAR
Target Address Register **($0D0_H$)** **Reset Value: $0000\ 0000_H$**



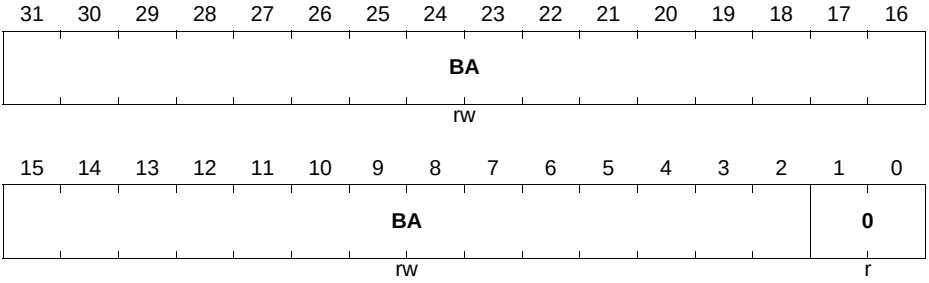
Field	Bits	Type	Description
0	[1:0]	r	**Reserved** Read as 0; should be written with 0.
TA	[31:2]	r	**Target Address** Contains the upper 30 bit of the target address for the next DMA transfer. The 32 bit target address must be word aligned. Thus the 2 LSBs are fixed to 0. It is updated each time a new Packet Frame is received completely.

Base Address Registers BAR

BAR contains the address in the system memory where the PSI5-S buffer for all channels is built up.

BAR must be configured by the application for an address space that is big enough for all channels that are enabled. TAR will wrap around after the upper limit (0xFFFF FFFF) if adding the offsets (based on ChID and FID) exceeds this limit.

BAR
Base Address Register **($0D4_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
0	[1:0]	r	**Reserved** Read as 0; should be written with 0.
BA	[31:2]	rw	**Base Address** Contains the upper 30 bits of the base address for the DMA transfers. The 32 bit base address must be word aligned. Thus the 2 LSBs are fixed to 0.

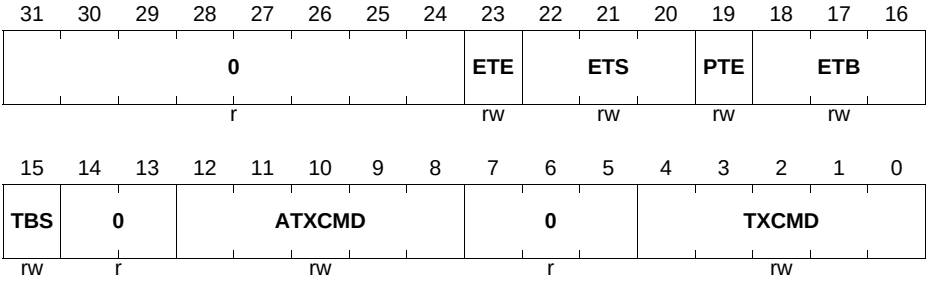
33.17.5 Sync Pulse Control

Pulse Generation Control Registers PGCx

The Pulse Generation Control Register PGC contains control data for the sync pulse generation. It contains as well the trigger control bits required for sending data from the PSI5-S module to the sensor / external PHY.

PGCx (x = 0-7)

Pulse Generation Control Register x($0F0_H$+x*4) **Reset Value: $0000\ 0000_H$**



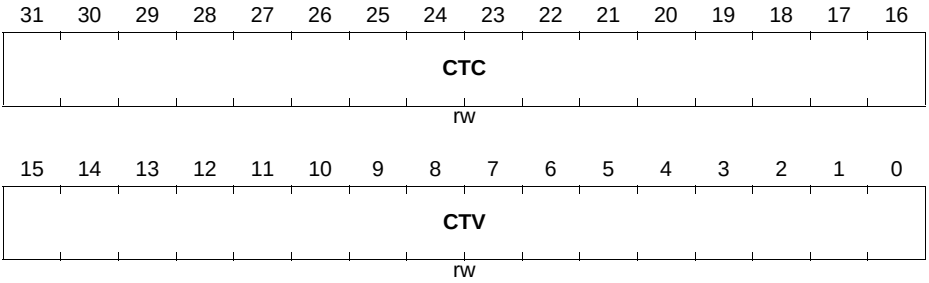
Field	Bits	Type	Description
TXCMD	[4:0]	rw	**TX Command** Defines the value that is copied to the ASC FIFO for coding a ‘0’.
ATXCMD	[12:8]	rw	**Alternate TX Command** Defines the value that is copied to the ASC FIFO for the alternate pulse width i.e. for coding a ‘1’.
TBS	15	rw	**Time Base Select** This bit selects the clock source for CTVx 0_B Internal, CTV counts in clock cycles of f_{TS} 1_B External, CTV counts in clock cycles of f_{TRIGx} according to the setting of bit ETB.
ETB	[18:16]	rw	**External Time Base Select** Selects the external clock line for counter CTVx. 000_B TRIG0 001_B TRIG1 $\ldots_B$ … 111_B TRIG7
PTE	19	rw	**Periodic Trigger Enable** Periodic trigger is defined by CTVx. Should be 0 if ETE is set. 0_B disabled 1_B enabled

Field	Bits	Type	Description
ETS	[22:20]	rw	**External Trigger Select** Selects the external trigger line for pulse generation (e.g. angle synchronous). 000_B TRIG0 001_B TRIG1 $\ldots_B$ … 111_B TRIG7
ETE	23	rw	**External Trigger Enable** “Angle sync. trigger”, external line is selected by ETS. Should be 0 if PTE is set. 0_B disabled 1_B enabled
0	[31:24], [14:13], [7:5]	r	**Reserved** Read as 0; should be written with 0.

Channel Trigger Value Register CTVx

CTV contains the value that determines the period of periodic triggers for each channel. It contains as well the counter that can be initialized with an offset so that the phase of harmonic trigger frequencies on different channels can be staggered.

CTVx (x = 0-7)
Channel Trigger Value Register x (110_H+x*4) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CTV	[15:0]	rw	**Channel Trigger Value CTV** Contains the compare value (exact match) of Channel Trigger CTC at which a sync pulse is triggered for channel x and the counter CTC is cleared. If cleared, CTC is stopped and no pulse triggered.
CTC	[31:16]	rw	**Channel Trigger Counter** This bit field allows to read the current counter value of the reset timer cell CTVx. If GCR.ETCx is cleared, CTC can be written.

Send Control Registers SCRx

The Send Control Register SCRx contains control data bits required for sending data from the PSI5-S module to the sensor / external PHY.

Data is collected in SDRx and the control bits are collected in SCRx.

The send control unit is build to transmit complete ECU to sensor frames.

SCRx (x = 0-7)
Send Control Register x **(130_H+x*4)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					TPF	0		STA	CRC	0					
r					r	r		rw	rw	r					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	FLUS	0					BSC	EPS		0	PLL				
r	w	r					rw	rw		r	rw				

Field	Bits	Type	Description
PLL	[4:0]	rw	**Pay Load Length of Registers SDRx** Defines the length that is taken into account: 00000_B length is 6 00001_B length is 6 ... ... 00110_B length is 6 ... ... 11000_B length is 24 ... ... 11111_B length is 24 PLL needs to written before SDRx is used for proper operation.
EPS	[7:6]	rw	**Enhanced Protocol Selection** EPS[0] controls the Bit Format and MSB Fill bit. (0: Tooth Gap, MSB Fill 1) (1: PWM, MSB Fill 0) EPS[1] controls the Frame Format (0: Frame Format 1 - 3) (1: Frame Format 4) 00_B Tooth Gap Method, '1' for filling the shift register from MSB; Frame format 1 -3 (3 bit start sequence, 3 bit stuffing distance, '1' for stuffing, 3 bit CRC). 01_B Pulse Width Method, '0' for filling the shift register from MSB; Frame format 1 -3 (3 bit start sequence, 3 bit stuffing distance, '1' for stuffing, 3 bit CRC). 10_B reserved, do not use! 11_B Pulse Width Method, '0' for filling the shift register from MSB; Frame Format 4 (9 bit start sequence, 6 bit stuffing distance, '0' for stuffing, 6 bit CRC).
BSC	8	rw	**Bit Stuffing Control** 0_B No automatic bit stuffing 1_B Automatic bit stuffing is enabled. Depending from bit EPS[1] after 3 bits a '1' is inserted (Frame Format 1 -3) or after 6 bits a '0' is inserted (Frame Format 4)

Field	Bits	Type	Description
FLUS	14	w	**Flush SDRx** Setting this bit stops shifting out the data in SDRx, the start sequence or CRC if any and clears the referring FSMs and counters, if EPS[0]=0 SDRx is flushed by setting all bits if EPS[0]=1 SDRx is flushed by clearing all bits clears TPF TPIx is issued at the end of successful flushing. Reads always as zero.
CRC	22	rw	**CRC Generation Control** 0_B CRC is not generated automatically, it still can be written by SW together with the data (e.g. to test the remote CRC) 1_B CRC is automatically generated by HW (according to EPS[1])
STA	23	rw	**Start Sequence Generation Control** 0_B no start sequence generated, shifting out payload starts at bit 0! 1_B automatically generated by HW (according to EPS[1]) shifting out payload starts after 3/9 bits (EPS[1] = 0/1)
TPF	26	r	**Transmit in Progress Flag** If set, data preparation and transmission is in progress: start sequence or CRC or stuffing bits or data from SDRx are being transferred. It is cleared automatically after preparation and transmitting is finished. If set, write access to SDRx will not change any data and issue TPOI.
0	[31:27], [25:24],[21:15], [13:9],5	r	**Reserved** Read as 0; should be written with 0.

Send Data Registers SDRx

The Send Data Register SDRx shows the data content of a data frame to be sent. CENx must be set for write access. For initialization SCRx.FLUS can be used.

SDRx (x = 0-7)
Send Data Register x **(150_H+x*4)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								SD23	SD22	SD21	SD20	SD19	SD18	SD17	SD16
r								rw	rw	rw	rw	rw	rw	rw	rw

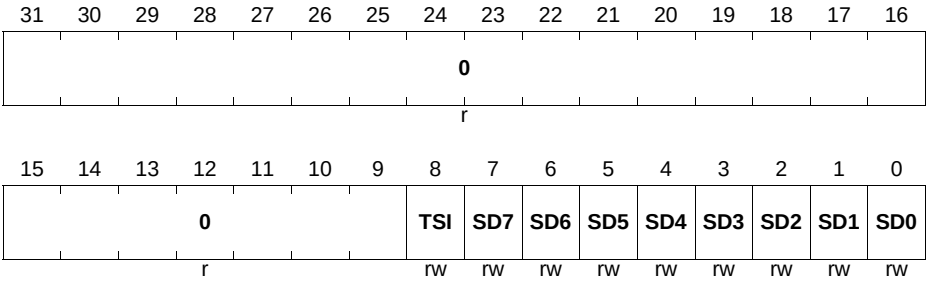
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SD15	SD14	SD13	SD12	SD11	SD10	SD9	SD8	SD7	SD6	SD5	SD4	SD3	SD2	SD1	SD0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
SDy (y = 0-23)	y	rw	**SDy** Send data of next ECU to Sensor frame. Each time a bit is shifted out, the whole content is shifted right by 1 position and the MSB is filled with ‘1’ or ‘0’ depending from EPS[0]. This allows to read back SDR and determine the status of the shift process by SW. The unused MSBs (bit position SCRx.PLL and higher) must be written with ‘0’ if EPS[0] is set (PWM Method) and with ‘1’ if EPS[0] is cleared (Tooth Gap Method). This is required, as the respective standard value is shifted into the register from MSB during shift out operation. SDRx will be filled with this value after shift out process.
0	[31:24]	r	**Reserved** Read as 0.

CPU Direct Write Registers CDW

The CPU Direct Write Register CDW allows the CPU to insert a command into the ASC FIFO. Note that Bits SD[7:5] select the channel for which the time stamp is captured. These bits are copied to the UART Frame Bit positions [2:0] (ChID) while SD[4:0] are copied to UART Frame Bit positions [7:3] (Command). See **Figure 33-6**.

CDW
CPU Direct Write Register **(170_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SDy (y = 0-7)	y	rw	**SDy** Send data of next ECU to Sensor frame.
TSI	8	rw	**Trigger Pulse Indicator** If this bit is set, a sync pulse is assumed and thus a time stamp is captured when the command leaves the FIFO and is written to ASC TX Register. Bits SD[7:5] select the channel for which the time stamp is captured. RCRAx.TSTS must be cleared. If set, the time stamp is captured on Packet Frame reception only.
0	[31:9]	r	**Reserved** Read as 0.

33.17.6 ASC Registers

The serial operating modes of the ASC module are controlled by its Control Register CON. This register contains control bits for mode and error check selection, and status flags for error identification.

CON
Control Register **(210_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
M	[2:0]	rw	**Mode Selection** 000_B 8-bit dataSynchronous Mode. MTX needs to be cleared as well for proper operation. 001_B 8-bit data Asynchronous Mode 010_B Reserved. Do not use this combination. 011_B 7-bit data + parity Asynchronous Mode 100_B 9-bit data Asynchronous Mode 101_B 8-bit data + wake up bit Asynchronous Mode 110_B Reserved. Do not use this combination. 111_B 8-bit data + parity Asynchronous Mode
STP	3	rw	**Number of Stop Bit Selection** 0_B One stop bit 1_B Two stop bits
REN	4	r	**Receiver Enable Control** 0_B Receiver disabled 1_B Receiver enabled Bit is reset by hardware after reception of a Byte in Synchronous Mode.
PEN	5	rw	**Parity Check Enable (asynchronous mode only)** 0_B Ignore parity 1_B Check parity

Field	Bits	Type	Description
FEN	6	rw	**Framing Check Enable (asynchronous mode only)** 0_B Ignore framing errors 1_B Check framing errors
OEN	7	rw	**Overrun Check Enable** 0_B Ignore overrun errors 1_B Check overrun errors
PE	8	r	**ASC Parity Error Flag** Set by hardware on a parity error (PEN = 1). Must be reset by software.
FE	9	r	**ASC Framing Error Flag** Set by hardware on a framing error (FEN = 1). Must be reset by software.
OE	10	r	**ASC Overrun Error Flag** Set by hardware on an overrun error (OEN = 1). Must be reset by software.
FDE	11	rw	**Fractional Divider Enable** 0_B Fractional divider disabled 1_B Fractional divider is enabled and used as prescaler for baud rate timer (bit BRS is don't care) FDE is don't care and assumed '0' in Synchr. Mode.
ODD	12	rw	**Parity Selection** 0_B Even parity selected (parity bit = 1 on odd number of 1s in data, parity bit = 0 on even number of 1s in data) 1_B Odd parity selected (parity bit = 1 on even number of 1s in data, parity bit = 0 on odd number of 1s in data)
BRS	13	rw	**Baud Rate Selection** 0_B Baud rate timer prescaler divide-by-2 selected 1_B Baud rate timer prescaler divide-by-3 selected BRS is don't care if FDE = 1 (fractional divider enabled) FDE is don't care and assumed '0' in Synchr. Mode.
LB	14	rw	**Loop-back Mode Enable** 0_B Loop-Back mode disabled 1_B Loop-Back mode enabled

Field	Bits	Type	Description
R	15	rw	**Baud Rate Generator Run Control** 0_B Baud rate generator disabled (ASC inactive) 1_B Baud rate generator enabled Register BG should only be written if R = 0.
MTX	[18:16]	rw	**Mode Selection TX direction** While bit field M controls the RX path, MTX controls the mode for the TX path. 000_B 8-bit data Synchronous Mode. M needs to be cleared as well for proper operation. 001_B 8-bit data Asynchronous Mode 010_B Reserved. Do not use this combination. 011_B 7-bit data + parity Asynchronous Mode 100_B 9-bit data Asynchronous Mode 101_B 8-bit data + wake up bit Asynchronous Mode 110_B Reserved. Do not use this combination. 111_B 8-bit data + parity Asynchronous Mode
ODDTX	28	rw	**Parity Selection TX direction** While bit field ODD controls the RX path, ODDTX controls the mode for the TX path. 0_B Even parity selected (parity bit = 1 on odd number of 1s in data, parity bit = 0 on even number of 1s in data) 1_B Odd parity selected (parity bit = 1 on even number of 1s in data, parity bit = 0 on odd number of 1s in data)
0	[31:29], [27:19]	r	**Reserved** Read as 0; should be written with 0.

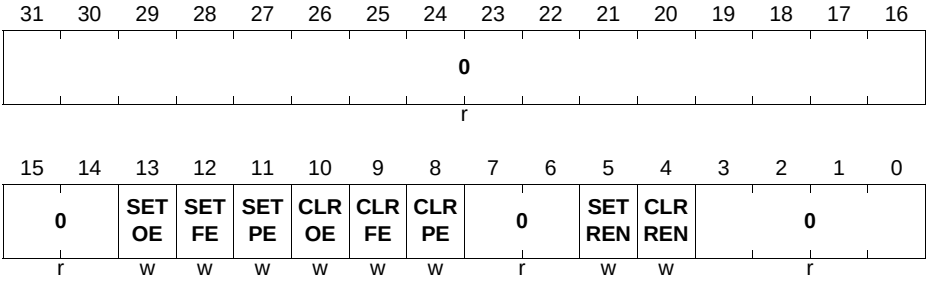
Serial data transmission or reception is possible only when the run bit CON.R is set to 1. Otherwise, the serial interface is idle. To avoid unpredictable behavior of the serial interface, do not program the mode control field CON.M to one of the reserved combinations.

Write Hardware Control Bits

The three error flags in register CON and the REN bit can be set or cleared by software via register WHBCON. WHBCON is a write-only register. Reading WHBCON always returns 0000 0000_H.

WHBCON

Write Hardware Bits Control Register (250_H) **Reset Value: $0000\ 0000_H$**



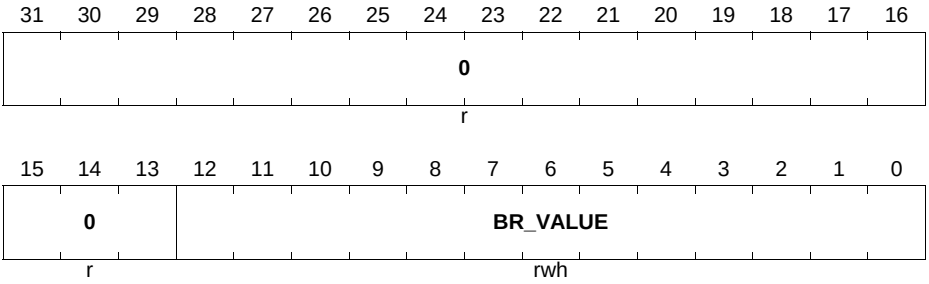
Field	Bits	Type	Description
CLRREN	4	w	**Clear Receiver Enable Bit** 0_B No effect 1_B Bit CON.REN is cleared. Bit is always read as 0.
SETREN	5	w	**Set Receiver Enable Bit** 0_B No effect 1_B Bit CON.REN is set. Bit is always read as 0.
CLRPE	8	w	**Clear Parity Error Flag** 0_B No effect 1_B Bit CON.PE is cleared. Bit is always read as 0.
CLRFE	9	w	**Clear Framing Error Flag** 0_B No effect 1_B Bit CON.FE is cleared. Bit is always read as 0.
CLROE	10	w	**Clear Overrun Error Flag** 0_B No effect 1_B Bit CON.OE is cleared. Bit is always read as 0.
SETPE	11	w	**Set Parity Error Flag** 0_B No effect 1_B Bit CON.PE is set. Bit is always read as 0.

Field	Bits	Type	Description
SETFE	12	w	**Set Framing Error Flag** 0_B No effect 1_B Bit CON.FE is set. Bit is always read as 0.
SETOE	13	w	**Set Overrun Error Flag** 0_B No effect 1_B Bit CON.OE is set. Bit is always read as 0.
0	[3:0], [7:6], [31:14]	r	**Reserved** Read as 0; should be written with 0.

Note: When the set and clear bits for an error flag are set at the same time during a WHBCON write operation (e.g SETPE = CLRPE = 1), the error flag in CON is not affected.

The Baud Rate Timer Reload Register BG of the ASC module contains the 13-bit reload value for the baud rate timer in Asynchronous and Synchronous Modes.

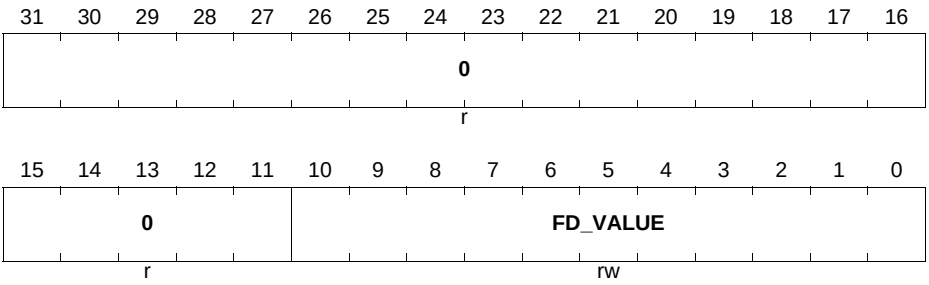
BG
Baud Rate Timer/Reload Register (214_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
BR_VALUE	[12:0]	rwh	**Baud Rate Timer/Reload Register Value** Reading BR_VALUE returns the 13-bit content of the baud rate timer. Writing BR_VALUE loads the baud rate timer reload register. BG should only be written if CON.R = 0.
0	[31:13]	r	**Reserved** Read as 0; should be written with 0.

The Fractional Divider Register FDV of the ASC module contains the 11-bit divider value for the fractional divider (asynchronous mode only).

FDV
Fractional Divider Register (218_H) Reset Value: 0000 0000$_H$

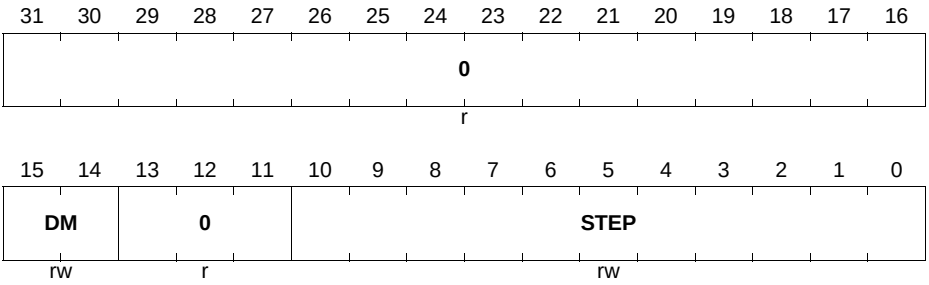


Field	Bits	Type	Description
FD_VALUE	[10:0]	rw	**Fractional Divider Register Value** FD_VALUE contains the 11-bit value n of the fractional divider which determines the fractional divider ratio n/2048 (n = 0-2047). With n = 0, the fractional divider is switched off (divider ratio = 1).
0	[31:11]	r	**Reserved** Read as 0; should be written with 0.

The Fractional Divider Register FDO contains the 11-bit divider value for the fractional divider that is generating $f_{PSISCLK}$ from f_{BAUD2}. PSISCLK is a clock that can be used on a pin to drive the external PHY.

FDO

Fractional Divider for Output CLK Register ($21C_H$) **Reset Value: $0000\ 0000_H$**

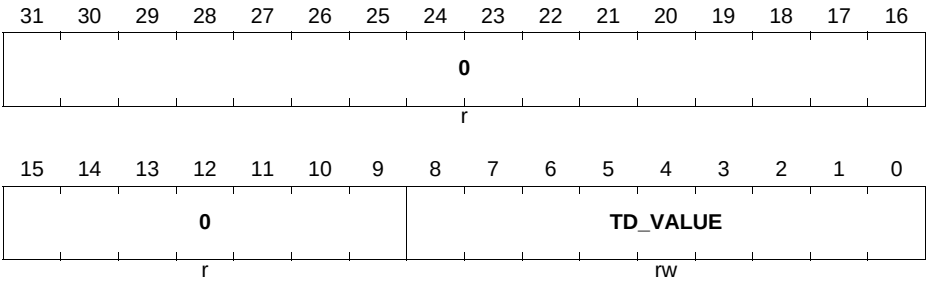


Field	Bits	Type	Description
STEP	[10:0]	rw	**Step Value** Reload or addition value for internal accumulator.
DM	[15:14]	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. (default after System Reset). 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated.

Field	Bits	Type	Description
0	[31:16], [13:11]	r	**Reserved** Read as 0; should be written with 0.

The Transmit Buffer Register TBUF of the ASC module contains the transmit data value in Asynchronous And Synchronous Modes. If GCR.ASC is cleared, TBUF is no longer writable by SW and interrupts are handled by the message reassembly block automatically.

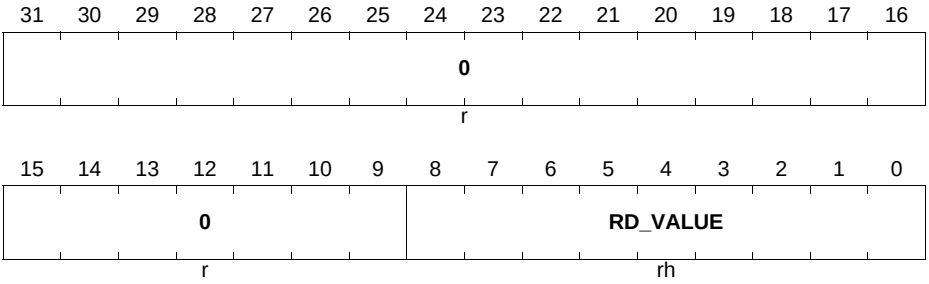
TBUF
Transmit Buffer Register **(220_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TD_VALUE	[8:0]	rw	**Transmit Data Register Value** TBUF contains the data to be transmitted in the asynchronous and synchronous operating modes of the ASC. Data transmission is double-buffered; therefore, a new value can be written to TBUF before the transmission of the previous value is complete.
0	[31:9]	r	**Reserved** Read as 0; should be written with 0.

The receive buffer register RBUF of the ASC module contains the receive data value in Asynchronous and Synchronous Modes.

RBUF
Receive Buffer Register **(224_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RD_VALUE	[8:0]	rh	**Receive Data Register Value** RBUF contains the received data bits and, depending on the selected mode, the parity bit in the asynchronous and synchronous operating modes of the ASC. In Asynchronous Mode, with CON.M = 011_B (7-bit data + parity), the received parity bit is written into RBUF.7. In Asynchronous Mode, with CON.M = 111_B (8-bit data + parity), the received parity bit is written into RBUF.8.
0	[31:9]	r	**Reserved** Read as 0.

33.17.7 Interrupt Control Registers

INTOV
Interrupt Overview Register **(300_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	[31:15]	r	**Reserved** Read as 0.

Interrupt Status Registers x

The Interrupt Status Registers INTSTATx contains status bits that show the status of any interrupt of PSI5-S channel x.

The bits are set independently from the referring Interrupt Enable in Register INTENx. Thus they can be used as status bits as well e.g. by a SW based on polling.

INTSTATx (x = 0-7)
Interrupt Status Register x **(260_H+x*4)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0							HDI	TPOI	TPI	CRCI	CHCI	TEI	RBI	RDI	RSI
r							rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RSI	0	rh	**Receive Success Interrupt Request Flag** This bit is set at the successfully received end of a frame. It indicates that this frame is free of the errors CRCI, XCRCI, TEI, PE, FE, OE, RBI, HDI if selected to be taken into account in register GCR. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.RSI. This bit can be set by bit INTSETx.RSI. This bit is set independently from INTENx.

Field	Bits	Type	Description
RDI	1	rh	**Receive Data Interrupt Request Flag** RDI is activated when a received frame is moved to a Receive Data Register RDR. Both RDI and RSI will be issued together at correct reception. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.RDI. This bit can be set by bit INTSETx.RDI. This bit is set independently from INTENx.
RBI	2	rh	**Receive Buffer Overflow Interrupt Request Flag** This bit is set after a frame has been received while the old one was not read from RDR. I.e. the kernel wants to set interrupt RDI and finds this interrupt already set. The old data is overwritten by the new data. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is NOT cleared by reading RDR. This bit can be cleared by bit INTCLRx.RBI. This bit can be set by bit INTSETx.RBI. This bit is set independently from INTENx.

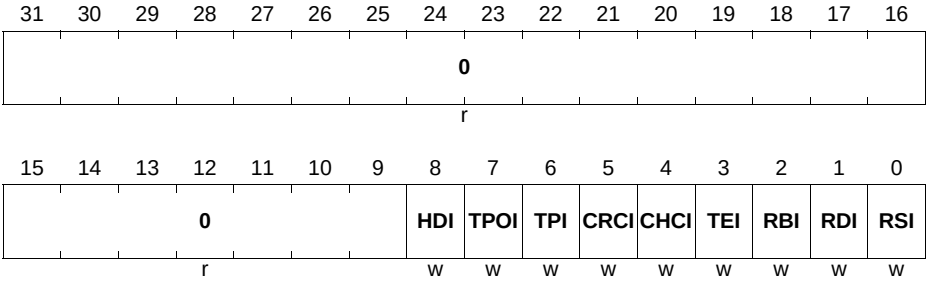
Field	Bits	Type	Description
TEI	3	rh	**Timing Error Interrupt Request Flag** This bit is set if the watch dog timer expired. Depending from RCRAx.WDMS either the distance between two RDIs is longer than specified in WDL or it expired without reception of CHCI in time. I.e. the time from issuing the sync pulse to reception of the last expected frame configured in NFC.NFx was too long. Note that the root cause might be a non recoverable frame! 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.TEI. This bit can be set by bit INTSETx.TEI. This bit is set independently from INTENx.
CHCI	4	rh	**Channel Completed Interrupt Request Flag** This bit is set if FCNT.FCx equals NFC.NFx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.CHCI. This bit can be set by bit INTSETx.CHCI. This bit is set independently from INTENx.
CRCI	5	rh	**CRC Error Request Flag** This bit is set if the CRC fails. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.CRCI. This bit can be set by bit INTSETx.CRCI. This bit is set independently from INTENx.

Field	Bits	Type	Description
TPI	6	rh	**Transfer Preparation Interrupt Request Flag** This bit is set after data to be transferred has been moved completely. Thus a new value can be written to SDRx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.TPI. This bit can be set by bit INTSETx.TPI. This bit is set independently from INTENx.
TPOI	7	rh	**Transmit Preparation Overflow Interrupt Request Flag** This bit is set if SDR is written while TPF is set. The old data is NOT overwritten. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.TPOI. This bit can be set by bit INTSETx.TPOI. This bit is set independently from INTENx.
HDI	8	rh	**Header Error Signalled Flag** This bit is set if at least one of the error signalling flags in the enveloping Packet Frame Err0 and Err1 is set. Up 0_B (Err0 OR Err1) = false (0) 1_B (Err0 OR Err1) = true (1)
0	[31:9]	r	**Reserved** Read as 0.

Interrupt Set Registers x

The Interrupt Set Registers INTSETx contain control bits that trigger an interrupt pulse for any interrupt of PSI5-S channel x.

INTSETx (x = 0-7)
Interrupt Set Register x **(280_H+x*4)** **Reset Value: 0000 0000_H**



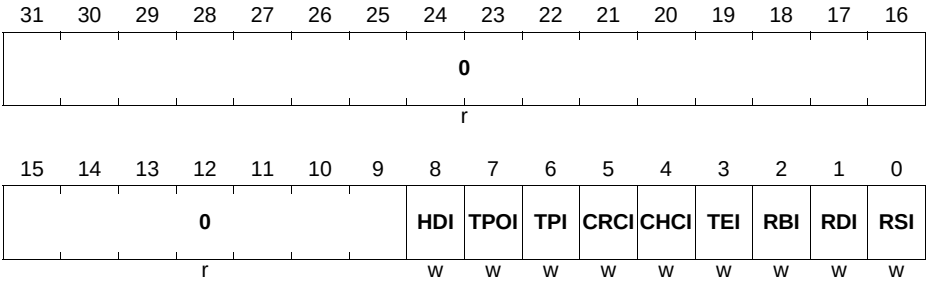
Field	Bits	Type	Description
RSI	0	w	**Set Interrupt Request Flag RSI** Setting this bit set bit INTSTATx.RSI. Clearing this bit has no effect. Reading this bit returns always zero.
RDI	1	w	**Set Interrupt Request Flag RDI** Setting this bit set bit INTSTATx.RDI. Clearing this bit has no effect. Reading this bit returns always zero.
RBI	2	w	**Set Interrupt Request Flag RBI** Setting this bit set bit INTSTATx.RBI. Clearing this bit has no effect. Reading this bit returns always zero.
TEI	3	w	**Set Interrupt Request Flag TEI** Setting this bit set bit INTSTATx.TEI. Clearing this bit has no effect. Reading this bit returns always zero.
CHCI	4	w	**Set Interrupt Request Flag CHCI** Setting this bit set bit INTSTATx.CHCI. Clearing this bit has no effect. Reading this bit returns always zero.

Field	Bits	Type	Description
CRCI	5	w	**Set Interrupt Request Flag CRCI** Setting this bit set bit INTSTATx.CRCI. Clearing this bit has no effect. Reading this bit returns always zero.
TPI	6	w	**Set Interrupt Request Flag TPI** Setting this bit set bit INTSTATx.TPI. Clearing this bit has no effect. Reading this bit returns always zero.
TPOI	7	w	**Set Interrupt Request Flag TPOI** Setting this bit set bit INTSTATx.TPOI. Clearing this bit has no effect. Reading this bit returns always zero.
HDI	8	w	**Set Interrupt Request Flag HDI** Setting this bit set bit INTSTATx.HDI. Clearing this bit has no effect. Reading this bit returns always zero.
0	[31:9]	r	**Reserved** Read as 0; should be written with 0.

Interrupt Clear Register x

The Interrupt Clear Register INTCLRx contain control bits that clear the status of any interrupt of PSI5-S channel x.

INTCLRx (x = 0-7)
Interrupt Clear Register x **($2A0_H$+x*4)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RSI	0	w	**Clear Interrupt Request Flag RSI** Setting this bit clears bit INTSTATx.RSI. Clearing this bit has no effect. Reading this bit returns always zero.
RDI	1	w	**Clear Interrupt Request Flag RDI** Setting this bit clears bit INTSTATx.RDI. Clearing this bit has no effect. Reading this bit returns always zero.
RBI	2	w	**Clear Interrupt Request Flag RBI** Setting this bit clears bit INTSTATx.RBI. Clearing this bit has no effect. Reading this bit returns always zero.
TEI	3	w	**Clear Interrupt Request Flag TEI** Setting this bit clears bit INTSTATx.TEI. Clearing this bit has no effect. Reading this bit returns always zero.
CHCI	4	w	**Clear Interrupt Request Flag CHCI** Setting this bit clears bit INTSTATx.CHCI. Clearing this bit has no effect. Reading this bit returns always zero.

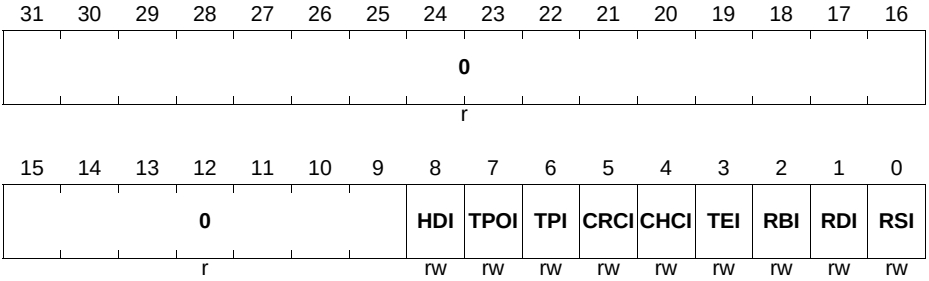
Field	Bits	Type	Description
CRCI	5	w	**Clear Interrupt Request Flag CRCI** Setting this bit clears bit INTSTATx.CRCI. Clearing this bit has no effect. Reading this bit returns always zero.
TPI	6	w	**Clear Interrupt Request Flag TPI** Setting this bit clears bit INTSTATx.TPI. Clearing this bit has no effect. Reading this bit returns always zero.
TPOI	7	w	**Clear Interrupt Request Flag TPOI** Setting this bit clears bit INTSTATx.TPOI. Clearing this bit has no effect. Reading this bit returns always zero.
HDI	8	w	**Clear Interrupt Request Flag HDI** Setting this bit clears bit INTSTATx.HDI. Clearing this bit has no effect. Reading this bit returns always zero.
0	[31:9]	r	**Reserved** Read as 0; should be written with 0.

Interrupt Enable Registers x

The Interrupt Enable Register INTEN x contain control bits that enable the interrupt source of any interrupt of PSI5-S channel x.

The Interrupt Status bits in register INTSTATx are set independently from the Interrupt Enable in Register INTENx.

INTENx (x = 0-7)
Interrupt Enable Register x **($2C0_H$+x*4)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RSI	0	rw	**Enable Interrupt Request RSI** 0_B No interrupt request can be generated for this source 1_B An interrupt request can be generated for this source
RDI	1	rw	**Enable Interrupt Request RDI** 0_B No interrupt request can be generated for this source 1_B An interrupt request can be generated for this source
RBI	2	rw	**Enable Interrupt Request RBI** 0_B No interrupt request can be generated for this source 1_B An interrupt request can be generated for this source

Field	Bits	Type	Description
TEI	3	rw	**Enable Interrupt Request TEI** 0_B No interrupt request can be generated for this source 1_B An interrupt request can be generated for this source
CHCI	4	rw	**Enable Interrupt Request CHCI** 0_B No interrupt request can be generated for this source 1_B An interrupt request can be generated for this source

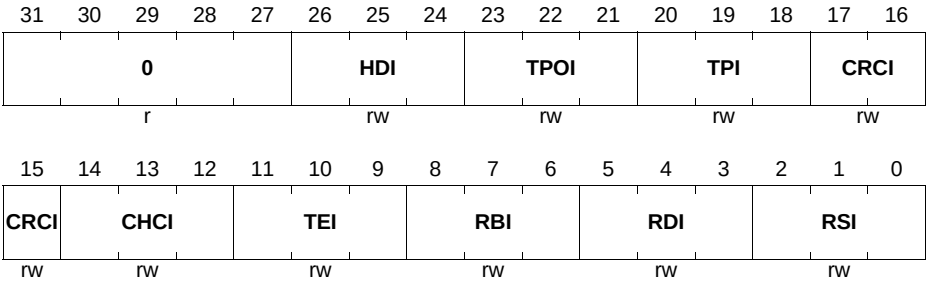
HDI	8	rw	**Enable Interrupt Request HDI** 0_B No interrupt request can be generated for this source 1_B An interrupt request can be generated for this source
0	[31:9]	r	**Reserved** Read as 0; should be written with 0.

Interrupt Node Pointer Registers x

The Interrupt Node Pointer Register INPx contains the node pointers of PSI5-S channel x.

INPx (x = 0-7)
Interrupt Node Pointer Register x (2E0$_H$+x*4) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RSI	[2:0]	rw	**Interrupt Node Pointer for Interrupt RSI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RSI (if enabled by bit INTENx.RSI). 000_B Trigger Output TRIGO 0 is selected 001_B Trigger Output TRIGO 1 is selected ... ... 111_B Trigger Output TRIGO 7 is selected
RDI	[5:3]	rw	**Interrupt Node Pointer for Interrupt RDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RDI (if enabled by bit INTENx.RDI). For bit field definition, see RSI.
RBI	[8:6]	rw	**Interrupt Node Pointer for Interrupt RBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RBI (if enabled by bit INTENx.RBI). For bit field definition, see RSI.

Field	Bits	Type	Description
TEI	[11:9]	rw	**Interrupt Node Pointer for Interrupt TEI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.TEI (if enabled by bit INTENx.TEI). For bit field definition, see RSI.
CHCI	[14:12]	rw	**Interrupt Node Pointer for Interrupt CHCI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.CHCI (if enabled by bit INTENx.CHCI). For bit field definition, see RSI.
CRCI	[17:15]	rw	**Interrupt Node Pointer for Interrupt CRCI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.CRCI. For bit field definition, see RSI.
TPI	[20:18]	rw	**Interrupt Node Pointer for Interrupt TOI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.TPI (if enabled by bit INTENx.TPI). For bit field definition, see RSI.
TPOI	[23:21]	rw	**Interrupt Node Pointer for TPOI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.TPOI. For bit field definition, see RSI.
HDI	[26:24]	rw	**Interrupt Node Pointer for HDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.HDI. For bit field definition, see RSI.
0	[31:27]	r	**Reserved** Read as 0; should be written with 0.

Interrupt Status Registers Global

The Interrupt Status Registers INTSTATG contains status bits that show the status of any global interrupt, i.e. of the ASC inside PSI5-S and XCRCI indicating a non recoverable message is received. On XCRCI, the non recoverable message is stored in ChID ‘0’, FID ’1’ with original IDs. INTSTATG contains as well FOI indicating a FIFO overrun condition. In a correct setup, this will never be set as the bandwidth of the ASC is assumed to be by far higher than the write bandwidth in order to have short delays.

The bits are set independently from the referring Interrupt Enable in Register INTENG. Thus they can be used as status bits as well e.g. by a SW based on polling.

INTSTATG
Interrupt Status Register G **(304_H)** **Reset Value: 0000 0000$_H$**

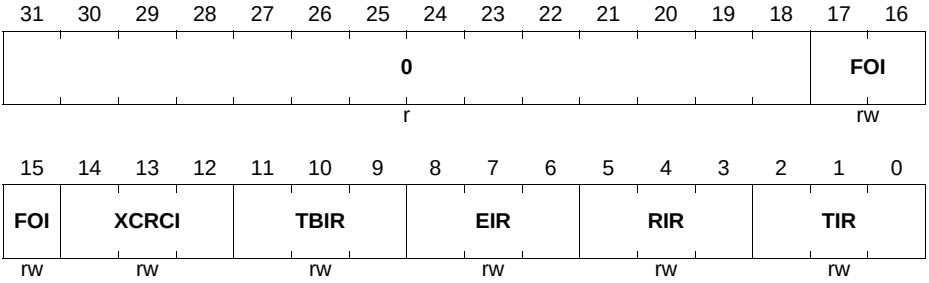
Interrupt Node Pointer Register Global

The Interrupt Node Pointer Register INPG contains the node pointers of PSI5-S ASC and XCRCI.

INPG
Interrupt Node Pointer G Register (314_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TIR	[2:0]	rw	**Interrupt Node Pointer for Interrupt TIR** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATG.TIR (if enabled by bit INTENG.TIR). 000_B Trigger Output TRIGO 0 is selected 001_B Trigger Output TRIGO 1 is selected ... ... 111_B Trigger Output TRIGO 7 is selected
RIR	[5:3]	rw	**Interrupt Node Pointer for Interrupt RIR** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATG.RIR (if enabled by bit INTENG.RIR). For bit field definition, see TIR.
EIR	[8:6]	rw	**Interrupt Node Pointer for Interrupt EIR** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATG.EIR (if enabled by bit INTENG.EIR). For bit field definition, see TIR.

Field	Bits	Type	Description
TBIR	[11:9]	rw	**Interrupt Node Pointer for Interrupt TBIR** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATG.TBIR (if enabled by bit INTENG.TBIR). For bit field definition, see TIR.
XCRCI	[14:12]	rw	**Interrupt Node Pointer for Interrupt XCRCI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATG.XCRCI (if enabled by bit INTENG.XCRCI). For bit field definition, see TIR.
FOI	[17:15]	rw	**Interrupt Node Pointer for Interrupt FOI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATG.FOI (if enabled by bit INTENG.FOI). For bit field definition, see TIR.
0	[31:18]	r	**Reserved** Read as 0; should be written with 0.

33.18 PSI5-S Module Implementation

This section describes the PSI5-S module interface as it is implemented in the TC27x. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

33.18.1 Interface Connections of the PSI5-S Module

Figure 33-35 shows the TC27x-specific implementation details and interconnections of the PSI5-S module.

The PSI5-S module is supplied with a separate clock control, address decoding, and interrupt control logic. The 8 modules' service request outputs are connected with the interrupt router. 8 outputs of the GTM module are connected to the timer inputs.

The serial data inputs PSISRXn of the receive channels of the PSI5-S module as well as the sender output PSISTX are connected to GPIO lines. If the output is used, it is mapped to a different port pin than the referring PSI5-S data input line.

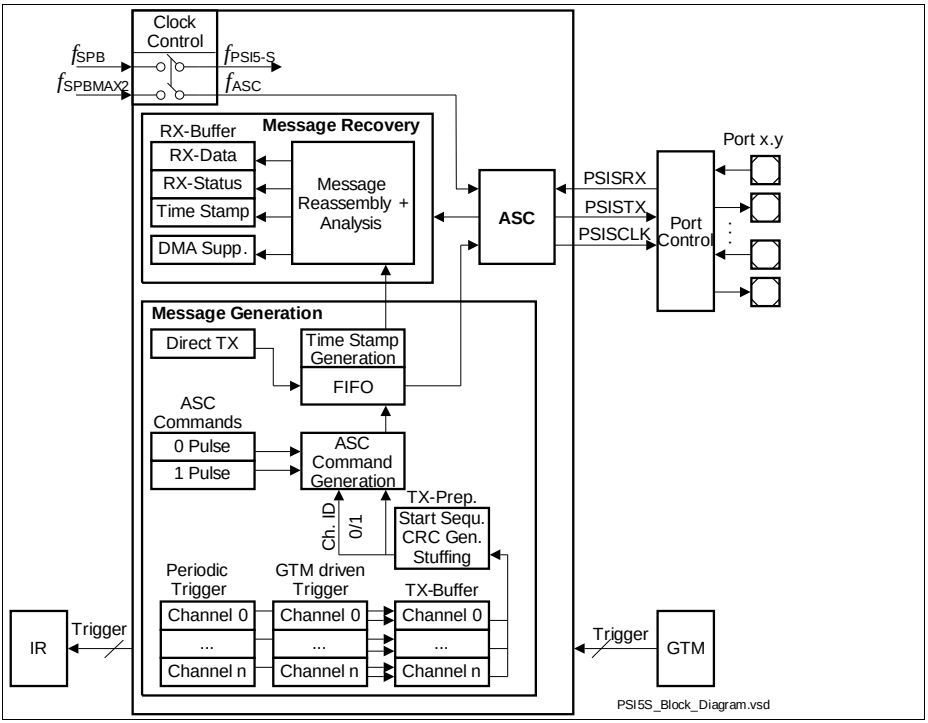


Figure 33-35 PSI5-S Module Implementation and Interconnections

33.18.1.1 On-Chip Connections

This section describes the on-chip connections of the PSI5-S module.

Interrupt Router Service Requests

The module has 8 Request Trigger outputs connecting it to the interrupt router (IR). The request lines are connected to the IR controller as shown in **Table 33-7**. Interrupt node pointers (INPx) select the line for each trigger source. Multiple nodes may point to the same line. In this case the triggers are combined with a simple OR logic.

Table 33-7 Service Request Lines of PSI5-S

INP value	Request Line	Connected to	Description
000b	TRIGO0	PSI5S_SRC0	PSI5-S Service Request Node 0
001b	TRIGO1	PSI5S_SRC1	PSI5-S Service Request Node 1
010b	TRIGO2	PSI5S_SRC2	PSI5-S Service Request Node 2
011b	TRIGO3	PSI5S_SRC3	PSI5-S Service Request Node 3
100b	TRIGO4	PSI5S_SRC4	PSI5-S Service Request Node 4
101b	TRIGO5	PSI5S_SRC5	PSI5-S Service Request Node 5
110b	TRIGO6	PSI5S_SRC6	PSI5-S Service Request Node 6
111b	TRIGO7	PSI5S_SRC7	PSI5-S Service Request Node 7

Trigger Inputs

The module has 8 PSI5-S Channels and 8 trigger inputs which can be randomly chosen by programming PGCx.ETS/ETB, FDRT.ECS and TSCNTA/B.ETB. The trigger inputs (TRIG[7:0]) of the PSI5-S module are connected to the GTM as shown in **Table 33-8**.

Table 33-8 Trigger Input Lines of PSI5-S

Request Line	Connected to	Description
TRIG0	gtm.psi5_0_trig_0_o	GTM Trigger Line TRIG0
TRIG1	gtm.psi5_1_trig_0_o	GTM Trigger Line TRIG1
TRIG2	gtm.psi5_2_trig_0_o	GTM Trigger Line TRIG2
TRIG3	gtm.psi5_3_trig_0_o	GTM Trigger Line TRIG3
TRIG4	gtm.psi5_4_trig_0_o	GTM Trigger Line TRIG4
TRIG5	gtm.psi5_5_trig_0_o	GTM Trigger Line TRIG5
TRIG6	gtm.psi5_6_trig_0_o	GTM Trigger Line TRIG6
TRIG7	gtm.psi5_7_trig_0_o	GTM Trigger Line TRIG7

33.18.2 PSI5-S Module-Related External Registers

The registers listed in **Figure 33-36** are not included in the PSI5-S module kernel but must be programmed for proper operation of the PSI5-S module.

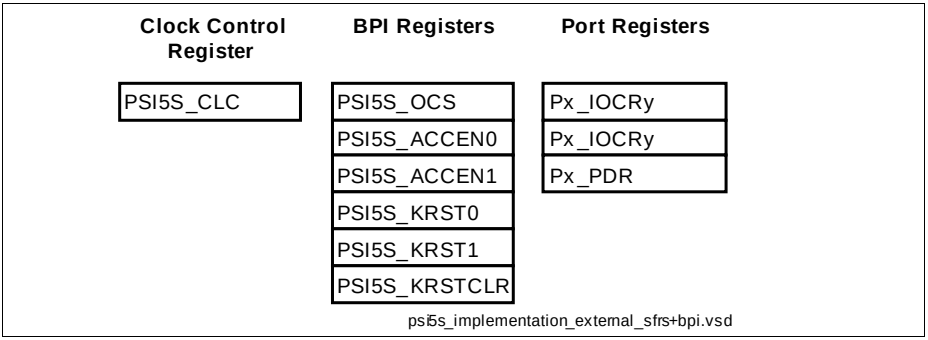

Figure 33-36 PSI5-S Implementation-specific Special Function Registers

33.18.2.1 Port Control

The Port Control Registers contain:

- Input/output function selection (Port IOCR registers)
- Pad driver characteristics selection for the outputs (Port PDR registers)

Input/Output Function Selection

Table 33-9 shows an overview how bits and bit fields must be programmed for the required I/O functionality of the PSI5-S I/O lines.
The PSI5-S interface input shares its input pins with digital ports.

For one PSI5-S module the output and input pins are next to each other. Not connected inputs are tied internally on chip.

The Module can be used as ASC only. PSI5-S message reassembly unit, message generation and pulse generation are not available in this mode.
If in this use case the module is switched to SSC mode, the port wiring is switched automatically in the following way:
- RXD line remains receive data input,
- CLK provides the synchronous transmit clock coming from the internal TXD signal and
- TXD provides the output data coming from the internal RXD signal.

This way the wiring is compatible with the wiring of other UART modules of the product family. See **Figure 33-37**.

33.19 Revision History

This Target Specification is based on: “PSI5 Specification **V2.0 2011-06**”.

Table 33-10 Revision History

Version Number	Changes to Previous Version
Rev_0.1D	First Draft (Bullet Points ++)
Rev_0.2	Review Version Addresses, Implementation ASC are the main areas that need further work
Rev_0.3	First Complete Version Addresses, integration of ASC, interrupts completed and details on DMA support
Rev_0.4	Version with lead customer feed back Added separate ASC Parity control for RX and TX Added SW control register SWAP to change buffer base address Added automatic timing of buffer swapping in BCRA.BPRP Added 3 Byte Packet Frames Added bit field UART Frames count per Packet frame (RCRA.UFC) Added description of reassembly process Added idle signal from ASC to reassembly unit for Packet Frame separation. Changed location of PSI5 Frame CRC to RDS Bit EPS changed to 2 bits to allow for Frame 1 -3 in with PWM Method APL enlarged from 4 to 4 Bits Renaming TSRA/B to TSCNTA/B, TSCx to TSCR Consistent naming convention for UART Frames, Packet Frames, PSI5 Frames Removed CLC.RMC (pre divider)
Rev_0.5	Renamed SPL/APL to TXCMD/ATXCMD Rephrased Loop Back description wrt. parity settings Renamed CDW.SP to TSI “Time Stamp Indicator” Deleted CDWx, only one CDW for all channels (typo) Added bit TSTS selecting trigger for time stamp Sync Pulse/Packet Frame Added bit FIDS selecting FID from Packet Frame/revolving number Added Register NFC supporting WD in angle synchronous channels Changed Module base and end address

Table 33-10 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.0	Frame Buffer in System Memory: Removed double buffer concept and replaced it by memory mapped concept. Removed registers for SW swapping and data consistency (ABAR, SWAP, BSRA, BSRB) Removed BFI Added CHCI Changed NFC.NFx definitions and added RCRAx.WDMS controlling the Watch Dog Timer behavior. Swapped addresses of RDS and TSM. Having the TS written at the end of a DMA transfer allows a simple check: all data in a buffer is consistent if the TS are strictly monotonic increasing from FID1 .. FID6 - within senseful boundaries. This does not work for extreme use cases. Added CLC.RMC and CLC.EDIS Removed automatic clear of TPI by writing SDRx. Moved XCRC to INTSTATG as it is not available for each channel but for Ch 0 only. Reduced INP bit field to 3 bit Added INTSTATx.HDI and INPx.HDI Removed RCRAx.EN (local channel enable), function is in GCR Added RCRAx.TSEN (Time Stamp enable) Removed TSCNTA/B.ACLR, CLR, TBE Added TSCNTA. CLRA, CLRB, TBEA, TBEB for simultaneous start/stop and clear of both timers. Removed bit SCR.TRQ, redundant with TPF.
Rev_1.1	Updated OCS description. Changed FID from 1 .. 6 to 0 .. 5; non recoverable frames ChID 0, FID 1, transceiver messages ChID 0, FID 0, rolling number FID for asynchronous frames is 0 .. 5 Change to TSP: for non recoverable messages, TSP is not relevant but TSCNTA is used always. Changed RDS.CRC to reverse order Changed RDS.HDI bit position to 13, ERR0/1 moved to 11/12 Added PFC to RDR, RDS, TSM Detailed definition of XCRC In Tooth Gap Method all commands are transferred to the UART even if it is a command for '0' i.e. for "no pulse" Replaced CLC.RMC by new register FDR. FIFO overrun condition is signalled by INSTATG.FOI

Table 33-10 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.2	Added INTOV.FOI corrected typos
Rev_1.3	Added paragraph on wrap around of BAR to register description of BAR. RBI depends on RDI only (no dependency on RSI any more) due to conflicts with GCR.RBI (loop back timing loop) R/TBUF are readable while GCR.ASC is cleared Added clarification: RDS.TEI is set for all frames till CHCI
Rev_1.4	Typo corrected in description of BAR.
Rev_1.5	Added FDO providing PSISCLK, clock out for PHY. Updated Pinning Table
Rev_1.6	Removed FDO.RESULT Removed GTC.ETC typo. Clarified that non recoverable messages are always stored in ChID '0', FID '1' but with original IDs as received. Updated pinning Added clarification to RDS.FID: Frames with FID [6:7] are copied to ChID 0, FID 1 with original IDs Added hint: CON.M and CON.MTX need to be cleared both for sync mode Added mux on port wiring for "ASC only in SSC mode" use case
Rev_1.7	Typo corrections Clarification added in NFC.FCx: FC is cleared with Sync Pulse only in Sync Mode (WDMS is set) Clarification added in RDS.TEI: when TEI is cleared in INTSTATx, it is no longer shown in RDS. Added hint to CDW clarifying the relation between layout of CDW and actual frame (updated **Figure 33-6** accordingly) Changed chapter **""Packet Frames" received from PHY" on Page 33-6** to allow reception of good frames w/o correct idle at the end
Rev_1.8	Correction of feature list entry on asynchronous channels Added RDS.AFC for debugging. Corrected CLC.EDIS description. Added section "Non Recoverable Frame Presentation in RDR and RDS" Moved PSISCLK from P02.2 O2 to P02.4 O4
Rev_1.9	Changed number of GTM inputs depending on product implementation
Rev_1.10	Updated details on DMA programming

34 Ethernet MAC (ETH)

This chapter describes the Ethernet MAC [1) 2)] of the TC27x.

34.1 Overview

Figure 34-1 shows the basic structure of the module:

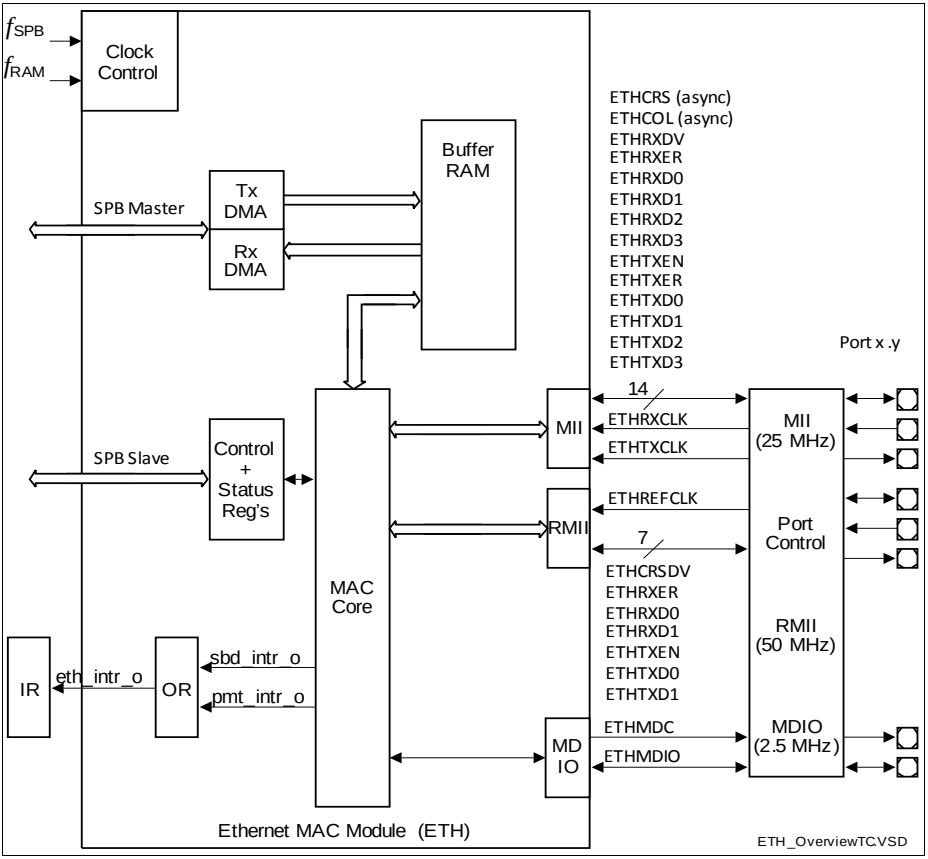

Figure 34-1 Ethernet MAC Module Overview

1) Excerpted portions are Synopsys Proprietary. Used with permission.

2) Module is not available in some variants. In these variants registers are still accessible but functionality cannot be guaranteed.

34.1.1 General Module Description

The DWC Ether MAC 10/100/1000 Universal, V3.7a, commonly referred to as GMAC-UNIV in this document, enables a host to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2002 standard. In TC27x it is configured to support 10 and 100 Mbit modes. Note that Gigabit mode is not configured, nevertheless the core is referred to as GMAC to avoid confusion with other cores.

The GMAC-UNIV provides an optimized (with respect to gate count and latency), configurable, flexible product to meet the needs of various applications and customers, and supports a multitude of industry standard interfaces to the PHY: Media Independent Interface (MII) defined in the IEEE 802.3 specifications and Reduced Media Independent Interface (RMII).The GMAC-AHB is designed to interface to the industry standard AMBA High-Performance Bus (AHB) on the application side. In TC27x an adaptation logic interfaces to the SPB bus.

The GMAC-UNIV is compliant to the following standards:

- IEEE 802.3-2002 for Ethernet MAC
- IEEE 1588-2008 standard for precision networked clock synchronization
- RMII specification from RMII consortium
- MII specification IEEE 802.3

Note: Although the naming convention used in this databook and the source code indicate “GMAC,” the databook is also applicable to the 10/100 Universal product.

34.1.2 System Overview

34.1.2.1 System-Level Block Diagram

A system-level block diagram is shown in **Figure 34-2**.

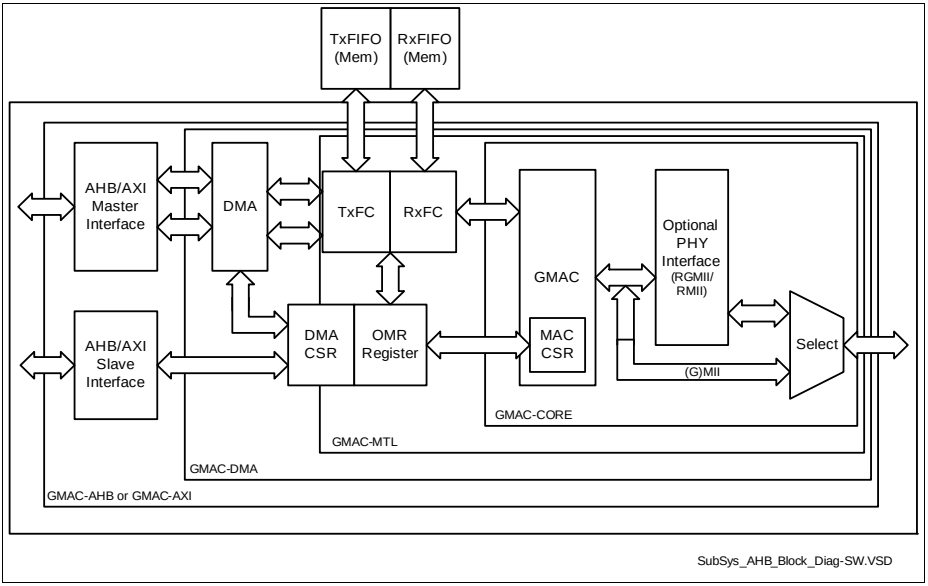

Figure 34-2 GMAC-UNIV Block Diagram

34.1.2.2 Interfaces

The GMAC-AHB transfers data to system memory through the AHB master interface. The host CPU uses the default 32-bit AHB Slave interface to access the GMAC subsystem's Control and Status registers (CSRs).

The GMAC-UNIV supports the following PHY interfaces:

- Media Independent Interface (MII)
- Reduced MII (RMII)

34.1.2.3 Transmit and Receive FIFOs

The Transmit FIFO (Tx FIFO) buffers data read from system memory by the DMA before transmission by the GMAC Core. Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they are transferred to system memory by

the DMA. These are asynchronous FIFOs, as they also transfer the data between the application clock and the GMAC line clocks.

Tx/Rx FIFOs are 32 bits wide and 4/4 kByte deep.

34.1.3 Features List

The GMAC-UNIV includes the following features, listed by category.

34.1.3.1 GMAC Core Features

- Supports 10/100-Mbit/s data transfer rates with the following PHY interfaces
  - IEEE 802.3-compliant RMII/MII (default) interface to communicate with an external Fast Ethernet PHY
- Supports both full-duplex and half-duplex operation
  - Supports CSMA/CD Protocol for half-duplex operation
  - Supports IEEE 802.3x flow control for full-duplex operation
  - Optional forwarding of received pause control frames to the user application in full-duplex operation
  - Back-pressure support for half-duplex operation
  - Automatic transmission of zero-quanta pause frame on deassertion of flow control input in full-duplex operation
- Preamble and start-of-frame data (SFD) insertion in Transmit, and deletion in Receive paths
- Automatic CRC and pad generation controllable on a per-frame basis
- Options for Automatic Pad/CRC Stripping on receive frames
- Programmable frame length to support Standard or Jumbo Ethernet frames with sizes up to 16 KB
- Programmable InterFrameGap (40-96 bit times in steps of 8)
- Supports a variety of flexible address filtering modes:
  - Up to 31 additional 48-bit perfect (DA) address filters with masks for each byte
  - Up to 31 48-bit SA address comparison check with masks for each byte
  - 64-bit Hash filter (optional) for multicast and uni-cast (DA) addresses
  - Option to pass all multicast addressed frames
  - Promiscuous mode support to pass all frames without any filtering for network monitoring
  - Passes all incoming packets (as per filter) with a status report
- Separate 32-bit status returned for transmission and reception packets
- Supports IEEE 802.1Q VLAN tag detection for reception frames
- Separate transmission, reception, and control interfaces to the Application
- Supports 32-bit data transfer interface on the system-side
- Complete network statistics (optional) with RMON/MIB Counters (RFC1757/RFC2819/RFC2665). It is completely under control of higher protocol level (SW) to make use of these counters.
- MDIO Master interface for PHY device configuration and management, e.g. for switching the PHY in external loopback mode.

- Optional module for detection of LAN wake-up frames and AMD Magic Packet frames
- Optional Receive module for checksum off-load for received IPv4 and TCP packets encapsulated by the Ethernet frame
- Optional Enhanced Receive module for checking IPv4 header checksum and TCP, UDP, or ICMP checksum encapsulated in IPv4 or IPv6 datagrams.
- Optional module to support Ethernet frame time stamping as described in IEEE 1588-2008. Sixty-four-bit time stamps are given in each frame's transmit or receive status.

34.1.3.2 DMA Block Features

The DMA block exchanges data between the MTL block and host memory. A set of registers (DMA CSR) to control DMA operation is accessible by the host.

DMA features include:

- 32-bit data transfers
- Single-channel Transmit and Receive engines
- Fully synchronous design operating on a single system clock (except for CSR module, when a separate CSR clock is configured)
- Optimization for packet-oriented DMA transfers with frame delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) or linked-list (chained) descriptor chaining
- Descriptor architecture, allowing large blocks of data transfer with minimum CPU intervention; each descriptor can transfer up to 8 KB of data
- Comprehensive status reporting for normal operation and transfers with errors
- Individual programmable burst size (SINGLE, INCR4/8, not supported by the System: INCR of undefined length) for Transmit and Receive DMA Engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions
- Per-frame Transmit/Receive complete interrupt control
- Round-robin or fixed-priority arbitration between Receive and Transmit engines
- Start/Stop modes
- Separate ports for host CSR access and host data interface

34.1.3.3 Transaction Layer (MTL) Features

The MTL block consists of two sets of FIFOs: a Transmit FIFO with programmable threshold capability, and a Receive FIFO with a configurable threshold (default of 64 bytes).

MTL features include:

- 32--bit Transaction Layer block providing a bridge between the application and the GMAC-CORE

- Single-channel Transmit and Receive engines
- Data transfers executed using simple FIFO-protocol
- Synchronization for all clocks in the design (Transmit, Receive and system clocks)
- Optimization for packet-oriented transfers with frame delimiters
- Four Separate ports for system-side and GMAC-CORE-side transmission and reception
- Two RAM-based asynchronous FIFOs with synchronous/asynchronous Read and Write operation with respect to the Read and Write clocks (one for transmission and one for reception)
- Receive Status vectors inserted into the Receive FIFO after the EOF transfer enables multiple-frame storage in the Receive FIFO without requiring another FIFO to store those frames' Receive Status.
- Configurable Receive FIFO threshold (default fixed at 64 bytes) in Cut-Through mode
- Option to filter all error frames on reception and not forward them to the application in Store-and-Forward mode
- Option to forward under-sized good frames
- Supports statistics by generating pulses for frames dropped or corrupted (due to overflow) in the Receive FIFO
- Supports Store and Forward mechanism for transmission to the GMAC core
- Supports threshold control for transmit buffer management
- Supports configurable number of frames to be stored in FIFO at any time. The default is up to 8 frames in GMAC-MTL configuration.
- Automatic generation of PAUSE frame control or backpressure signal to the GMAC core based on Receive FIFO-fill (threshold configurable) level.
- Handles automatic retransmission of Collision frames for transmission
- Discards frames on late collision, excessive collisions, excessive deferral and underrun conditions
- Software control to flush Tx FIFO
- Data FIFO RAM chip-select disabled when inactive, to reduce power consumption
- Optional module to calculate and insert IPv4 header checksum and TCP, UDP, or ICMP checksum in frames transmitted in Store-and-Forward mode.

34.1.3.4 Monitoring, Test, and Debugging Support Features

- Supports internal loopback on the MII for debugging
- external loopback is supported via the integrated MDIO controlling the PHY
- DMA states (Tx and Rx) given as status bits
- Debug status register that gives status of FSMs in Transmit and Receive data-paths and FIFO fill-levels.
- Application Abort status bits
- MMC (RMON) module in the GMAC core
- Current Tx/Rx Buffer pointer as status registers
- Current Tx/Rx Descriptor pointer as status registers

34.2 Architecture

34.2.1 Introduction

The GMAC-UNIV is a highly configurable product with multiple interfaces to the system side or the PHY side. Major modules and functions are only selected when required. A block diagram of the GMAC-UNIV's system configuration is provided in **Figure 34-3**.

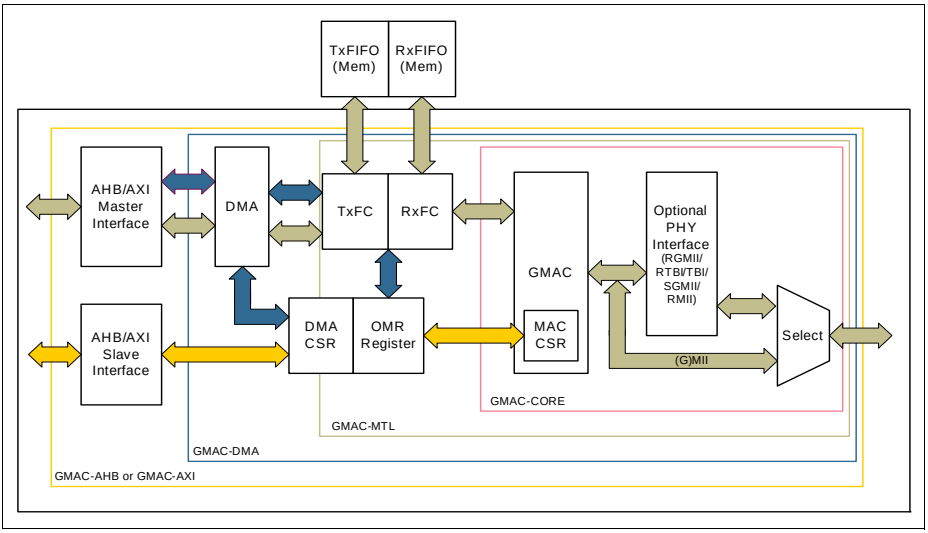

Figure 34-3 GMAC-UNIV Block Diagram

The following sections describe the functionality of the major blocks and timing behavior of the interfaces.

- **Section 34.2.2** provides an overview of precision network time synchronization using the Precision Time Protocol established under the IEEE 1588 standard.
- **Section 34.2.3** describes the functionality of the AHB interfaces in GMAC-AHB configuration
- **Section 34.2.4** describes the functioning of the DMA.
- **Section 34.2.5** explains the functioning of the MAC Transaction Layer (MTL) module which controls the Receive and Transmit FIFO memories.
- **Section 34.2.6** describes the functionality of the (G)MAC core transmitter and receiver.
- **Section 34.2.7**, **Section 34.2.8**, and **Section 34.2.8** describe the optional RMON, Power Management, and SMA interface modules.
- **Section 34.2.11** describes the Interrupt signal structure in the (G)MAC core.

34.2.2 IEEE 1588-2002 Overview

The IEEE 1588 standard defines a protocol enabling precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The protocol applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The messaged-based protocol, named Precision Time Protocol (PTP), is transported over UDP/IP. The system or network is classified into Master and Slave nodes for distributing the timing/clock information. The protocol's technique for synchronizing a slave node to a master node by exchanging PTP messages is depicted in **Figure 34-4**.

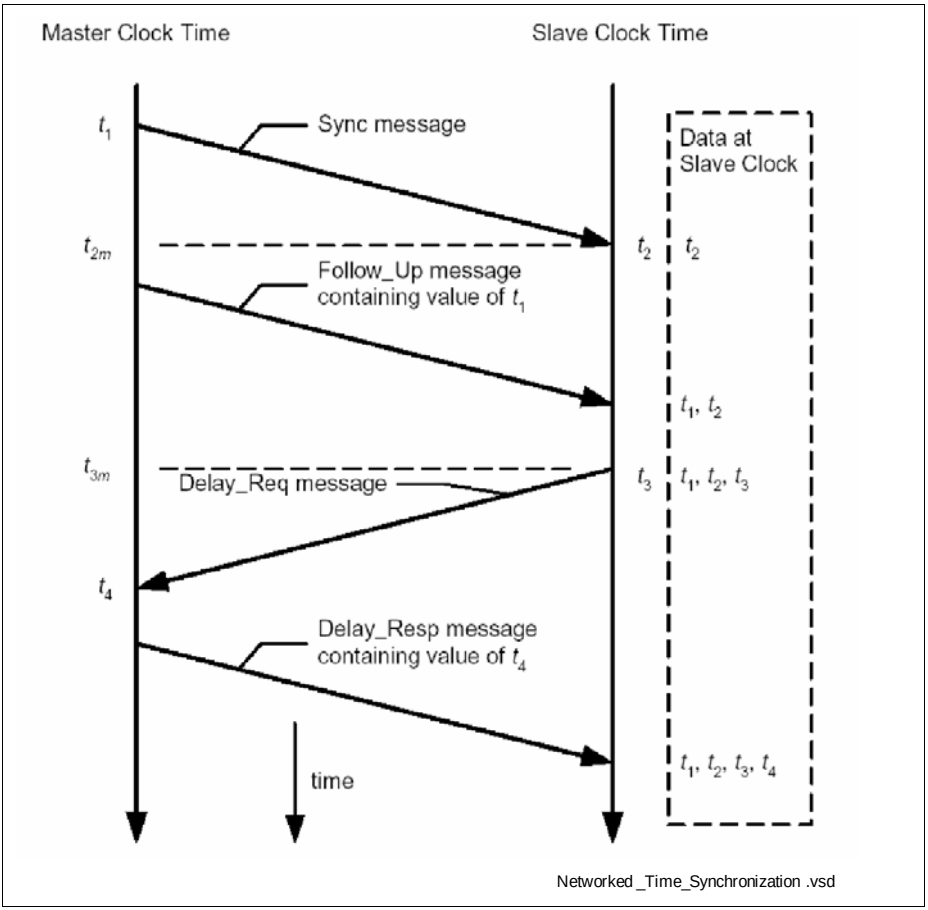

Figure 34-4 Networked Time Synchronization

1. The master broadcasts PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is t1 and must, for Ethernet ports, be captured at the MII.
2. A slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master then sends the slave a Follow_up message, which contains t1 information for later use.
4. The slave sends the master a Delay_Req message, noting the exact time, t3, at which this frame leaves the MII.

5. The master receives this message, capturing the exact time, t4, at which it enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the master's timing reference.

Most of the protocol implementation occurs in the software, above the UDP layer. As described above, however, hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII. This timing information must be captured and returned to the software for the proper implementation of PTP with high accuracy.

34.2.2.1 Reference Timing Source

To get a snapshot of the time, the core requires a reference time in 64-bit format (split into two 32-bit channels, with the upper 32-bits providing time in seconds, and the lower 32-bits indicating time in nanoseconds) as defined in the IEEE 1588 specification.

Internal Reference Time

This takes only the reference clock input and uses it to generate the Reference time (also called the System Time) internally and use it to capture time stamps. The generation, update, and modification of the System Time are described in **System Time Register Module**.

34.2.2.2 Transmit Path Functions

When a frame's SFD is output on the MII, a time stamp is captured. Frames for which capturing a time stamp is required are controllable on a per-frame basis. In other words, each transmit frame can be marked to indicate whether or not a time stamp must be captured for that frame.

No snooping or processing of the transmitted frames is performed to identify PTP frames. Framewise control is exercised through control bits in the transmit descriptor (as described in **Descriptor Format With IEEE 1588 Time Stamping Enabled**).

Captured time stamps are returned to the application in a manner similar to that in which status is provided for frames. The time stamp is returned to software inside the corresponding transmit descriptor, thus connecting the time stamp automatically to the specific PTP frame. The 64-bit time stamp information is written back to the TDES2 and TDES3 fields, with TDES2 holding the time stamp's 32 least significant bits, except as described in **Transmit Time Stamp Field**.

Note: When the alternate (enhanced) descriptor is selected, the 64-bit time-stamp is written in TDES6 and TDES7, respectively

34.2.2.3 Receive Path Functions

When the IEEE 1588 time-stamping feature is selected and enabled, the Ethernet MAC captures the time stamp of all frames received on the MII. No snooping or processing of the received frames is performed to identify PTP frames in the default mode (Advanced Time Stamp feature is not selected).

The core returns the time-stamp to the software in the corresponding receive descriptor. The 64-bit time stamp information is written back to the RDES2 and RDES3 fields, with RDES2 holding the time stamp's 32 least significant bits, except as mentioned in **Receive Time Stamp** The time stamp is only written to the receive descriptor for which the Last Descriptor status field has been set to 1 (the EOF marker). When the time stamp is not available (for example, due to an RxFIFO overflow) an all-ones pattern is written to the descriptors (RDES2 and RDES3), indicating that time stamp is not correct. If the software uses a control register bit to disable time stamping, the DMA does not alter RDES2 or RDES3.

Note: When the alternate (enhanced) descriptor is selected, the 64-bit time-stamp is written in RDES6 and RDES7, respectively. RDES0[7] will indicate whether the time-stamp is updated in RDES6/7 or not.

34.2.2.4 Time Stamp Error Margin

According to the IEEE 1588 specifications, the time stamp must be captured at the SFD of transmitted and received frames at the MII interface. Since the reference timing source (the PTP clock, clk_ptp_ref_i) is different from the MII clocks, a small error margin is introduced, due to the transfer of information across asynchronous clock domains.

In the transmit path, the captured and reported time stamp has a maximum error margin of 2 PTP clocks. In other words, the captured time stamp has the value of the reference time source given within 2 clocks after the SFD has been transmitted on the MII.

Similarly, on the receive path, the error margin is 3 MII clocks, plus up to 2 PTP clocks. You can ignore the error margin due to the 3 MII clocks by assuming that this constant delay is present in the system (or link) before the SFD data reaches the GMAC's MII interface.

34.2.2.5 Frequency Range of Reference Timing Clock

Because asynchronous logic is in place for time stamp information transfers across clock domain, a minimum delay is required between two consecutive time stamp captures. This delay is 3 clock cycles of both the MII and PTP clocks. If the gap is shorter, the GMAC does not take a time stamp snapshot for the second frame.

The maximum PTP clock frequency is limited by the maximum resolution of the reference time and the timing constraints achievable for logic operating on the PTP clock. Another factor to consider is that the resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Hence, a higher PTP clock

frequency gives better system performance. The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes. Because the MII clock frequency is fixed by IEEE specification, the minimum PTP clock frequency required for proper operation depends on the core's operating mode and operating speed.

For example, in 100 Mbit/s full-duplex operation, the minimum gap between two SFDs is 160 MII clocks (128 clocks for a 64-byte frame + 24 clocks of min IFG + 8 clocks of preamble).

In the example, (3 x PTP) + (3 x MII) ≤ 160 x MII; thus, the minimum PTP clock frequency is about 0.5 MHz ((160 - 3) x 40 ns / 3 = 2.093 ns period)

34.2.2.6 Advanced Time Stamp Feature Support

In addition to the basic features for time stamp mentioned in **IEEE 1588-2002 Overview**, the advanced time stamp option has the following features.

- Support for the IEEE 1588-2008 (Version 2) timestamp format.
- Option to take snapshot for all frames or for PTP type frames.
- Option for taking snapshot for event messages only.
- Option to take the snapshot based on the clock type (ordinary, boundary, end-to-end and peer-to-peer)
- Option to select the node to be a Master or Slave for ordinary and boundary clock.
- Identification of PTP message type, version, and PTP payload sent directly over Ethernet given as status.
- Option to measure time in digital or binary format.

Peer-to-Peer PTP (Pdelay) Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 version supports Pdelay message in addition to SYNC, Delay Request, Follow-up and Delay Response messages. **Figure 34-5** shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

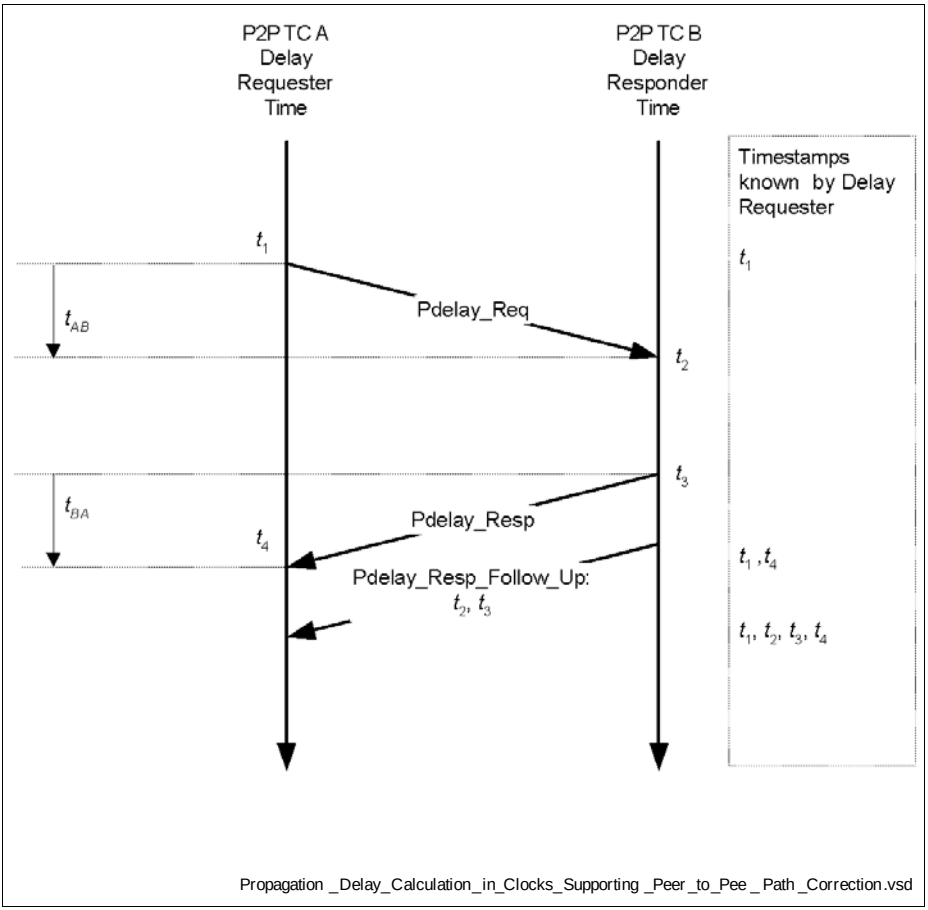

Figure 34-5 Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction

The link delay measurement starts with port-1 issuing a “Pdelay_Req” message and generating a timestamp, for the Pdelay_Req message. Port-2 receives the “Pdelay_Req” message and generates a timestamp, t2, for this message. Port-2 returns a Pdelay_Resp message and generates a timestamp, t3, for this message. To minimize errors due to any frequency offset between the two ports, Port-2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message.

Port-2 either:

- Returns the difference between the timestamps t2 and t3 in the Pdelay_Resp message,
- Returns the difference between the timestamps t2 and t3 in a Pdelay_Resp_Follow_Up message, or
- Returns the timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages respectively.

Port-1 generates a timestamp, t4, upon receiving the Pdelay_Resp message. Port-1 then uses these four timestamps to compute the mean link delay.

Clock Types

The type of clock nodes supported in IEEE 1588-2008 is described in this section. The corresponding support provided by the advanced time stamp feature for each of the clock type is also mentioned.

1. Ordinary clock support: In this type the clock can be a grandmaster or a slave clock. This clock has a single PTP state.
   Table 34-1 shows the messages for which time-stamp snapshot is taken on the receive side for Master and Slave nodes.
   The ordinary clock in the domain supports a single copy of the protocol and has a single PTP state and will typically be a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as sensors and actuators. In telecom applications, the ordinary clock may be associated with a timing demarcation device.
   Typically for ordinary clock, you will need to take snapshot for only one type of PTP messages. For e.g. you will require supporting either version 1 or 2 PTP messages, not both.
   The following features are supported.
   a) Sends and receives PTP messages. The time stamp snapshot can be controlled as described in **32-bit Register - Timestamp_Control**.
   b) Maintains the data sets (e.g., time stamp values).
2. Boundary clock support: This type of clock is similar to the ordinary clock except for the following.
   Hence the features of ordinary clock holds good for the boundary clock also.
   The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy and signaling terminate in the protocol engine of the boundary clock and are not forwarded. The PTP message type status given by the core (refer to **Receive Path Functions**) will help you to quickly identify the type of message and take appropriate action.
   a) The clock data sets are common to all ports of the boundary clock
   b) The local clock is common to all ports of the boundary clock.
3. End to end transparent clock support: The end-to-end transparent clock forwards all messages like normal bridge, router or repeater. The resident time needs to be

computed to update the correctionField. Hence snapshot needs to be taken for the messages mentioned in **Table 34-2**.

In the end-to-end transparent clock, the residence times are accumulated in a special field (correctionField) of the PTP event (SYNC) message or the associated Follow-up (FOLLOW_UP) Message. Hence it is important to take a snapshot for these messages alone. This can be quickly done by setting the control bit (TSEVNTENA), which enables snapshot to be taken for event messages and also selecting the type of clock in the “Time Stamp Control Register”.

The residence time is also corrected for Delay_Req messages (but snapshot of the timestamp is not required). The message type statuses provided helps you to quickly identity the message and update the correctionField.

The message type status provided will also help in taking appropriate action depending on the type of PTP message received.

4. Peer to peer transparent clock support: In this type of clock the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp and Pdelay_Resp_Follow_Up messages with the link peer. Hence support for taking snapshot for the event messages related to Pdelay is added. **Table 34-3**.

   The transparent clock corrects only the SYNC and Follow-up message. As discussed earlier this can be achieved using the message status provided.

   The type of clock to be implemented will be configurable through control register, as mentioned in **32-bit Register - Timestamp_Control**. To ensure that the snapshot is taken only for the messages indicated in the table for the corresponding clock type, the “TSEVNTENA: Enable Time Stamp Snapshot for Event Messages” bit has to be set.

Table 34-1 PTP Messages for which Snapshot is Taken on Receive Side for Ordinary Clock

PTP Processing and Control

The common message header for PTP messages is shown below. This format is taken from IEEE standard 1588-2008 (Revision of IEEE Std. 1588-2002).

Table 34-4 Message Format Defined in IEEE 1588-2008

BITS		OCTETS	OFFSET
transportSpecific	messageType	1	0
Reserved	versionPTP	1	1
messageLength		2	2
domainNumber		1	4
Reserved		1	5
flagField		2	6
correctionField		8	8
Reserved		4	16
sourcePortIdentity		10	20
sequenceId		2	30
controlField[1)]		1	32
logMessageInterva		1	33

1) controlField is used in version 1. For version 2, messageType field will be used for detecting different message types.

There are some fields in the PTP frame that are used to detect the type and control the snapshot to be taken. This is different for PTP frames sent directly over Ethernet, PTP frames sent over UDP / IPv4 and PTP frames that are sent over UDP / IPv6. The following sections provide information on the fields that are used to control taking the snapshot.

PTP Frame Over IPv4

Table 34-5 gives the details of the fields that will be matched to control snapshot for PTP packets over UDP over IPv4 for IEEE 1588 version 1 and 2. Note that the octet positions

for tagged frames will be offset by 4. This is based on Appendix-D of the IEEE 1588-2008 standard and the message format defined in **Table 34-4**.

Table 34-5 IPv4-UDP PTP Frame Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Frame type	12, 13	0x0800	IPv4 datagram
IP Version and Header Length	14	0x45	IP version is IPv4
Layer-4 protocol	23	0x11	UDP
IP Multicast address (IEEE 1588 version 1)	30, 31, 32, 33	0xE0,0x00, 0x01,0x81 (or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed. 224.0.1.129 224.0.1.130 224.0.1.131 224.0.1.132
IP Multicast address (IEEE 1588 version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex) 0xE0, 0x00, 0x00, 0x6B (Hex)	PTP-primary multicast address: 224.0.1.129 PTP-Pdelay multicast address: 224.0.0.107
UDP destination port	36, 37	0x013F, 0x0140	0x013F – PTP event message[1)] 0x0140 – PTP general messages
PTP control field (IEEE version 1)	74	0x00/0x01/0x02 /0x03/0x04	0x00 – SYNC, 0x01 – Delay_Req, 0x02 – Follow_Up 0x03 – Delay_Resp 0x04 – Management

Table 34-5 IPv4-UDP PTP Frame Fields Required for Control and Status (cont'd)

Field Matched	Octet Position	Matched Value	Description
PTP Message Type Field (IEEE version 2)	42 (nibble)	0x0/0x1/0x2/0x3/0x8/0x9/0xB/0xC/0xD	0x0 – SYNC 0x1 – Delay_Req 0x2 – Pdelay_Req 0x3 – Pdelay_Resp 0x8 – Follow_Up 0x9 – Delay_Resp 0xA – Pdelay_Resp_Follow_Up 0xB – Announce 0xC – Signaling 0xD - Management
PTP version field	43 (nibble)	0x1 or 0x2	0x1 – Supports PTP version 1 0x2 – Supports PTP version 2

1) PTP event messages are SYNC, Delay_Req (IEEE 1588 version 1 and 2) or Pdelay_Req, Pdelay_Resp (IEEE 1588 version 2 only).

PTP Frame Over IPv6

Table 34-6 gives the details of the fields that will be matched to control snapshot for PTP packets over UDP over IPv6 for IEEE 1588 version 1 and 2. Note that the octet positions for tagged frames will be offset by 4. This is based on Appendix-E of the IEEE 1588-2008 standard and the message format defined in **Table 34-4**.

Table 34-6 IPv6-UDP PTP Frame Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Frame type	12, 13	0x86DD	IP datagram
IP version	14 (bits [7:4])	0x6	IP version is IPv6
Layer-4 protocol	20[1)]	0x11	UDP
PTP Multicast address	38 – 53	FF0x:0:0:0:0:0:0:181 (Hex) FF02:0:0:0:0:0:0:6B (Hex)	PTP – primary multicast address: FF0x:0:0:0:0:0:0:0:181 (Hex) PTP – Pdelay multicast address: FF02:0:0:0:0:0:0:0:6B (Hex)

Table 34-6 IPv6-UDP PTP Frame Fields Required for Control and Status (cont'd)

Field Matched	Octet Position	Matched Value	Description
UDP destination port	56, 57 (*)	0x013F, 0x140	0x013F – PTP event message 0x0140 – PTP general messages
PTP control field (IEEE 1588 Version 1)	93 (*)	0x00/0x01/0x02/ 0x03/0x04	0x00 – SYNC, 0x01 – Delay_Req, 0x02 – Follow_Up 0x03 – Delay_Resp 0x04 – Management (version1)
PTP Message Type Field (IEEE version 2)	74 (*) (nibble)	0x0/0x1/0x2/0x3/ 0x8/0x9/0xB/0xC /0xD	0x0 – SYNC 0x1 – Delay_Req 0x2 – Pdelay_Req 0x3 – Pdelay_Resp 0x8 – Follow_Up 0x9 – Delay_Resp 0xA – Pdelay_Resp_Follow_Up 0xB – Announce 0xC – Signaling 0xD - Management
PTP version field	75 (nibble)	0x1 or 0x2	0x1 – Supports PTP version 1 0x2 – Supports PTP version 2

1) The Extension Header is not defined for PTP packets.

PTP Frame Over Ethernet

Table 34-7 gives the details of the fields that will be matched to control snapshot for PTP packets over Ethernet for IEEE 1588 version 1 and 2. Note that the octet positions for tagged frames will be offset by 4. This is based on Appendix-E of the IEEE 1588-2008 standard and the message format defined in **Table 34-4**.

Table 34-7 Ethernet PTP Frame Fields Required for Control And Status

Field Matched	Octet Position	Matched Value	Description
MAC Frame type	12, 13	0x88F7	PTP Ethernet frame.
PTP control field (IEEE Version 1)	45	0x00/0x01/0x02/ 0x03/0x04	0x00 – SYNC 0x01 – Delay_Req 0x02 – Follow_Up 0x03 – Delay_Resp 0x04 – Management
PTP Message Type Field (IEEE version 2)	14 (nibble)	0x0/0x1/0x2/0x3/0x8/0x9/0xB/ 0xC/0xD	0x0 – SYNC 0x1 – Delay_Req 0x2 – Pdelay_Req 0x3 – Pdelay_Resp 0x8 – Follow_Up 0x9 – Delay_Resp 0xA – Pdelay_Resp_Follow_Up 0xB – Announce 0xC – Signaling 0xD – Management
MAC Destination multicast address[1)]	0-5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All except peer delay messages - 01-1B-19-00-00-00 Pdelay messages - 01-80-C2-00-00-0E
PTP version field	15 (nibble)	0x1 or 0x2	0x1 – Supports PTP version 1 0x2 – Supports PTP version 2

1) In addition, the address match of destination addresses (DA) programmed in MAC address 1 to 31 will be used, if the control bit 18 (TSENMACADDR: Enable MAC address for PTP frame filtering) of the Time Stamp Control register is set.

Reference Timing Source (for Advance Timestamp Feature)

The updated functionality for advanced timestamp support is mentioned in the following points.

1. The IEEE 1588-2008 standard defines the seconds field of the time to be 48 bits wide. The fields to time-stamp will be the following.
   a) UInteger48- seconds field
   b) UInteger32-nanoseconds field
   The “seconds” field is the integer portion of the timestamp in units of seconds. The

"nanoseconds" field is the fractional portion of the timestamp in units of nanoseconds. E.g. 2.000000001 seconds is represented as secondsField = 0x0000_0000_0002 and nanoSeconds = 0x0000_0001. Thus the maximum value in nanoseconds field in this format will be 0x3B9A_C9FF value (i.e (10e9-1) nano-seconds). This is defined as digital rollover mode of operation. It will also support the older mode in which the nano-seconds field will roll-over and increment the seconds field after the value of 0x7FFF_FFFF. (Accuracy is ~0.466 ns per bit). This is defined as the binary rollover mode. The modes can be controlled using the "TSCTRLSSR: Time Stamp Digital or Binary rollover control" bit of the time stamp control register.

2. When the Advanced IEEE 1588 time-stamp feature is selected time maintained in the core will still be 64-bit wide, as the overflow to the upper 16-bits of seconds register happens once in 130 years. The value of the upper 16-bits of the seconds field can only be obtained from the CSR register. This is optional and can be controlled by the coreKit parameter "IEEE1588 Higher Word Register Enable" described in Chapter 6. A CSR status bit which indicates if the 32-bit "seconds" field has overflowed is also provided.
3. There is also a pulse-per-second output given to indicate 1 second interval (default). Option is provided to change the interval. Refer **32-bit Register - Timestamp_Control**. for more information.
4. Option to take auxiliary time-stamp snapshot with an external event is supported. Refer to section **Auxiliary Snapshot** for details.

Transmit Path Functions

There are no changes in the transmit path functions for GMAC-CORE and GMAC-MTL configuration for the Advanced time stamp option.

The structure of the descriptor changes when Advanced IEEE 1588 version support is enabled. The IEEE 1588 timestamp feature is supported using Alternate (Enhanced) descriptors format only. The descriptor is 32-bytes long (8 DWORDS) and the snapshot of the timestamp is written in descriptor 6 and 7.

Receive Path Functions

When the advanced time stamp feature is selected, processing of the received frames to identify valid PTP frames is done. The snapshot of the time to be sent to the application can be controlled.

The following options are provided in the time stamp control register to control the snapshot.

1. Option to enable snapshot for all frames.
2. Enable snapshot for IEEE 1588 version 2 or version 1 time stamp.
3. Enable snapshot for PTP frames transmitted directly over Ethernet or UDP-IP-Ethernet.

4. Enable time stamp snapshot for the received frame for IPv4 or IPv6.
5. Enable time stamp snapshot for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ or PDELAY_RESP) only.
6. Enable the node to be a Master or Slave. This will control the type of messages for which snap-shot will be taken (this depends on the type of clock that is selected and is valid for ordinary or boundary clock only).

Note that PTP messages over VLAN frames are also supported.

The time stamp is returned to the software inside the corresponding Transmit and Receive Descriptor. The Advanced time stamp feature is supported using Alternate (Enhanced) descriptors only which is 32-bytes long. Extended status containing the time stamp message status and the IPC offload status is written back in descriptor 4 and the snapshot of the time stamp is written back in descriptor 6 and 7. The complete details on the descriptors when the advanced time stamping is enabled are provided in **Alternate or Enhanced Descriptors**.

Auxiliary Snapshot

The auxiliary snap shot feature allows you to store a snapshot of the system time based on an external event. The event is considered to be the rising edge of the sideband signal ptp_aux_ts_trig_i. This feature is independent of whether the system time is generated internally or given as input (on ptp_timestamp_i bus). Such snap-shots are stored in a 4-deep FIFO. Only 64-bit of the time will be stored in the FIFO. The upper 16-bits of the seconds register can be read from “Time Stamp Higher Word Register” when it is present.

The storing of the snapshot can be indicated to the host with an interrupt. The value of the snapshot is read out through a FIFO register access (see **32-bit Register - Timestamp_Control**). When the FIFO becomes full and an external trigger to take the snapshot is asserted, then a snapshot trigger-missed status is set in the Time Stamp Status Register. This indicates that the latest auxiliary snapshot of the timestamp was not stored in the FIFO. The latest snapshot will not be written to the FIFO when it is full. When the host reads the 64-bit timestamp from the FIFO, space is available to store the next snapshot. This FIFO can be cleared using the control bit “ATSFC: Auxiliary Snapshot FIFO clear” defined in the Time Stamp Control Register. When multiple snapshots are present in the FIFO, the count is indicated in the “ATSNS: Auxiliary Time Stamp Number of Snapshots” bits of the Time Stamp Status Register.

34.2.3 AHB Application Host Interface

In the GMAC-AHB core, the DMA Controller interfaces with the Host through the AMBA AHB Interface. The AHB Master Interface controls data transfers while the AHB Slave interface accesses CSR space. The DMA can be used in embedded applications where DMA is required to optimize data transfer between the GMAC and system memory.

The AHB Master interface converts the internal DMA request cycles into AHB cycles.

Characteristics of this interface include the following:

- Fully AMBA 2.0-compliant AHB Master: with restrictions
- You can choose fixed burst length only (SINGLE, INCR4, INCR8) by programming the FB in the DMA Bus Mode register (see **Register Description**).
  – When fixed burst length is chosen, the AHB master always initiates a burst with SINGLE or INCR4/8type. But when such a burst is responded with SPLIT/RETRY/early burst termination, the AHB master will re-initiate the pending transfers of the burst with INCR or SINGLE burst-length type. It will terminate such INCR bursts when the original requested fixed-burst is transferred. In Fixed Burst-Length mode, if the DMA requests a burst transfer that is not equal to INCR4/8, the AHB Host interface splits the transfer into multiple burst transactions. For example, if the DMA requests a 15-beat burst transfer, the AHB interface splits it into multiple transfers of INCR8 and INCR4 and 3 SINGLE transactions.
- The AHB slaves interfaced to the GMAC-AHB must support SINGLE and INCR transfers, at a minimum.
- Takes care of AHB SPLIT, RETRY, and ERROR conditions. Any ERROR response will halt all further transactions for that DMA, and indicate the error as fatal through the CSR and interrupt. The application must give a hard or soft reset to the module to restart the operation.
- Takes care of AHB 1K boundary breaking
- Handles all data transfers (according to the data bus width configuration), except for Descriptor Status Write accesses (which are always 32-bit). In any burst data transfer, the address bus value is always aligned to the data bus width and need not be aligned to the beat size.
  All AHB burst transfers can be aligned to an address value by enabling the DMA Bus Mode register's AAL bit. If both the FB and AAL bits are set to 1, the AHB interface and the DMA together ensure that all initiated beats are aligned to the address, completing the frame transfer in the minimum number of required beats.
  For example, in 32-bit data bus mode, if a data buffer transfer's start address is 0xF000_0008 and the DMA is configured for a maximum beat size of 8, the AHB transfers occur in the following sequence:
  – 2 SINGLE transfers at addresses 0xF000_0008 and 0xF000_000C
  – 1 INCR4 transfer at address 0xF000_0010
  – All subsequent beats are INCR8 transfers starting from address 0xF000_0020. For an address-aligned INCR8 transfer, the 5 least-significant bits of the address must be 0.
- The DMA Controller requests an AHB Burst Read transfer only when it can accept the received burst data completely. Data read from the AHB is always pushed into the DMA without any delay or BUSY cycles.
- The DMA requests an AHB Burst Write transfer only when it has the sufficient data to transfer the burst completely. The AHB interface always assumes that it has data available to push into the AHB bus. However, the DMA can prematurely indicate end-

of-valid data (due to the transfer of end-of-frame of an Ethernet frame) during the burst. In Fixed Burst Length mode, the AHB Master interface continues the burst with dummy data until the specified length is completed.

The AHB 32-bit Slave interface provides access to the DMA and GMAC CSR space. Characteristics of this interface include the following:

- Fully AMBA 2.0 Compliant AHB Slave—no restrictions
- Supports single and INCR4/8 transfers
- Supports busy and early terminations
- Supports 32-bit, 16-bit, and 8-bit write/read transfers to the CSR; 32-bit access to the CSR are recommended to avoid any SW synchronization problems.
- Generates OKAY only response; does not generate SPLIT, RETRY, or ERROR responses.

34.2.4 DMA Controller

The DMA has independent Transmit and Receive engines, and a CSR space. The Transmit Engine transfers data from system memory to the device port (MTL), while the Receive Engine transfers data from the device port to system memory. The controller utilizes descriptors to efficiently move data from source to destination with minimal Host CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. The controller can be programmed to interrupt the Host CPU for situations such as Frame Transmit and Receive transfer completion, and other normal/error conditions.

The DMA and the Host driver communicate through two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

Control and Status registers are described in detail in **Chapter 34.3.1.1**. Descriptors are described in detail in **Chapter 34.4**.

The DMA transfers data frames received by the core to the Receive Buffer in the Host memory, and Transmit data frames from the Transmit Buffer in the Host memory. Descriptors that reside in the Host memory act as pointers to these buffers.

There are two descriptor lists; one for reception, and one for transmission. The base address of each list is written into DMA Registers 3 and 4, respectively. A descriptor list is forward linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by setting the second address chained in both Receive and Transmit descriptors (RDES1[24] and TDES1[24]). The descriptor lists resides in the Host physical memory address space. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the Host physical memory space, and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data, buffer

status is maintained in the descriptor. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA will skip to the next frame buffer when end-of-frame is detected. Data chaining can be enabled or disabled.

The descriptor ring and chain structure is shown in **Figure 34-6**.

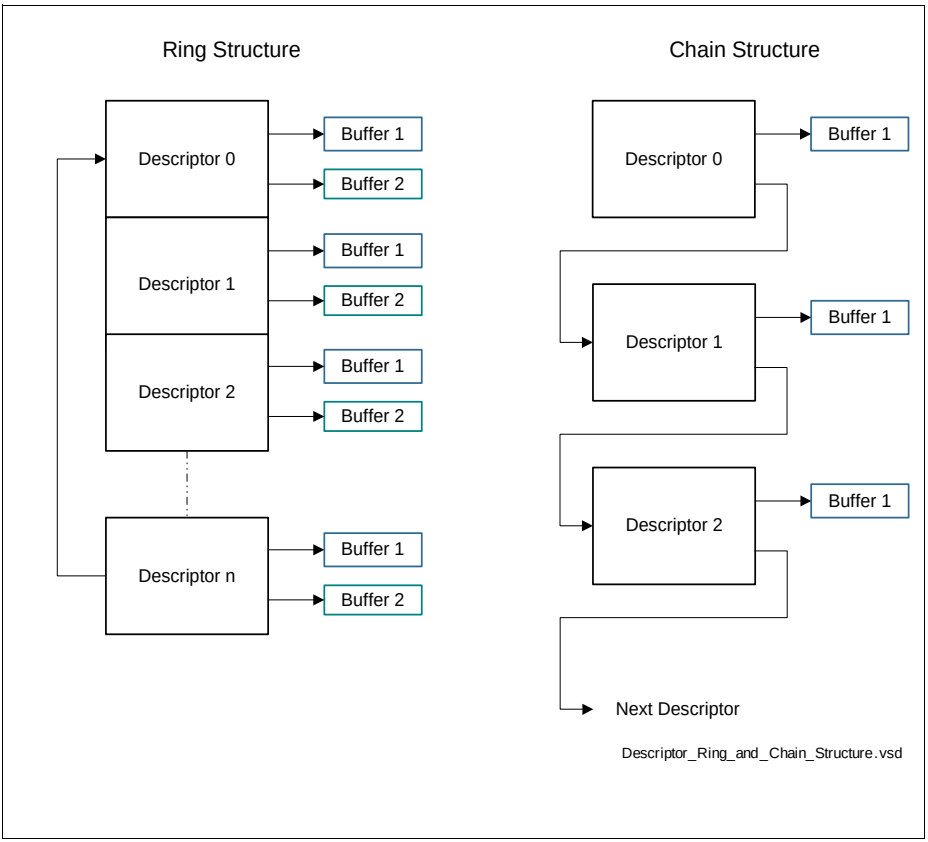

Figure 34-6 Descriptor Ring and Chain Structure

34.2.4.1 Initialization

Initialization for the GMAC is as follows.

1. Write to DMA Register 0 to set Host bus access parameters.
2. Write to DMA Register 7 to mask unnecessary interrupt causes.

3. The software driver creates the Transmit and Receive descriptor lists. Then it writes to both DMA Register 3 and DMA Register 4, providing the DMA with the starting address of each list.
4. Write to GMAC Registers 1, 2, and 3 for desired filtering options.
5. Write to GMAC Register 0 to configure and enable the Transmit and Receive operating modes. The PS and DM bits are set based on the auto-negotiation result (read from the PHY).
6. Write to DMA Register 6 to set bits 13 and 1 to start transmission and reception.
7. The Transmit and Receive engines enter the Running state and attempt to acquire descriptors from the respective descriptor lists. The Receive and Transmit engines then begin processing Receive and Transmit operations. The Transmit and Receive processes are independent of each other and can be started or stopped separately.

Host Bus Burst Access

The DMA will attempt to execute fixed-length Burst transfers on the AHBMaster interface if configured to do so (FB bit of DMA Register 0). The maximum Burst length is indicated and limited by the PBL field (DMA Register 0[13:8]). The Receive and Transmit descriptors are always accessed in the maximum possible (limited by PBL or 16 * 8/bus width) burst-size for the 16-bytes to be read.

The Transmit DMA will initiate a data transfer only when sufficient space to accommodate the configured burst is available in MTL Transmit FIFO or the number of bytes till the end of frame (when it is less than the configured burst-length). The DMA will indicate the start address and the number of transfers required to the AHB Master Interface. When the AHB Interface is configured for fixed-length burst, then it will transfer data using the best combination of INCR4/8 and SINGLE transactions.

The Receive DMA will initiate a data transfer only when sufficient data to accommodate the configured burst is available in MTL Receive FIFO or when the end of frame (when it is less than the configured burst-length) is detected in the Receive FIFO. The DMA will indicate the start address and the number of transfers required to the AHB Master Interface. When the AHB Interface is configured for fixed-length burst, then it will transfer data using the best combination of INCR4/8 and SINGLE transactions. If the end-of frame is reached before the fixed-burst ends on the AHB interface, then dummy transfers are performed in-order to complete the fixed-burst.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer the AHB initiates is less than or equal to the size of the configured PBL. Thus, all subsequent beats start at an address that is aligned to the configured PBL. The DMA can only align the address for beats up to size 8 (for PBL > 8), because the AHB interface does not support more than INCR8.

Host Data Buffer Alignment

The Transmit and Receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates transfers with address aligned to the bus width with dummy data for the byte lanes not required. This typically happens during the transfer of the beginning or end of an Ethernet frame.

Example - Buffer Read

If the Transmit buffer address is 32'h00000FF2 (for 32-bit data bus), and 15 bytes need to be transferred, then the DMA will read five full words from address 32'h00000FF0, but when transferring data to the MTL Transmit FIFO, the extra bytes (the first two bytes) will be dropped or ignored. Similarly, the last 3 bytes of the last transfer will also be ignored. The DMA always ensures it transfers a full 32-bit data to the MTL Transmit FIFO, unless it is the end-of-frame.

Buffer Size Calculations

The DMA does not update the size fields in the Transmit and Receive descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The transmit DMA transfers the exact number of bytes (indicated by buffer size field of TDES1) towards the GMAC core. If a descriptor is marked as first (FS bit of TDES1 is set), then the DMA marks the first transfer from the buffer as the start of frame. If a descriptor is marked as last (LS bit of TDES1), then the DMA marks the last transfer from that data buffer as the end-of frame to the MTL.

The Receive DMA transfers data to a buffer until the buffer is full or the end-of frame is received from the MTL. If a descriptor is not marked as last (LS bit of RDES0), then the descriptor's corresponding buffer(s) are full and the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits of RDES0[29:16]) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The Receive DMA always transfers the start of next frame with a new descriptor.

Note: Even when the start address of a receive buffer is not aligned to the system bus's data width, the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1.024-byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the Receive descriptor to have a 0x1002 offset. The Receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual

useful space in this buffer is 1.022 bytes, even though the buffer size is programmed as 1.024 bytes, due to the start address offset.

DMA Arbiter

The arbiter inside the DMA module performs the arbitration between the Transmit and Receive channel accesses to the AHB Master interface. Two types of arbitrations are possible: round-robin, and fixed-priority.

When round-robin arbitration is selected (DA bit of DMA Register 0 is reset), the arbiter allocates the data bus in the ratio set by the PR bits of DMA Register 0, when both Transmit and Receive DMAs are requesting for access simultaneously. When the DA bit is set, the Receive DMA always gets priority over the Transmit DMA for data access.

34.2.4.2 Transmission

TxDMA Operation: Default (Non-OSF) Mode

The Transmit DMA engine in default mode proceeds as follows:

1. The Host sets up the transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet Frame data.
2. Once the ST bit (DMA Register 6[13]) is set, the DMA enters the Run state.
3. While in the Run state, the DMA polls the Transmit Descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the Host, or if an error condition occurs, transmission is suspended and both the Transmit Buffer Unavailable (DMA Register 5[2]) and Normal Interrupt Summary (DMA Register 5[16]) bits are set. The Transmit Engine proceeds to Step 8.
4. If the acquired descriptor is flagged as owned by DMA (TDES0[31] = 1’b1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.
5. The DMA fetches the Transmit data from the Host memory and transfers the data to the MTL for transmission.
6. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps Step 2, Step 3, and Step 4 are repeated until the end-of-Ethernet-frame data is transferred to the MTL.
7. When frame transmission is complete, if IEEE 1588 time stamping was enabled for the frame (as indicated in the transmit status) the time-stamp value obtained from MTL is written to the transmit descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. The status information is then written to this transmit descriptor (TDES0). Because the Own bit is cleared during this step, the Host now owns this

descriptor. If time stamping was not enabled for this frame, the DMA does not alter the contents of TDES2 and TDES3.

8. Transmit Interrupt (DMA Register 5[0]) is set after completing transmission of a frame that has Interrupt on Completion (TDES1[31]) set in its Last Descriptor. The DMA engine then returns to Step 2.
9. In the Suspend state, the DMA tries to re-acquire the descriptor (and thereby return to Step 2) when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared.

The TxDMA transmission flow in default mode is shown in **Figure 34-7**.

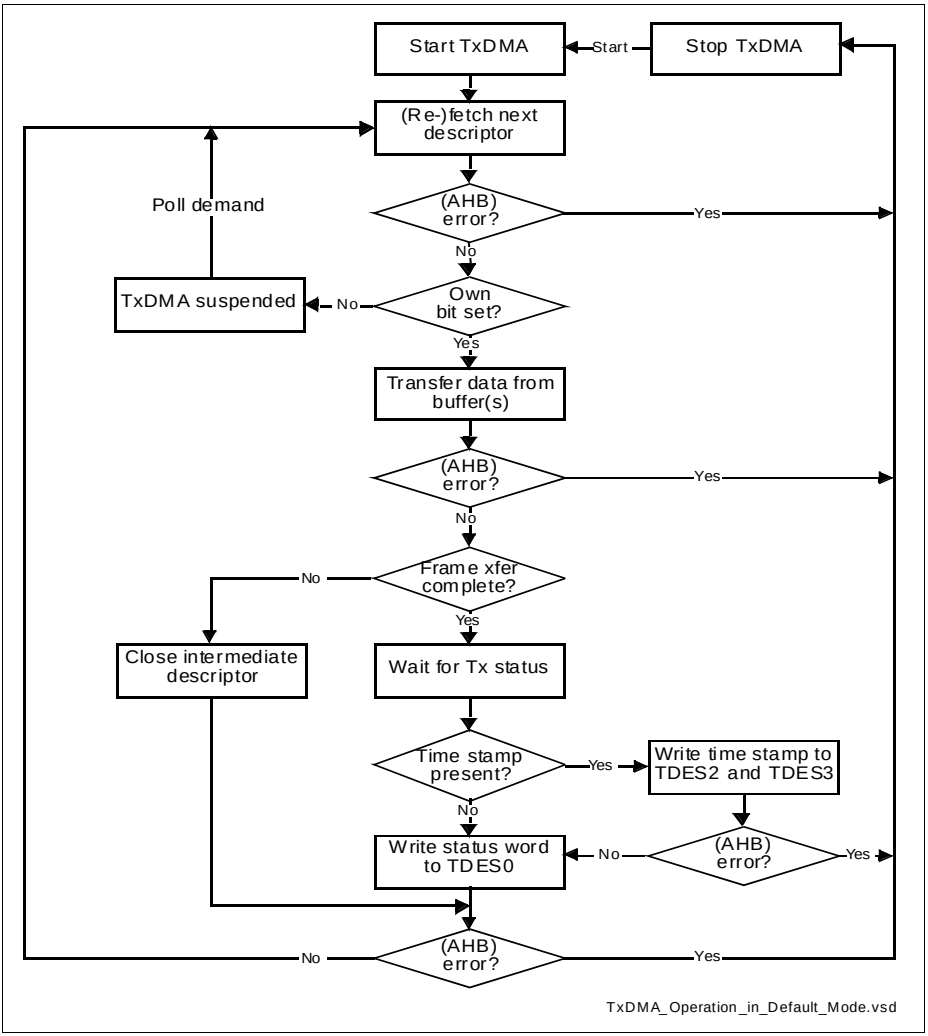

Figure 34-7 TxDMA Operation in Default Mode

TxDMA Operation: OSF Mode

While in the Run state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first (if the OSF bit is set in DMA Register 6[2]). As the transmit process finishes transferring the first frame, it immediately polls the

Transmit Descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information.

In OSF mode, the Run state Transmit DMA operates in the following sequence:

1. The DMA operates as described in Step 1–Step 5 of the TxDMA (default mode).
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to Step 6.
4. The DMA fetches the Transmit frame from the Host memory and transfers the frame to the MTL until the End-of-Frame data is transferred, closing the intermediate descriptors if this frame is split across multiple descriptors.
5. The DMA waits for the previous frame's frame transmission status and time stamp. Once the status is available, the DMA writes the time stamp to TDES2 and TDES3, if such time stamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared Own bit, to the corresponding TDES0, thus closing the descriptor. If time stamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3.
6. If enabled, the Transmit interrupt is set, the DMA fetches the next descriptor, then proceeds to Step 2 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (Step 6).
7. In Suspend mode, if a pending status and time stamp are received from the MTL, the DMA writes the time stamp (if enabled for the current frame) to TDES2 and TDES3, then writes the status to the corresponding TDES0. It then sets relevant interrupts and returns to Suspend mode.
8. The DMA can exit Suspend mode and enter the Run state (go to Step 1 or Step 2 depending on pending status) only after receiving a Transmit Poll demand (DMA Register 1).

Note: As the DMA fetches the next descriptor in advance before closing the current descriptor, the descriptor chain should have more than 2 different descriptors for correct and proper operation.

The basic flow is charted in **Figure 34-8**.

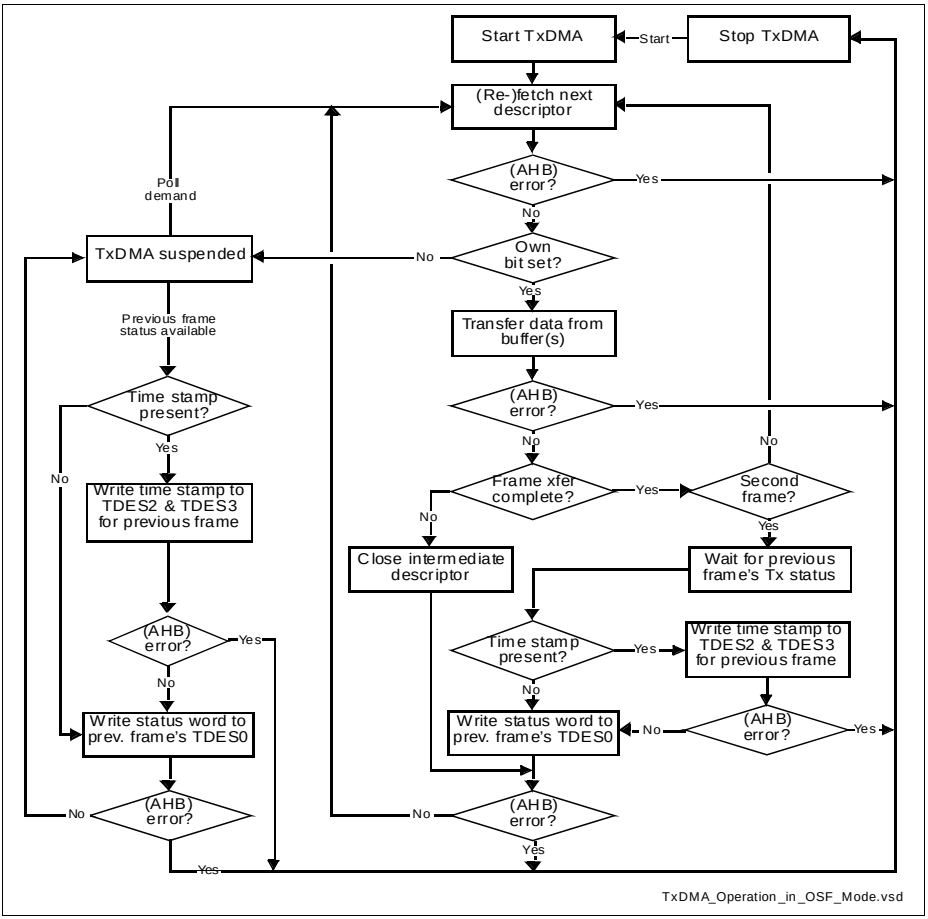

Figure 34-8 TxDMA Operation in OSF Mode

Transmit Frame Processing

The Transmit DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and FCS fields. The DA, SA, and Type/Len fields contain valid data. If the Transmit Descriptor indicates that the MAC core must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes.

Frames can be data-chained and can span several buffers. Frames must be delimited by the First Descriptor (TDES1[29]) and the Last Descriptor (TDES1[30]), respectively.

As transmission starts, the First Descriptor must have (TDES1[29]) set. When this occurs, frame data transfers from the Host buffer to the MTL Transmit FIFO. Concurrently, if the current frame has the Last Descriptor (TDES1[30]) clear, the Transmit Process attempts to acquire the Next Descriptor. The Transmit Process expects this descriptor to have TDES1[29] clear. If TDES1[30] is clear, it indicates an intermediary buffer. If TDES1[30] is set, it indicates the last buffer of the frame.

After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 0 (TDES0) word of the descriptor that has the last segment set in Transmit Descriptor 1 (TDES1[30]). At this time, if Interrupt on Completion (TDES1[31]) was set, Transmit Interrupt (DMA Register 5[0]) is set, the Next Descriptor is fetched, and the process repeats.

Actual frame transmission begins after the MTL Transmit FIFO has reached either a programmable transmit threshold (DMA Register 6[16:14]), or a full frame is contained in the FIFO. There is also an option for Store and Forward Mode (DMA Register 6[21]). Descriptors are released (Own bit TDES0[31] clears) when the DMA finishes transferring the frame.

Transmit Polling Suspended

Transmit polling can be suspended by either of the following conditions:

- The DMA detects a descriptor owned by the Host (TDES0[31]=0). To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command.
- A frame transmission is aborted when a transmit error due to underflow is detected. The appropriate Transmit Descriptor 0 (TDES0) bit is set.

If the second condition occur, both Abnormal Interrupt Summary (DMA Register 5[15]) and Transmit Underflow bits (DMA Register 5 [5]) are set, and the information is written to Transmit Descriptor 0, causing the suspension. If the DMA goes into SUSPEND state due to the first condition, then both Normal Interrupt Summary (DMA Register 5 [16]) and Transmit Buffer Unavailable (DMA Register 5 [2]) are set.

In both cases, the position in the Transmit List is retained. The retained position is that of the descriptor following the Last Descriptor closed by the DMA.

The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause.

34.2.4.3 Reception

The Receive DMA engine's reception sequence is depicted in **Figure 34-9** and proceeds as follows:

1. The host sets up Receive descriptors (RDES0-RDES3) and sets the Own bit (RDES0[31]).

2. Once the SR (DMA Register 6[1]) bit is set, the DMA enters the Run state. While in the Run state, the DMA polls the Receive Descriptor list, attempting to acquire free descriptors. If the fetched descriptor is not free (is owned by the host), the DMA enters the Suspend state and jumps to Step 8.
3. The DMA decodes the receive data buffer address from the acquired descriptors.
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.
5. When the buffer is full or the frame transfer is complete, the Receive engine fetches the next descriptor.
6. If the current frame transfer is complete, the DMA proceeds to Step 6. If the DMA does not own the next fetched descriptor and the frame transfer is not complete (EOF is not yet transferred), the DMA sets the Descriptor Error bit in the RDES0 (unless flushing is disabled). The DMA closes the current descriptor (clears the Own bit) and marks it as intermediate by clearing the Last Segment (LS) bit in the RDES0 value (marks it as Last Descriptor if flushing is not disabled), then proceeds to Step 7. If the DMA does own the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to Step 3.
7. If IEEE 1588 time stamping is enabled, the DMA writes the time stamp (if available) to the current descriptor's RDES2 and RDES3. It then takes the receive frame's status from the MTL and writes the status word to the current descriptor's RDES0, with the Own bit cleared and the Last Segment bit set.
8. The Receive engine checks the latest descriptor's Own bit. If the host owns the descriptor (Own bit is 1'b0) the Receive Buffer Unavailable bit (Register 5[7]) is set and the DMA Receive engine enters the Suspended state (Step 8). If the DMA owns the descriptor, the engine returns to Step 3 and awaits the next frame.
9. Before the Receive engine enters the Suspend state, partial frames are flushed from the Receive FIFO (You can control flushing using Bit 24 of DMA Register 6).
10. The Receive DMA exits the Suspend state when a Receive Poll demand is given or the start of next frame is available from the MTL's Receive FIFO. The engine proceeds to Step 1 and refetches the next descriptor.

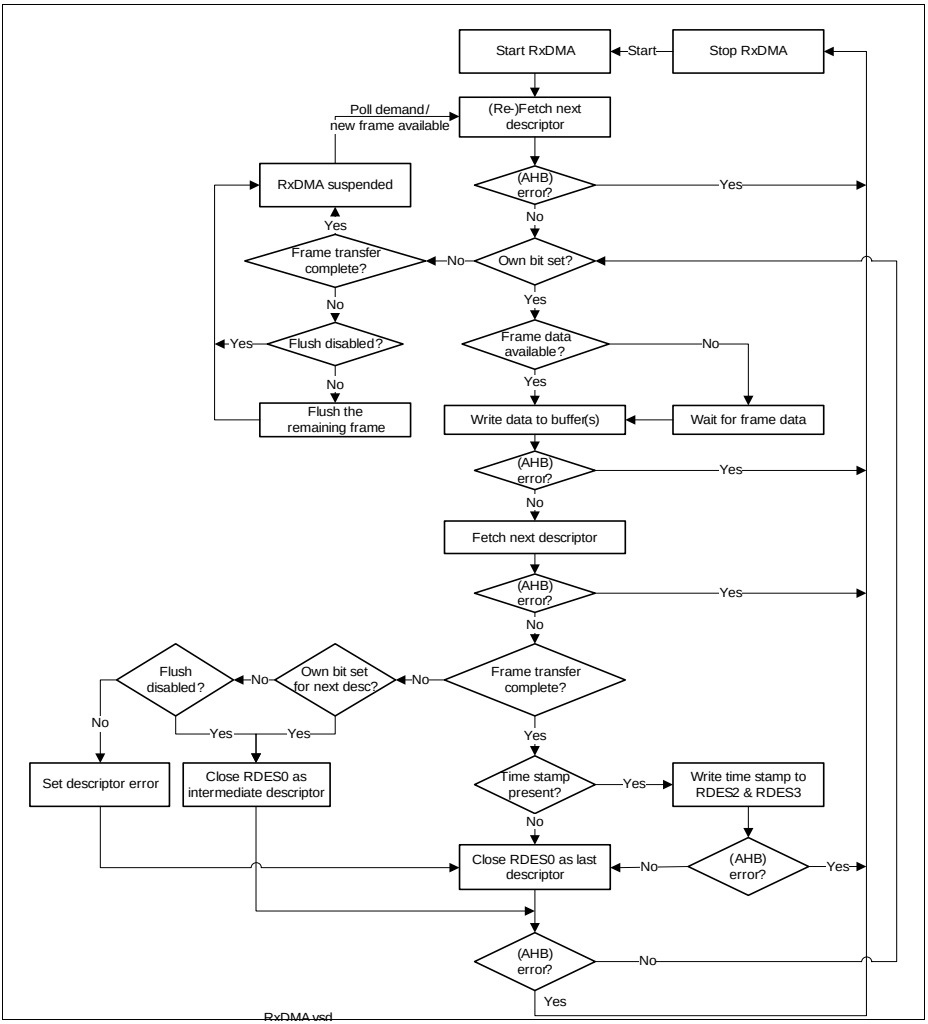

Figure 34-9 Receive DMA Operation

The DMA does not acknowledge accepting the status from the MTL until it has completed the time stamp write-back and is ready to perform status write-back to the descriptor.

If software has enabled time stamping through CSR, when a valid time stamp value is not available for the frame (for example, because the receive FIFO was full before the time stamp could be written to it), the DMA writes all-ones to RDES2 and RDES3.

Otherwise (that is, if time stamping is not enabled), the RDES2 and RDES3 remain unchanged.

Receive Descriptor Acquisition

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- The receive Start/Stop bit (Register 6[1]) has been set immediately after being placed in the Run state.
- The data buffer of current descriptor is full before the frame ends for the current transfer.
- The controller has completed frame reception, but the current Receive Descriptor is not yet closed.
- The receive process has been suspended because of a host-owned buffer (RDES0[31] = 0) and a new frame is received.
- A Receive poll demand has been issued.

Receive Frame Processing

The GMAC transfers the received frames to the Host memory only when the frame passes the address filter and frame size is greater than or equal to configurable threshold bytes set for the Receive FIFO of MTL, or when the complete frame is written to the FIFO in Store-and-Forward mode.

If the frame fails the address filtering, it is dropped in the GMAC block itself (unless Receive All GMAC Register 1[31] bit is set). Frames that are shorter than 64 bytes, because of collision or premature termination, can be purged from the MTL Receive FIFO.

After 64 (configurable threshold) bytes have been received, the MTL block requests the DMA block to begin transferring the frame data to the Receive Buffer pointed to by the current descriptor. The DMA sets First Descriptor (RDES0[9]) after the DMA Host Interface (AHB/AXI or MDC) becomes ready to receive a data transfer (if DMA is not fetching transmit data from the host), to delimit the frame. The descriptors are released when the Own (RDES[31]) bit is reset to 1’b0, either as the Data buffer fills up or as the last segment of the frame is transferred to the Receive buffer. If the frame is contained in a single descriptor, both Last Descriptor (RDES[8]) and First Descriptor (RDES[9]) are set.

The DMA fetches the next descriptor, sets the Last Descriptor (RDES[8]) bit, and releases the RDES0 status bits in the previous frame descriptor. Then the DMA sets Receive Interrupt (Register 5[6]). The same process repeats unless the DMA encounters a descriptor flagged as being owned by the host. If this occurs, the Receive Process sets Receive Buffer Unavailable (Register 5[7]) and then enters the Suspend state. The position in the receive list is retained.

Receive Process Suspended

If a new Receive frame arrives while the Receive Process is in Suspend state, the DMA refetches the current descriptor in the Host memory. If the descriptor is now owned by the DMA, the Receive Process re-enters the Run state and starts frame reception. If the descriptor is still owned by the host, by default, the DMA discards the current frame at the top of the MTL Rx FIFO and increments the missed frame counter. If more than one frame is stored in the MTL Rx FIFO, the process repeats.

The discarding or flushing of the frame at the top of the MTL Rx FIFO can be avoided by setting Operation Mode register bit 24 (DFF). In such conditions, the receive process sets the Receive Buffer Unavailable status and returns to the Suspend state.

34.2.4.4 Interrupts

Interrupts can be generated as a result of various events. DMA Register 5 contains all the bits that might cause an interrupt. DMA Register 7 contains an enable bit for each of the events that can cause an interrupt.

There are two groups of interrupts, Normal and Abnormal, as described in DMA Register 5. Interrupts are cleared by writing a 1’b1 to the corresponding bit position. When all the enabled interrupts within a group are cleared, the corresponding summary bit is cleared. When both the summary bits are cleared, the interrupt signal sbd_intr_o is deasserted. If the GMAC core is the cause for assertion of the interrupt, then any of the GLI, GMI, or GPI bits of DMA Register 5 will be set high.

Note: DMA Register 5 is the (interrupt) status register. The interrupt pin (sbd_intr_o) will be asserted due to any event in this status register only if the corresponding interrupt enable bit is set in DMA Register 7.

Interrupts are not queued and if the interrupt event occurs before the driver has responded to it, no additional interrupts are generated. For example, Receive Interrupt (DMA Register 5[6]) indicates that one or more frames was transferred to the Host buffer. The driver must scan all descriptors, from the last recorded position to the first one owned by the DMA.

An interrupt is generated only once for simultaneous, multiple events. The driver must scan DMA Register 5 for the cause of the interrupt. The interrupt is not generated again unless a new interrupting event occurs, after the driver has cleared the appropriate bit in DMA Register 5. For example, the controller generates a Receive interrupt (DMA Register 5[6]) and the driver begins reading DMA Register 5. Next, Receive Buffer Unavailable (DMA Register 5[7]) occurs. The driver clears the Receive interrupt. Even then, the sbd_intr_o signal is not deasserted, due to the active or pending Receive Buffer Unavailable interrupt.

An interrupt timer is given for flexible control of Receive Interrupt (DMA register 5[6]). When this Interrupt timer is programmed with a non-zero value, it will get activated as soon as the RxDMA completes a transfer of a received frame to system memory without

asserting the Receive Interrupt because it is not enabled in the corresponding Receive Descriptor (RDES1[31] in Table 7-3). When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding RI is enabled in DMA Register 7. This timer gets disabled before it runs out, when a frame is transferred to memory and the RI is set because it is enabled for that descriptor.

34.2.5 MAC Transaction Layer (MTL)

The MAC Transaction Layer provides FIFO memory to buffer and regulate the frames between the application system memory and the GMAC core. It also enables the data to be transferred between the application clock domain and the GMAC clock domains. The MTL layer has 2 data paths, namely the Transmit path and the Receive Path. The data path for both directions is 32-bit wide and operates with a simple FIFO protocol.

The GMAC-MTL communicates with the application side with the Application Transmit Interface (ATI), Application Receive Interface (ARI), and the MAC Control Interface (MCI).

34.2.5.1 Transmit Path

The DMA controls all transactions for the transmit path through the ATI. Ethernet frames read from the system memory is pushed into the FIFO by the DMA. The frame is then popped out and transferred to the GMAC core when triggered. When the end-of-frame is transferred, the status of the transmission is taken from the GMAC core and transferred back to the DMA.

The Transmit FIFO has a depth of 4K bytes. 4FIFO-fill level is indicated to the DMA so that it can initiate a data fetch in required bursts from the system memory, using the AHB interface. The data from the AHB Master interface is pushed into the FIFO with the appropriate byte lanes qualified by the DMA. The DMA also indicates the start-of-frame (SOF) and end-of-frame (EOF) transfers along with a few sideband signals controlling the pad-insertion/CRC generation for that frame in the GMAC core.

Per-frame control bits, such as Automatic Pad/CRC Stripping disable, time stamp capture, and so forth are taken as sideband control inputs on the ATI, stored in a separate register FIFO, and passed on to the core transmitter when the corresponding frame data is read from the Transmit FIFO.

There are two modes of operation for popping data towards the GMAC core. In Threshold mode, as soon as the number of bytes in the FIFO crosses the configured threshold level (or when the end-of-frame is written before the threshold is crossed), the data is ready to be popped out and forwarded to the GMAC core. The threshold level is configured using the TTC bits of DMA Register 0. In store-and-forward mode, the MTL pops the frame towards the GMAC core only when one or more of the following conditions are true:

- When a complete frame is stored in the FIFO

- When the TX FIFO becomes almost full
- When the ATI watermark becomes low. The watermark becomes low when the requested FIFO does not have space to accommodate the requested burst-length on the ATI.

Therefore, the MTL never stops in the store-and-forward mode even if the Ethernet frame length is bigger than the Tx FIFO depth.

The application can flush the Transmit FIFO of all contents by setting the FTF (DMA Register 6[20]) bit. This bit is self-clearing and initializes the FIFO pointers to the default state. If the FTF bit is set during a frame transfer from the MTL to the GMAC core, then the MTL stops further transfer as the FIFO is considered to be empty. Hence an underflow event occurs at the GMAC transmitter and the corresponding Status word is forwarded to the DMA.

Initialization through **Transmit Status Word** detail initialization and transmit operations for the MTL Layer.

Initialization

Upon reset, the MTL is ready to manage the flow of data to and from the DMA and the GMAC.

There are no requirements for enabling the MTL. However, the GMAC block and the DMA controller must be enabled individually through their respective CSRs.

Single-Packet Transmit Operation

During a transmit operation, the MTL block is slaved to the DMA controller. The general sequence of events for a transmit operation is as follows.

1. If the system has data to be transferred, the DMA controller, if enabled, fetches data from the Host through the AHB/AXI Master interface and starts forwarding it to the MTL. The MTL pushes the data received from the DMA into the FIFO. It continues to receive the data until the end-of frame of the frame is transferred.
2. The data is taken out of the FIFO and sent to the MAC by the FIFO controller engine. When the threshold level is crossed or a full packet of data is received into the FIFO, the MTL pops out the frame data and drives them to the GMAC core. The engine continues to transfer data from the FIFO until a complete packet has been transferred to the MAC. Upon completion of the frame, the MTL receives the Status from the GMAC and then notifies the DMA controller

Transmit Operation—Two Packets in the Buffer

1. Because the DMA must update the descriptor status before releasing it to the Host, there can be at the most two frames inside a transmit FIFO. The second frame will be fetched by the DMA and put into the FIFO only if the OSF (Operate on Second

Frame bit is set). If this bit is not set, the next frame will be fetched from the memory only after the MAC has completely processed the frame and the DMA has released the descriptors.

2. If the OSF bit is set, the DMA starts fetching the second frame immediately after completing the transfer of the first frame to the FIFO. It does not wait for the status to be updated. The MTL, in the meantime, receives the second frame into the FIFO while transmitting the first frame. As soon as the first frame has been transferred and the status is received from the MAC, the MTL pushes it to the DMA. If the DMA has already completed sending the second packet to the MTL, it must wait for the status of the first packet before proceeding to the next frame.

Transmit Operation—Multiple Packets in Buffer

In GMAC-MTL configuration, the transmit FIFO can be configured to accept more than 2 packets at a time. This option limits the number of status words that can be stored in the MTL before it is transferred to the DMA/host. By default, this number is limited to 2 but can be configured for 4 or 8 as well. Once the MTL FIFO accepts the number of frames equal to the status FIFO depth, it will stop accepting further frames unless the transmit Status that is given out and accepted by the host/DMA thus freeing up the space in this small FIFO.

Retransmission During Collision

While a frame is being transferred from the MTL to the GMAC, a collision event occurs on the GMAC line interface in Half-Duplex mode. The GMAC then indicates a retry attempt to the MTL by giving the status even before the end-of-frame is transferred from MTL. Then the MTL will enable the retransmission by popping out the frame again from the FIFO.

After more than 96 bytes are popped towards the GMAC core, the FIFO controller frees up that space and makes it available to the DMA to push in more data. This means that the retransmission is not possible after this threshold is crossed or when the GMAC core indicates a late-collision event.

Transmit FIFO Flush Operation

The GMAC provides a control to the software to flush the Transmit FIFO in the MTL layer through the use of Bit 20 of the Operation Mode register. The Flush operation is immediate and the MTL clears the Tx FIFO and the corresponding pointers to the initial state even if it is in the middle of transferring a frame to the GMAC Core. The data which is already accepted by the MAC transmitter will not be flushed. It will be scheduled for transmission and will result in underflow as TxFIFO does not complete the transfer of rest of the frame. As in all underflow conditions, a runt frame will be transmitted and observed on the line. The status of such a frame will be marked with both Underflow and Frame Flush events (TDES0 bits 13 and 1).

The MTL layer also stops accepting any data from the application (DMA) during the Flush operation. It will generate and transfer Transmit Status Words to the application for the number of frames that is flushed inside the MTL (including partial frames). Frames that are completely flushed in the MTL will have the Frame Flush Status bit (TDES0 13) set. The MTL completes the Flush operation when the application (DMA) accepts all of the Status Words for the frames that were flushed, and then clears the Transmit FIFO Flush control register bit. At this point, the MTL starts accepting new frames from the application (DMA).

Transmit Status Word

At the end of transfer of the Ethernet frame to the GMAC core and after the core completes the transmission of the frame, the MTL outputs the transmit status to the application.The detailed description of the Transmit Status is the same as for bits [23:0] of TDES0, given in **Table 34-28**.

If IEEE 1588 time stamping is enabled, the MTL returns specific frame's 64-bit time stamp, along with the ATI's transmit status.

Transmit Checksum Offload Engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the GMAC-UNIV has an Checksum Offload Engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path. This section explains the operation of the Checksum Offload Engine for transmitted frames.

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete frame, then inserted into its corresponding header field. Due to this requirement, this function is enabled only when the Transmit FIFO is configured for Store-and-Forward mode (that is, when the TSF bit is set in DMA Register 6). If the core is configured for Threshold (cut-through) mode, the Transmit COE is bypassed.

Note: You must make sure that the Transmit FIFO is deep enough to store a complete frame before that frame is transferred to the GMAC Core transmitter. The reason being that when space is not available to accept the programmed burst length of the data, then the MTL TxFIFO starts reading to avoid dead-lock. Once reading starts, then checksum insertion engine fails and consequently all succeeding frames may get corrupted due to improper recovery. Therefore, you must enable the checksum insertion only in the frames that are less than the following number of bytes in size (even in the store-and-forward mode):
FIFO Depth – PBL – 3 FIFO Locations
The PBL is the programmed burst-length.

This module supports two types of checksum calculation and insertion. This checksum engine can be controlled for each frame by setting the CIC bits (Bits 28:27 of TDES1, described in **Transmit Descriptor 1 (TDES1)**) in GMAC-AHB or GMAC-DMA configurations.

Note: See IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460, and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6, and ICMPv6 packet header specifications, respectively.

IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Ethernet frame's Type field has the value 0x0800 and the IP datagram's Version field has the value 0x4. The input frame's checksum field is ignored during calculation and replaced with the calculated value.

IPv6 headers do not have a checksum field; thus, the COE does not modify IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 16 in **Table 34-28**). This status bit is set whenever the values of the Ethernet Type field and the IP header's Version field are not consistent, or when the Ethernet frame does not have enough data, as indicated by the IP header Length field.

In other words, this bit is set when an IP header error is asserted under the following circumstances:

For IPv4 datagrams

- The received Ethernet type is 0x0800, but the IP header's Version field does not equal 0x4
- The IPv4 Header Length field indicates a value less than 0x5 (20 bytes)
- The total frame length is less than the value given in the IPv4 Header Length field

For IPv6 datagrams

- The Ethernet type is 0x86dd but the IP header Version field does not equal 0x6
- The frame ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

Even when the COE detects such an IP header error, it inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.

TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP.

Note: For non-TCP, -UDP, or -ICMP/ICMPv6 payloads, this checksum engine is bypassed and nothing further is modified in the frame.

Note: Fragmented IP frames (IPv4 or IPv6), IP frames with security features (such as an authentication header or encapsulated security payload), and IPv6 frames with routing headers are not processed by this engine, and therefore must be bypassed. In other words, payload checksum insertion must not be enabled for such frames.

The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. This engine can work in the following two modes:

- In the first mode, the TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the input frame's Checksum field. This engine includes the Checksum field in the checksum calculation, then replaces the Checksum field with the final calculated checksum.
- In the second mode, the engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

Note: For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16'h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 12 in **Table 34-28**). This engine sets the Payload Checksum Error status bit when it detects that the frame has been forwarded to the MAC Transmitter engine in Store-and-Forward mode without the end-of-frame being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

34.2.5.2 Receive Path

This module receives the frames given out by the GMAC core and pushes them into the Rx FIFO. The status (fill level) of this FIFO is indicated to the DMA once it crosses the configured Receive threshold (RTC of DMA Register 6). The MTL also indicates the FIFO fill level so that the DMA can initiate pre-configured burst transfers towards the AHB interface.

Receive Operation through **Receive Status Word** detail receive operations for the MTL Layer.

Receive Operation

During an Rx operation, the MTL is slaved to the GMAC. The general sequence of Receive operation events is as follows:

1. When the GMAC receives a frame, it pushes in data along with byte enables. The GMAC also indicates the SOF and EOF. The MTL accepts the data and pushes it into the Rx FIFO. After the EOF is transferred, the GMAC drives the status word, which is also pushed into the same Rx FIFO by the MTL.
2. When IEEE 1588 time stamping is enabled and the 64-bit time stamp is available along with the receive status, it is appended to the frame received from the GMAC and is pushed into the RxFIFO before the corresponding receive status word is written. Thus, two additional locations per frame are taken for storing the time stamp in the RxFIFO.
3. The MTL_RX engine takes the data out of the FIFO and sends it to the DMA. In the default Cut-Through mode, when 64 bytes (configured with RTC bits of DMA Register 6) or a full packet of data are received into the FIFO, the MTL_RX engine pops out the data and indicates its availability to the DMA. Once the DMA initiates the transfer to the AHBinterface, the MTL_RX engine continues to transfer data from the FIFO until a complete packet has been transferred. Upon completion of the EOF frame transfer, the MTL pops out the status word and sends it to the DMA controller.
4. In Rx FIFO Store-and-Forward mode (configured by the RSF bit of DMA Register 6), a frame is read out only after being written completely into the Receive FIFO. In this mode, all error frames are dropped (if the core is configured to do so) such that only valid frames are read out and forwarded to the application. In Cut-Through mode, some error frames are not dropped, because the error status is received at the end-of-frame, by which time the start of that frame has already been read out of the FIFO.

Note: In 32-bit data bus mode, the time-stamp transfer takes two clock cycles and the lower 32-bit of the time-stamp is given out first. The status also may be extended to two cycles when Advanced Time-stamp feature is enabled.

Receive Operation Multiframe Handling

Since the status is available immediately following the data, the MTL is capable of storing any number of frames into the FIFO, as long as it is not full.

GMAC Flow Control

The flow control operation of the GMAC can also be enabled (EFC bit of DMA Register 6) by the Rx FIFO control logic. The flow control signal to the GMAC is asserted whenever the Rx FIFO fill level crosses the configured threshold (RFA bits of DMA Register 6). This flow control signal is deasserted once the FIFO fill-level falls below the

configured threshold (RFD bits). This operation is independent of whether the GMAC is configured for full-duplex or half-duplex.

The above hardware flow control operation is applicable only when the Rx FIFO is 4.096 or more bytes deep. A separate sideband flow control signal (sbd_flowctrl_i) is optionally provided at the top-level I/O for all GMAC-AHB, GMAC-AXI, GMAC-DMA and GMAC-MTL configurations. For 4.096-byte or larger Rx FIFOs, this sideband signal is logically ORed with the hardware flow control signal. Thus, flow control is enabled when either of these signals is asserted and disabled when both these signals are deasserted.

Error Handling

If the MTL Rx FIFO is full before it receives the EOF data from the GMAC, an overflow is declared, the whole frame (including the status word) is dropped, and the overflow counter in the DMA (Register 8) is incremented. This is true even if the Forward Error Frame (FEF bit of DMA Register 6) is set. If the start address of such a frame has already been transferred to the Read Controller, the rest of the frame is dropped and a dummy EOF is written to the FIFO along with the status word. The status will indicate a partial frame due to overflow. In such frames, the Frame Length field is invalid.

The MTL Rx Control logic can filter error and undersized frames, if enabled (using the DMA Register 6 FEF and FUF bits). If the start address of such a frame has already been transferred to the Rx FIFO Read Controller, that frame is not filtered. The start address of the frame is transferred to the Read Controller after the frame crosses the receive threshold (set by the DMA Register 6 RTC bits).

If the MTL Receive FIFO is configured to operate in Store-and-Forward mode, all error frames can be filtered and dropped.

Receive Status Word

At the end of the transfer of the Ethernet frame to the host, the MTL outputs the receive status to the Application. The detailed description of the receive status is the same as for Bits[31:0] of RDES0, given in **Table 34-23**, except that Bits 31, 14, 9, and 8 are reserved and have a reset of 1'b0 by default. When the status of a partial frame due to overflow is given out, the Frame Length field in the status word is not valid.

*Note: When Advanced Time Stamp feature is enabled, the status is composed of two parts - normal (default [31:0]), and extended. The extended status[63:32] gives the information about the received ethernet payload when it is carrying PTP packets or TCP/UDP/ICMP over IP packets. In 32-bit data-bus, these are transferred over two clock cycles. The detailed description of the receive status is the same as described in RDES0 and RDES4 in **Receive Descriptor** , except that bits 31, 14, 9, and 8 of normal status is reserved and have a reset value of 1'b0. When the status of a partial frame due to overflow is given out, the Frame Length field in the status word is not valid.*

34.2.6 GMAC Core

The GMAC core supports many interfaces towards the PHY chip. In TC27x MII and RMII are implemented. The PHY interface can be selected only once after reset. The GMAC core communicates with the application side with the MAC Transmit Interface (MTI), MAC Receive Interface (MRI) and the MAC Control Interface (MCI).

34.2.6.1 Transmission

Transmission is initiated when the MTL Application pushes in data with the SOF . When the SOF signal is detected, the GMAC accepts the data and begins transmitting to the MII. The time required to transmit the frame data to the RMII/MII after the Application initiates transmission is variable, depending on delay factors like IFG delay, time to transmit preamble/SFD, and any back-off delays for Half-Duplex mode. Until then, the GMAC does not accept the data received from MTL.

After the EOF is transferred to the GMAC Core, the core complete normal transmission and then gives the Status of Transmission back to the MTL. If a normal collision (in Half-duplex mode) occurs during transmission, the GMAC core makes valid the Transmit Status to the MTL. It then accepts and drops all further data until the next SOF is received. The MTL block should retransmit the same frame from SOF on observing a Retry request (in the Status) from the GMAC.

The GMAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. During the normal transfer of a frame from MTL, if the GMAC receives a SOF without getting an EOF for the previous frame, then it (the SOF) is ignored and the new frame is considered as continuation of the previous frame.

The following six modules constitute the transmission function of the GMAC:

- Transmit Bus Interface Module (TBU)
- Transmit Frame Controller Module (TFC)
- Transmit Protocol Engine Module (TPE)
- Transmit Scheduler Module (STX)
- Transmit CRC Generator Module (CTX)
- Transmit Flow Control Module (FTX)

Transmit Bus Interface Module

This module interfaces the transmit path of the GMAC core with the external frame with a FIFO interface.

This module also outputs the (32-bit) Transmit Status to the application at the end of normal transmission or collision.

Additionally, this module outputs the Transmit Snapshot register value.

Transmit Frame Controller Module

The Transmit Frame Controller (TFC) consists of two registers to hold data, byte enables, and the last data control received from the TBU. The register provides a buffer between the Application and the TPE to regulate data flow as well as converts the input data into an 8-bit bus towards the TPE.

When the number of bytes received from the Application falls below 60 (DA+SA+LT+DATA), the state machine that interfaces with the TBU automatically appends zeros to the transmitting frame to make the data length exactly 46 bytes to meet the minimum data field requirement of IEEE 802.3. The GMAC can be programmed not to append any padding.

The cyclic redundancy check (CRC) for the Frame Check Sequence (FCS) field is calculated before transmission to the TPE module. This value is computed by CTX module. The TFC module receives the computed CRC and appends it to the data being transmitted to the TPE module. When the GMAC is programmed to not append the CRC value to the end of Ethernet frames, the TFC module ignores the computed CRC and transmits only the data received from the TBU module to the TPE module. An exception to this rule is that when the GMAC is programmed to append pads for frames (DA+SA+LT+DATA) less than 60 bytes sent by the TBU module, the TFC module will append the CRC at the end of padded frame.

The TFC converts the data received on the 32/64/128-bit interface from the TBU into 8-bit data for the TPE module.

Transmit Protocol Engine Module

The Transmit Protocol Engine (TPE) module consists of a transmit state machine that controls the operation of Ethernet frame transmission. The module's transmit state machine performs the following functions to meet the IEEE 802.3 specifications.

- Generates preamble and SFD
- Generates jam pattern in Half-Duplex mode
- Jabber timeout
- Flow control for Half-Duplex mode (back pressure)
- Generates transmit frame status
- Contains time stamp snapshot logic for IEEE 1588 support

When a new frame transmission from the TFC is requested, the transmit state machine sends out the preamble and SFD, followed by the data received. The preamble is defined as 7 bytes of 8'b10101010 pattern, and the SFD is defined as 1 byte of 8b'10101011 pattern.

The collision window is defined as 1 slot time (512 bit times for 10/100 Mbit/s Ethernet). The jam pattern generation is applicable only to Half-Duplex mode, not to Full-Duplex mode. In Full-Duplex mode, the transmit state machine ignores the phy_col_i signal from the PHY.

In MII mode, if a collision occurs any time from the beginning of the frame to the end of the CRC field, the transmit state machine sends a 32-bit jam pattern of 32'h55555555 on the MII to inform all other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, the transmit state machine completes the transmission of preamble and SFD and then sends the jam pattern.

If the collision occurs after the collision window and before the end of the FCS field (or the end of Burst if the Frame Burst mode is enabled), the transmit state machine sends a 32-bit jam pattern and sets the late collision bit in the transmit frame status.

The TPE module maintains a jabber timer (only in 10/100-Mbit/sMbit/s mode) to cut off the transmission of Ethernet frames if the TFC module transfers more than 2.048 (default) bytes. The time-out is changed to 10.240 bytes when the Jumbo frame is enabled.

The Transmit state machine uses the deferral mechanism for the flow control (Back Pressure) in Half-Duplex mode. When the Application requests to stop receiving frames, the Transmit state machine sends a JAM pattern of 32 bytes whenever it senses a reception of a frame, provided the transmit flow control is enabled. This will result in a collision and the remote station will back off. The Application requests the flow control by setting BPA bit of Regsiter6. If the application requests a frame to be transmitted, then it will be scheduled and transmitted even when the backpressure is activated. Note that if the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur) then the remote stations will abort their transmissions due to excessive collisions.

If IEEE 1588 time stamping is enabled for the transmit frame, this block takes a snapshot of the system time when the SFD is put onto the transmit MII bus. The system time source is either an external input or internally generated, according to the configuration selected.

Transmit Scheduler Module

The Transmit Scheduler (STX) module is responsible for scheduling the frame transmission on the MII. The two major functions of this module are to maintain the inter-frame gap between two transmitted frames and to follow the Truncated Binary Exponential Back-off algorithm for Half-Duplex mode. This module provides an enable signal to the TPE module after satisfying the IFG and Back-off delays.

The STX module maintains an idle period of the configured inter-frame gap (IFG bits of Register 0 between any two transmitted frames. If frames from the TFC arrive at the TPE module sooner than the configured IFG time, the TPE module waits for the enable signal from the STX module before starting the transmission on the MII. The STX module starts its IFG counter as soon as the carrier signal of the MII goes inactive. At the end of programmed IFG value, the module issues an enable signal to the TPE module in Full-Duplex mode. In Half-Duplex mode and when IFG is configured for 96 bit times, the STX module follows the rule of deference specified in Section 4.2.3.2.1 of the IEEE 802.3

specification. The module resets its IFG counter if a carrier is detected during the first two-thirds (64-bit times for all IFG values) of the IFG interval. If the carrier is detected during the final one third of the IFG interval, the STX module continues the IFG count and enables the transmitter after the IFG interval.

The STX module implements the Truncated Binary Exponential Back-off algorithm when it operates in Half-Duplex mode.

Transmit CRC Generator Module

The Transmit CRC Generator (CTX) module interfaces with the TFC module to generate CRC for the FCS field of the Ethernet frame. The TFC module sends the frame data and any necessary padding to the CTX module through an 8-bit interface.

This module calculates the 32-bit CRC for the FCS field of the Ethernet frame. The encoding is defined by the following generating polynomial.

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1

The module gets the Ethernet frame's byte data from the TFC module (DA + SA + LT + DATA + PAD) qualified with a Data Valid signal. The TFC also indicates to the CTX when to reset the previously calculated CRC and to start the new CRC calculation for the coming frame. The TFC module issues the start command before sending the new frame data for calculation. The calculated CRC is valid on the next clock after the data is received.

Transmit Flow Control Module

The Transmit Flow Control (FTX) module generates Pause frames and transmit them to the TFC module as necessary, in Full-Duplex mode. The TFC module receives the Pause frame from the FTX module, appends the calculated CRC, and sends the frame to the TPE module. Pause frame generation can be initiated in two ways. The Application can request the FTX module to send a Pause frame either by setting the FCB bit in the Flow Control register Register 6 or by asserting the mti_flowctrl_i signal in response to the receive FIFO full conditions (packet buffer).

If the Application has requested the flow control by setting the FCB bit of Register 6, the FTX module will generate and transmit a single Pause frame to the TFC module. The value of the Pause Time in the generated frame contains the programmed Pause Time value in Register 6. To extend the pause or end the pause prior to the time specified in the previously transmitted Pause frame, the application must request another Pause frame transmission after programming the Pause Time register with appropriate value.

If the Application has requested the flow control by asserting the mti_flowctrl_i signal, the FTX module will generate and transmit a Pause frame to the TFC module. The value of the Pause Time in the generated frame contains the programmed Pause Time value in the Register 6. The FTX module monitors the mti_flowctrl_i signal. If it remains asserted at a configurable number of slot-times (PLT bits of GMAC Register 6) before this Pause-

time runs-out, a second Pause frame will be transmitted to the TFC module. The process will be repeated as long as the mti_flowctrl signal remains asserted.

If the mti_flowctrl_i signal goes inactive prior to the sampling time, the FTX module will transmit a Pause frame with zero Pause Time to indicate to the remote end that the receive buffer is ready to receive new data frames.

34.2.6.2 MAC Transmit Interface Protocol

The MAC Transmit Interface (MTI) connects the application (MTL module in the GMAC) with the GMAC to provide the Ethernet data for transmission.

The application initiates the Ethernet frame transmission by writing the first data of the frame to the GMAC, provided the GMAC is ready to accept data . The Application can push-in data as long as the GMAC core is ready to accept it.

If the frame transmission is not successful (due to underflow, collision, jabber timeout, excessive deferral events), the GMAC core will assert the transmit status even before the EOF is received. The Application will have to take the appropriate action as per the status. The GMAC will drop all further data input to it until the next SOF.

34.2.6.3 Reception

A receive operation is initiated when the GMAC detects an SFD on the MII. The core strips the preamble and SFD before proceeding to process the frame. The header fields are checked for the filtering and the FCS field used to verify the CRC for the frame. The received frame is stored in a shallow buffer until the address filtering is performed. The frame is dropped in the core if it fails the address filter.

The following are the functional blocks in the Receive path of the GMAC core.

- Receive Protocol Engine Module (RPE)
- Receive CRC Module (CRX)
- Receive Frame Controller Module (RFC)
- Receive Flow Control Module (FRX)
- Receive IP Checksum checker (IPC)
- Receive Bus Interface Unit Module (RBU)
- Address Filtering Module (AFM)

Receive Protocol Engine Module

The RPE consists of the receive state machine which strips the preamble and SFD. Once the phy_rxdv_i signal of the MII becomes active, the RPE's receive state machine begins hunting for the SFD field from the receive modifier logic. Until then, the state machine drops the receiving preambles. Once the SFD is detected, the state machine begins sending the data of the Ethernet frame to the RFC module, beginning with the first byte following the SFD (destination address).

If IEEE 1588 time stamping is enabled, the RPE takes a snapshot of the system time when any frame's SFD is detected on the MII. Unless the MAC filters out and drops the frame, this time stamp is passed on to the application.

In MII mode, the RPE converts the received nibble data into bytes, then forwards the valid frame data to the RFC module

The receive state machine of the RPE module decodes the Length/Type field of the receiving Ethernet frame. If the Length/Type field is less than 600 (hex) and if the MAC is programmed for the auto crc/pad stripping option, the state machine sends the data of the frame up to the count specified in the Length/Type field, then starts dropping bytes (including the FCS field). The state machine of the RPE module decodes the Length/Type field and checks for the Length interpretation.

If the Length/Type field is greater than or equal to 600 (hex), the RPE module will send all received Ethernet frame data to the RFC module, irrespective of the value on the programmed auto-CRC strip option.

As a default, the GMAC is programmed for watchdog timer to be enabled, that is, frames above 2.048 (10.240 if Jumbo Frame is enabled) bytes (DA + SA + LT + DATA + PAD + FCS) are cut off at the RPE module. This feature can be disabled by programming the GMAC Configuration register, Watchdog Disable. However even if the watchdog timer is disabled, frames greater than 16 KB in size are cut off and a watchdog time-out status is given.

The GMAC supports loopback of transmitted frames onto its receiver. As a default, the GMAC loopback function is disabled, but this feature can be enabled by programming the GMAC Configuration register, Loopback bit. The transmit and receive clocks can have an asynchronous timing relationship, so an asynchronous FIFO is used to make the loopback path of the phy_txd_o data onto the receive path. The asynchronous FIFO is 10 bits (6 bits in 10/100 Mbit/s mode) wide to accommodate phy_txd_o, phy_txen_o, and phy_txer_o. The FIFO nine deep in 10/100 Mbit/s mode and free-running to write on the write clock (clk_tx_i) and read on every read clock (clk_rx_i).

The write and read pointers gets re-initialized to have an offset of 2 (4 in 10/100 Mbit/s mode) at the start of each frame read out of the FIFO. This helps to avoid overflow/underflow during the transfer of a frame, and ensures that the overflow/underflow occurs only during the IFG period between the frames. Please note that the FIFO depth of nine is sufficient to prevent data corruption for frame sizes up to 9.022 bytes with a difference of 200 ppm between the MII Transmit and Receive clock frequencies. Hence, bigger frames should not be looped back, as they may get corrupted in this loopback FIFO.

At the end of every received frame, the RPE module generates received frame status and sends it to the RFC module. Control, missed frame, and filter fail status are added to the receive status in the RFC module.

Receive CRC Module

The Receive CRC (CRX) interfaces to the RPE module to check for any CRC error in the receiving frame.

This module calculates the 32-bit CRC for the received frame that includes the Destination address field through the FCS field. The encoding is defined by the following generating polynomial.

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1

The module gets the data from the RPE module (DA+SA+LT+DATA+PAD+FCS). The RPE module also sends a control signal that indicates the validity of the data. Irrespective of the auto pad/CRC strip, the CRX module receives the entire frame to compute the CRC check for received frame. As a note on the auto pad/CRC strip settings, the entire frame is not transferred between the RPE and RFC 8-bit interface.

Receive Checksum Offload Engine

The Checksum Offload engine is optional (not available in the default configuration) and selectable during configuration. Two types of Receive Checksum Offload engine are available for configuration. Full Checksum Offload, the Type 2 engine is instantiated.

Type 2

In this mode, both IPv4 and IPv6 frames in the received Ethernet frames are detected and processed for data integrity. You can enable this module by setting the IPC bit in the GMAC Configuration register. The GMAC receiver identifies IPv4 or IPv6 frames by checking for value 0x0800 or 0x86DD, respectively, in the received Ethernet frames' Type field. This identification applies to VLAN-tagged frames as well.

The Receive Checksum Offload engine calculates IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received frame does not have enough bytes, as indicated by the IPv4 header's Length field (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP/UDP/ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not tally to the expected payload length given in the IP header.

As mentioned in **TCP/UDP/ICMP Checksum Engine**, this engine bypasses the payload of fragmented IP datagrams, IP datagrams with security features, IPv6 routing headers, and payloads other than TCP, UDP or ICMP.

In this configuration, the core does not append any payload checksum bytes to the received Ethernet frames.

Receive Frame Controller Module

The Receive Frame Controller (RFC) receives the Ethernet frame data and status from the RPE module. The RFC module consists of a FIFO of parameterized depth (default set to 4 deep and 37 bits wide) and two state machines for writing and reading the FIFO. The FIFO holds the received Ethernet frame data and byte enables, along with a control bit to indicate the last data. The state machines manage the FIFO and provide a frame buffering for the receiving Ethernet frame from the RPE module. The main functions of the RFC module are:

- Data path conversion, which converts the 8-bit data to 32-bit data to the RBU module.
- Frame filtering
- Attaching the calculated IP Checksum input from IPC.
- Update the Receive Status and forward to RBU.

If the RA bit of the GMAC CSR Frame Filter register is set, the RFC module initiates the data transfer to the RBU module as soon as 4 bytes of Ethernet data are received from the RPE module. At the end of the data transfer, the RFC module sends out the received frame status that includes the frame filter bits (SA Filterfail and DAFilterfail) and status from the RFC module. These bits are generated based on the filter-fail signals from the AFM module. This status bit indicates to the Application whether the received frame has passed the filter controls (both address filter and Frame Filter controls from CSR). The RFC module will not drop any frame on its own in this mode.

If the RA bit is reset, the RFC module performs frame filtering based on the destination/source address (the Application still needs to perform another level of filtering if it decides not to receive any bad frames like runt, CRC error frames, etc. The RFC module waits to receive the first 14 bytes of received data (type field) from the RPE module. Until then, the module will not initiate any transfers to the RBU module. After receiving the destination/source address bytes, the RFC checks the filter-fail signal from the AFM module for an address match. On detecting a filter-fail from AFB, the frame is dropped at the RFC module and not transferred to the Application.

On a delayed filter response from the AFM (this can only occur if you change the AFM logic), the RFC module waits until the FIFO is full, and then proceeds with the frame transfer to the RBU module. However, it will still take the delayed response from the AFM module and if it is a (DA/SA) filter failure, then it will drop the rest of the frame and send the Rx Status Word (with zero frame-length, CRC Error and Runt Error bits set) immediately indicating the filter-fail. If there is no response from the AFM until the end of frame is transmitted, the filter fail status in the Rx Status Word is updated accordingly.

When the PMT module is configured for power-down mode, all received frames are dropped by this block, and are not forwarded to the application.

Receive Flow Control Module

The Receive Flow Controller (FRX) detects the receiving Pause frame and pauses the frame transmission for the delay specified within the received Pause frame. The FRX module is enabled only in Full-Duplex mode. The Pause frame detection function can be enabled or disabled with the RFE bit of GMAC CSR Register 6.

Once the receive flow control is enabled, the FRX module begins monitoring the received frame destination address for any match with the multicast address of the control frame (48'h0180C2000001). If a match is detected, the FRX module indicates to the RFC module, that the destination address of the received frame matches the reserved control frame destination address. The RFC module then decides whether or not to transfer the received control frame to the Application, based on the (PCF) bit setting of GMAC CSR Register 1 (Filter register).

The FRX module also decodes the Type, Op-code, and Pause Timer field of the receiving control frame. At the end of received frame, the FRX module gets the received frame status from RPE. If the byte count of the status indicates 64 bytes, and if there is no CRC error, the FRX module requests the MAC transmitter to pause the transmission of any data frame for the duration of the decoded Pause Time value, multiplied by the slot time (64 byte times). Meanwhile, if another Pause frame is detected with a zero Pause Time value, the FRX module resets the Pause Time and gives another pause request to the Transmitter. If the received control frame matches neither the Type field (16'h8808), Opcode (16'h00001), nor byte length (64 bytes), or if there is a CRC error, the FRX module does not generate a Pause request to Transmitter.

In the case of a pause frame with a multicast destination address, the RFC filters the frame based on the address match from the FRX module. For a pause frame with a unicast destination address, the filtering in the FRX module depends on whether the DA matched the contents of the MAC Address Register 0 and the UP Bit of GMAC Core Register 6 is set (detecting a pause frame even with a unicast destination address). The PCF register bits (Bit [7:6] of GMAC Register 1) controls the filtering for control frames in addition to the Address filter module.

Receive Bus Interface Unit Module

The Receive Bus Interface Unit (RBU) converts the 32-bit data received from the RFC module into a 32-bit FIFO protocol on the Application side. The RBU module interfaces with the Application through the MAC receive interface (MRI).

If IEEE 1588 time stamping is enabled, the RBU also outputs the time stamp captured from the received frame.

Address Filtering Module

The Address Filtering (AFM) module performs the destination and source address checking function on all received frames and reports the address filtering status to the RFC module. The address checking is based on different parameters (Frame Filter register) chosen by the Application. These parameters are inputs to the AFM module as control signals, and the AFM module reports the status of the address filtering based on the combination of these inputs. The AFM module does not filter the receive frames by itself, but reports the status of the address filtering (whether to drop the frame or not) to the RFC module. The AFM module also reports whether the receiving frame is a multicast frame or a broadcast frame, as well as the address filter status.

The AFM module probes the 8-bit receive data path between the RPE module and the RFC module and checks the destination and source address field of each incoming packet. In MII mode the module takes 14/26 clocks (from the start of frame) to compare the destination/ source address of the receiving frame. The AFM module gets the station's physical (MAC) address and the Multicast Hash table from CSR module for address checking. The CSR module provides the Frame Filter register parameters to AFM.

Unicast Destination Address Filter

The AFM supports up to 32 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of Frame Filter register is reset), the AFM compares all 48 bits of the received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled, other addresses MacAddr1–MacAddr31 are selected with an individual enable bit. Each byte of these other addresses (MacAddr1–MacAddr31) can be masked during comparison with the corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This helps group address filtering for the DA.

In Hash filtering mode (When HUC bit is set), the AFM performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the AFM uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 000000 selects Bit 0 of the selected register, and a value of 111111 selects Bit 63 of the Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.

Multicast Destination Address Filter

The GMAC can be programmed to pass all multicast frames by setting the PM bit in the Frame Filter register. If the PM bit is reset, the AFM performs the filtering for multicast addresses based on the HMC bit of Frame Filter register. In Perfect Filtering mode, the multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported.

In Hash filtering mode, the AFM performs imperfect filtering using a 64-bit Hash table. For hash filtering, the AFM uses the upper 6 bits CRC of the received multicast address to index the content of the Hash table. A value of 000000 selects Bit 0 of the selected register and a value of 111111 selects Bit 63 of the Hash Table register.

If the corresponding bit is set to 1, then the multicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.

Hash or Perfect Address Filter

The DA filter can be configured to pass a frame when its DA matches either the Hash filter or the Perfect filter by setting the HPF bit of the Frame Filter register and setting the corresponding HUC or HMC bits. This configuration applies to both unicast and multicast frames. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to the received frame.

Broadcast Address Filter

The AFM doesn't filter any broadcast frames in the default mode. However, if the GMAC is programmed to reject all broadcast frames by setting the DBF bit in the Frame Filter register, the DAF module asserts the Filter fail signal to RFC, whenever a broadcast frame is received. This will tell the RFC module to drop the frame.

Unicast Source Address Filter

The GMAC can also perform a perfect filtering based on the source address field of the received frames. By default, the AFM compares the SA field with the values programmed in the SA registers. The MAC Address registers [1:31] can be configured to contain SA instead of DA for comparison, by setting Bit 30 of the corresponding Register. Group filtering with SA is also supported. The frames that fail the SA Filter are dropped by the GMAC if the SAF bit of Frame Filter register is set.

When SAF bit is set, the result of SA Filter and DA filter is AND'ed to decide whether the frame needs to be forwarded. This means that either of the filter fail result will drop the frame and both filters have to pass in-order to forward the frame to the application.

Inverse Filtering Operation

For both Destination and Source address filtering, there is an option to invert the filter-match result at the final output. These are controlled by the DAIF and SAIF bits of the Frame Filter register respectively. The DAIF bit is applicable for both Unicast and Multicast DA frames. The result of the unicast/multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Table 34-8 and **Table 34-9** summarize the Destination and Source Address filtering based on the type of frames received.

Table 34-8 Destination Address Filtering Table

Frame Type	PR	HPF	HUC	DAIF	HMC	PM	DB	DA Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all frames.
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match.
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match.
	0	0	1	0	X	X	X	Pass on Hash filter match.
	0	0	1	1	X	X	X	Fail on Hash filter match.
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match.
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match.
Multicast	1	X	X	X	X	X	X	Pass all frames.
	X	X	X	X	X	1	X	Pass all frames.
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.
	0	0	X	0	1	0	X	Pass on Hash filter match and drop PAUSE control frames if PCF = 0x.
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.

Table 34-8 Destination Address Filtering Table (cont'd)

Frame Type	PR	HPF	HUC	DAIF	HMC	PM	DB	DA Filter Operation
	0	0	X	1	1	0	X	Fail on Hash filter match and drop PAUSE control frames if PCF = 0x.
	0	1	X	1	1	0	X	Fail on Hash or Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.

Table 34-9 Source Address Filtering Table

Frame Type	PR	SAIF	SAF	SA Filter Operation
Unicast	1	X	X	Pass all frames.
	0	0	0	Pass status on Perfect/Group filter match but do not drop frames that fail.
	0	1	0	Fail status on Perfect/Group filter match but do not drop frame.
	0	0	1	Pass on Perfect/Group filter match and drop frames that fail.
	0	1	1	Fail on Perfect/Group filter match and drop frames that fail.

34.2.6.4 System Time Register Module

64-bit time is maintained in this module and updated using the input reference clock. This time is the source for taking snapshots (time stamps) of Ethernet frames being transmitted or received at the MII.

The System Time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Time Stamp Update register. For initialization, the System Time counter is written with the value in the Time Stamp Update registers, while for system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, a slave clock's frequency drift with respect to the master clock (as defined in IEEE 1588) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register, as shown in

Figure 34-10. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency multiplier or divider.

This algorithm is depicted in **Figure 34-10**:

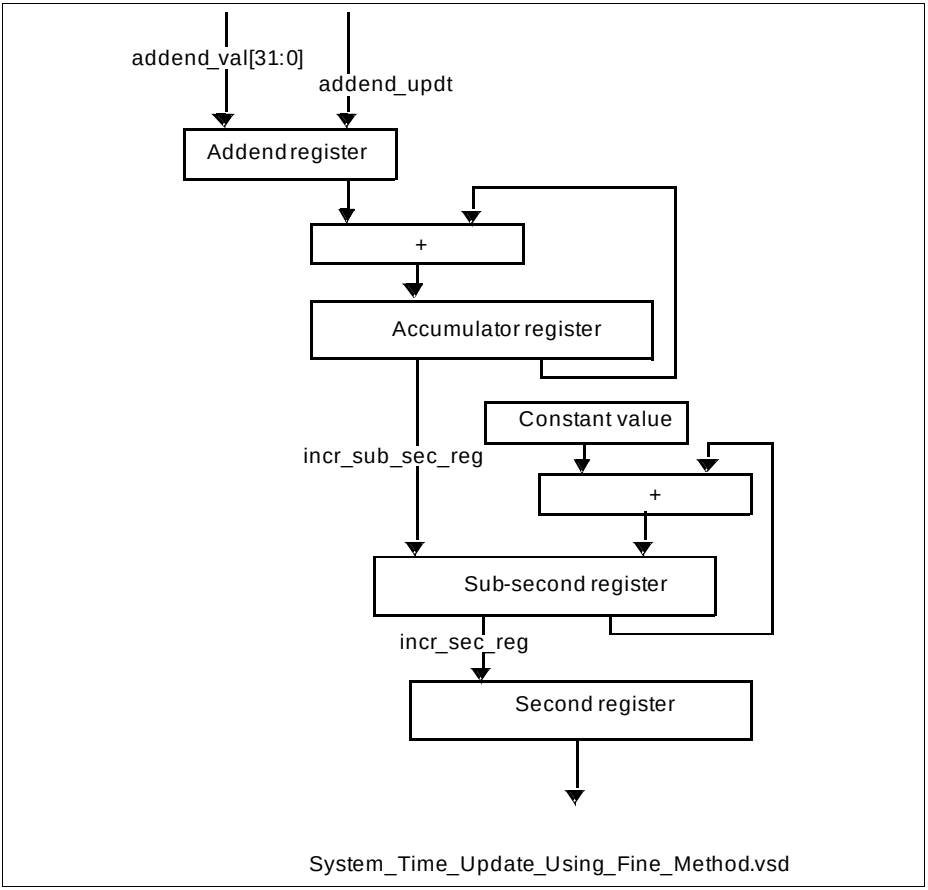

Figure 34-10 System Time Update Using Fine Method

The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. Hence, if the reference clock (clk_ptp_ref_i) is, for example, 66 MHz, this ratio is calculated as 66 MHz / 50 MHz = 1.32. Hence, the default addend value to be set in the register is 2^{32} / 1.32, 0xC1F07C1F.

If the reference clock drifts lower, to 65 MHz for example, the ratio is 65 / 50, or 1.3 and the value to set in the addend register is 2^{32} / 1.30, or 0xC4EC4EC4. If the clock drifts higher, to 67 MHz for example, the addend register must be set to 0xBF0B7672. When the clock drift is nil, the default addend value of 0xC1F07C1F (2^{32} / 1.32) must be programmed.

In **Figure 34-10**, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20-ns steps). Two different methods are used to update the System Time register, depending on which configuration you choose (See **Architecture**).

The software must calculate the drift in frequency based on the Sync messages and update the Addend register accordingly.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$FreqCompensationValue_0 = 2^{32} / FreqDivisionRatio$

If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm described below must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.

The algorithm is as follows:

- At time $MasterSyncTime_n$ the master sends the slave clock a Sync message. The slave receives this message when its local clock is $SlaveClockTime_n$ and computes $MasterClockTime_n$ as:
  $MasterClockTime_n = MasterSyncTime_n + MasterToSlaveDelay_n$
- The master clock count for current Sync cycle, $MasterClockCount_n$ is given by:
  $MasterClockCount_n = MasterClockTime_n – MasterClockTime_{n-1}$ (assuming that MasterToSlaveDelay is the same for Sync cycles n and n – 1)
- The slave clock count for current Sync cycle, $SlaveClockCount_n$ is given by:
  $SlaveClockCount_n = SlaveClockTime_n – SlaveClockTime_{n-1}$
- The difference between master and slave clock counts for current Sync cycle, $ClockDiffCount_n$ is given by:
  $ClockDiffCount_n = MasterClockCount_n – SlaveClockCount_n$
- The frequency-scaling factor for slave clock, $FreqScaleFactor_n$ is given by:
  $FreqScaleFactor_n = (MasterClockCount_n + ClockDiffCount_n) / SlaveClockCount_n$
- The frequency compensation value for Addend register, $FreqCompensationValue_n$ is given by:
  $FreqCompensationValue_n = FreqScaleFactor_n * FreqCompensationValue_{n-1}$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, due to changing network propagation delays and operating conditions.

This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm will correct it at the cost of more Sync cycles.

34.2.7 MAC Management Counters

The counters in the MAC Management Counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted frames. These include a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the MAC Control Interface (MCI). Each register is 32 bits wide. The write data is qualified with the corresponding mci_be_i signals. Thus, non-32-bit accesses are allowed as long as the address is word-aligned.

The organization of these registers is shown in **Table 1-17**. The MMCs are accessed using transactions, in the same way the CSR address space is accessed. The following sections in the chapter describe the various counters and list the address for each of the statistics counters. This address will be used for Read/Write accesses to the desired transmit/receive counter.

The Receive MMC counters are updated for frames that are passed by the Address Filter (AFM) block. Statistics of frames that are dropped by the AFM module are not updated unless they are runt frames of less than 6 bytes (DA bytes are not received fully).

The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet frames. This gathering is only enabled when Full Checksum Offload Engine is selected during RTL configuration. The address map of the corresponding registers, 0x0200–0x02FC, is given in **Table 1-17**.

34.2.7.1 Address Assignments

The MMC register naming convention is as follows.

- “tx” as a prefix or suffix indicates counters associated with transmission
- “rx” as a prefix or suffix indicates counters associated with reception
- “_g” as a suffix indicates registers that count good frames only
- “_gb” as a suffix indicates registers that count frames regardless of whether they are good or bad

The following explanations pertain to terminology used in **Table 1-17** through **Table 1-24**.

Transmitted frames are considered “good” if transmitted successfully. In other words, a transmitted frame is good if the frame transmission is not aborted due to any of the following errors:

- Jabber Timeout

- No Carrier/Loss of Carrier
- Late Collision
- Frame Underflow
- Excessive Deferral
- Excessive Collision

Received frames are considered “good” if none of the following errors exists:

- CRC error
- Runt Frame (shorter than 64 bytes)
- Alignment error (in 10/100 Mbit/s only)
- Length error (non-Type frames only)
- Out of Range (non-Type frames only, longer than maximum size)

The maximum frame size depends on the frame type, as follows:

- Untagged frame maxsize = 1518
- VLAN Frame maxsize = 1522
- Jumbo Frame maxsize = 9018
- JumboVLAN Frame maxsize = 9022

Table 34-10 MMC Register Map

GMAC CSR Register No.	Address Offset	Register Name	Register Description
64	0x0100	mmc_cntrl	MMC Control establishes the operating mode of MMC. For more details, refer to **Table 1-18**.
65	0x0104	mmc_intr_rx	MMC Receive Interrupt maintains the interrupt generated from all of the receive statistic counters. For more details, refer to **Table 1-19**.
66	0x0108	mmc_intr_tx	MMC Transmit Interrupt maintains the interrupt generated from all of the transmit statistic counters. For more details, refer to **Table 1-20**.
67	0x010C	mmc_intr_mask_rx	MMC Receive Interrupt mask maintains the mask for the interrupt generated from all of the receive statistic counters. For more details, refer to **Table 1-21**.

Table 34-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
68	0x0110	mmc_intr_mask_tx	MMC Transmit Interrupt Mask maintains the mask for the interrupt generated from all of the transmit statistic counters. For more details, refer to **Table 1-22**.
69	0x0114	txoctetcount_gb	Number of bytes transmitted, exclusive of preamble and retried bytes, in good and bad frames.
70	0x0118	txframecount_gb	Number of good and bad frames transmitted, exclusive of retried frames.
71	0x011C	txbroadcastframes_g	Number of good broadcast frames transmitted.
72	0x0120	txmulticastframes_g	Number of good multicast frames transmitted.
73	0x0124	tx64octets_gb	Number of good and bad frames transmitted with length 64 bytes, exclusive of preamble and retried frames.
74	0x0128	tx65to127octets_gb	Number of good and bad frames transmitted with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames.
75	0x012C	tx128to255octets_gb	Number of good and bad frames transmitted with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames.
76	0x0130	tx256to511octets_gb	Number of good and bad frames transmitted with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames.
77	0x0134	tx512to1023octets_gb	Number of good and bad frames transmitted with length between 512 and 1.023 (inclusive) bytes, exclusive of preamble and retried frames.

Table 34-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
78	0x0138	tx1024tomaxoctets_gb	Number of good and bad frames transmitted with length between 1.024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.
79	0x013C	txunicastframes_gb	Number of good and bad unicast frames transmitted.
80	0x0140	txmulticastframes_gb	Number of good and bad multicast frames transmitted.
81	0x0144	txbroadcastframes_gb	Number of good and bad broadcast frames transmitted.
82	0x0148	txunderflowerror	Number of frames aborted due to frame underflow error.
83	0x014C	txsinglecol_g	Number of successfully transmitted frames after a single collision in Half-duplex mode.
84	0x0150	txmulticol_g	Number of successfully transmitted frames after more than a single collision in Half-duplex mode.
85	0x0154	txdeferred	Number of successfully transmitted frames after a deferral in Half-duplex mode.
86	0x0158	txlatecol	Number of frames aborted due to late collision error.
87	0x015C	txexesscol	Number of frames aborted due to excessive (16) collision errors.
88	0x0160	txcarriererror	Number of frames aborted due to carrier sense error (no carrier or loss of carrier).
89	0x0164	txoctetcount_g	Number of bytes transmitted, exclusive of preamble, in good frames only.
90	0x0168	txframecount_g	Number of good frames transmitted.
91	0x016C	txexcessdef	Number of frames aborted due to excessive deferral error (deferred for more than two max-sized frame times).

Table 34-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
92	0x0170	txpauseframes	Number of good PAUSE frames transmitted.
93	0x0174	txvlanframes_g	Number of good VLAN frames transmitted, exclusive of retried frames.
94	0x0178	Reserved	
95	0x017C	Reserved	
96	0x0180	rxframecount_gb	Number of good and bad frames received.
97	0x0184	rxoctetcount_gb	Number of bytes received, exclusive of preamble, in good and bad frames.
98	0x0188	rxoctetcount_g	Number of bytes received, exclusive of preamble, only in good frames.
99	0x018C	rxbroadcastframes_g	Number of good broadcast frames received.
100	0x0190	rxmulticastframes_g	Number of good multicast frames received.
101	0x0194	rxcrcerror	Number of frames received with CRC error.
102	0x0198	rxalignmenterror	Number of frames received with alignment (dribble) error.
103	0x019C	rxrunterror	Number of frames received with runt (<64 bytes and CRC error) error.
104	0x01A0	rxjabbererror	Number of giant frames received with length (including CRC) greater than 1.518 bytes (1.522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames.
105	0x01A4	rxundersize_g	Number of frames received with length less than 64 bytes, without any errors.
106	0x01A8	rxoversize_g	Number of frames received with length greater than the maxsize (1.518 or 1.522 for VLAN tagged frames), without errors.

Table 34-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
107	0x01AC	rx64octets_gb	Number of good and bad frames received with length 64 bytes, exclusive of preamble.
108	0x01B0	rx65to127octets_gb	Number of good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble.
109	0x01B4	rx128to255octets_gb	Number of good and bad frames received with length between 128 and 255 (inclusive) bytes, exclusive of preamble.
110	0x01B8	rx256to511octets_gb	Number of good and bad frames received with length between 256 and 511 (inclusive) bytes, exclusive of preamble.
111	0x01BC	rx512to1023octets_gb	Number of good and bad frames received with length between 512 and 1.023 (inclusive) bytes, exclusive of preamble.
112	0x01C0	rx1024tomaxoctets_gb	Number of good and bad frames received with length between 1.024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.
113	0x01C4	rxunicastframes_g	Number of good unicast frames received.
114	0x01C8	rxlengtherror	Number of frames received with length error (Length type field ¼ frame size), for all frames with valid length field.
115	0x01CC	rxoutofrangetype	Number of frames received with length field not equal to the valid frame size (greater than 1.500 but less than 1.536).
116	0x01D0	rxpauseframes	Number of good and valid PAUSE frames received.
117	0x01D4	rxfifooverflow	Number of missed received frames due to FIFO overflow.
118	0x01D8	rxvlanframes_gb	Number of good and bad VLAN frames received.

Table 34-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
119	0x01DC	rxwatchdogerror	Number of frames received with error due to watchdog timeout error (frames with a data load larger than 2.048 bytes).
120:127	0x01E0–0x01FC	Reserved	
128	0x0200	mmc_ipc_intr_mask_rx	MMC IPC Receive Checksum Offload Interrupt Mask maintains the mask for the interrupt generated from the receive IPC statistic counters. See **Table 1-23** for further detail.
129	0x0204	Reserved	
130	0x0208	mmc_ipc_intr_rx	MMC Receive Checksum Offload Interrupt maintains the interrupt that the receive IPC statistic counters generate. See **Table 1-24** for further detail.
131	0x020C	Reserved	
132	0x0210	rxipv4_gd_frms	Number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload
133	0x0214	rxipv4_hdrerr_frms	Number of IPv4 datagrams received with header (checksum, length, or version mismatch) errors
134	0x0218	rxipv4_nopay_frms	Number of IPv4 datagram frames received that did not have a TCP, UDP, or ICMP payload processed by the Checksum engine
135	0x021C	rxipv4_frag_frms	Number of good IPv4 datagrams with fragmentation
136	0x0220	rxipv4_udsbl_frms	Number of good IPv4 datagrams received that had a UDP payload with checksum disabled
137	0x0224	rxipv6_gd_frms	Number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads

Table 34-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
138	0x0228	rxipv6_hdrerr_frms	Number of IPv6 datagrams received with header errors (length or version mismatch)
139	0x022C	rxipv6_nopay_frms	Number of IPv6 datagram frames received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers
140	0x0230	rxudp_gd_frms	Number of good IP datagrams with a good UDP payload. This counter is not updated when the rxipv4_udsbl_frms counter is incremented.
141	0x0234	rxudp_err_frms	Number of good IP datagrams whose UDP payload has a checksum error
142	0x0238	rxtcp_gd_frms	Number of good IP datagrams with a good TCP payload
143	0x023C	rxtcp_err_frms	Number of good IP datagrams whose TCP payload has a checksum error
144	0x0240	rxicmp_gd_frms	Number of good IP datagrams with a good ICMP payload
145	0x0244	rxicmp_err_frms	Number of good IP datagrams whose ICMP payload has a checksum error
146:147	0x0248–0x024C	Reserved	
148	0x0250	rxipv4_gd_octets	Number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter or in the octet counters listed below).
149	0x0254	rxipv4_hdrerr_octets	Number of bytes received in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter.

Table 34-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
150	0x0258	rxipv4_nopay_octets	Number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 header's Length field is used to update this counter.
151	0x025C	rxipv4_frag_octets	Number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 header's Length field is used to update this counter.
152	0x0260	rxipv4_udsbl_octets	Number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes.
153	0x0264	rxipv6_gd_octets	Number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data
154	0x0268	rxipv6_hdrerr_octets	Number of bytes received in IPv6 datagrams with header errors (length, version mismatch). The value in the IPv6 header's Length field is used to update this counter.
155	0x026C	rxipv6_nopay_octets	Number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv6 header's Length field is used to update this counter.
156	0x0270	rxudp_gd_octets	Number of bytes received in a good UDP segment. This counter (and the counters below) does not count IP header bytes.
157	0x0274	rxudp_err_octets	Number of bytes received in a UDP segment that had checksum errors
158	0x0278	rxtcp_gd_octets	Number of bytes received in a good TCP segment

Table 34-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
159	0x027C	rxtcp_err_octets	Number of bytes received in a TCP segment with checksum errors
160	0x0280	rxicmp_gd_octets	Number of bytes received in a good ICMP segment
161	0x0284	rxicmp_err_octets	Number of bytes received in an ICMP segment with checksum errors
162:191	0x0288–0x02FC	Reserved	

34.2.7.2 MMC Register Description

MMC Control Register

The MMC Control register establishes the operating mode of the management counters.

Table 34-11 MMC Control Register

Bit	Access Type	Reset Value	Description
31:6	R	0000_000H	Reserved
5	rw	0	Full-Half preset When low and bit4 is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16) When high and bit4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16)

Table 34-11 MMC Control Register (cont'd)

Bit	Access Type	Reset Value	Description
4	rwh	0	Counters Preset When set, all counters will be initialized or preset to almost full or almost half as per Bit5 above. This bit will be cleared automatically after 1 clock cycle. This bit along with bit5 is useful for debugging and testing the assertion of interrupts due to MMC counter becoming half-full or full.
3	rw	0	MMC Counter Freeze When set, this bit freezes all the MMC counters to their current value. (None of the MMC counters are updated due to any transmitted or received frame until this bit is reset to 0. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.)
2	rw	0	Reset on Read When set, the MMC counters will be reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read.
1	rw	0	Counter Stop Rollover When set, counter after reaching maximum value will not roll over to zero.
0	rwh	0	Counters Reset When set, all counters will be reset. This bit will be cleared automatically after 1 clock cycle

Note: When Bit 0 and Bit 4 are set in the same cycle, Counters get preset immediately after getting cleared.

MMC Receive Interrupt Register

The MMC Receive Interrupt register maintains the interrupts generated when the receive statistic counters reach half their maximum values (0x8000_0000), and when they cross their maximum values (0xFFFF_FFFF). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Note: Access restriction applies: Any read access to the register clears this register!

Table 34-12 MMC Receive Interrupt Register

Bit	Access Type	Reset Value	Description
31:24	r	00H	Reserved
23	rh	0	The bit is set when the rxwatchdog error counter reaches half the maximum value, and also when it reaches the maximum value.
22	rh	0	The bit is set when the rxvlanframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.
21	rh	0	The bit is set when the rxfifooverflow counter reaches half the maximum value, and also when it reaches the maximum value.
20	rh	0	The bit is set when the rxpauseframes counter reaches half the maximum value, and also when it reaches the maximum value.
19	rh	0	The bit is set when the rxoutofrangetype counter reaches half the maximum value, and also when it reaches the maximum value.
18	rh	0	The bit is set when the rxlengtherror counter reaches half the maximum value, and also when it reaches the maximum value.
17	rh	0	The bit is set when the rxunicastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
16	rh	0	The bit is set when the rx1024tomaxoctets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
15	rh	0	The bit is set when the rx512to1023octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
14	rh	0	The bit is set when the rx256to511octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
13	rh	0	The bit is set when the rx128to255octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.

Table 34-12 MMC Receive Interrupt Register (cont'd)

Bit	Access Type	Reset Value	Description
12	rh	0	The bit is set when the rx65to127octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
11	rh	0	The bit is set when the rx64octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
10	rh	0	The bit is set when the rxoversize_g counter reaches half the maximum value, and also when it reaches the maximum value.
9	rh	0	The bit is set when the rxundersize_g counter reaches half the maximum value, and also when it reaches the maximum value.
8	rh	0	The bit is set when the rxjabbererror counter reaches half the maximum value, and also when it reaches the maximum value.
7	rh	0	The bit is set when the rxrunterror counter reaches half the maximum value, and also when it reaches the maximum value.
6	rh	0	The bit is set when the rxalignmenterror counter reaches half the maximum value, and also when it reaches the maximum value.
5	rh	0	The bit is set when the rxcrcerror counter reaches half the maximum value, and also when it reaches the maximum value.
4	rh	0	The bit is set when the rxmulticastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
3	rh	0	The bit is set when the rxbroadcastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
2	rh	0	The bit is set when the rxoctetcount_g counter reaches half the maximum value, and also when it reaches the maximum value.

Table 34-12 MMC Receive Interrupt Register (cont'd)

Bit	Access Type	Reset Value	Description
1	rh	0	The bit is set when the rxoctetcount_gb counter reaches half the maximum value, and also when it reaches the maximum value.
0	rh	0	The bit is set when the rxframecount_gb counter reaches half the maximum value, and also when it reaches the maximum value.

Note: rh means that this register bit is set internally and is cleared when the Counter register is read.

MMC Transmit Interrupt Register

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000), and when they cross their maximum values (0xFFFF_FFFF). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Note: Access restriction applies: Any read access to the register clears this register!

Table 34-13 MMC Transmit Interrupt Register

Bit	Access Type	Reset Value	Description
31:25	r	00_H	Reserved
24	rh	0	The bit is set when the txvlanframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
23	rh	0	The bit is set when the txpauseframes error counter reaches half the maximum value, and also when it reaches the maximum value.
22	rh	0	The bit is set when the txoexcessdef counter reaches half the maximum value, and also when it reaches the maximum value.
21	rh	0	The bit is set when the txframecount_g counter reaches half the maximum value, and also when it reaches the maximum value.

Table 34-13 MMC Transmit Interrupt Register (cont'd)

Bit	Access Type	Reset Value	Description
20	rh	0	The bit is set when the txoctetcount_g counter reaches half the maximum value, and also when it reaches the maximum value.
19	rh	0	The bit is set when the txcarriererror counter reaches half the maximum value, and also when it reaches the maximum value.
18	rh	0	The bit is set when the txexesscol counter reaches half the maximum value, and also when it reaches the maximum value.
17	rh	0	The bit is set when the txlatecol counter reaches half the maximum value, and also when it reaches the maximum value.
16	rh	0	The bit is set when the txdeferred counter reaches half the maximum value, and also when it reaches the maximum value.
15	rh	0	The bit is set when the txmulticol_g counter reaches half the maximum value, and also when it reaches the maximum value.
14	rh	0	The bit is set when the txsinglecol_g counter reaches half the maximum value, and also when it reaches the maximum value.
13	rh	0	The bit is set when the txunderflowerror counter reaches half the maximum value, and also when it reaches the maximum value.
12	rh	0	The bit is set when the txbroadcastframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.
11	rh	0	The bit is set when the txmulticastframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.
10	rh	0	The bit is set when the txunicastframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.

Table 34-13 MMC Transmit Interrupt Register (cont'd)

Bit	Access Type	Reset Value	Description
9	rh	0	The bit is set when the tx1024tomaxoctets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
8	rh	0	The bit is set when the tx512to1023octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
7	rh	0	The bit is set when the tx256to511octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
6	rh	0	The bit is set when the tx128to255octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
5	rh	0	The bit is set when the tx65to127octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
4	rh	0	The bit is set when the tx64octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
3	rh	0	The bit is set when the txmulticastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
2	rh	0	The bit is set when the txbroadcastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
1	rh	0	The bit is set when the txframecount_gb counter reaches half the maximum value, and also when it reaches the maximum value.
0	rh	0	The bit is set when the txoctetcount_gb counter reaches half the maximum value, and also when it reaches the maximum value.

MMC Receive Interrupt Mask Register

The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when receive statistic counters reach half their maximum value, and when they reach their maximum values. This register is 32 bits wide.

Table 34-14 MMC Receive Interrupt Mask Interrupt Register

Bit	Access Type	Reset Value	Description
31:24	r	00_H	Reserved
23	rw	0	Setting this bit masks the interrupt when the rxwatchdog counter reaches half the maximum value, and also when it reaches the maximum value.
22	rw	0	Setting this bit masks the interrupt when the rxvlanframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.
21	rw	0	Setting this bit masks the interrupt when the rxfifooverflow counter reaches half the maximum value, and also when it reaches the maximum value.
20	rw	0	Setting this bit masks the interrupt when the rxpauseframes counter reaches half the maximum value, and also when it reaches the maximum value.
….	rw	…	… Same as above for corresponding counters in **MMC Receive Interrupt Register**
1	rw	0	Setting this bit masks the interrupt when the rxoctetcount_gb counter reaches half the maximum value, and also when it reaches the maximum value.
0	rw	0	Setting this bit masks the interrupt when the rxframecount_gb counter reaches half the maximum value, and also when it reaches the maximum value.

MMC Transmit Interrupt Mask Register

The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when transmit statistic counters reach half their maximum value, and when they reach their maximum values. This register is 32 bits wide.

Table 34-15 MMC Transmit Interrupt Mask Register

Bit	Access Type	Reset Value	Description
31:25	r	00_H	Reserved
24	rw	0	Setting this bit masks the interrupt when the txvlanframes_g counter reaches half the maximum value, and also when it reaches the maximum value.

Table 34-15 MMC Transmit Interrupt Mask Register (cont'd)

Bit	Access Type	Reset Value	Description
23	rw	0	Setting this bit masks the interrupt when the txpauseframes counter reaches half the maximum value, and also when it reaches the maximum value.
22	rw	0	Setting this bit masks the interrupt when the txoexcessdef counter reaches half the maximum value, and also when it reaches the maximum value.
21	rw	0	Setting this bit masks the interrupt when the txframecount_g counter reaches half the maximum value, and also when it reaches the maximum value.
….	rw	…	… Same as above for corresponding counters in **MMC Transmit Interrupt Register**
1	rw	0	Setting this bit masks the interrupt when the txframecount_gb counter reaches half the maximum value, and also when it reaches the maximum value.
0	rw	0	Setting this bit masks the interrupt when the txoctetcount_gb counter reaches half the maximum value, and also when it reaches the maximum value.

MMC Receive Checksum Offload Interrupt Mask Register

The MMC Receive Checksum Offload Interrupt Mask register maintains the masks for the interrupts generated when the receive IPC (Checksum Offload) statistic counters reach half their maximum value , and when they reach their maximum values. This register is 32-bits wide.

Table 34-16 MMC Receive Checksum Offload Interrupt Mask Register

Bit	Access Type	Reset Value	Description
31:30	r	00	Reserved
29	rw	0	Setting this bit masks the interrupt when the rxicmp_err_octets counter reaches half the maximum value, and also when it reaches the maximum value.
28	rw	0	Setting this bit masks the interrupt when the rxicmp_gd_octets counter reaches half the maximum value, and also when it reaches the maximum value.

Table 34-16 MMC Receive Checksum Offload Interrupt Mask Register (cont'd)

Bit	Access Type	Reset Value	Description
27	rw	0	Setting this bit masks the interrupt when the rxtcp_err_octets counter reaches half the maximum value, and also when it reaches the maximum value.
26	rw	0	Setting this bit masks the interrupt when the rxtcp_gd_octets counter reaches half the maximum value, and also when it reaches the maximum value.
25	rw	0	Setting this bit masks the interrupt when the rxudp_err_octets counter reaches half the maximum value, and also when it reaches the maximum value.
24	rw	0	Setting this bit masks the interrupt when the rxudp_gd_octets counter reaches half the maximum value, and also when it reaches the maximum value.
23	rw	0	Setting this bit masks the interrupt when the rxipv6_nopay_octets counter reaches half the maximum value, and also when it reaches the maximum value.
22	rw	0	Setting this bit masks the interrupt when the rxipv6_hdrerr_octets counter reaches half the maximum value, and also when it reaches the maximum value.
21	rw	0	Setting this bit masks the interrupt when the rxipv6_gd_octets counter reaches half the maximum value, and also when it reaches the maximum value.
20	rw	0	Setting this bit masks the interrupt when the rxipv4_udsbl_octets counter reaches half the maximum value, and also when it reaches the maximum value.
19	rw	0	Setting this bit masks the interrupt when the rxipv4_frag_octets counter reaches half the maximum value, and also when it reaches the maximum value.
18	rw	0	Setting this bit masks the interrupt when the rxipv4_nopay_octets counter reaches half the maximum value, and also when it reaches the maximum value.
17	rw	0	Setting this bit masks the interrupt when the rxipv4_hdrerr_octets counter reaches half the maximum value, and also when it reaches the maximum value.

Table 34-16 MMC Receive Checksum Offload Interrupt Mask Register (cont'd)

Bit	Access Type	Reset Value	Description

15:14	r	0	Reserved
13	rw	0	Setting this bit masks the interrupt when the rxicmp_err_frms counter reaches half the maximum value, and also when it reaches the maximum value.
12	rw	0	Setting this bit masks the interrupt when the rxicmp_gd_frms counter reaches half the maximum value, and also when it reaches the maximum value.
11	rw	0	Setting this bit masks the interrupt when the rxtcp_err_frms counter reaches half the maximum value, and also when it reaches the maximum value.
10	rw	0	Setting this bit masks the interrupt when the rxtcp_gd_frms counter reaches half the maximum value, and also when it reaches the maximum value.
9	rw	0	Setting this bit masks the interrupt when the rxudp_err_frms counter reaches half the maximum value, and also when it reaches the maximum value.
8	rw	0	Setting this bit masks the interrupt when the rxudp_gd_frms counter reaches half the maximum value, and also when it reaches the maximum value.
7	rw	0	Setting this bit masks the interrupt when the rxipv6_nopay_frms counter reaches half the maximum value, and also when it reaches the maximum value.
6	rw	0	Setting this bit masks the interrupt when the rxipv6_hdrerr_frms counter reaches half the maximum value, and also when it reaches the maximum value.
5	rw	0	Setting this bit masks the interrupt when the rxipv6_gd_frms counter reaches half the maximum value, and also when it reaches the maximum value.
4	rw	0	Setting this bit masks the interrupt when the rxipv4_udsbl_frms counter reaches half the maximum value, and also when it reaches the maximum value.

Table 34-16 MMC Receive Checksum Offload Interrupt Mask Register (cont'd)

Bit	Access Type	Reset Value	Description
3	rw	0	Setting this bit masks the interrupt when the rxipv4_frag_frms counter reaches half the maximum value, and also when it reaches the maximum value.
2	rw	0	Setting this bit masks the interrupt when the rxipv4_nopay_frms counter reaches half the maximum value, and also when it reaches the maximum value.
1	rw	0	Setting this bit masks the interrupt when the rxipv4_hdrerr_frms counter reaches half the maximum value, and also when it reaches the maximum value.
0	rw	0	Setting this bit masks the interrupt when the rxipv4_gd_frms counter reaches half the maximum value, and also when it reaches the maximum value.

MMC Receive Checksum Offload Interrupt Register

The MMC Receive Checksum Offload Interrupt register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000), and when they cross their maximum values (0xFFFF_FFFF). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32 bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits[7:0]) must be read to clear the interrupt bit.

Note: Access restriction applies: Any read access to the register clears this register!

Table 34-17 MMC Receive Checksum Offload Interrupt Register

Bit	Access Type	Reset Value	Description
31:30	r	00	Reserved
29	rh	0	The bit is set when the rxicmp_err_octets counter reaches half the maximum value, and also when it reaches the maximum value.
28	rh	0	The bit is set when the rxicmp_gd_octets counter reaches half the maximum value, and also when it reaches the maximum value.

2	rh	0	The bit is set when the rxipv4_nopay_frms counter reaches half the maximum value, and also when it reaches the maximum value.
1	rh	0	The bit is set when the rxipv4_hdrerr_frms counter reaches half the maximum value, and also when it reaches the maximum value.
0	rh	0	The bit is set when the rxipv4_gd_frms counter reaches half the maximum value, and also when it reaches the maximum value.

34.2.8 Power Management Block

This section describes the power management (PMT) mechanisms supported by the GMAC. PMT supports the reception of network (remote) wake-up frames and Magic Packet frames. PMT does not perform the clock gate function, but generates interrupts for wake-up frames and Magic Packets received by the GMAC. The PMT block sits on the receiver path of the GMAC and is enabled with remote wake-up frame enable and Magic Packet enable. These enables are in the PMT Control and Status register and are programmed by the Application. You can include the optional PMT module by selecting it in the coreKit during configuration. You have the option to select either or both types of power-management frames (remote wake-up and Magic Packet)

PMT registers are accessed in the same manner as with GMAC-CSR registers. Refer to registers 10 and 11, for mapping information.

When the power down mode is enabled in the PMT, then all received frames are dropped by the core and they are not forwarded to the application. The core comes out of the power down mode only when either a Magic Packet or a Remote Wake-up frame is received and the corresponding detection is enabled.

34.2.8.1 PMT Block Description

PMT Control and Status Register

The PMT CSR program the request wake-up events and monitor the wake-up events.

Note: Access restriction applies: Any read access to the register clears this register!

Table 34-18 PMT Control and Status Register

Bit	Access Type	Reset Value	Description
31	rwh	0	Wake-Up Frame Filter Register Pointer Reset When set, resets the Remote Wake-up Frame Filter register pointer to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies: setting sets + clearing has no effect.
30:10	R	0000_00_H	Reserved
9	rw	00	Global Unicast When set, enables any unicast packet filtered by the GMAC (DAF) address recognition to be a wake-up frame.
8:7	R	0	Reserved
6	rh	0	Wake-Up Frame Received When set, this bit indicates the power management event was generated due to reception of a wake-up frame. This bit is cleared by a Read into this register.
5	rh	0	Magic Packet Received When set, this bit indicates the power management event was generated by the reception of a Magic Packet. This bit is cleared by a Read into this register.
4:3	R	00	Reserved
2	rw	0	Wake-Up Frame Enable When set, enables generation of a power management event due to wake-up frame reception.

Table 34-18 PMT Control and Status Register (cont'd)

Bit	Access Type	Reset Value	Description
1	rw	0	Magic Packet Enable When set, enables generation of a power management event due to Magic Packet reception.
0	rwh	0	Power Down When set, all received frames will be dropped. This bit is cleared automatically when a magic packet or Wake-Up frame is received, and Power-Down mode is disabled. Frames received after this bit is cleared are forwarded to the application.This bit must only be set when either the Magic Packet Enable, Global Unicast, or Wake-Up Frame Enable bit is set high. Access restriction applies: setting sets + clearing has no effect.

Remote Wake-Up Frame Filter Register

The register wkupfmfilter_reg, address (028_H), loads the Wake-up Frame Filter register. To load values in a Wake-up Frame Filter register, the entire register (wkupfmfilter_reg) must be written. The wkupfmfilter_reg register is loaded by sequentially loading the eight register values in address (028) for wkupfmfilter_reg0, wkupfmfilter_reg1,... wkupfmfilter_reg7, respectively. wkupfmfilter_reg is read in the same way.

Note: The internal counter to access the appropriate wkupfmfilter_reg is incremented when lane3 is accessed by the CPU. This should be kept in mind if you are accessing these registers in byte or half-word mode.

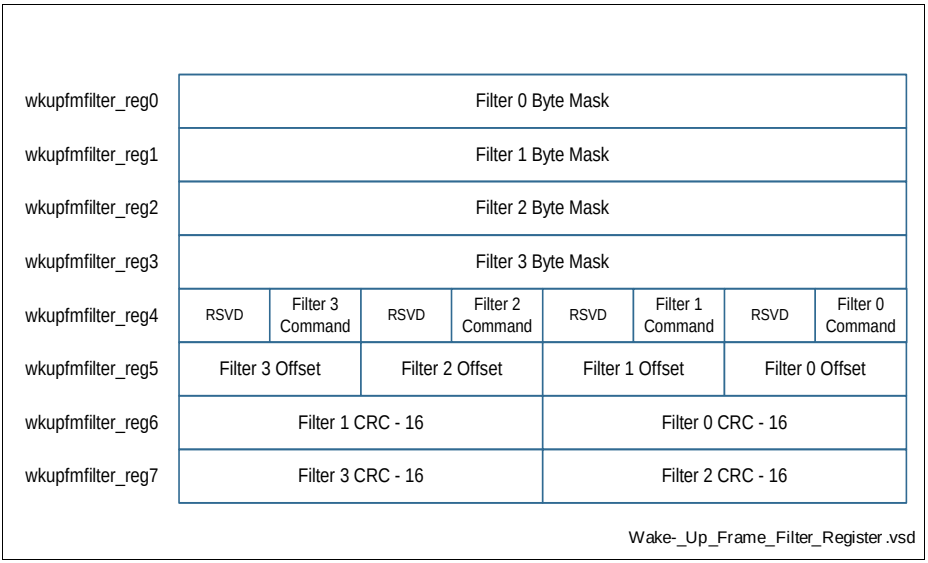

Figure 34-11 Wake-Up Frame Filter Register

Filter i Byte Mask

This register defines which bytes of the frame are examined by filter i (0, 1, 2, and 3) in order to determine whether or not the frame is a wake-up frame. The MSB (thirty-first bit) must be zero. Bit j [30:0] is the Byte Mask. If bit j (byte number) of the Byte Mask is set, then Filter i Offset + j of the incoming frame is processed by the CRC block; otherwise Filter i Offset + j is ignored.

Filter i Command

This 4-bit command controls the filter i operation. Bit 3 specifies the address type, defining the pattern's destination address type. When the bit is set, the pattern applies to only multicast frames; when the bit is reset, the pattern applies only to unicast frame. Bit 2 and Bit 1 are reserved. Bit 0 is the enable for filter i; if Bit 0 is not set, filter i is disabled.

Filter i Offset

This register defines the offset (within the frame) from which the frames are examined by filter i. This 8-bit pattern-offset is the offset for the filter i first byte to examined. The minimum allowed is 12, which refers to the 13th byte of the frame (offset value 0 refers to the first byte of the frame).

Filter i CRC-16

This register contains the CRC_16 value calculated from the pattern, as well as the byte mask programmed to the wake-up filter register block.

34.2.8.2 Remote Wake-Up Frame Detection

When the GMAC is in sleep mode and the remote wake-up bit is enabled in PMT Control and Status register (002C), normal operation is resumed after receiving a remote wake-up frame. The Application writes all eight wake-up filter registers, by performing a sequential Write to address (0028). The Application enables remote wake-up by writing a 1 to Bit 2 of the PMT Control and Status register.

PMT supports four programmable filters that allow support of different receive frame patterns. If the incoming frame passes the address filtering of Filter Command, and if Filter CRC-16 matches the incoming examined pattern, then the wake-up frame is received.

Filter_offset (minimum value 12, which refers to the 13th byte of the frame) determines the offset from which the frame is to be examined. Filter Byte Mask determines which bytes of the frame must be examined. The thirty-first bit of Byte Mask must be set to zero.

The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The wake-up frame is checked only for length error, FCS error, dribble bit error, GMII error, collision, and to ensure that it is not a runt frame. Even if the wake-up frame is more than 512 bytes long, if the frame has a valid CRC value, it is considered valid. Wake-up frame detection is updated in the PMT Control and Status register for every remote Wake-up frame received. A PMT interrupt to the Application triggers a Read to the PMT Control and Status register to determine reception of a wake-up frame.

34.2.8.3 Magic Packet Detection

The Magic Packet frame is based on a method that uses Advanced Micro Device's Magic Packet technology to power up the sleeping device on the network. The GMAC receives a specific packet of information, called a Magic Packet, addressed to the node on the network.

Only Magic Packets that are addressed to the device or a broadcast address will be checked to determine whether they meet the wake-up requirements. Magic Packets that pass the address filtering (unicast or broadcast) will be checked to determine whether they meet the remote Wake-on-LAN data format of 6 bytes of all ones followed by a GMAC Address appearing 16 times.

The application enables Magic Packet wake-up by writing a 1 to Bit 1 of the PMT Control and Status register. The PMT block constantly monitors each frame addressed to the node for a specific Magic Packet pattern. Each frame received is checked for a 48'hFF_FF_FF_FF_FF_FF pattern following the destination and source address field. The PMT block then checks the frame for 16 repetitions of the GMAC address without

any breaks or interruptions. In case of a break in the 16 repetitions of the address, the 48'hFF_FF_FF_FF_FF_FF pattern is scanned for again in the incoming frame. The 16 repetitions can be anywhere in the frame, but must be preceded by the synchronization stream (48'hFF_FF_FF_FF_FF_FF). The device will also accept a multicast frame, as long as the 16 duplications of the GMAC address are detected.

If the MAC address of a node is 48'h00_11_22_33_44_55, then the GMAC scans for the data sequence:

```
Destination Address Source Address …….. FF FF FF FF FF FF
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
…CRC
```

Magic Packet detection is updated in the PMT Control and Status register for Magic Packet received. A PMT interrupt to the Application triggers a read to the PMT CSR to determine whether a Magic Packet frame has been received.

34.2.8.4 System Considerations During Power-Down

GMAC-UNIV neither gates nor stops clocks when Power-Down mode is enabled. Power saving by clock gating must be done outside the core by the application. The receive data path must be clocked with clk_rx_i during Power-Down mode, because it is involved in magic packet/wake-on-LAN frame detection. However, the transmit path and the application path clocks can be gated off during Power-Down mode.

The pmt_intr_o signal is asserted when a valid wake-up frame is received. This signal is generated in the clk_rx_i domain.

The recommended power-down and wake-up sequence is as follows.

1. Disable the Transmit DMA (if applicable) and wait for any previous frame transmissions to complete. These transmissions can be detected when Transmit Interrupt (TI–DMA Register 5[0]) is received.
2. Disable the MAC transmitter and MAC receiver by clearing the appropriate bits in the MAC Configuration register.
3. Wait until the Receive DMA empties all the frames from the Rx FIFO (a software timer may be required).
4. Enable Power-Down mode by appropriately configuring the PMT registers.
5. Enable the MAC Receiver and enter Power-Down mode.

6. Gate the application and transmit clock inputs to the core (and other relevant clocks in the system) to reduce power and enter Sleep mode.
7. On receiving a valid wake-up frame, the GMAC-UNIV asserts the pmt_intr_o signal and exits Power-Down mode.
8. On receiving the interrupt, the system must enable the application and transmit clock inputs to the core.
9. Read the PMT Status register to clear the interrupt, then enable the other modules in the system and resume normal operation.

34.2.9 Station Management Agent

The Station Management Agent (SMA) module allows the Application to access any PHY registers through a 2-wire Station Management interface (MIM). The interface supports accessing up to 32 PHYs.

The application can select one of the 32 PHYs and one of the 32 registers within any PHY and send control data or receive status information. Only one register in one PHY can be addressed at any given time. For more details on the communication from the Application to the PHYs, refer to the Reconciliation Sublayer and Media Independent Interface Specifications section of the IEEE 802.3z specification, 1000BASE Ethernet. The application sends the control data to the PHY and receives status information from the PHY through the SMA module, as shown in **Figure 34-12**.

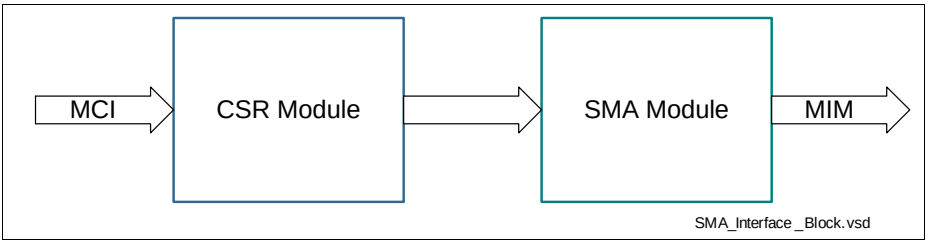

Figure 34-12 SMA Interface Block

34.2.9.1 Functions

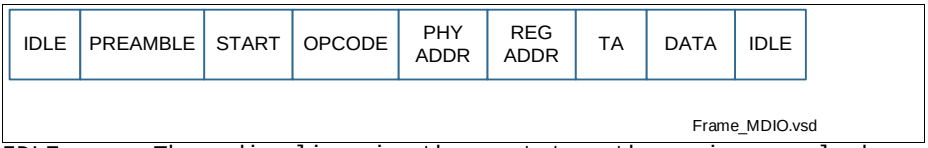
The GMAC initiates the Management Write/Read operation. The clock gmii_mdc_o is a divided clock from the Application clock clk_csr_i. The divide factor depends on the clock range setting in the GMII Address register. Clock range is set as follows:

Selection	clk_csr_i	MDC Clock
0000	60-100 MHz	clk_csr_i/42
0001	100-150 MHz	clk_csr_i/62
0010	20-35 MHz	clk_csr_i/16

Selection	clk_csr_i	MDC Clock
0011	35-60 MHz	clk_csr_i/26
0100	150-250 MHz	clk_csr_i/102
0101	250-300 MHz	clk_csr_i/124
0110, 0111	Reserved	

The gmii_mdc_o is the derivative of the Application clock clk_csr_i. The Management operation is performed through the gmii_mdi_i, gmii_mdo_o and gmii_mdo_o_e signals. A three-state buffer is implemented outside the GMAC to interface with an external PHY.

The frame structure on the MDIO line is shown below.



```
IDLE        The mdio line is three-state; there is no clock on
gmii_mdc_o
PREAMBLE    32 continuous bits of value 1
START       Start-of-frame is 2'01
OPCODE      2'b10 for Read and 2'b01 for Write
PHY ADDR    5-bit address select for one of 32 PHYs
REG ADDR    Register address in the selected PHY
TA          Turnaround is 2'bZ0 for Read and 2'b10 for Write
DATA        Any 16-bit value. In a Write operation, the GMAC drives
mdio; in a Read
            operation, PHY drives it.
```

34.2.9.2 MII Management Write Operation

When the user sets the GMII Write and Busy bits (see GMII Address Register, **"32-bit Register - GMII_Address" on Page 1-309**), the GMAC CSR module transfers the PHY address, the register address in PHY, and the write data (GMII Data Register) to the SMA to initiate a Write operation into the PHY registers. At this point, the SMA module starts a Write operation on the GMII Management Interface using the Management Frame Format specified in the GMII specifications (Section 22.2.4.5 of IEEE Standard). The application should not change the GMII Address register contents or the GMII Data register while the transaction is ongoing. Write operations to the GMII Address register or the GMII Data Register during this period are ignored (the Busy bit is high), and the transaction is completed without any error on the MCI interface.

After the Write operation has completed, the SMA indicates this to the CSR which then resets the Busy bit. The SMA module divides the CSR (Application) clock with the clock divider programmed (CR bits of GMII Address Register) to generate the MDC clock for this interface. The GMAC drives the MDIO line for the complete duration of the frame. The frame format for the Write operation is as follows:

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	1111...11	01	01	AAAAA	RRRRR	10	DDD . . . .DDD	Z

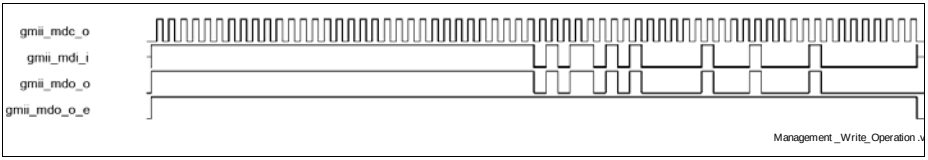


Figure 34-13 Management Write Operation

Figure 34-13 is a reference for the Write operation.

34.2.9.3 MII Management Read Operation

When the user sets the GMII Busy bit (see GMII Address Register, **“32-bit Register - GMII_Address” on Page 1-309**) with the GMII Write bit as 0, the GMAC CSR module transfers the PHY address and the register address in PHY to the SMA to initiate a Read operation in the PHY registers. At this point, the SMA module starts a Read operation on the GMII Management Interface using the Management Frame Format specified in the GMII specifications (Section 22.2.4.5 of IEEE Standard). The application should not change the GMII Address register contents or the GMII Data register while the transaction is ongoing. Write operations to the GMII Address register or GMII Data Register during this period are ignored (the Busy bit is high) and the transaction completed without any error on the MCI interface.

After the Read operation has completed, the SMA indicates this to the CSR, which then resets the Busy bit and updates the GMII Data register with the data read from the PHY. The SMA module divides the CSR (Application) clock with the clock divider programmed (CR bits of GMII Address Register) to generate the MDC clock for this interface. The GMAC drives the MDIO line for the complete duration of the frame except during the Data fields when the PHY is driving the MDIO line. The frame format for the Read operation is as follows:

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	1111...11	01	10	AAAAA	RRRRR	Z0	DDD . . . .DDD	Z

Figure 34-14 is a reference for the read operation.

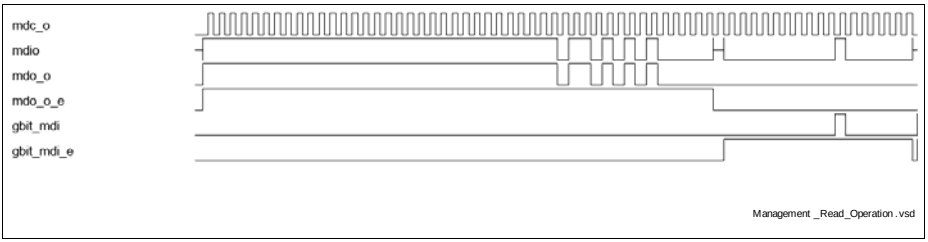

Figure 34-14 Management Read Operation

34.2.10 Reduced Media Independent Interface

The Reduced Media Independent Interface (RMII) specification reduces the pin count between Ethernet PHYs and Switch ASICs (only in 10/100 mode). According to the IEEE 802.3u standard, an MII contains 16 pins for data and control. In devices incorporating multiple MAC or PHY interfaces (such as switches), the number of pins adds significant cost with increase in port count. The RMII specification addresses this problem by reducing the pin count to 7 for each port — a 62.5% decrease in pin count.

- The RMII module is instantiated between the GMAC and the PHY. This helps translation of the MAC's MII into the RMII. The RMII block has the following characteristics:
- Supports 10 Mbit/s and 100 Mbit/s operating rates.
- Two clock references are sourced externally, providing independent, 2-bit wide transmit and receive paths.

34.2.10.1 Block Diagram

Figure 34-15 shows the position of the RMII block relative to the Ethernet MAC and RMII PHY. The RMII block is placed in front of the Ethernet MAC to translate the MII signals to RMII signals.

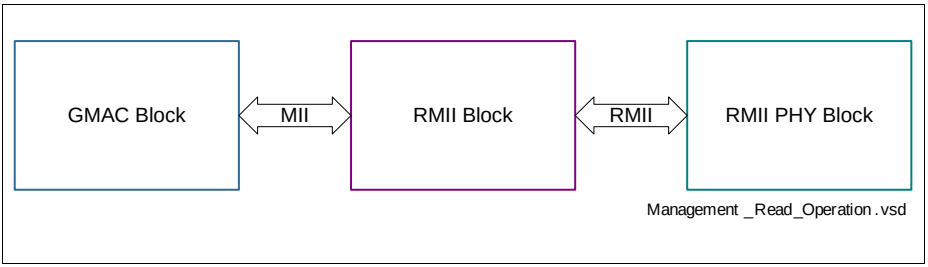

Figure 34-15 RMII Block Diagram

34.2.10.2 Block Overview

The following list describes the RMII's hardware components, which are shown in **Figure 34-16**. Each of these blocks is briefly described in the following sections.

MII-RMII Transmit (MRT) Block: This block translates all MII transmit signals to RMII transmit signals. All RMII signals are synchronous to clk_rmii_i.

MII-RMII Receive (MRR) Block: This block translates all RMII receive signals to MII receive signals. All MII signals are synchronous to clk_rx_i. You must ensure that the same clock is connected to both clk_tx_i and clk_rx_i clock input ports in RMII mode. This is required because clock-MUXing logic is avoided inside the GMAC core.

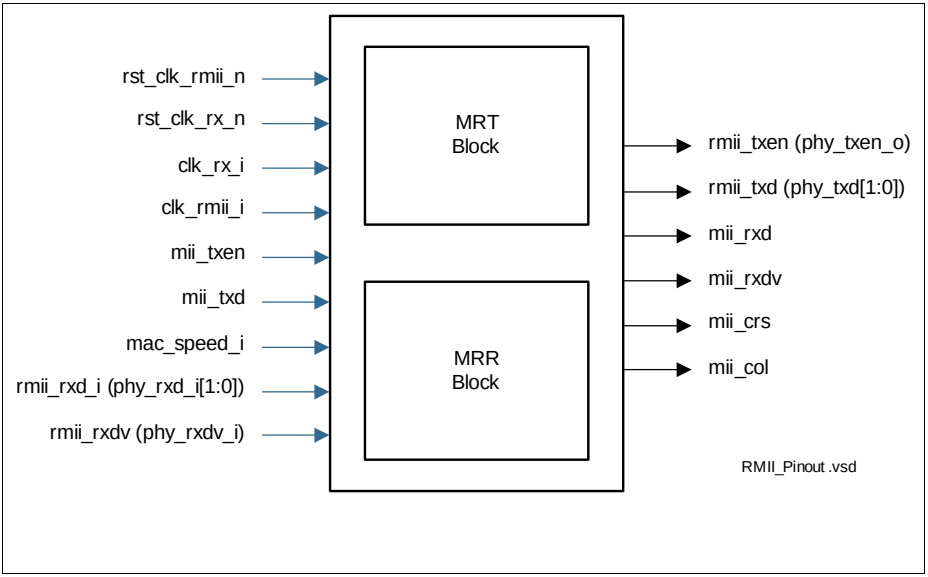

Figure 34-16 RMII Pinout

Note: The mac_speed_i signal configures the RMII to operate at 10 Mbit/s or 100 Mbit/s. This signal is driven from the MAC Configuration register's FES bit.

34.2.10.3 Transmit Bit Ordering

Each nibble from the MII must be transmitted on the RMII a di-bit at a time with the order of di-bit transmission shown in **Figure 34-17**. The lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

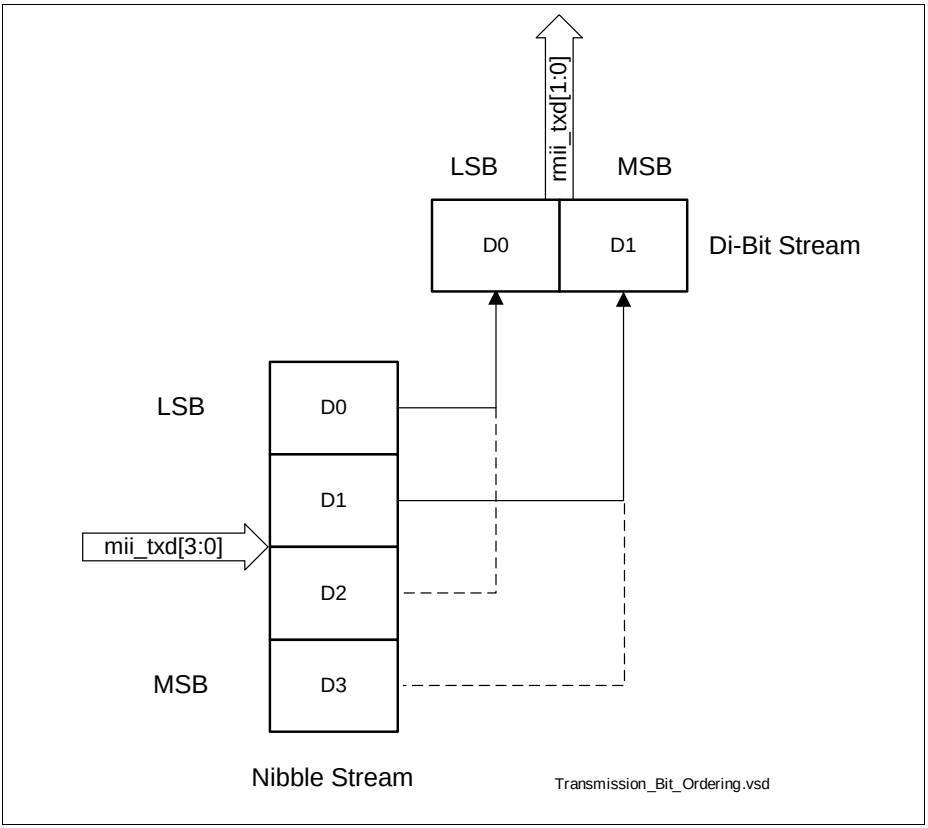

Figure 34-17 Transmission Bit Ordering

34.2.10.4 RMII Transmit Timing Diagrams

Figure 34-18 through **Figure 34-21** show MII-to-RMII transaction timing.

Figure 34-18 shows the start of MII transmission and the following RMII transmission in 100 Mbit/s mode.

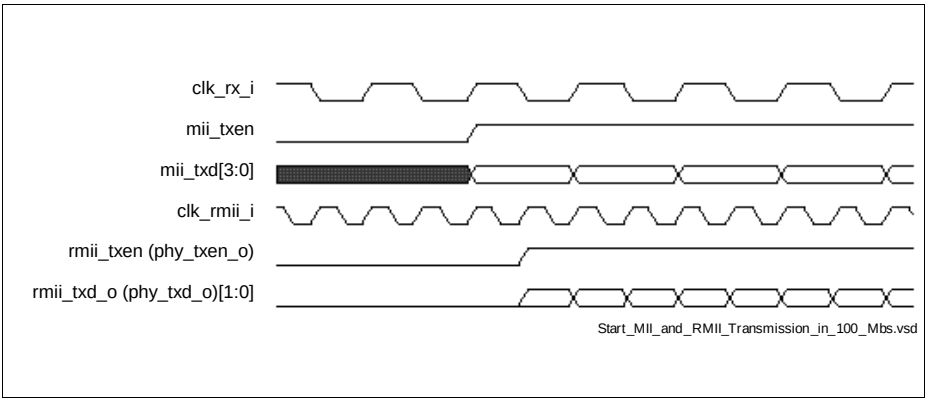

Figure 34-18 Start of MII and RMII Transmission in 100 Mbit/s Mode

Figure 34-19 shows the end of frame transmission for MII and RMII in 100 Mbit/s mode.

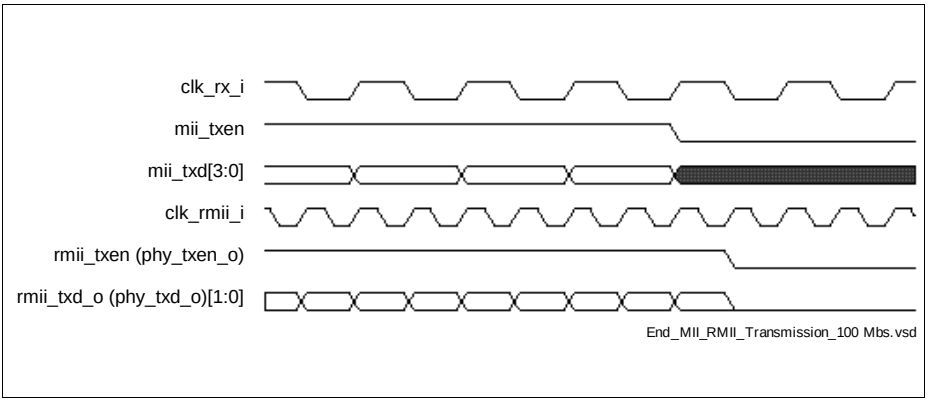

Figure 34-19 End of MII and RMII Transmission in 100 Mbit/s Mode

Figure 34-20 shows the start of MII transmission and the following RMII transmission in 10 Mbit/s mode.

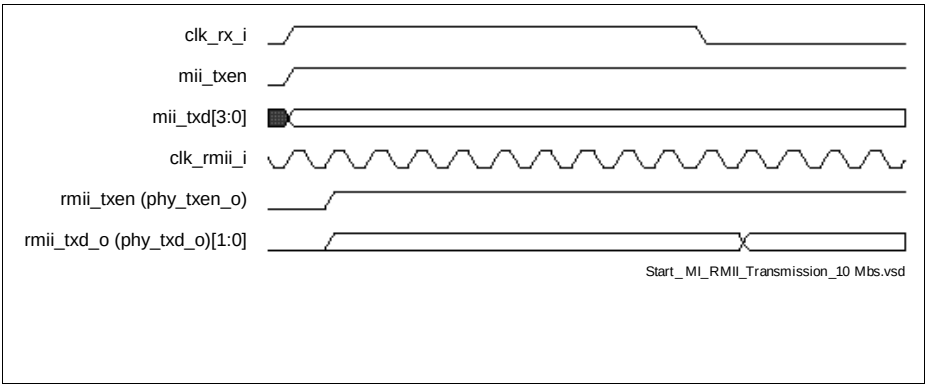

Figure 34-20 Start of MII and RMII Transmission in 10 Mbit/s Mode

Figure 34-21 shows the end of MII transmission and RMII transmission in 10 Mbit/s mode.

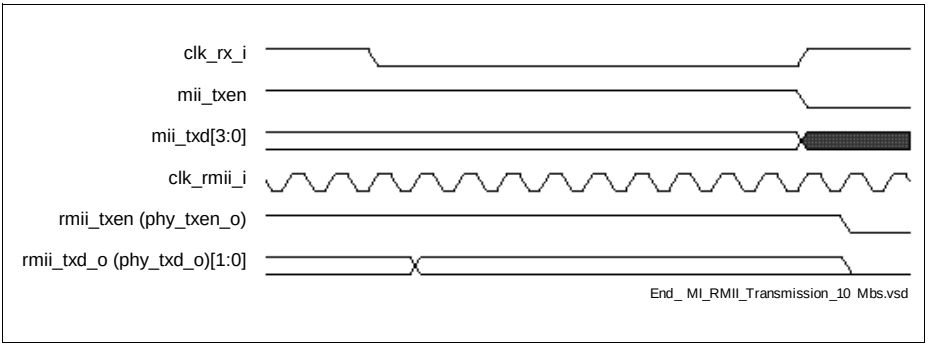

Figure 34-21 End of MII and RMII Transmission in 10 Mbit/s Mode

Receive Bit Ordering

Each nibble is transmitted to the MII from the di-bit received from the RMII in the nibble transmission order shown in **Figure 34-22**. The lower order bits (D0 and D1) are received first, followed by the higher order bits (D2 and D3).

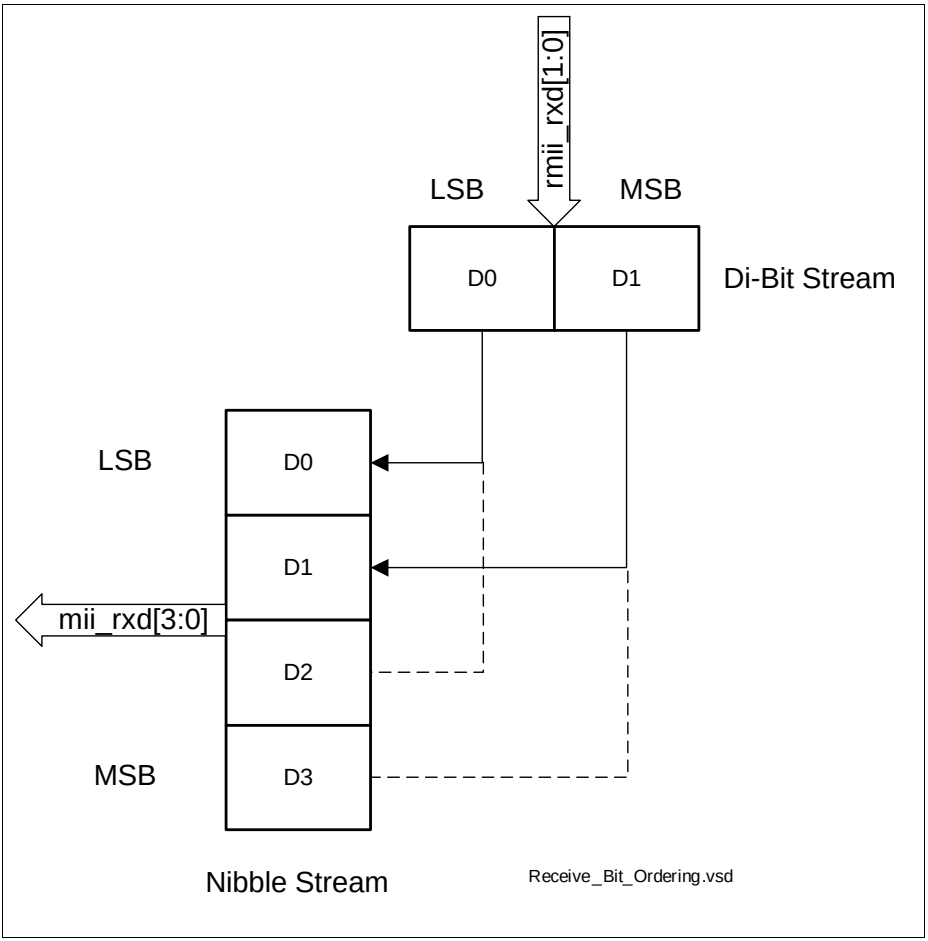

Figure 34-22 Receive Bit Ordering

34.2.11 Interrupts From the GMAC Core

Interrupts can be generated from the GMAC core as a result of various events in the optional modules in it.

The Interrupt Status register in the GMAC Register Map (**"GMAC Register Map" on Page 1-281**) describes the events that can cause an interrupt from the GMAC core. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the Interrupt Mask register.

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt. For example, Bit 0 of the Interrupt register, set high, indicates that the link status on the RGMII interface has changed. You must read Register 54 (the RGMII Status register) to clear this interrupt event.

The interrupts from the RGMII and PCS blocks are combined (OR'ed) and given as the GLI bit in the DMA Status register. The TTI, GPI, and GMI signals in **Figure 34-23** refer to the bits that can be read in the DMA Status register.

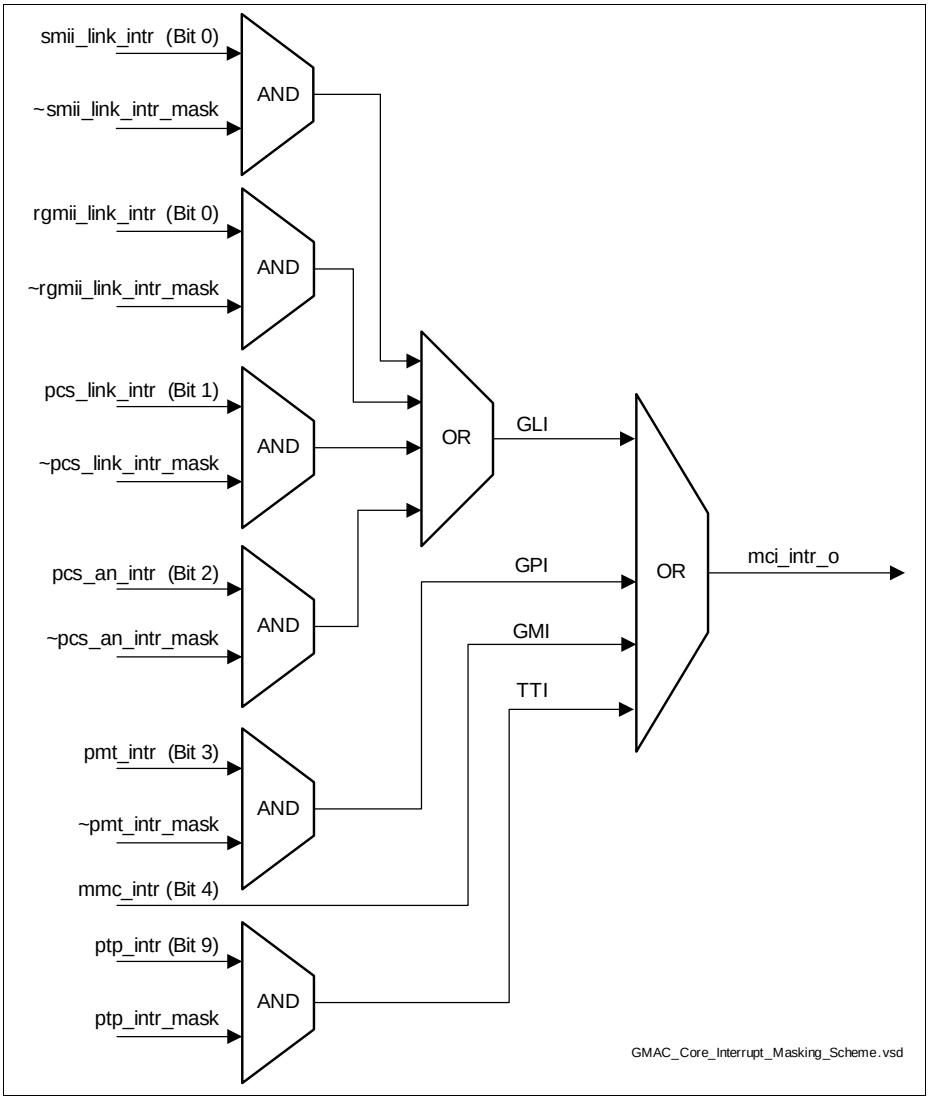

Figure 34-23 GMAC Core Interrupt Masking Scheme

34.3 Register

General notes on registers:

- All CSRs are implemented as 32-bit registers and can be accessed in 1 read/write cycle with a 32-bit MCI interface (or 32-bit AHB slave port). If you initiate a non-32-bit register access, the byte enable signals (mci_be_i[3:0]) qualify the corresponding register bytes. Only write operations are qualified with byte enables, while read operations are always 32-bit, unless the register is affected by a read operation. Byte enable signals qualify reads to such registers as, for example, the MMC counter registers.
- The transfer of particular register contents (e.g., MAC DA address register) to the Transmit or Receive clock domains are initiated when a particular byte is written. This is indicated in the register descriptions, where applicable.
- When any Register content is being transferred to a different clock domain after a write operation, there should not be any further writes to the same location until the first write is updated. Otherwise, the second write operation will not get updated to the destination clock domain. Thus the delay between two writes to the same register location should be at least 4 cycles of the destination clock (PHY receive clock or PHY transmit clock).

34.3.1 Register Maps

The register maps in this section provide high-level summaries of each register or group of registers. The detailed register descriptions in **“Register Description” on Page 1-292**.

Reserved address space (marked as “do not use”) will generate no bus error (nBE).

All registers in the DMA and MAC Registers map (1000_H - 2058_H) are P = ACCEN protected. The registers for additional Module Control are ACCEN protected according to **Figure 34-22**).

34.3.1.1 Register Overview

Table 34-19 Registers Address Space - ETH Module

Module	Base Address	End Address	Note
ETH	F001 $D000_H$	F001 $F0FF_H$	-

34.3.1.2 DMA Register Map

Table 34-20 DMA Register Map

DMA Register No.	Offset Address	Register Name and Description
0	2000_H	**DMA Register 0 (Bus Mode Register)** Controls the Host Interface Mode.
1	2004_H	**DMA Register 1 (Transmit Poll Demand Register)** Used by the host to instruct the DMA to poll the Transmit Descriptor List.
2	2008_H	**DMA Register 2 (Receive Poll Demand Register)** Used by the Host to instruct the DMA to poll the Receive Descriptor List.
3	$200C_H$	**DMA Register 3 (Receive Descriptor List Address Register)** Points the DMA to the start of the Receive Descriptor list.
4	2010_H	**DMA Register 4 (Transmit Descriptor List Address Register)** Points the DMA to the start of the Transmit Descriptor List.
5	2014_H	**DMA Register 5 (Status Register)** The Software driver (application) reads this register during interrupt service routine or polling to determine the status of the DMA.
6	2018_H	**DMA Register 6 (Operation Mode Register)** Establishes the Receive and Transmit operating modes and command.
7	$201C_H$	**DMA Register 7 (Interrupt Enable Register)** Enables the interrupts reported by the Status Register.
8	2020_H	**DMA Register 8 (Missed Frame and Buffer Overflow Counter Register)** Contains the counters for discarded frames because no host Receive Descriptor was available, and discarded frames because of Receive FIFO Overflow.
9	2024_H	**DMA Register 9 (Receive Interrupt Watchdog Timer Register)** Watchdog time-out for Receive Interrupt (RI) from DMA
12-17	2030_H-2044_H	Do not use

Table 34-20 DMA Register Map

DMA Register No.	Offset Address	Register Name and Description
18	2048_H	**DMA Register 18 (Current Host Transmit Descriptor Register)** Points to the start of current Transmit Descriptor read by the DMA.
19	$204C_H$	**DMA Register 19 (Current Host Receive Descriptor Register)** Points to the start of current Receive Descriptor read by the DMA.
20	2050_H	**DMA Register 20 (Current Host Transmit Buffer Address Register)** Points to the current Transmit Buffer address read by the DMA.
21	2054_H	**DMA Register 21 (Current Host Receive Buffer Address Register)** Points to the current Receive Buffer address read by the DMA.
22	2058_H	**DMA Register 22 (HW Feature Register)** Indicates the presence of the optional features of the core.
23-63	$205C_H$-$20FC_H$	Do not use

34.3.1.3 GMAC Register Map

Table 1-59 provides the address map of the GMAC core registers.

Table 34-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
0	1000_H	**GMAC Register 0 (MAC Configuration Register)** This is the operation mode register for the MAC.
1	1004_H	**GMAC Register 1 (MAC Frame Filter)** Contains the frame filtering controls.

Table 34-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
2	1008_H	**GMAC Register 2 (Hash Table High Register)** Contains the higher 32 bits of the Multicast Hash table.This register is present only when the Hash filter function is selected in coreConsultant. (See Table ??)
3	$100C_H$	**GMAC Register 3 (Hash Table Low Register)** Contains the lower 32 bits of the Multicast Hash table. This register is present only when the Hash filter function is selected in coreConsultant. (See Table ??)
4	1010_H	**GMAC Register 4 (GMII Address Register)** Controls the management cycles to an external PHY. This register is present only when the Station Management (MDIO) feature is selected in coreConsultant. (See Table ??)
5	1014_H	**GMAC Register 5 (GMII Data Register)** Contains the data to be written to or read from the PHY register. This register is present only when the Station Management (MDIO) feature is selected in coreConsultant. (See Table ??)
6	1018_H	**GMAC Register 6 (Flow Control Register)** Controls the generation of control frames.
7	$101C_H$	**GMAC Register 7 (VLAN Tag Register)** Identifies IEEE 802.1Q VLAN type frames.
8	1020_H	**GMAC Register 8 (Version Register)** Identifies the version of the Core
9	1024_H	**GMAC Register 9 (Debug Register)** Gives the status of various internal blocks for debugging

Table 34-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
10	1028_H	**Remote Wake-Up Frame Filter** This is the address through which the remote Wake-up Frame Filter registers (wkupfmfilter_reg) are written/read by the Application. wkupfmfilter_reg is actually a pointer to eight (not transparent) such wkupfmfilter_reg registers. Eight sequential Writes to this address (028) will write all wkupfmfilter_reg registers. Eight sequential Reads from this address (028) will read all wkupfmfilter_reg registers. This register contains the higher 16 bits of the 7th MAC address. This register is present only when the PMT module Remote Wake-up feature is selected in coreConsultant. (See Table ??) Refer to “Remote Wake-Up Frame Filter Register” on page ?? for additional information.
11	$102C_H$	**PMT Control and Status** This register is present only when the PMT module is selected in coreConsultant. (See Table ??) Refer to “PMT Control and Status Register” on page ?? for additional information.
12-13	1030_H - 1034_H	Do not use
14	1038_H	**GMAC Register 14 (Interrupt Status Register)** Contains the interrupt status.
15	$103C_H$	**GMAC Register 15 (Interrupt Mask Register)** Contains the masks for generating the interrupts.
16	1040_H	**GMAC Register 16 (MAC Address 0 High Register)** Contains the higher 16 bits of the first MAC address.
17	1044_H	**GMAC Register 17 (MAC Address 0 Low Register)** Contains the lower 32 bits of the first MAC address.
18	1048_H	**GMAC Register 18 (MAC Address 1 High Register)** Contains the higher 16 bits of the second MAC address. This register is present only when Enable MAC Address 1 is selected in coreConsultant. (See Table ??).

Table 34-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
19	$104C_H$	**GMAC Register 19 (MAC Address 1 Low Register)** Contains the lower 32 bits of the second MAC address. This register is present only when Enable MAC Address 1 is selected in coreConsultant. (See Table ??).
20	1050_H	**MAC Address 2 High Register** Contains the higher 32 bits of the third MAC address. This register is present only when Enable MAC Address 2 is selected in coreConsultant. (See Table ??).
21	1054_H	**MAC Address 2 Low Register** Contains the lower 32 bits of the third MAC address. This register is present only when Enable MAC Address 2 is selected in coreConsultant. (See Table ??).
22	1058_H	**MAC Address 3 High Register** Contains the higher 16 bits of the fourth MAC address. This register is present only when Enable MAC Address 3 is selected in coreConsultant. (See Table ??).
23	$105C_H$	**MAC Address 3 Low Register** Contains the lower 32 bits of the fourth MAC address. This register is present only when Enable MAC Address 3 is selected in coreConsultant. (See Table ??).
24	1060_H	**MAC Address 4 High Register** Contains the higher 16 bits of the fifth MAC address. This register is present only when Enable MAC Address 4 is selected in coreConsultant. (See Table ??).
25	1064_H	**MAC Address 4 Low Register** Contains the lower 32 bits of the fifth MAC address. This register is present only when Enable MAC Address 4 is selected in coreConsultant. (See Table ??).
26	1068_H	**MAC Address 5 High Register** Contains the higher 16 bits of the sixth MAC address. This register is present only when Enable MAC Address 5 is selected in coreConsultant. (See Table ??).

Table 34-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
27	$106C_H$	**MAC Address 5 Low Register** Contains the lower 32 bits of the sixth MAC address. This register is present only when Enable MAC Address 5 is selected in coreConsultant. (See Table ??).
28	1070_H	**MAC Address 6 High Register** Contains the higher 16 bits of the seventh MAC address.This register is present only when Enable MAC Address 6 is selected in coreConsultant. (See Table ??).
29	1074_H	**MAC Address 6 Low Register** Contains the lower 32 bits of the seventh MAC address. This register is present only when Enable MAC Address 6 is selected in coreConsultant. (See Table ??).
30	1078_H	**MAC Address 7 High Register** Contains the higher 16 bits of the eighth MAC address. This register is present only when Enable MAC Address 7 is selected in coreConsultant. (See Table ??).
31	$107C_H$	**MAC Address 7 Low Register** Contains the lower 32 bits of the eighth MAC address. This register is present only when Enable MAC Address 7 is selected in coreConsultant. (See Table ??).
32	1080_H	**MAC Address 8 High Register** Contains the higher 16 bits of the ninth MAC address. This register is present only when Enable MAC Address 8 is selected in coreConsultant. (See Table ??).
33	1084_H	**MAC Address 8 Low Register** Contains the lower 32 bits of the ninth MAC address. This register is present only when Enable MAC Address 8 is selected in coreConsultant. (See Table ??).
34	1088_H	**MAC Address 9 High Register** Contains the higher 16 bits of the tenth MAC address. This register is present only when Enable MAC Address 9 is selected in coreConsultant. (See Table ??).

Table 34-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
35	$108C_H$	**MAC Address 9 Low Register** Contains the lower 32 bits of the tenth MAC address. This register is present only when Enable MAC Address 9 is selected in coreConsultant. (See Table ??).
36	1090_H	**MAC Address 10 High Register** Contains the higher 16 bits of the eleventh MAC address. This register is present only when Enable MAC Address 10 is selected in coreConsultant. (See Table ??).
37	1094_H	**MAC Address 10 Low Register** Contains the lower 32 bits of the eleventh MAC address. This register is present only when Enable MAC Address 10 is selected in coreConsultant. (See Table ??).
38	1098_H	**MAC Address 11 High Register** This register contains the higher 16 bits of the twelfth MAC address. This register is present only when Enable MAC Address 11 is selected in coreConsultant. (See Table ??).
39	$109C_H$	**MAC Address 11 Low Register** Contains the lower 32 bits of the twelfth MAC address. This register is present only when Enable MAC Address 11 is selected in coreConsultant. (See Table ??).
40	$10A0_H$	**MAC Address 12 High Register** Contains the higher 16 bits of the thirteenth MAC address. This register is present only when Enable MAC Address 12 is selected in coreConsultant. (See Table ??).
41	$10A4_H$	**MAC Address 12 Low Register** Contains the lower 32 bits of the thirteenth MAC address. This register is present only when Enable MAC Address 12 is selected in coreConsultant. (See Table ??).
42	$10A8_H$	**MAC Address 13 High Register** Contains the higher 16 bits of the fourteenth MAC address. This register is present only when Enable MAC Address 13 is selected in coreConsultant. (See Table ??).

Table 34-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
43	$10AC_H$	**MAC Address 13 Low Register** Contains the lower 32 bits of the fourteenth MAC address. This register is present only when Enable MAC Address 13 is selected in coreConsultant. (See Table ??).
44	$10B0_H$	**MAC Address 14 High Register** Contains the higher 16 bits of the fifteenth MAC address. This register is present only when Enable MAC Address 14 is selected in coreConsultant. (See Table ??).
45	$10B4_H$	**MAC Address 14 Low Register** Contains the lower 32 bits of the fifteenth MAC address. This register is present only when Enable MAC Address 14 is selected in coreConsultant. (See Table ??).
46	$10B8_H$	**MAC Address 15 High Register** Contains the higher 16 bits of the sixteenth MAC address. This register is present only when Enable MAC Address 15 is selected in coreConsultant. (See Table ??).
47	$10BC_H$	**MAC Address 15 Low Register** Contains the lower 32 bits of the sixteenth MAC address. This register is present only when Enable MAC Address 15 is selected in coreConsultant. (See Table ??).
55-63	$10DC_H$ - $10FC_H$	Do not use
64-191	1100_H - $12FC_H$	MMC Register Map See **Table 1-17 “MMC Register Map” on Page 1-131**.
192-447	1300_H - $16FC_H$	Do not use
448	1700_H	**Register 448 (Time Stamp Control Register)** Controls the time stamp generation and update logic.
449	1704_H	**Register 449 (Sub-Second Increment Register)** Contains the 8-bit value by which the Sub-Second register is incremented.This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.

Table 34-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
450	1708_H	**Register 450 (System Time - Seconds Register)** Contains the lower 32 bits of the seconds field of the system time. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
451	$170C_H$	**Register 451 (System Time - Nanoseconds Register)** Contains 32 bits of the nanoseconds field of the system time. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
452	1710_H	**Register 452 (System Time - Seconds Update Register)** Contains the lower 32 bits of the seconds field to be written to, added to, or subtracted from the System Time value. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
453	1714_H	**Register 453 (System Time - Nanoseconds Update Register)** Contains 32 bits of the nanoseconds field to be written to, added to, or subtracted from the System Time value. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
454	1718_H	**Register 454 (Time Stamp Addend Register)** This register is used by the software to readjust the clock frequency linearly to match the master clock frequency. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
455	$171C_H$	**Register 455 (Target Time Seconds Register)** Contains the higher 32 bits of time to be compared with the system time for interrupt event generation. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
456	1720_H	**Register 456 (Target Time Nanoseconds Register)** Contains the lower 32 bits of time to be compared with the system time for interrupt event generation. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.

Table 34-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
457	1724_H	**Register 457 (System Time - Higher Word Seconds Register)** Contains the most significant 16-bits of the time stamp seconds value. This register is optional and can be selected using the coreKit parameter identified in “IEEE 1588 Time Stamp Block” on page ??.
458	1728_H	**Register 458 (Time Stamp Status Register)** Contains the PTP status. This register is available only when the advanced IEEE 1588 timestamp feature is selected.
459	$172C_H$	**Register 459 (PPS Control Register)** This register is used to control the interval of the PPS signal output, such that a duration of less than 1 second can be achieved between pulses.
460	1730_H	**Register 460 (Auxiliary Time Stamp - Nanoseconds Register)** Contains the lower 32 bits (nanoseconds field) of the auxiliary time stamp register.
461	1734_H	**Register 461 (Auxiliary Time Stamp - Seconds Register)** Contains the upper 32 bits (seconds field) of the auxiliary time stamp register.
462-511	1738_H - $17FC_H$	Do not use
512-511	1738_H - $17FC_H$	Do not use
512	1800_H	**MAC Address 16 High Register** Contains the higher 16 bits of the seventeenth MAC address.
513	1804_H	**MAC Address 16 Low Register** Contains the lower 32 bits of the seventeenth MAC address.
514	1808_H	**MAC Address 17 High Register** Contains the higher 16 bits of the eighteenth MAC address.
...	...	...
543	$187C_H$	**MAC Address 31 Low Register** Contains the lower 32 bits of the thirty-second MAC address.

Table 34-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
543	1880_H	**MAC Address 32 High Register** Contains the lower 32 bits of the thirty-third MAC address.
	$1F84_H$ - $1FFC_H$	Do not use

34.3.1.4 Ethernet MAC Additional Module Control Registers

This section describes the additional module control registers of the Ethernet MAC module. All Ethernet MAC register names described in this section will be referenced in other parts of the TC27x User's Manual by the module name prefix "Ethernet MAC_" for the Ethernet MAC interface.

All registers in the Ethernet MAC address spaces are reset with the application reset (definition see SCU section "Reset Operation"). P = ACCEN protection

Table 34-22 Register Overview - ETH Add. Mod. Contr. Registers

Register Short Name	Register Long Name	Offset [1]	Access Mode		Description see
			Read	Write	
Module Control Registers

-	reserved	0020_H - $0FFF_H$	nBE	nBE	

1) The absolute register address is calculated as follows:
Module Base Address (**Table 1-60**) + Offset Address (shown in this column)

34.3.2 Register Description

This section defines the bits for each register.

32-bit Register - MAC_Configuration

The MAC Configuration register establishes receive and transmit operating modes.

ETH_MAC_CONFIGURATION
Register 0 - MAC Configuration Register (1000_H) **Reset Value: $0000\ 8000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RESERVED_31	SARC			TWOKPE	SFTERR	CST	TC	WD	JD	BE	JE	IFG			DCRS
r	r			rw	r	rw	r	rw	rw	r	rw	rw			rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PS	FES	DO	LM	DM	IPC	DR	LUD	ACS	BL		DC	TE	RE	PRELEN	
r	rw	rw	rw	rw	rw	rw	r	rw	rw		rw	rw	rw	rw	

Field	Bits	Type	Description
PRELEN	[1:0]	rw	**Preamble Length for Transmit Frames** These bits control the number of preamble bytes that are added to the beginning of every Transmit frame. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. * 2'b00: 7 bytes of preamble * 2'b01: 5 byte of preamble * 2'b10: 3 bytes of preamble * 2'b11: reserved
RE	2	rw	**Receiver Enable** When this bit is set, the receiver state machine of the MAC is enabled for receiving frames from the GMII or MII. When this bit is reset, the MAC receive state machine is disabled after the completion of the reception of the current frame, and does not receive any further frames from the GMII or MII.

Field	Bits	Type	Description
TE	3	rw	**Transmitter Enable** When this bit is set, the transmit state machine of the MAC is enabled for transmission on the GMII or MII. When this bit is reset, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and does not transmit any further frames.
DC	4	rw	**Deferral Check** When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status, when the transmit state machine is deferred for more than 24,288 bit times in the 10 or 100 Mbps mode. If the MAC is configured for 1000 Mbps operation, or if the Jumbo frame mode is enabled in the 10 or 100 Mbps mode, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active carrier sense signal (CRS) on GMII or MII. Defer time is not cumulative. When the transmitter defers for 10,000 bit times, it transmits, collides, backs off, and then defers again after completion of back-off. The deferral timer resets to 0 and restarts. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode and is reserved (RO) in the full-duplex-only configuration.

Field	Bits	Type	Description
BL	[6:5]	rw	**Back-Off Limit** The Back-Off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000 Mbps and 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. This bit is applicable only in the half-duplex mode and is reserved (RO) in the full-duplex-only configuration. * 00: k = min (n, 10) * 01: k = min (n, 8) * 10: k = min (n, 4) * 11: k = min (n, 1) where n = retransmission attempt. The random integer r takes the value in the range 0 <= r < kth power of 2
ACS	7	rw	**Automatic Pad or CRC Stripping** When this bit is set, the MAC strips the Pad or FCS field on the incoming frames only if the value of the length field is less than 1,536 bytes. All received frames with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming frames, without modifying them, to the Host.
LUD	8	r	**Link Up or Down** This bit indicates whether the link is up or down during the transmission of configuration in the RGMII, SGMII, or SMII interface: * 0: Link Down * 1: Link Up This bit is reserved (RO with default value) and is enabled when the RGMII, SGMII, or SMII interface is enabled during core configuration.

Field	Bits	Type	Description
DR	9	rw	**Disable Retry** When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current frame transmission and reports a Frame Abort with excessive collision error in the transmit frame status. When this bit is reset, the MAC attempts retries based on the settings of the BL field (Bits [6:5]). This bit is applicable only in the half-duplex mode and is reserved (RO with default value) in the full-duplex-only configuration.
IPC	10	rw	**Checksum Offload** When this bit is set, the MAC calculates the 16-bit one's complement of the one's complement sum of all received Ethernet frame payloads. It also checks whether the IPv4 Header checksum (assumed to be bytes 2526 or 2930 (VLAN-tagged) of the received Ethernet frame) is correct for the received frame and gives the status in the receive status word. The MAC also appends the 16-bit checksum calculated for the IP header datagram payload (bytes after the IPv4 header) and appends it to the Ethernet frame transferred to the application (when Type 2 COE is deselected). When this bit is reset, this function is disabled. When Type 2 COE is selected, this bit, when set, enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled and the corresponding PCE and IP HCE status bits are always cleared. If the IP Checksum Offload feature is not enabled during core configuration, this bit is reserved (RO with default value).
DM	11	rw	**Duplex Mode** When this bit is set, the MAC operates in the full-duplex mode where it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the full-duplex-only configuration.

Field	Bits	Type	Description
LM	12	rw	**Loopback Mode** When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Receive clock input (clk_rx_i) is required for the loopback to work properly, because the Transmit clock is not looped-back internally.
DO	13	rw	**Disable Receive Own** When this bit is set, the MAC disables the reception of frames when the gmii_txen_o is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets that are given by the PHY while transmitting. This bit is not applicable if the MAC is operating in the full-duplex mode. This bit is reserved (RO with default value) if the MAC is configured for the full-duplex-only operation.
FES	14	rw	**Speed** This bit selects the speed in the MII, RMII, SMII, RGMII, SGMII, or RevMII interface: * 0: 10 Mbps * 1: 100 Mbps This bit is reserved (RO) by default and is enabled only when the RMII, SMII, RGMII, SGMII, or RevMII interface is enabled during core configuration. This bit generates link speed encoding when TC (Bit 24) is set in the RGMII, SMII, or SGMII mode. This bit is always driven for RevMII. If the MAC is configured with an RMII, SMII, SGMII, or RGMII PHY interface, this bit can optionally be driven as an output signal (mac_speed_o[0]) to reflect the value of this bit in the mac_speed_o signal. In addition, this bit is reserved when RMII is enabled without enabling the Output Port for speed selection option during core configuration.

Field	Bits	Type	Description
PS	15	r	**Port Select** This bit selects between GMII and MII: * 0: GMII (1000 Mbps) * 1: MII (10/100 Mbps) In the 10 or 100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only with the appropriate value. In the default 10/100/1000 Mbps configurations, this bit is R_W. The mac_portselect_o signal reflects the value of this bit.
DCRS	16	rw	**Disable Carrier Sense During Transmission** When set high, this bit makes the MAC transmitter ignore the (G)MII CRS signal during frame transmission in the half-duplex mode. This request results in no errors generated because of Loss of Carrier or No Carrier during such transmission. When this bit is low, the MAC transmitter generates such errors because of Carrier Sense and can even abort the transmissions. This bit is reserved (and RO) in the full-duplex-only configurations.
IFG	[19:17]	rw	**Inter-Frame Gap** These bits control the minimum IFG between frames during transmission. * 000: 96 bit times * 001: 88 bit times * 010: 80 bit times * ... * 111: 40 bit times In the half-duplex mode, the minimum IFG can be configured only for 64 bit times (IFG = 100). Lower values are not considered. In the 1000-Mbps mode, the minimum IFG supported is 64 bit times (and above) in the GMAC-CORE configuration and 80 bit times (and above) in other configurations.
JE	20	rw	**Jumbo Frame Enable** When this bit is set, the MAC allows Jumbo frames of 9,018 bytes (9,022 bytes for VLAN tagged frames) without reporting a giant frame error in the receive frame status.

Field	Bits	Type	Description
BE	21	r	**Frame Burst Enable** When this bit is set, the MAC allows frame bursting during transmission in the GMII half-duplex mode. This bit is reserved (and RO) in the 10/100 Mbps only or full-duplex-only configurations.
JD	22	rw	**Jabber Disable** When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer frames of up to 16,384 bytes. When this bit is reset, the MAC cuts off the transmitter if the application sends out more than 2,048 bytes of data (10,240 if JE is set high) during transmission.
WD	23	rw	**Watchdog Disable** When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive frames of up to 16,384 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the frame being received. The MAC cuts off any bytes received after 2,048 bytes.
TC	24	r	**Transmit Configuration in RGMII, SGMII, or SMII** When set, this bit enables the transmission of duplex mode, link speed, and link up or down information to the PHY in the RGMII, SMII, or SGMII port. When this bit is reset, no such information is driven to the PHY. This bit is reserved (and RO) if the RGMII, SMII, or SGMII PHY port is not selected during core configuration.
CST	25	rw	**CRC Stripping of Type Frames** When set, the last 4 bytes (FCS) of all frames of Ether type (type field greater than 0x0600) are stripped and dropped before forwarding the frame to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver.
SFTERR	26	r	**SMII Force Transmit Error** When set, this bit indicates to the PHY to force a transmit error in the SMII frame being transmitted. This bit is reserved if the SMII PHY port is not selected during core configuration.

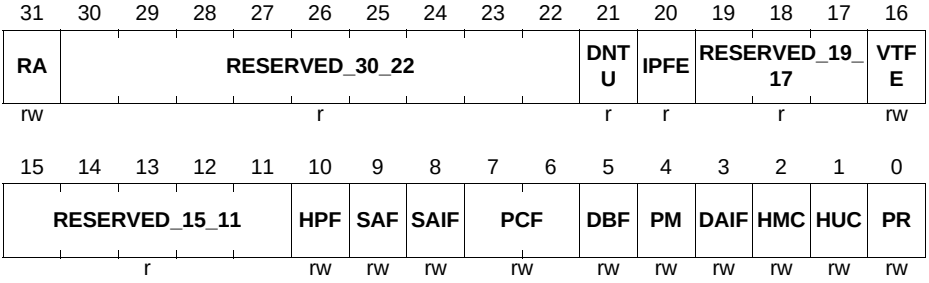
Field	Bits	Type	Description
TWOKPE	27	rw	**IEEE 802.3as support for 2K packets Enable** When set, the MAC considers all frames, with up to 2,000 bytes length, as normal packets. When Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 2K bytes as Giant frames. When this bit is reset and Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 1,518 bytes (1,522 bytes for tagged) as Giant frames. When Bit 20 (Jumbo Enable) is set, setting this bit has no effect on Giant Frame status.

Field	Bits	Type	Description
SARC	[30:28]	r	**Source Address Insertion or Replacement Control** This field controls the source address insertion or replacement for all transmitted frames. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits [29:28]: * 2'b0x: The input signals mti_sa_ctrl_i and ati_sa_ctrl_i control the SA field generation. * 2'b10: - If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers (registers 16 and 17) in the SA field of all transmitted frames. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected during core configuration, the MAC inserts the content of the MAC Address 1 registers (registers 18 and 19) in the SA field of all transmitted frames. * 2'b11: - If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers (registers 16 and 17) in the SA field of all transmitted frames. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected during core configuration, the MAC replaces the content of the MAC Address 1 registers (registers 18 and 19) in the SA field of all transmitted frames. Note: - Changes to this field take effect only on the start of a frame. If you write this register field when a frame is being transmitted, only the subsequent frame can use the updated value, that is, the current frame does not use the updated value. - These bits are reserved and RO when the Enable SA, VLAN, and CRC Insertion on TX feature is not selected during core configuration.
RESERVED_31	31	r	**RESERVED_31**

32-bit Register - MAC_Frame_Filter

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

ETH_MAC_FRAME_FILTER
Register 1 - MAC Frame Filter **(1004_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
PR	0	rw	**Promiscuous Mode** When this bit is set, the Address Filter module passes all incoming frames regardless of its destination or source address. The SA or DA Filter Fails status bits of the Receive Status Word are always cleared when PR is set.
HUC	1	rw	**Hash Unicast** When set, MAC performs destination address filtering of unicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for unicast frames, that is, it compares the DA field with the values programmed in DA registers. If Hash Filter is not selected during core configuration, this bit is reserved (and RO).

Field	Bits	Type	Description
HMC	2	rw	**Hash Multicast** When set, MAC performs destination address filtering of received multicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for multicast frames, that is, it compares the DA field with the values programmed in DA registers. If Hash Filter is not selected during core configuration, this bit is reserved (and RO).
DAIF	3	rw	**DA Inverse Filtering** When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast frames. When reset, normal filtering of frames is performed.
PM	4	rw	**Pass All Multicast** When set, this bit indicates that all received frames with a multicast destination address (first bit in the destination address field is '1') are passed. When reset, filtering of multicast frame depends on HMC bit.
DBF	5	rw	**Disable Broadcast Frames** When this bit is set, the AFM module filters all incoming broadcast frames. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast frames.

Field	Bits	Type	Description
PCF	[7:6]	rw	**Pass Control Frames** These bits control the forwarding of all control frames (including unicast and multicast PAUSE frames). * 00: MAC filters all control frames from reaching the application. * 01: MAC forwards all control frames except PAUSE control frames to application even if they fail the Address filter. * 10: MAC forwards all control frames to application even if they fail the Address Filter. * 11: MAC forwards control frames that pass the Address Filter. The following conditions should be true for the PAUSE control frames processing: * Condition 1: The MAC is in the full-duplex mode and flow control is enabled by setting Bit 2 (RFE) of Register 6 (Flow Control Register) to 1. * Condition 2: The destination address (DA) of the received frame matches the special multicast address or the MAC Address 0 when Bit 3 (UP) of the Register 6 (Flow Control Register) is set. * Condition 3: The Type field of the received frame is 0x8808 and the OPCODE field is 0x0001. Note: This field should be set to 01 only when the Condition 1 is true, that is, the MAC is programmed to operate in the full-duplex mode and the RFE bit is enabled. Otherwise, the PAUSE frame filtering may be inconsistent. When Condition 1 is false, the PAUSE frames are considered as generic control frames. Therefore, to pass all control frames (including PAUSE control frames) when the full-duplex mode and flow control is not enabled, you should set the PCF field to 10 or 11 (as required by the application).

Field	Bits	Type	Description
SAIF	8	rw	**SA Inverse Filtering** When this bit is set, the Address Check block operates in inverse filtering mode for the SA address comparison. The frames whose SA matches the SA registers are marked as failing the SA Address filter. When this bit is reset, frames whose SA does not match the SA registers are marked as failing the SA Address filter.
SAF	9	rw	**Source Address Filter Enable** When this bit is set, the MAC compares the SA field of the received frames with the values programmed in the enabled SA registers. If the comparison matches, then the SA Match bit of RxStatus Word is set high. When this bit is set high and the SA filter fails, the MAC drops the frame. When this bit is reset, the MAC forwards the received frame to the application and with the updated SA Match bit of the RxStatus depending on the SA address comparison.
HPF	10	rw	**Hash or Perfect Filter** When this bit is set, it configures the address filter to pass a frame if it matches either the perfect filtering or the hash filtering as set by the HMC or HUC bits. When this bit is low and the HUC or HMC bit is set, the frame is passed only if it matches the Hash filter. This bit is reserved (and RO) if the Hash filter is not selected during core configuration.
RESERVED_15_11	[15:11]	r	**RESERVED_15_11**
VTFE	16	rw	**VLAN Tag Filter Enable** When set, this bit enables the MAC to drop VLAN tagged frames that do not match the VLAN Tag comparison. When reset, the MAC forwards all frames irrespective of the match status of the VLAN Tag.
RESERVED_19_17	[19:17]	r	**RESERVED_19_17**

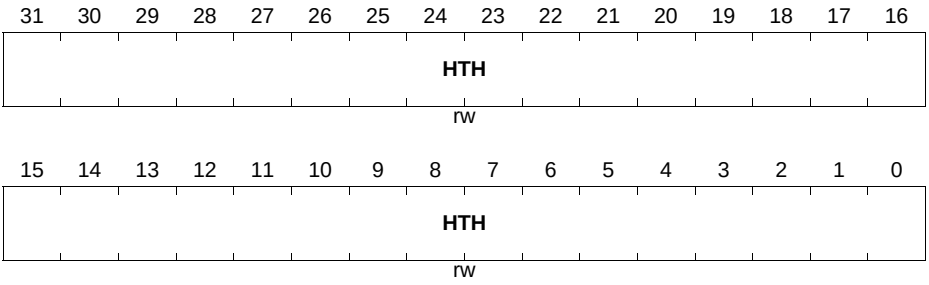
Field	Bits	Type	Description
IPFE	20	r	**Layer 3 and Layer 4 Filter Enable** When set, this bit enables the MAC to drop frames that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When reset, the MAC forwards all frames irrespective of the match status of the Layer 3 and Layer 4 fields. If the Layer 3 and Layer 4 Filtering feature is not selected during core configuration, this bit is reserved (RO with default value).
DNTU	21	r	**Drop non-TCP/UDP over IP Frames** When set, this bit enables the MAC to drop the non-TCP or UDP over IP frames. The MAC forward only those frames that are processed by the Layer 4 filter. When reset, this bit enables the MAC to forward all non-TCP or UDP over IP frames. If the Layer 3 and Layer 4 Filtering feature is not selected during core configuration, this bit is reserved (RO with default value).
RESERVED_30_22	[30:22]	r	**RESERVED_30_22**
RA	31	rw	**Receive All** When this bit is set, the MAC Receiver module passes all received frames, irrespective of whether they pass the address filter or not, to the Application. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bits in the Receive Status Word. When this bit is reset, the Receiver module passes only those frames to the Application that pass the SA or DA address filter.

32-bit Register - Hash_Table_High

The 64-bit Hash table is used for group address filtering. For hash filtering, the contents of the destination address in the incoming frame is passed through the CRC logic, and the upper 6 bits of the CRC register are used to index the contents of the Hash table. The most significant bit determines the register to be used (Hash Table High or Hash Table Low), and the other 5 bits determine which bit within the register. A hash value of 5b'00000 selects Bit 0 of the selected register, and a value of 5b'11111 selects Bit 31 of the selected register. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
 2. Perform bitwise reversal for the value obtained in Step 1.
 3. Take the upper 6 bits from the value obtained in Step 2.
 For example, if the DA of the incoming frame is received as 0x1F52419CB6AF (0x1F is the first byte received on GMII interface), then the internally calculated 6-bit Hash value is 0x2C and Bit 12 of Hash Table High register is checked for filtering. If the DA of the incoming frame is received as 0xA00A98000045, then the calculated 6-bit Hash value is 0x07 and Bit 7 of Hash Table Low register is checked for filtering. Note: To help you program the hash table, a sample C routine that generates a DA's 6-bit hash is included in the /sample_codes/ directory of your workspace. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the PM (Pass All Multicast) bit is set in Register 1, then all multicast frames are accepted regardless of the multicast hash values. If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table High or Low registers are written. Consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain when double-synchronization is enabled. The Hash Table High register contains the higher 32 bits of the Hash table.

ETH_HASH_TABLE_HIGH

Register 2 - Hash Table High Register (1008_H) **Reset Value: $0000\ 0000_H$**



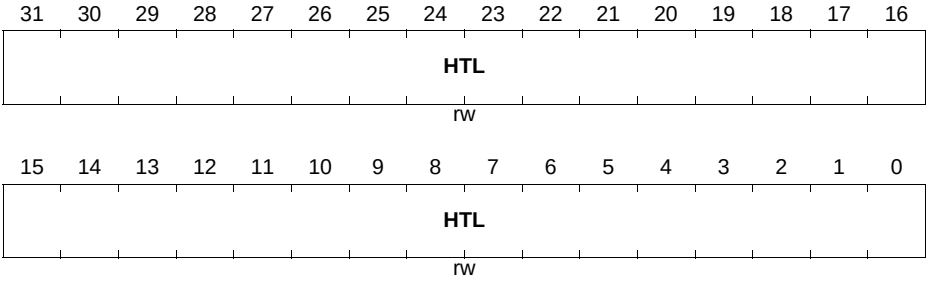
Field	Bits	Type	Description
HTH	[31:0]	rw	**Hash Table High** This field contains the upper 32 bits of the Hash table.

32-bit Register - Hash_Table_Low

The Hash Table Low register contains the lower 32 bits of the Hash table. Both Register 2 and Register 3 are reserved if the Hash Filter Function is disabled or the 128-bit or 256-bit Hash Table is selected during core configuration.

ETH_HASH_TABLE_LOW

Register 3 - Hash Table Low Register ($100C_H$) **Reset Value: $0000\ 0000_H$**

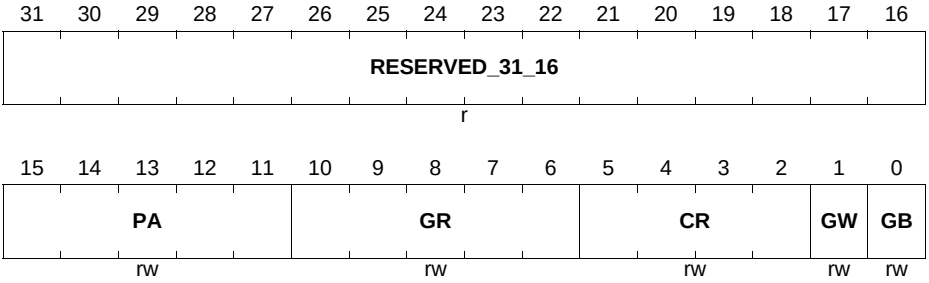


Field	Bits	Type	Description
HTL	[31:0]	rw	**Hash Table Low** This field contains the lower 32 bits of the Hash table.

32-bit Register - GMII_Address

The GMII Address register controls the management cycles to the external PHY through the management interface.

ETH_GMII_ADDRESS
Register 4 - GMII Address Register (1010$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
GB	0	rw	**GMII Busy** This bit should read logic 0 before writing to Register 4 and Register 5. During a PHY or RevMII register access, the software sets this bit to 1'b1 to indicate that a Read or Write access is in progress. The Register 5 is invalid until this bit is cleared by the MAC. Therefore, Register 5 (GMII Data) should be kept valid until the MAC clears this bit during a PHY Write operation. Similarly for a read operation, the contents of Register 5 are not valid until this bit is cleared. The subsequent read or write operation should happen only after the previous operation is complete. Because there is no acknowledgment from the PHY to MAC after a read or write operation is completed, there is no change in the functionality of this bit even when the PHY is not present.
GW	1	rw	**GMII Write** When set, this bit indicates to the PHY or RevMII that this is a Write operation using the GMII Data register. If this bit is not set, it indicates that this is a Read operation, that is, placing the data in the GMII Data register.

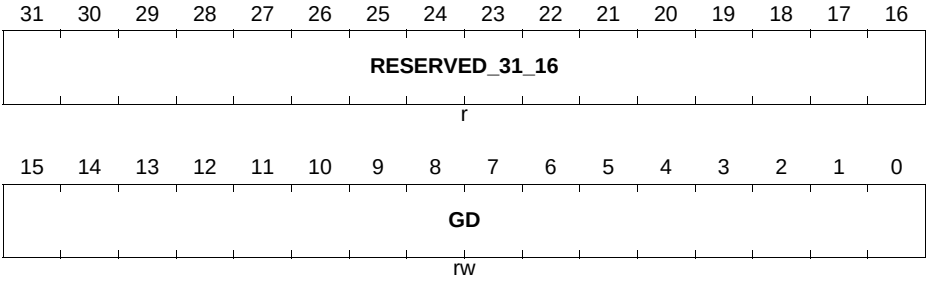
Field	Bits	Type	Description
CR	[5:2]	rw	**CSR Clock Range** The CSR Clock Range selection determines the frequency of the MDC clock according to the clk_csr_i frequency used in your design. The suggested range of clk_csr_i frequency applicable for each value (when Bit[5] = 0) ensures that the MDC clock is approximately between the frequency range 1.0 MHz - 2.5 MHz. - 0000: The frequency of the clk_csr_i clock is 60-100 MHz and the MDC clock is clk_csr_i/42. - 0001: The frequency of the clk_csr_i clock is 100-150 MHz and the MDC clock is clk_csr_i/62. - 0010: The frequency of the clk_csr_i clock is 20-35 MHz and the MDC clock is clk_csr_i/16. - 0011: The frequency of the clk_csr_i clock is 35-60 MHz and the MDC clock is clk_csr_i/26. - 0100: The frequency of the clk_csr_i clock is 150-250 MHz and the MDC clock is clk_csr_i/102. - 0100: The frequency of the clk_csr_i clock is 250-300 MHz and the MDC clock is clk_csr_i/124. - 0110 and 0111: Reserved When Bit 5 is set, you can achieve MDC clock of frequency higher than the IEEE 802.3 specified frequency limit of 2.5 MHz and program a clock divider of lower value. For example, when clk_csr_i is of 100 MHz frequency and you program these bits as 1010, then the resultant MDC clock is of 12.5 MHz which is outside the limit of IEEE 802.3 specified range. Program the following values only if the interfacing chips support faster MDC clocks: - 1000: clk_csr_i/4 - 1001: clk_csr_i/6 - 1010: clk_csr_i/8 - 1011: clk_csr_i/10 - 1100: clk_csr_i/12 - 1101: clk_csr_i/14 - 1110: clk_csr_i/16 - 1111: clk_csr_i/18 These bits are not used for accessing RevMII. These bits are read-only if the RevMII interface is selected as single PHY interface.

Field	Bits	Type	Description
GR	[10:6]	rw	**GMII Register** These bits select the desired GMII register in the selected PHY device. For RevMII, these bits select the desired CSR register in the RevMII Registers set.
PA	[15:11]	rw	**Physical Layer Address** This field indicates which of the 32 possible PHY devices are being accessed. For RevMII, this field gives the PHY Address of the RevMII module.
RESERVED_31_16	[31:16]	r	**RESERVED_31_16**

32-bit Register - GMII_Data

The GMII Data register stores Write data to be written to the PHY register located at the address specified in Register 4 (GMII Address Register). This register also stores the Read data from the PHY register located at the address specified by Register 4.

ETH_GMII_DATA
Register 5 - GMII Data Register (1014$_H$) Reset Value: 0000 0000$_H$

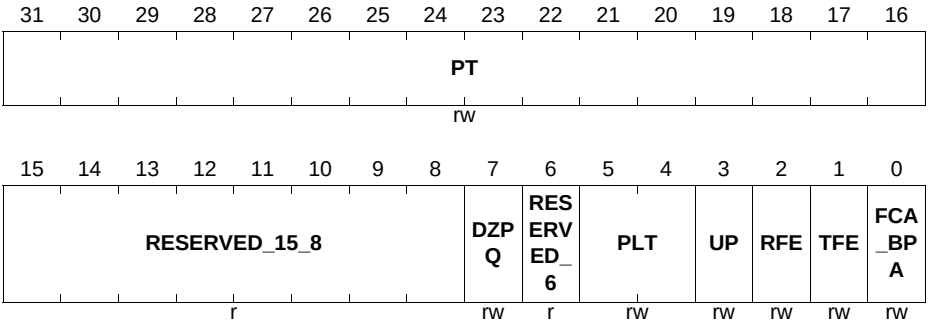


Field	Bits	Type	Description
GD	[15:0]	rw	**GMII Data** This field contains the 16-bit data value read from the PHY or RevMII after a Management Read operation or the 16-bit data value to be written to the PHY or RevMII before a Management Write operation.
RESERVED_31_16	[31:16]	r	**RESERVED_31_16**

32-bit Register - Flow_Control

The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control module. A Write to a register with the Busy bit set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

ETH_FLOW_CONTROL
Register 6 - Flow Control Register (1018$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
FCA_BPA	0	rw	**Flow Control Busy or Backpressure Activate** This bit initiates a Pause Control frame in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. In the full-duplex mode, this bit should be read as 1'b0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 1'b1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 1'b0. The Flow Control register should not be written to until this bit is cleared. In the half-duplex mode, when this bit is set (and TFE is set), then backpressure is asserted by the MAC. During backpressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled.
TFE	1	rw	**Transmit Flow Control Enable** In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames. In half-duplex mode, when this bit is set, the MAC enables the back-pressure operation. When this bit is reset, the back-pressure feature is disabled.
RFE	2	rw	**Receive Flow Control Enable** When this bit is set, the MAC decodes the received Pause frame and disables its transmitter for a specified (Pause) time. When this bit is reset, the decode function of the Pause frame is disabled.

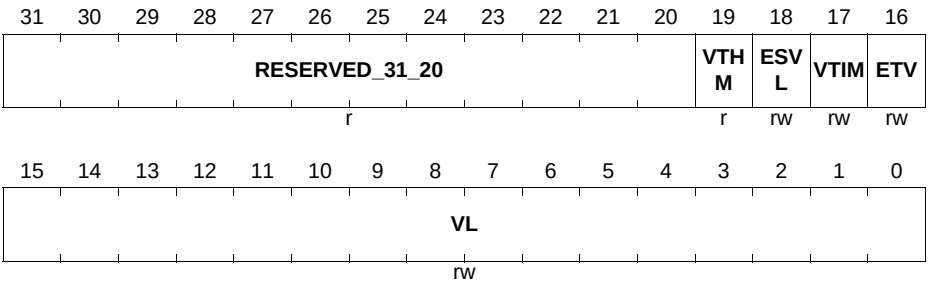
Field	Bits	Type	Description
UP	3	rw	**Unicast Pause Frame Detect** When this bit is set, then in addition to the detecting Pause frames with the unique multicast address, the MAC detects the Pause frames with the station's unicast address specified in the MAC Address0 High Register and MAC Address0 Low Register. When this bit is reset, the MAC detects only a Pause frame with the unique multicast address specified in the 802.3x standard.
PLT	[5:4]	rw	**Pause Low Threshold** This field configures the threshold of the PAUSE timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of PAUSE Frame. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot-times), and PLT = 01, then a second PAUSE frame is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256 - 28) slot times after the first PAUSE frame is transmitted. The following list provides the threshold values for different values: - 00: The threshold is Pause time minus 4 slot times (PT - 4 slot times). - 01: The threshold is Pause time minus 28 slot times (PT - 28 slot times). - 10: The threshold is Pause time minus 144 slot times (PT - 144 slot times). - 11: The threshold is Pause time minus 256 slot times (PT - 256 slot times). The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface.
RESERVED_6	6	r	**RESERVED_6**

Field	Bits	Type	Description
DZPQ	7	rw	**Disable Zero-Quanta Pause** When this bit is set, it disables the automatic generation of the Zero-Quanta Pause Control frames on the de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i/mti_flowctrl_i). When this bit is reset, normal operation with automatic Zero-Quanta Pause Control frame generation is enabled.
RESERVED_15_8	[15:8]	r	**RESERVED_15_8**
PT	[31:16]	rw	**Pause Time** This field holds the value to be used in the Pause Time field in the transmit control frame. If the Pause Time bits is configured to be double-synchronized to the (G)MII clock domain, then consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.

32-bit Register - VLAN_Tag

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. If the VLAN Tag register is configured to be double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

ETH_VLAN_TAG
Register 7 - VLAN Tag Register (101C$_H$) Reset Value: 0000 0000$_H$



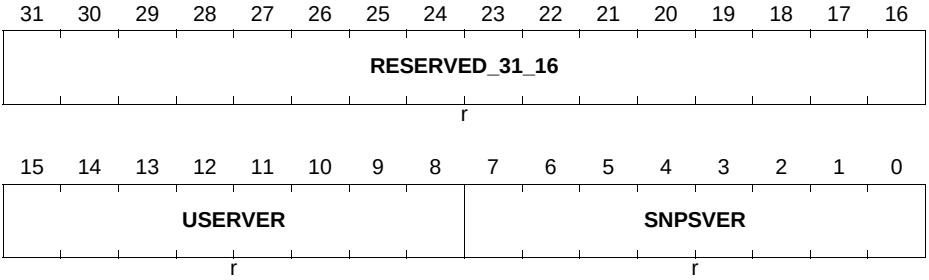
Field	Bits	Type	Description
VL	[15:0]	rw	**VLAN Tag Identifier for Receive Frames** This field contains the 802.1Q VLAN tag to identify the VLAN frames and is compared to the 15th and 16th bytes of the frames being received for VLAN frames. The following list describes the bits of this field: * Bits [15:13]: User Priority * Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) * Bits[11:0]: VLAN tag's VLAN Identifier (VID) field When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison. If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and 16th bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 or 0x88a8 as VLAN frames.

Field	Bits	Type	Description
ETV	16	rw	**Enable 12-Bit VLAN Tag Comparison** When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. Similarly, when enabled, only 12 bits of the VLAN tag in the received frame are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN frame are used for comparison and VLAN hash filtering.
VTIM	17	rw	**VLAN Tag Inverse Match Enable** When set, this bit enables the VLAN Tag inverse matching. The frames that do not have matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The frames with matched VLAN Tag are marked as matched.
ESVL	18	rw	**Enable S-VLAN** When this bit is set, the MAC transmitter and receiver also consider the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames.
VTHM	19	r	**VLAN Tag Hash Table Match Enable** When set, the most significant four bits of the VLAN tag¡Çs CRC are used to index the content of Register 354 (VLAN Hash Table Register). A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the frame matched the VLAN hash table. When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison. When reset, the VLAN Hash Match operation is not performed. If the VLAN Hash feature is not enabled during core configuration, this bit is reserved (RO with default value).
RESERVED_31_20	[31:20]	r	**RESERVED_31_20**

32-bit Register - Version

The Version registers identifies the version of the DWC_gmac. This register contains two bytes: one that Synopsys uses to identify the core release number, and the other that you set during core configuration.

ETH_VERSION
Register 8 - Version Register **(1020_H)** **Reset Value: $0000\ 5537_H$**

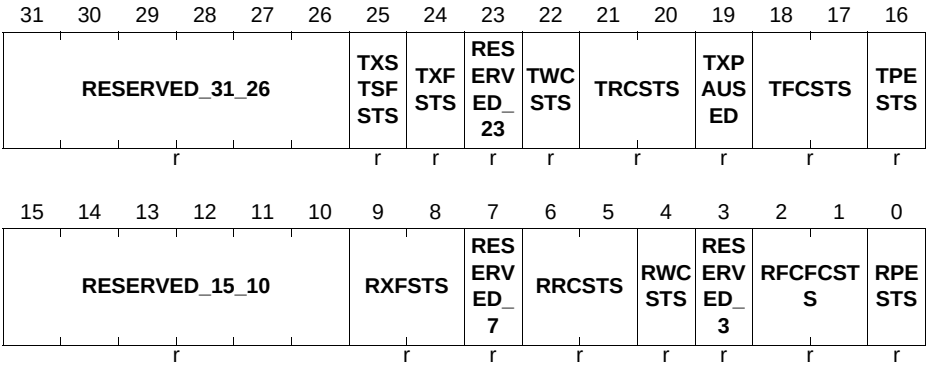


Field	Bits	Type	Description
SNPSVER	[7:0]	r	**SNPSVER** Synopsys-defined Version (3.7)
USERVER	[15:8]	r	**USERVER** User-defined Version (Configured with the coreConsultant)
RESERVED_31_16	[31:16]	r	**RESERVED_31_16**

32-bit Register - Debug

The Debug register gives the status of all main modules of the transmit and receive data-paths and the FIFOs. An all-zero status indicates that the MAC is in idle state (and FIFOs are empty) and no activity is going on in the data-paths. Note: The reset values, given for the Debug register, are valid only if the following clocks are present during the reset operation: * clk_csr_i, clk_app_i, hclk_i, or aclk_i * clk_tx_i * clk_rx_i

ETH_DEBUG
Register 9 - Debug Register (1024_H) Reset Value: $0000\ 0100_H$



Field	Bits	Type	Description
RPESTS	0	r	**MAC GMII or MII Receive Protocol Engine Status** When high, this bit indicates that the MAC GMII or MII receive protocol engine is actively receiving data and not in IDLE state.
RFCFCSTS	[2:1]	r	**MAC Receive Frame Controller FIFO Status** When high, this field indicates the active state of the small FIFO Read and Write controllers of the MAC Receive Frame Controller Module.
RESERVED_3	3	r	**RESERVED_3**
RWCSTS	4	r	**MTL Rx FIFO Write Controller Active Status** When high, this bit indicates that the MTL Rx FIFO Write Controller is active and is transferring a received frame to the FIFO.

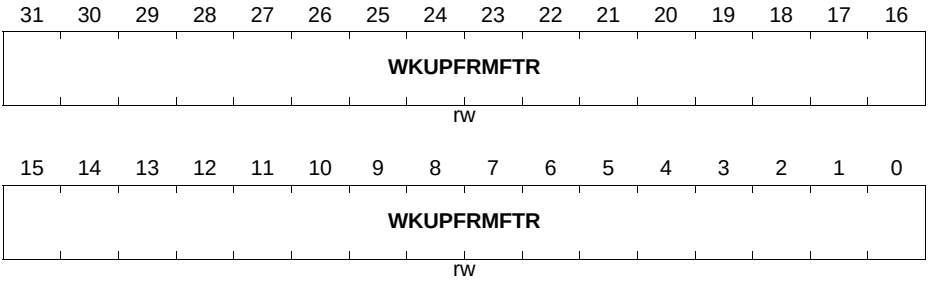
Field	Bits	Type	Description
RRCSTS	[6:5]	r	**MTL Rx FIFO Read Controller State** This field gives the state of the Rx FIFO read Controller: * 00: IDLE state * 01: Reading frame data * 10: Reading frame status (or timestamp) * 11: Flushing the frame data and status
RESERVED_7	7	r	**RESERVED_7**
RXFSTS	[9:8]	r	**MTL Rx FIFO Fill-level Status** This field gives the status of the fill-level of the Rx FIFO: * 00: Rx FIFO Empty * 01: Rx FIFO fill level is below the flow-control deactivate threshold * 10: Rx FIFO fill level is above the flow-control activate threshold * 11: Rx FIFO Full
RESERVED_15_10	[15:10]	r	**RESERVED_15_10**
TPESTS	16	r	**MAC GMII or MII Transmit Protocol Engine Status** When high, this bit indicates that the MAC GMII or MII transmit protocol engine is actively transmitting data and is not in the IDLE state.
TFCSTS	[18:17]	r	**MAC Transmit Frame Controller Status** This field indicates the state of the MAC Transmit Frame Controller module: * 00: IDLE state * 01: Waiting for Status of previous frame or IFG or backoff period to be over * 10: Generating and transmitting a PAUSE control frame (in the full-duplex mode) * 11: Transferring input frame for transmission
TXPAUSED	19	r	**MAC transmitter in PAUSE** When high, this bit indicates that the MAC transmitter is in the PAUSE condition (in the full-duplex only mode) and hence does not schedule any frame for transmission.

Field	Bits	Type	Description
TRCSTS	[21:20]	r	**MTL Tx FIFO Read Controller Status** This field indicates the state of the Tx FIFO Read Controller: * 00: IDLE state * 01: READ state (transferring data to MAC transmitter) * 10: Waiting for TxStatus from MAC transmitter * 11: Writing the received TxStatus or flushing the Tx FIFO
TWCSTS	22	r	**MTL Tx FIFO Write Controller Active Status** When high, this bit indicates that the MTL Tx FIFO Write Controller is active and transferring data to the Tx FIFO.
RESERVED_23	23	r	**RESERVED_23**
TXFSTS	24	r	**MTL Tx FIFO Not Empty Status** When high, this bit indicates that the MTL Tx FIFO is not empty and some data is left for transmission.
TXSTSFSTS	25	r	**MTL TxStatus FIFO Full Status** When high, this bit indicates that the MTL TxStatus FIFO is full. Therefore, the MTL cannot accept any more frames for transmission. This bit is reserved in the GMAC-AHB and GMAC-DMA configurations.
RESERVED_31_26	[31:26]	r	**RESERVED_31_26**

32-bit Register - Remote_Wake_Up_Frame_Filter

This is the address through which the application writes or reads the remote wake-up frame filter registers (wkupfmfilter_reg). The wkupfmfilter_reg register is a pointer to eight wkupfmfilter_reg registers. The wkupfmfilter_reg register is loaded by sequentially loading the eight register values. Eight sequential writes to this address (0x0028) writes all wkupfmfilter_reg registers. Similarly, eight sequential reads from this address (0x0028) read all wkupfmfilter_reg registers. This register contains the higher 16 bits of the seventh MAC address. This register is present only when you select the PMT module Remote Wake-up feature in coreConsultant.

ETH_REMOTE_WAKE_UP_FRAME_FILTER
Register 10 - Remote Wake-Up Frame Filter Register (1028_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
WKUPFRMFTR	[31:0]	rw	**WKUPFRMFTR** Remote Wake-Up Frame Filter

32-bit Register - PMT_Control_Status

This register is present only when you select the PMT module in the coreConsultant.

ETH_PMT_CONTROL_STATUS

Register 11 - PMT Control and Status Register ($102C_H$) Reset Value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r						rw	r		r	r	r		rw	rw	rw

Field	Bits	Type	Description
PWRDWN	0	rw	**Power Down** When set, the MAC receiver drops all received frames until it receives the expected magic packet or wake-up frame. This bit is then self-cleared and the power-down mode is disabled. The Software can also clear this bit before the expected magic packet or wake-up frame is received. The frames, received by the MAC after this bit is cleared, are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Wake-Up Frame Enable bit is set high. Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit.
MGKPKTEN	1	rw	**Magic Packet Enable** When set, enables generation of a power management event because of magic packet reception.
RWKPKTEN	2	rw	**Wake-Up Frame Enable** When set, enables generation of a power management event because of wake-up frame reception.

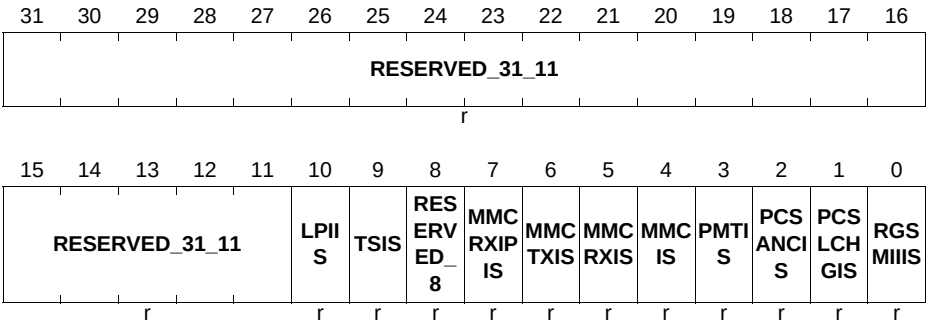
Field	Bits	Type	Description
RESERVED_4_3	[4:3]	r	**RESERVED_4_3**
MGKPRCVD	5	r	**Magic Packet Received** When set, this bit indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared by a Read into this register.
RWKPRCVD	6	r	**Wake-Up Frame Received** When set, this bit indicates the power management event is generated because of the reception of a wake-up frame. This bit is cleared by a Read into this register.
RESERVED_8_7	[8:7]	r	**RESERVED_8_7**
GLBLUCAST	9	rw	**Global Unicast** When set, enables any unicast packet filtered by the MAC (DAF) address recognition to be a wake-up frame.
RESERVED_30_10	[30:10]	r	**RESERVED_30_10**
RWKFILTRST	31	rw	**Wake-Up Frame Filter Register Pointer Reset** When set, resets the remote wake-up frame filter register pointer to 3¡Çb000. It is automatically cleared after 1 clock cycle.

32-bit Register - Interrupt_Status

The Interrupt Status register identifies the events in the MAC that can generate interrupt. All interrupt events are generated only when the corresponding optional feature is selected during core configuration and enabled during operation. Therefore, these bits are reserved when the corresponding features are not present in the core.

ETH_INTERRUPT_STATUS

Register 14 - Interrupt Register (1038$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
RGSMIIIS	0	r	**RGMII or SMII Interrupt Status** This bit is set because of any change in value of the Link Status of RGMII or SMII interface (Bit 3 in Register 54 (SGMII/RGMII/SMII Status Register)). This bit is cleared when you perform a read operation on the SGMII/RGMII/SMII Status Register. This bit is valid only when you select the optional RGMII or SMII PHY interface during core configuration and operation.
PCSLCHGIS	1	r	**PCS Link Status Changed** This bit is set because of any change in Link Status in the TBI, RTBI, or SGMII PHY interface (Bit 2 in Register 49 (AN Status Register)). This bit is cleared when you perform a read operation on the AN Status register. This bit is valid only when you select the optional TBI, RTBI, or SGMII PHY interface during core configuration and operation.

Field	Bits	Type	Description
PCSANCIS	2	r	**PCS Auto-Negotiation Complete** This bit is set when the Auto-negotiation is completed in the TBI, RTBI, or SGMII PHY interface (Bit 5 in Register 49 (AN Status Register)). This bit is cleared when you perform a read operation to the AN Status register. This bit is valid only when you select the optional TBI, RTBI, or SGMII PHY interface during core configuration and operation.
PMTIS	3	r	**PMT Interrupt Status** This bit is set when a Magic packet or Wake-on-LAN frame is received in the power-down mode (see Bits 5 and 6 in the PMT Control and Status Register). This bit is cleared when both Bits[6:5] are cleared because of a read operation to the PMT Control and Status register. This bit is valid only when you select the optional PMT module during core configuration.
MMCIS	4	r	**MMC Interrupt Status** This bit is set high when any of the Bits [7:5] is set high and cleared only when all of these bits are low. This bit is valid only when you select the optional MMC module during core configuration.
MMCRXIS	5	r	**MMC Receive Interrupt Status** This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared. This bit is valid only when you select the optional MMC module during core configuration.
MMCTXIS	6	r	**MMC Transmit Interrupt Status** This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared. This bit is valid only when you select the optional MMC module during core configuration.

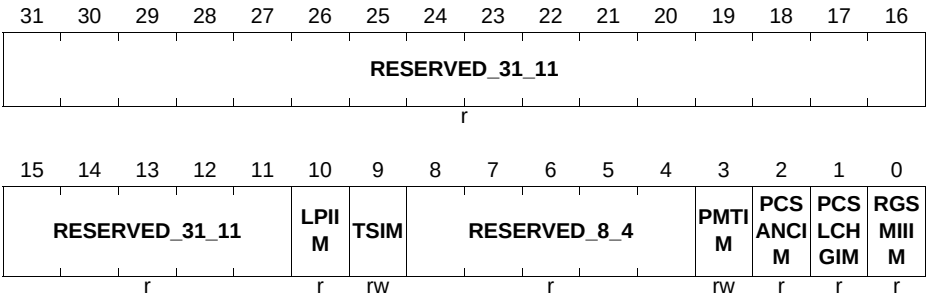
Field	Bits	Type	Description
MMCRXIPIS	7	r	**MMC Receive Checksum Offload Interrupt Status** This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared. This bit is valid only when you select the optional MMC module and Checksum Offload Engine (Type 2) during core configuration.
RESERVED_8	8	r	**RESERVED_8**
TSIS	9	r	**Timestamp Interrupt Status** When the Advanced Timestamp feature is enabled, this bit is set when any of the following conditions is true: * The system time value equals or exceeds the value specified in the Target Time High and Low registers. * There is an overflow in the seconds register. * The Auxiliary snapshot trigger is asserted. This bit is cleared on reading Bit 0 of the Register 458 (Timestamp Status Register). If default Timestamping is enabled, when set, this bit indicates that the system time value is equal to or exceeds the value specified in the Target Time registers. In this mode, this bit is cleared after the completion of the read of this bit. In all other modes, this bit is reserved.
LPIIS	10	r	**LPI Interrupt Status** When the Energy Efficient Ethernet feature is enabled, this bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared on reading Bit 0 of Register 12 (LPI Control and Status Register). In all other modes, this bit is reserved.
RESERVED_31_11	[31:11]	r	**RESERVED_31_11**

32-bit Register - Interrupt_Mask

The Interrupt Mask Register bits enable you to mask the interrupt signal because of the corresponding event in the Interrupt Status Register. The interrupt signal is sbd_intr_o in the GMAC-AHB, GMAC-AXI, and GMAC-DMA configuration and mci_intr_o in the GMAC-MTL and GMAC-CORE configuration.

ETH_INTERRUPT_MASK

Register 15 - Interrupt Mask Register ($103C_H$) **Reset Value: $0000\ 0000_H$**



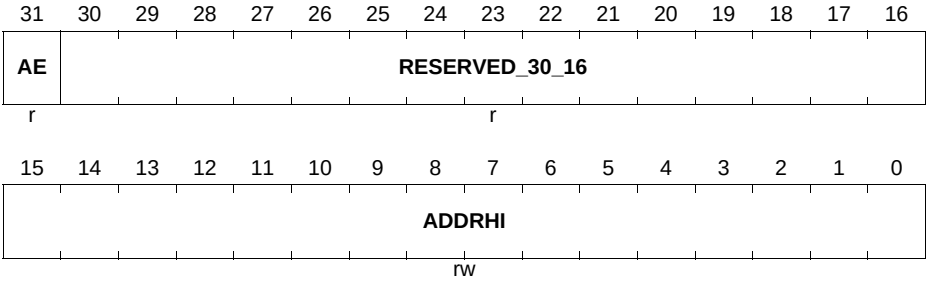
Field	Bits	Type	Description
RGSMIIIM	0	r	**RGMII or SMII Interrupt Mask** When set, this bit disables the assertion of the interrupt signal because of the setting of the RGMII or SMII Interrupt Status bit in Register 14 (Interrupt Status Register).
PCSLCHGIM	1	r	**PCS Link Status Interrupt Mask** When set, this bit disables the assertion of the interrupt signal because of the setting of the PCS Link-status changed bit in Register 14 (Interrupt Status Register).
PCSANCIM	2	r	**PCS AN Completion Interrupt Mask** When set, this bit disables the assertion of the interrupt signal because of the setting of PCS Auto-negotiation complete bit in Register 14 (Interrupt Status Register).
PMTIM	3	rw	**PMT Interrupt Mask** When set, this bit disables the assertion of the interrupt signal because of the setting of PMT Interrupt Status bit in Register 14 (Interrupt Status Register).
RESERVED_8_4	[8:4]	r	**RESERVED_8_4**

Field	Bits	Type	Description
TSIM	9	rw	**Timestamp Interrupt Mask** When set, this bit disables the assertion of the interrupt signal because of the setting of Timestamp Interrupt Status bit in Register 14 (Interrupt Status Register). This bit is valid only when IEEE1588 timestamping is enabled. In all other modes, this bit is reserved.
LPIIM	10	r	**LPI Interrupt Mask** When set, this bit disables the assertion of the interrupt signal because of the setting of the LPI Interrupt Status bit in Register 14 (Interrupt Status Register). This bit is valid only when you select the Energy Efficient Ethernet feature during core configuration. In all other modes, this bit is reserved.
RESERVED_31_11	[31:11]	r	**RESERVED_31_11**

32-bit Register - MAC_Address0_High

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS0_HIGH
Register 16 - MAC Address0 High Register (1040_H) **Reset Value: $8000\ FFFF_H$**



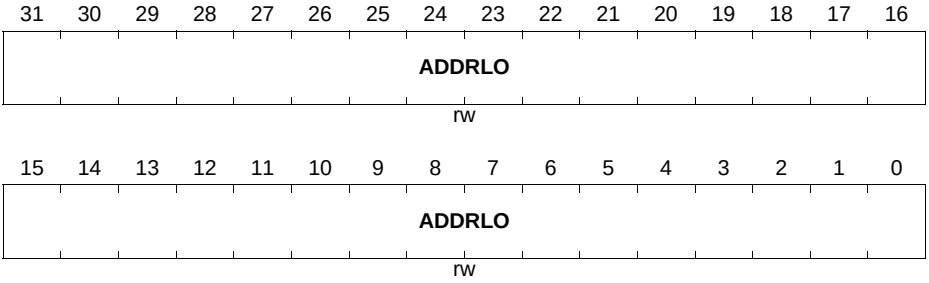
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address0 [47:32]** This field contains the upper 16 bits (47:32) of the first 6-byte MAC address. The MAC uses this field for filtering the received frames and inserting the MAC address in the Transmit Flow Control (PAUSE) Frames.
RESERVED_30_16	[30:16]	r	**RESERVED_30_16**
AE	31	r	**Address Enable** This bit is always set to 1.

32-bit Register - MAC_Address0_Low

The MAC Address0 Low register holds the lower 32 bits of the first 6-byte MAC address of the station.

ETH_MAC_ADDRESS0_LOW

Register 17 - MAC Address0 Low Register (1044_H) **Reset Value: FFFF FFFF$_H$**



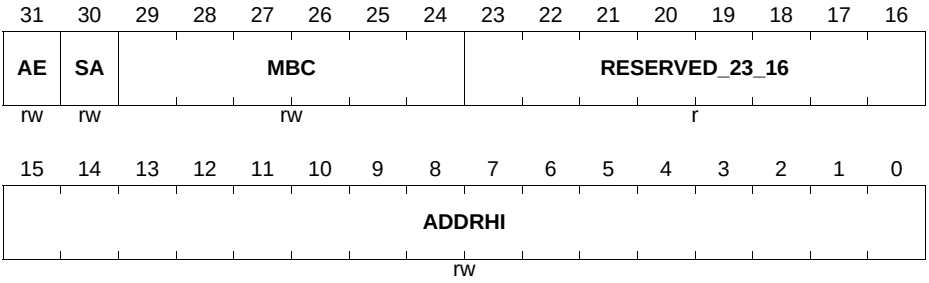
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address0 [31:0]** This field contains the lower 32 bits of the first 6-byte MAC address. This is used by the MAC for filtering the received frames and inserting the MAC address in the Transmit Flow Control (PAUSE) Frames.

32-bit Register - MAC_Address1_High

The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS1_HIGH

Register 18 - MAC Address1 High Register (1048_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address1 [47:32]** This field contains the upper 16 bits (47:32) of the second 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**

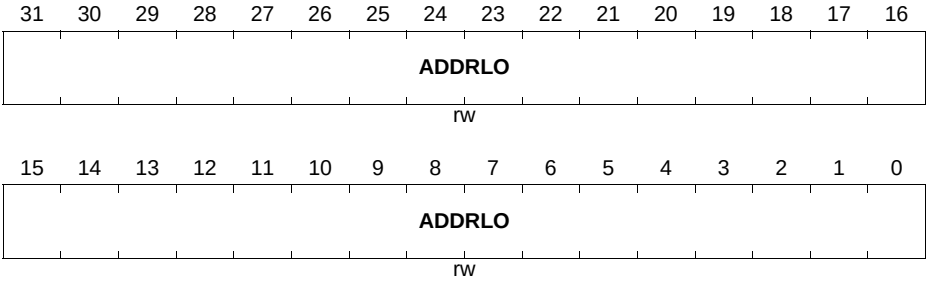
Field	Bits	Type	Description
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
SA	30	rw	**Source Address** When this bit is set, the MAC Address1[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address1[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address1_Low

The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

ETH_MAC_ADDRESS1_LOW

Register 19 - MAC Address1 Low Register ($104C_H$) **Reset Value: $FFFF\ FFFF_H$**



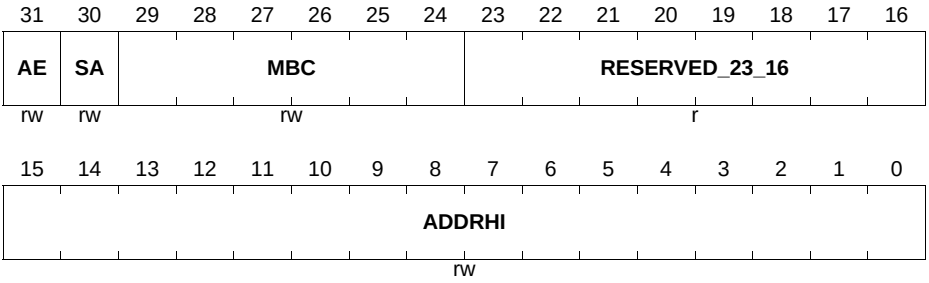
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address1 [31:0]** This field contains the lower 32 bits of the second 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address2_High

The MAC Address2 High register holds the upper 16 bits of the third 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address2 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address2 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS2_HIGH

Register 20 - MAC Address2 High Register (1050_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address2 [47:32]** This field contains the upper 16 bits (47:32) of the third 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address2 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

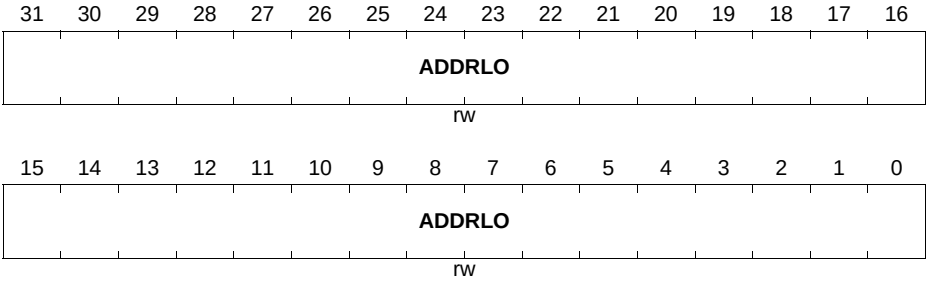
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address2[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address2[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the third MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address2_Low

The MAC Address2 Low register holds the lower 32 bits of the third 6-byte MAC address of the station.

ETH_MAC_ADDRESS2_LOW

Register 21 - MAC Address2 Low Register (1054_H) **Reset Value: $FFFF\ FFFF_H$**



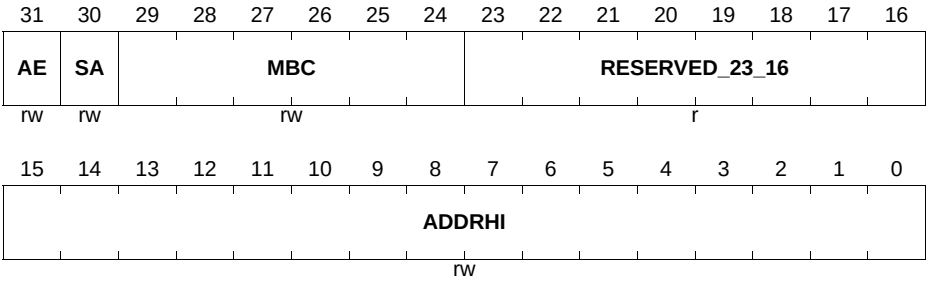
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address2 [31:0]** This field contains the lower 32 bits of the third 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address3_High

The MAC Address3 High register holds the upper 16 bits of the fourth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address3 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address3 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS3_HIGH

Register 22 - MAC Address3 High Register (1058_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address3 [47:32]** This field contains the upper 16 bits (47:32) of the fourth 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address3 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

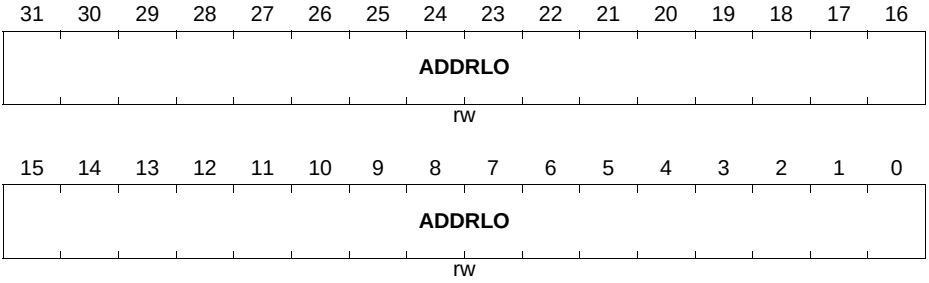
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address3[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address3[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the fourth MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address3_Low

The MAC Address3 Low register holds the lower 32 bits of the fourth 6-byte MAC address of the station.

ETH_MAC_ADDRESS3_LOW

Register 23 - MAC Address3 Low Register ($105C_H$) **Reset Value: $FFFF\ FFFF_H$**



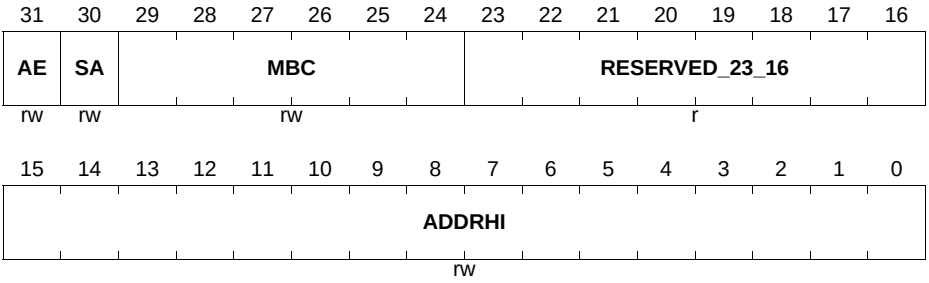
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address3 [31:0]** This field contains the lower 32 bits of the fourth 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address4_High

The MAC Address4 High register holds the upper 16 bits of the fifth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address4 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address4 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS4_HIGH

Register 24 - MAC Address4 High Register (1060_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address4 [47:32]** This field contains the upper 16 bits (47:32) of the fifth 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address4 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

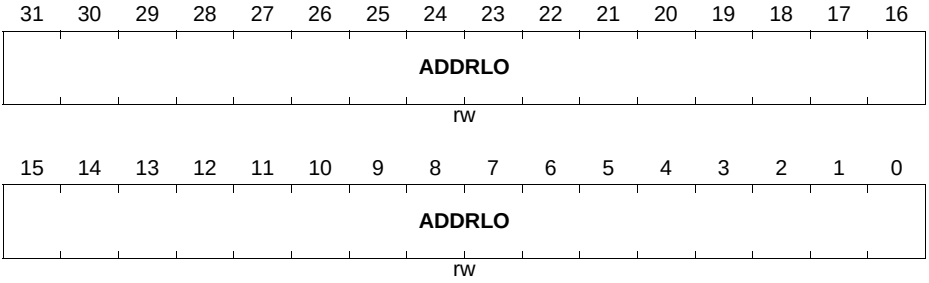
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address4[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address4[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the fifth MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address4_Low

The MAC Address4 Low register holds the lower 32 bits of the fifth 6-byte MAC address of the station.

ETH_MAC_ADDRESS4_LOW

Register 25 - MAC Address4 Low Register (1064_H) **Reset Value: $FFFF\ FFFF_H$**



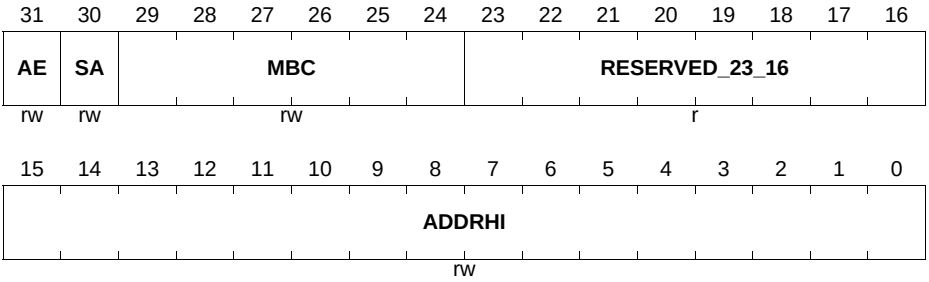
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address4 [31:0]** This field contains the lower 32 bits of the fifth 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address5_High

The MAC Address5 High register holds the upper 16 bits of the sixth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address5 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address5 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS5_HIGH

Register 26 - MAC Address5 High Register (1068_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address5 [47:32]** This field contains the upper 16 bits (47:32) of the sixth 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address5 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

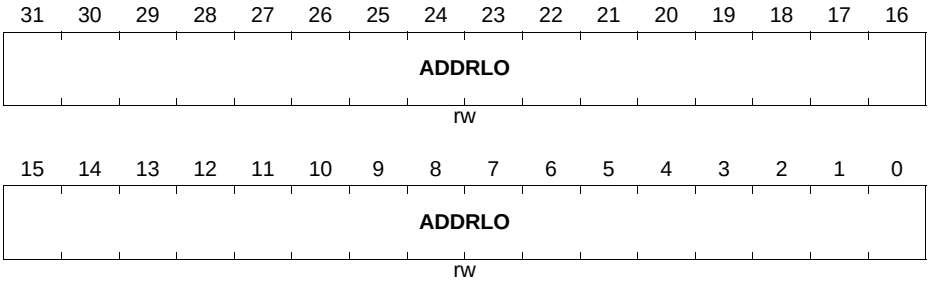
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address5[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address5[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the sixth MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address5_Low

The MAC Address5 Low register holds the lower 32 bits of the sixth 6-byte MAC address of the station.

ETH_MAC_ADDRESS5_LOW

Register 27 - MAC Address5 Low Register ($106C_H$) **Reset Value: $FFFF\ FFFF_H$**



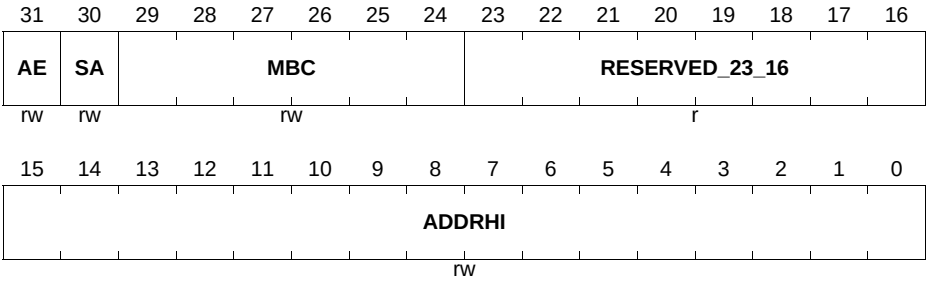
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address5 [31:0]** This field contains the lower 32 bits of the sixth 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address6_High

The MAC Address6 High register holds the upper 16 bits of the seventh 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address6 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address6 Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS6_HIGH

Register 28 - MAC Address6 High Register (1070_H) **Reset Value: $0000\ FFFF_H$**



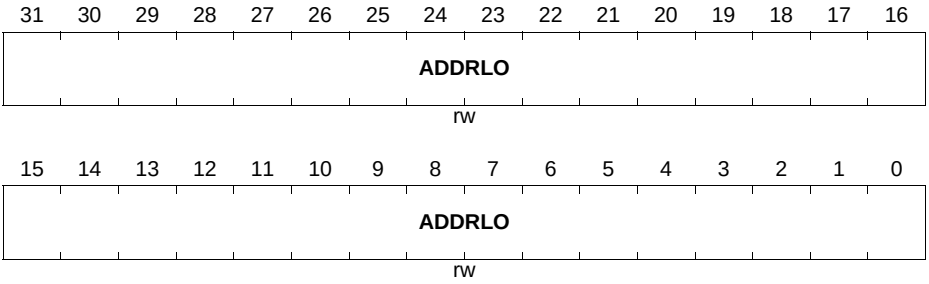
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address6 [47:32]** This field contains the upper 16 bits (47:32) of the seventh 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address6 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address6[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address6[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the seventh MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address6_Low

The MAC Address6 Low register holds the lower 32 bits of the seventh 6-byte MAC address of the station.

ETH_MAC_ADDRESS6_LOW
Register 29 - MAC Address6 Low Register (1074_H) **Reset Value: FFFF FFFF$_H$**



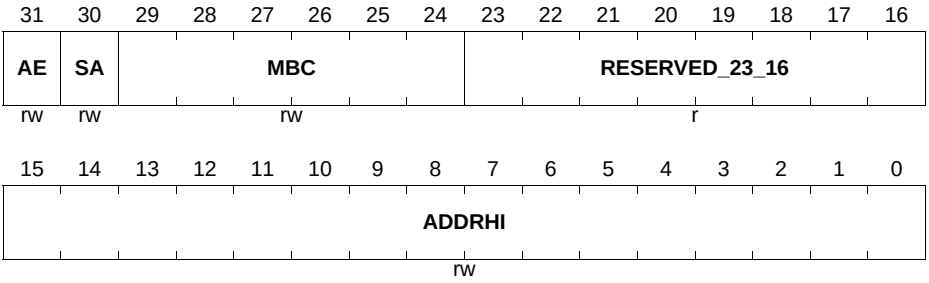
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address6 [31:0]** This field contains the lower 32 bits of the seventh 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address7_High

The MAC Address7 High register holds the upper 16 bits of the eighth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address7 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address7 Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS7_HIGH

Register 30 - MAC Address7 High Register (1078_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address7 [47:32]** This field contains the upper 16 bits (47:32) of the eighth 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address6 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

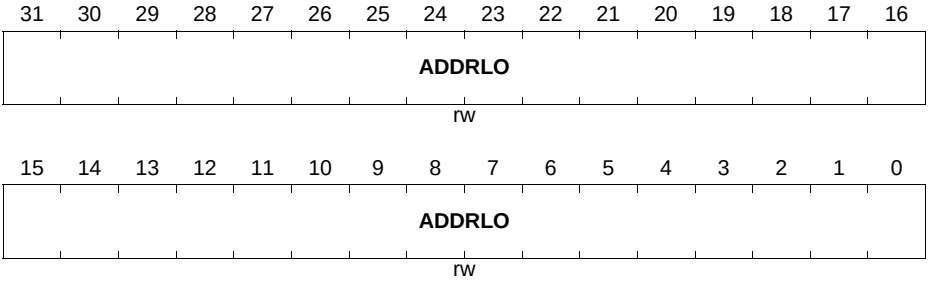
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address7[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address7[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the eighth MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address7_Low

The MAC Address7 Low register holds the lower 32 bits of the eighth 6-byte MAC address of the station.

ETH_MAC_ADDRESS7_LOW

Register 31 - MAC Address7 Low Register ($107C_H$) **Reset Value: $FFFF\ FFFF_H$**



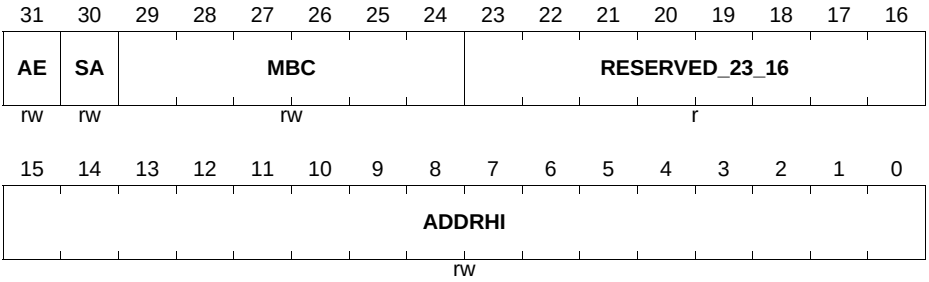
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address7 [31:0]** This field contains the lower 32 bits of the eighth 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address8_High

The MAC Address8 High register holds the upper 16 bits of the nineth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address8 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address8 Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS8_HIGH

Register 32 - MAC Address8 High Register (1080_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address8 [47:32]** This field contains the upper 16 bits (47:32) of the nineth 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address8 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

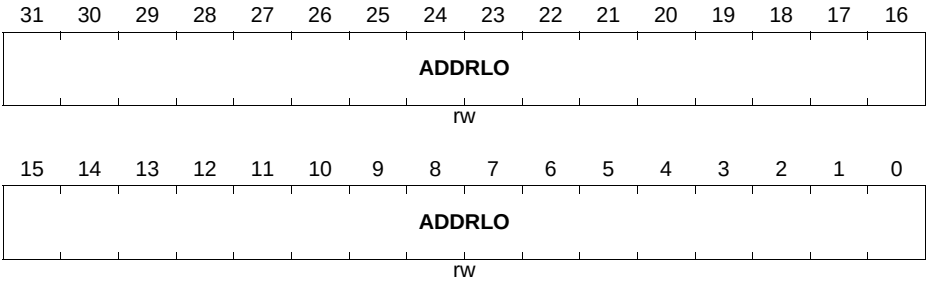
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address8[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address8[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the nineth MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address8_Low

The MAC Address8 Low register holds the lower 32 bits of the nineth 6-byte MAC address of the station.

ETH_MAC_ADDRESS8_LOW

Register 33 - MAC Address8 Low Register (1084_H) **Reset Value: $FFFF\ FFFF_H$**



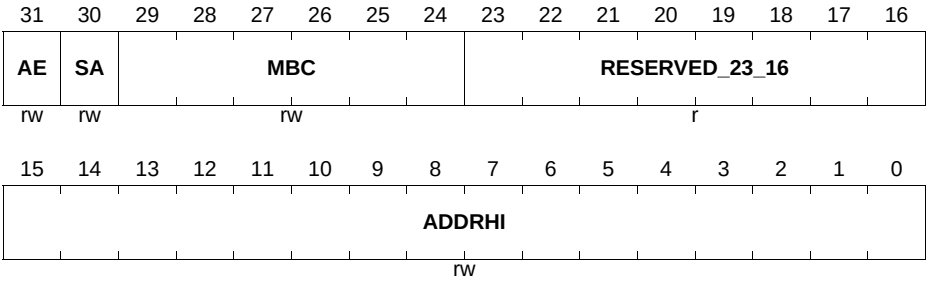
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address8 [31:0]** This field contains the lower 32 bits of the nineth 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address9_High

The MAC Address9 High register holds the upper 16 bits of the tenth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address9 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address9 Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS9_HIGH

Register 34 - MAC Address9 High Register (1088_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address9 [47:32]** This field contains the upper 16 bits (47:32) of the tenth 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address9 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

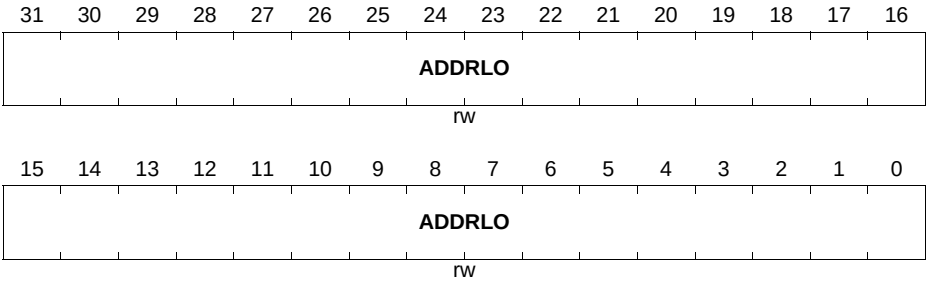
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address9[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address9[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the tenth MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address9_Low

The MAC Address9 Low register holds the lower 32 bits of the tenth 6-byte MAC address of the station.

ETH_MAC_ADDRESS9_LOW

Register 35 - MAC Address9 Low Register ($108C_H$) **Reset Value: $FFFF\ FFFF_H$**



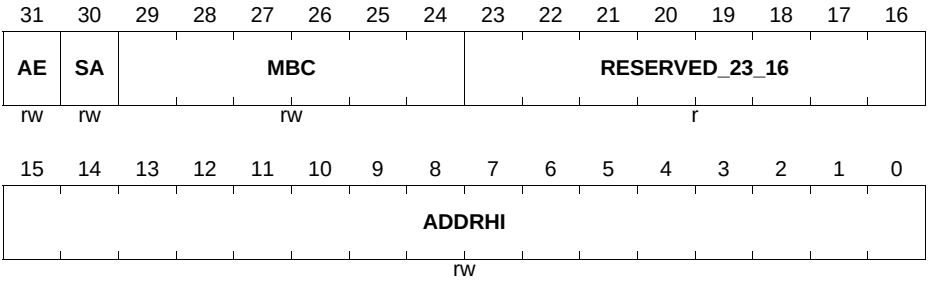
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address9 [31:0]** This field contains the lower 32 bits of the tenth 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address10_High

The MAC Address10 High register holds the upper 16 bits of the 11th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address10 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address10 Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS10_HIGH

Register 36 - MAC Address10 High Register (1090_H) **Reset Value: $0000\ FFFF_H$**



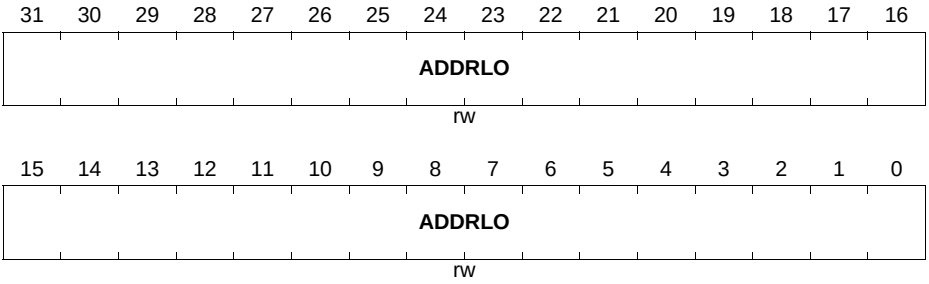
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address10 [47:32]** This field contains the upper 16 bits (47:32) of the 11th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address10 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address10[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address10[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 11th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address10_Low

The MAC Address10 Low register holds the lower 32 bits of the 11th 6-byte MAC address of the station.

ETH_MAC_ADDRESS10_LOW
Register 37 - MAC Address10 Low Register (1094_H) **Reset Value: FFFF FFFF$_H$**



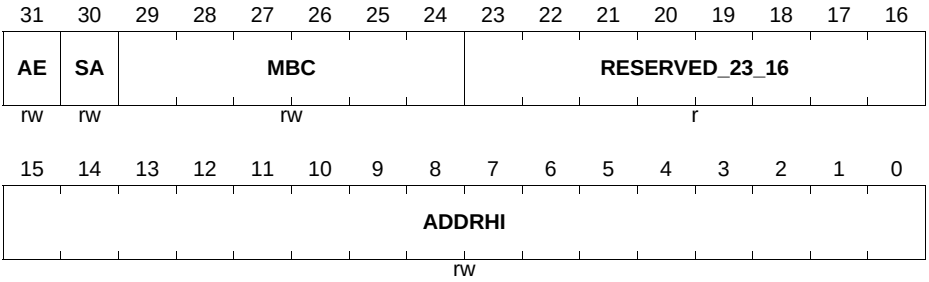
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address10 [31:0]** This field contains the lower 32 bits of the 11th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address11_High

The MAC Address11 High register holds the upper 16 bits of the 12th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address11 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address11 Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS11_HIGH

Register 38 - MAC Address11 High Register (1098_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address11 [47:32]** This field contains the upper 16 bits (47:32) of the 12th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address11 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

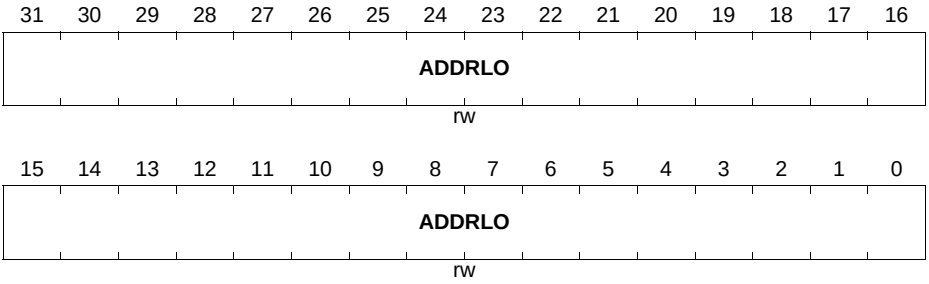
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address11[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address11[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the twelfth MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address11_Low

The MAC Address11 Low register holds the lower 32 bits of the 12th 6-byte MAC address of the station.

ETH_MAC_ADDRESS11_LOW

Register 39 - MAC Address1 Low Register ($109C_H$) **Reset Value: $FFFF\ FFFF_H$**

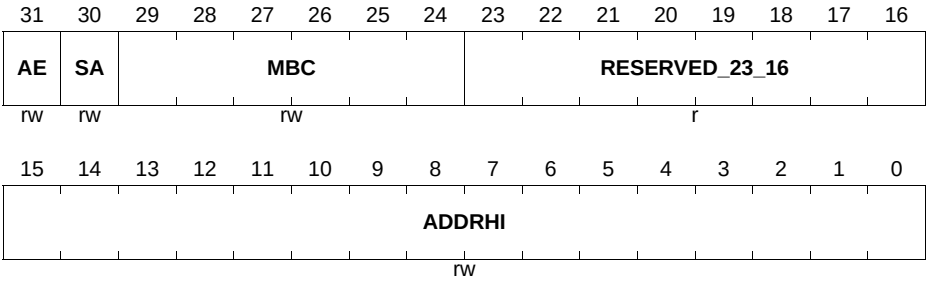


Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address11 [31:0]** This field contains the lower 32 bits of the 12th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address12_High

The MAC Address12 High register holds the upper 16 bits of the 13th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address13 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address12 Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS12_HIGH
Register 40 - MAC Address12 High Register ($10A0_H$) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address12 [47:32]** This field contains the upper 16 bits (47:32) of the 13th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address12 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

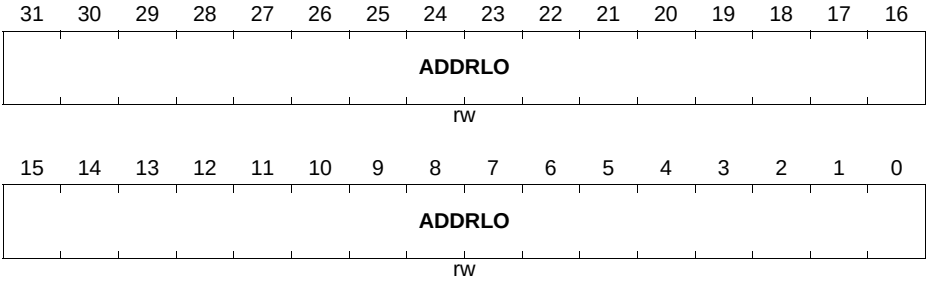
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address12[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address12[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 13th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address12_Low

The MAC Address12 Low register holds the lower 32 bits of the 13th 6-byte MAC address of the station.

ETH_MAC_ADDRESS12_LOW

Register 41 - MAC Address12 Low Register ($10A4_H$) **Reset Value: $FFFF\ FFFF_H$**



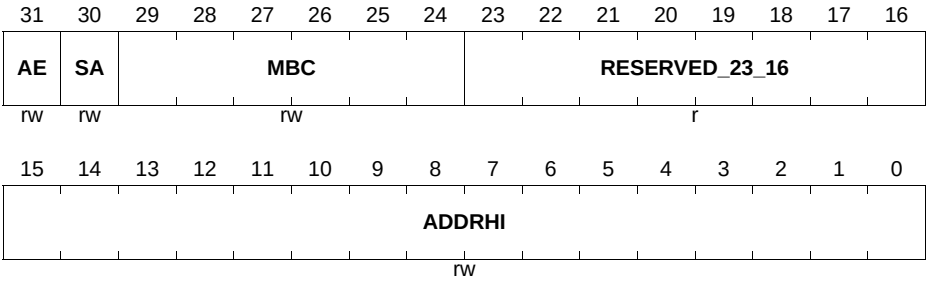
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address12 [31:0]** This field contains the lower 32 bits of the 13th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address13_High

The MAC Address13 High register holds the upper 16 bits of the 14th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address13 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address13 Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS13_HIGH

Register 42 - MAC Address13 High Register ($10A8_H$) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address13 [47:32]** This field contains the upper 16 bits (47:32) of the 14th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address13 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

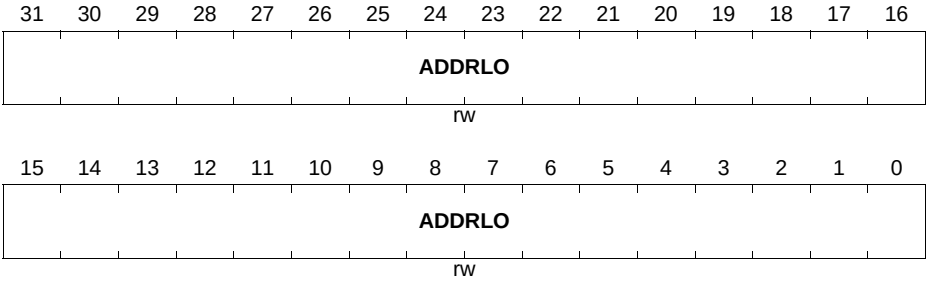
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address13[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address13[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 14th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address13_Low

The MAC Address13 Low register holds the lower 32 bits of the 14th 6-byte MAC address of the station.

ETH_MAC_ADDRESS13_LOW

Register 43 - MAC Address13 Low Register ($10AC_H$) **Reset Value: $FFFF\ FFFF_H$**



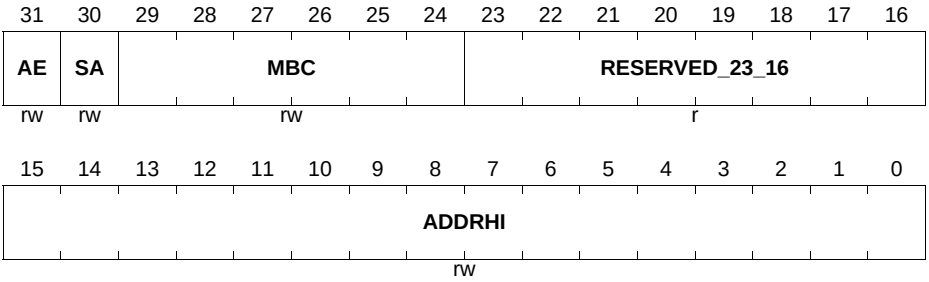
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address13 [31:0]** This field contains the lower 32 bits of the 14th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address14_High

The MAC Address14 High register holds the upper 16 bits of the 15th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address15 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address14 Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS14_HIGH

Register 44 - MAC Address14 High Register ($10B0_H$) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address14 [47:32]** This field contains the upper 16 bits (47:32) of the 15th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address14 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

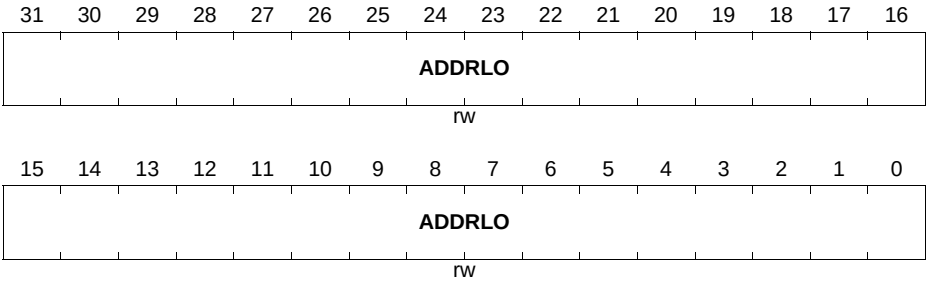
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address14[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address14[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 15th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address14_Low

The MAC Address14 Low register holds the lower 32 bits of the 15th 6-byte MAC address of the station.

ETH_MAC_ADDRESS14_LOW

Register 45 - MAC Address14 Low Register ($10B4_H$) **Reset Value: $FFFF\ FFFF_H$**



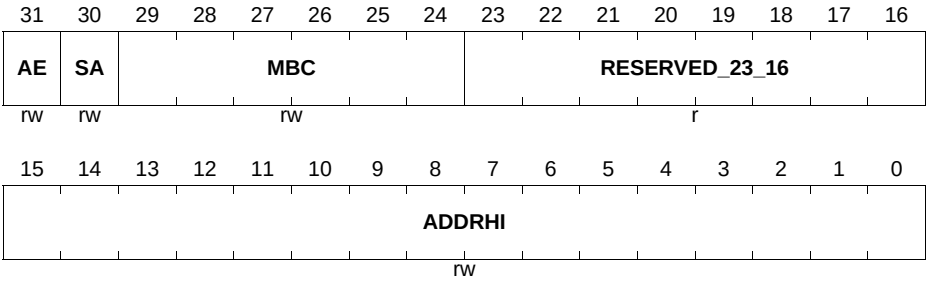
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address14 [31:0]** This field contains the lower 32 bits of the 15th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address15_High

The MAC Address15 High register holds the upper 16 bits of the 16th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address15 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address15 Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS15_HIGH

Register 46 - MAC Address15 High Register ($10B8_H$) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**ADDRHI** MAC Address15 [47:32] This field contains the upper 16 bits (47:32) of the 16th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address15 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

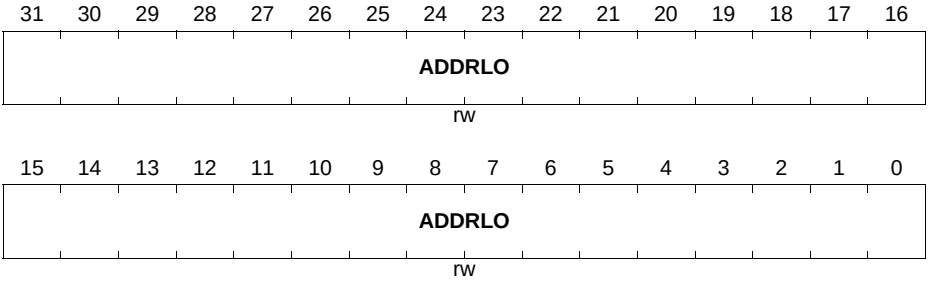
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address15[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address15[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 16th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address15_Low

The MAC Address15 Low register holds the lower 32 bits of the 16th 6-byte MAC address of the station.

ETH_MAC_ADDRESS15_LOW

Register 47 - MAC Address15 Low Register ($10BC_H$) **Reset Value: $FFFF\ FFFF_H$**



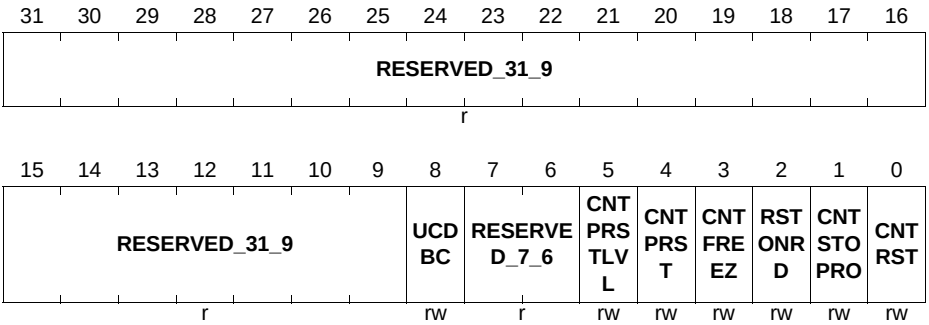
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address15 [31:0]** This field contains the lower 32 bits of the 16th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MMC_Control

The MMC Control register establishes the operating mode of the management counters. Note: The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

ETH_MMC_CONTROL

Register 64 - MMC Control Register (1100_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CNTRST	0	rw	**Counters Reset** When this bit is set, all counters are reset. This bit is cleared automatically after one clock cycle.
CNTSTOPRO	1	rw	**Counters Stop Rollover** When this bit is set, after reaching maximum value, the counter does not roll over to zero.
RSTONRD	2	rw	**Reset on Read** When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read.
CNTFREEZ	3	rw	**MMC Counter Freeze** When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received frame. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.

Field	Bits	Type	Description
CNTPRST	4	rw	**Counters Preset** When this bit is set, all counters are initialized or preset to almost full or almost half according to bit 5. This bit is cleared automatically after 1 clock cycle. This bit, along with bit 5, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full.
CNTPRSTLVL	5	rw	**Full-Half Preset** When low and bit 4 is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16). When this bit is high and bit 4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and frame counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0.
RESERVED_7_6	[7:6]	r	**RESERVED_7_6**
UCDBC	8	rw	**Update MMC Counters for Dropped Broadcast Frames** When set, this bit enables MAC to update all the related MMC Counters for Broadcast frames dropped due to setting of DBF bit (Disable Broadcast Frames) of MAC Filter Register at offset 0x0004. When reset, MMC Counters are not updated for dropped Broadcast frames.
RESERVED_31_9	[31:9]	r	**RESERVED_31_9**

32-bit Register - MMC_Receive_Interrupt

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter). * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

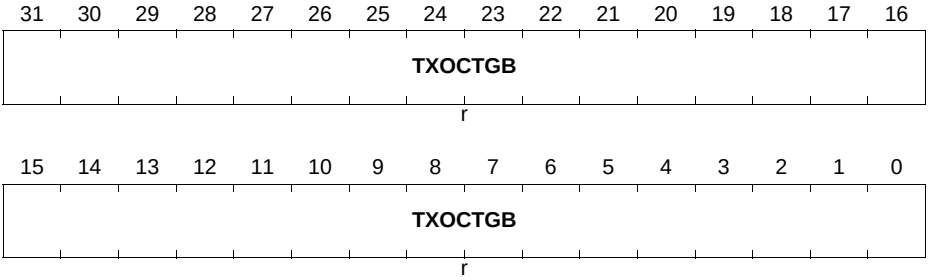
32-bit Register - Tx_Octet_Count_Good_Bad

This register maintains the number of bytes transmitted in good and bad frames exclusive of preamble and retried bytes.

ETH_TX_OCTET_COUNT_GOOD_BAD
Register 69 - Transmit Octet Count for Good and Bad Frames (1114_H) Reset Value: $0000\ 0000_H$

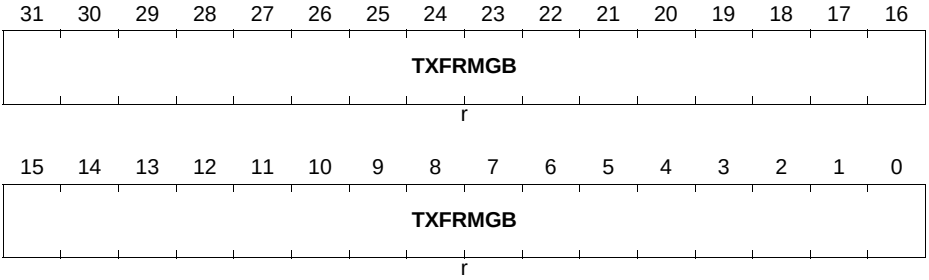


Field	Bits	Type	Description
TXOCTGB	[31:0]	r	**TXOCTGB** This field indicates the number of bytes transmitted in good and bad frames exclusive of preamble and retried bytes.

32-bit Register - Tx_Frame_Count_Good_Bad

This register maintains the number of good and bad frames transmitted, exclusive of retried frames.

ETH_TX_FRAME_COUNT_GOOD_BAD
Register 70 - Transmit Frame Count for Good and Bad Frames (1118_H) Reset Value: $0000\ 0000_H$

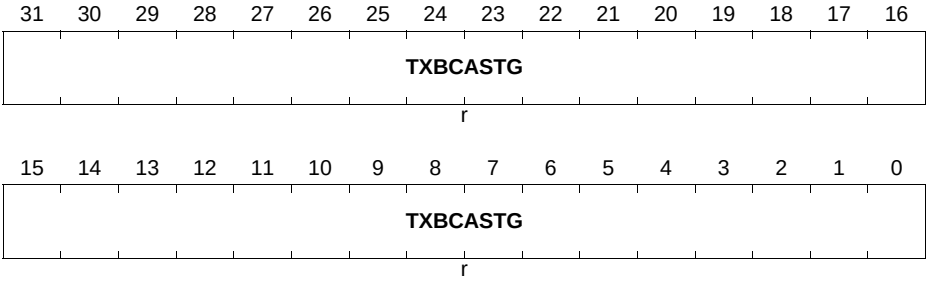


Field	Bits	Type	Description
TXFRMGB	[31:0]	r	**TXFRMGB** This field indicates the number of good and bad frames transmitted, exclusive of retried frames

32-bit Register - Tx_Broadcast_Frames_Good

This register maintains the number of transmitted good broadcast frames.

ETH_TX_BROADCAST_FRAMES_GOOD
Register 71 - Transmit Frame Count for Good Broadcast Frames ($111C_H$) Reset Value: $0000\ 0000_H$

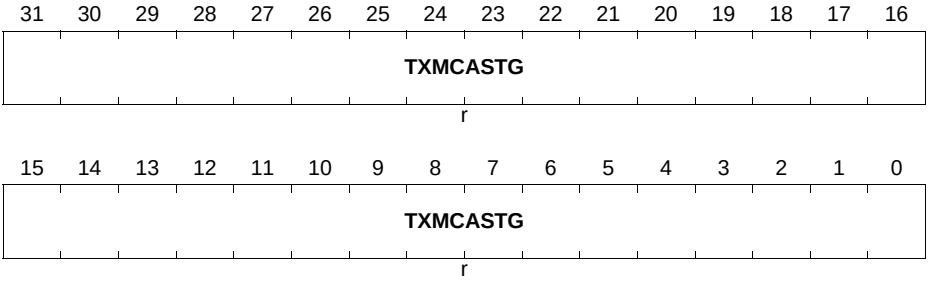


Field	Bits	Type	Description
TXBCASTG	[31:0]	r	**TXBCASTG** This field indicates the number of transmitted good broadcast frames.

32-bit Register - Tx_Multicast_Frames_Good

This register maintains the number of transmitted good multicast frames.

ETH_TX_MULTICAST_FRAMES_GOOD
Register 72 - Transmit Frame Count for Good Multicast Frames (1120_H) Reset Value: $0000\ 0000_H$

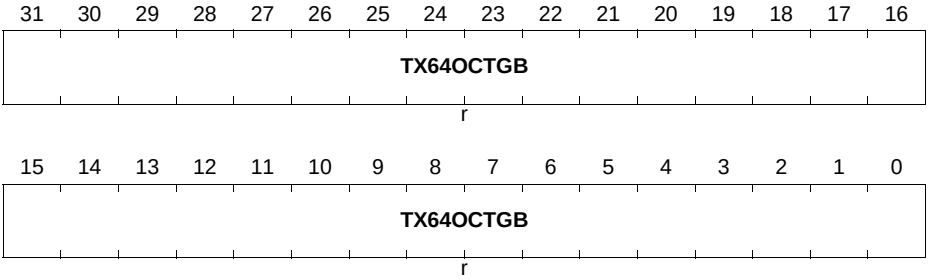


Field	Bits	Type	Description
TXMCASTG	[31:0]	r	**TXMCASTG** This field indicates the number of transmitted good multicast frames.

32-bit Register - Tx_64Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length of 64 bytes, exclusive of preamble and retried frames.

ETH_TX_64OCTETS_FRAMES_GOOD_BAD
Register 73 - Transmit Octet Count for Good and Bad 64 Byte Frames (1124_H)
Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
TX64OCTGB	[31:0]	r	**TX64OCTGB** This field indicates the number of transmitted good and bad frames with length of 64 bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_65To127Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames.

ETH_TX_65TO127OCTETS_FRAMES_GOOD_BAD
Register 74 - Transmit Octet Count for Good and Bad 65 to 127 Bytes Frames (1128_H) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
TX65_127 OCTGB	[31:0]	r	**TX65_127OCTGB** This field indicates the number of transmitted good and bad frames with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_128To255Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames.

ETH_TX_128TO255OCTETS_FRAMES_GOOD_BAD
Register 75 - Transmit Octet Count for Good and Bad 128 to 255 Bytes Frames ($112C_H$) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
TX128_255OCTGB	[31:0]	r	**TX128_255OCTGB** This field indicates the number of transmitted good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_256To511Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames.

ETH_TX_256TO511OCTETS_FRAMES_GOOD_BAD
Register 76 - Transmit Octet Count for Good and Bad 256 to 511 Bytes Frames (1130_H) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
TX256_511OCTGB	[31:0]	r	**TX256_511OCTGB** This field indicates the number of transmitted good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_512To1023Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble and retried frames.

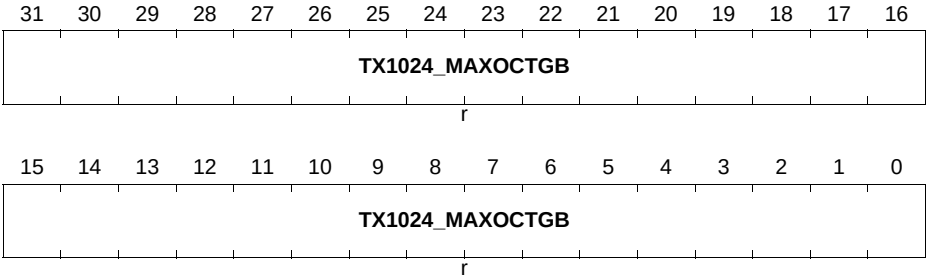
ETH_TX_512TO1023OCTETS_FRAMES_GOOD_BAD
Register 77 - Transmit Octet Count for Good and Bad 512 to 1023 Bytes Frames (1134_H) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
TX512_1023OCTGB	[31:0]	r	**TX512_1023OCTGB** This field indicates the number of transmitted good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_1024ToMaxOctets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.

ETH_TX_1024TOMAXOCTETS_FRAMES_GOOD_BAD
Register 78 - Transmit Octet Count for Good and Bad 1024 to Maxsize Bytes Frames (1138_H) Reset Value: $0000\ 0000_H$

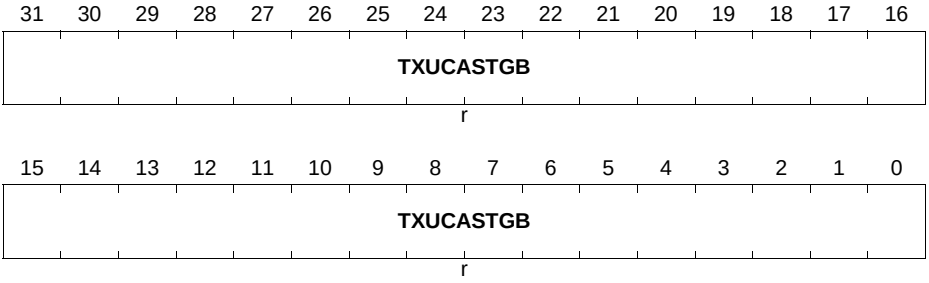


Field	Bits	Type	Description
TX1024_MAXOCTGB	[31:0]	r	**TX1024_MAXOCTGB** This field indicates the number of good and bad frames transmitted with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_Unicast_Frames_Good_Bad

This register maintains the number of transmitted good and bad unicast frames.

ETH_TX_UNICAST_FRAMES_GOOD_BAD
Register 79 - Transmit Frame Count for Good and Bad Unicast Frames ($113C_H$)
Reset Value: $0000\ 0000_H$

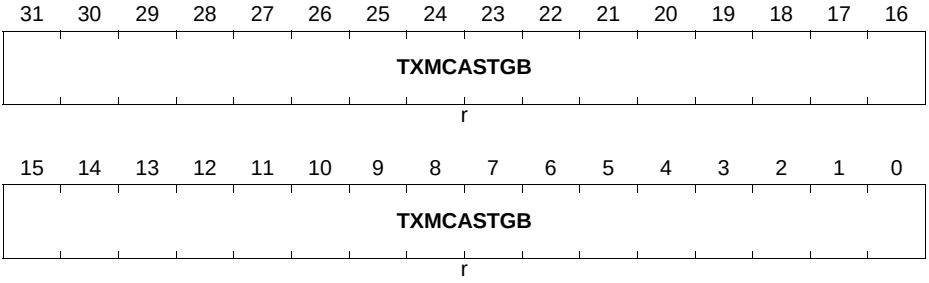


Field	Bits	Type	Description
TXUCASTGB	[31:0]	r	**TXUCASTGB** This field indicates the number of transmitted good and bad unicast frames.

32-bit Register - Tx_Multicast_Frames_Good_Bad

This register maintains the number of transmitted good and bad multicast frames.

ETH_TX_MULTICAST_FRAMES_GOOD_BAD
Register 80 - Transmit Frame Count for Good and Bad Multicast Frames (1140_H)
Reset Value: $0000\ 0000_H$

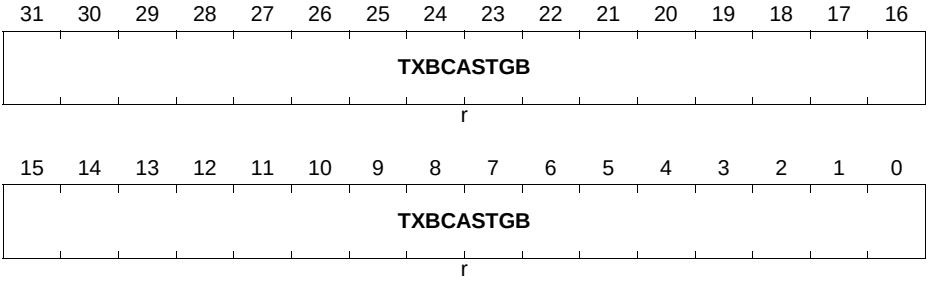


Field	Bits	Type	Description
TXMCASTGB	[31:0]	r	**TXMCASTGB** This field indicates the number of transmitted good and bad multicast frames.

32-bit Register - Tx_Broadcast_Frames_Good_Bad

This register maintains the number of transmitted good and bad broadcast frames.

ETH_TX_BROADCAST_FRAMES_GOOD_BAD
Register 81 - Transmit Frame Count for Good and Bad Broadcast Frames (1144_H)
Reset Value: $0000\ 0000_H$

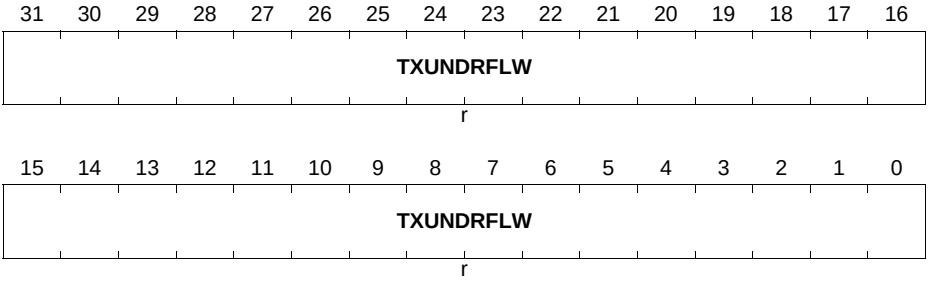


Field	Bits	Type	Description
TXBCASTGB	[31:0]	r	**TXBCASTGB** This field indicates the number of transmitted good and bad broadcast frames.

32-bit Register - Tx_Underflow_Error_Frames

This register maintains the number of frames aborted because of frame underflow error.

ETH_TX_UNDERFLOW_ERROR_FRAMES
Register 82 - Transmit Frame Count for Underflow Error Frames (1148_H) Reset Value: $0000\ 0000_H$

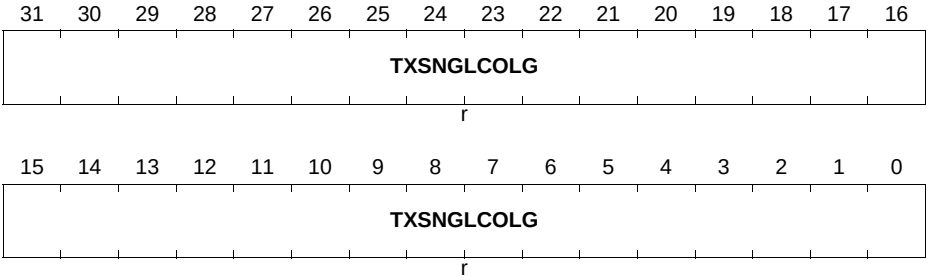


Field	Bits	Type	Description
TXUNDRFLW	[31:0]	r	**TXUNDRFLW** This field indicates the number of frames aborted because of frame underflow error.

32-bit Register - Tx_Single_Collision_Good_Frames

This register maintains the number of successfully transmitted frames after a single collision in the half-duplex mode.

ETH_TX_SINGLE_COLLISION_GOOD_FRAMES
Register 83 - Transmit Frame Count for Frames Transmitted after Single Collision ($114C_H$) **Reset Value: $0000\ 0000_H$**

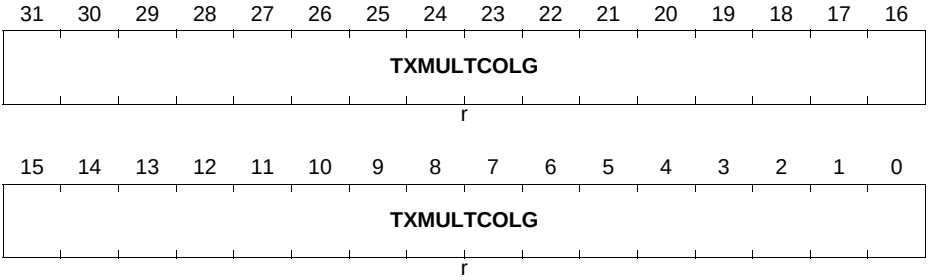


Field	Bits	Type	Description
TXSNGLCOLG	[31:0]	r	**TXSNGLCOLG** This field indicates the number of successfully transmitted frames after a single collision in the half-duplex mode.

32-bit Register - Tx_Multiple_Collision_Good_Frames

This register maintains the number of successfully transmitted frames after multiple collisions in the half-duplex mode.

ETH_TX_MULTIPLE_COLLISION_GOOD_FRAMES
Register 84 - Transmit Frame Count for Frames Transmitted after Multiple Collision (1150_H) Reset Value: $0000\ 0000_H$

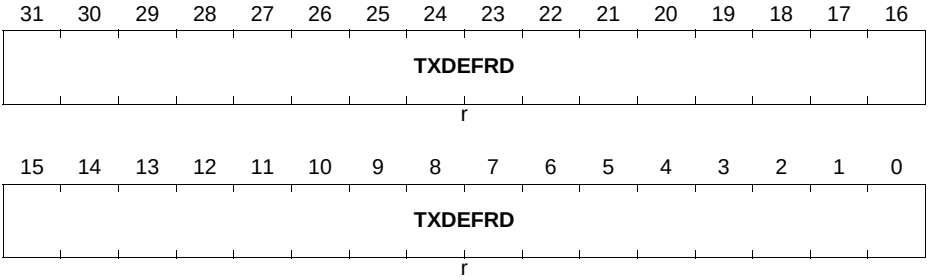


Field	Bits	Type	Description
TXMULTCOLG	[31:0]	r	**TXMULTCOLG** This field indicates the number of successfully transmitted frames after multiple collisions in the half-duplex mode.

32-bit Register - Tx_Deferred_Frames

This register maintains the number of successfully transmitted frames after a deferral in the half-duplex mode.

ETH_TX_DEFERRED_FRAMES
Register 85 - Transmit Frame Count for Deferred Frames (1154_H) Reset Value: $0000\ 0000_H$

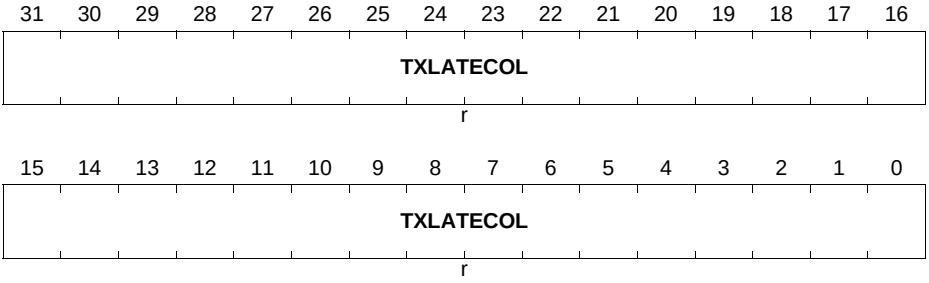


Field	Bits	Type	Description
TXDEFRD	[31:0]	r	**TXDEFRD** This field indicates the number of successfully transmitted frames after a deferral in the half-duplex mode.

32-bit Register - Tx_Late_Collision_Frames

This register maintains the number of frames aborted because of late collision error.

ETH_TX_LATE_COLLISION_FRAMES
Register 86 - Transmit Frame Count for Late Collision Error Frames (1158_H) Reset Value: $0000\ 0000_H$

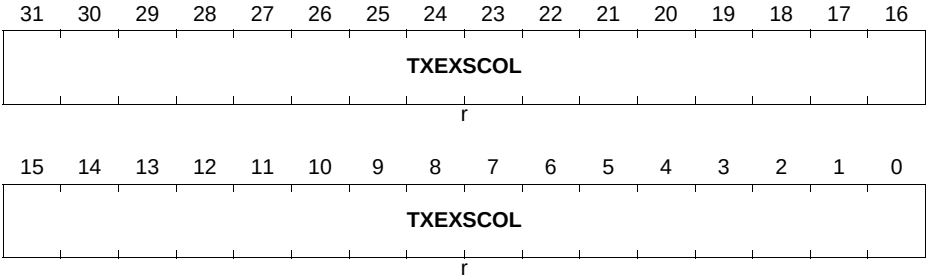


Field	Bits	Type	Description
TXLATECOL	[31:0]	r	**TXLATECOL** This field indicates the number of frames aborted because of late collision error.

32-bit Register - Tx_Excessive_Collision_Frames

This register maintains the number of frames aborted because of excessive (16) collision error.

ETH_TX_EXCESSIVE_COLLISION_FRAMES
Register 87 - Transmit Frame Count for Excessive Collision Error Frames ($115C_H$) **Reset Value: $0000\ 0000_H$**

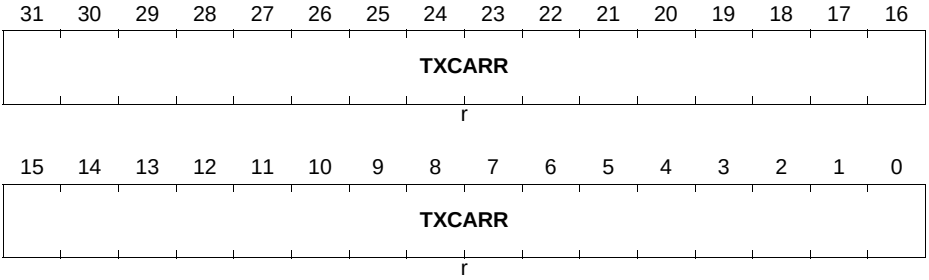


Field	Bits	Type	Description
TXEXSCOL	[31:0]	r	**TXEXSCOL** This field indicates the number of frames aborted because of excessive (16) collision error.

32-bit Register - Tx_Carrier_Error_Frames

This register maintains the number of frames aborted because of carrier sense error (no carrier or loss of carrier).

ETH_TX_CARRIER_ERROR_FRAMES
Register 88 - Transmit Frame Count for Carrier Sense Error Frames (1160_H) Reset Value: $0000\ 0000_H$

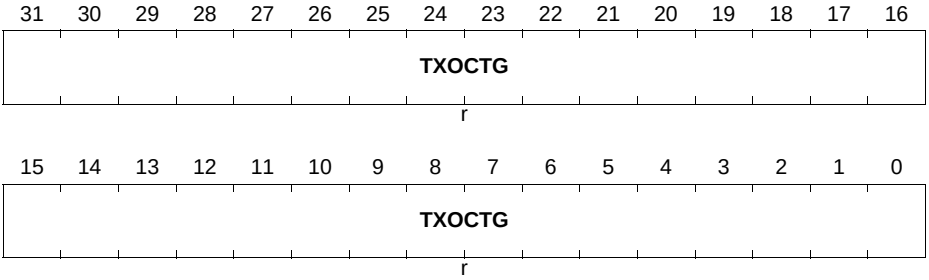


Field	Bits	Type	Description
TXCARR	[31:0]	r	**TXCARR** This field indicates the number of frames aborted because of carrier sense error (no carrier or loss of carrier).

32-bit Register - Tx_Octet_Count_Good

This register maintains the number of bytes transmitted, exclusive of preamble, in good frames.

ETH_TX_OCTET_COUNT_GOOD
Register 89 - Transmit Octet Count for Good Frames (1164_H) Reset Value: $0000\ 0000_H$



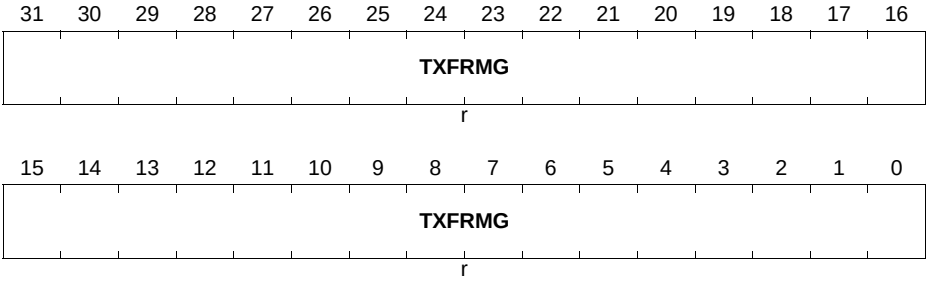
Field	Bits	Type	Description
TXOCTG	[31:0]	r	**TXOCTG** This field indicates the number of bytes transmitted, exclusive of preamble, in good frames.

32-bit Register - Tx_Frame_Count_Good

This register maintains the number of transmitted good frames, exclusive of preamble.

ETH_TX_FRAME_COUNT_GOOD

Register 90 - Transmit Frame Count for Good Frames (1168_H) Reset Value: 0000 0000_H

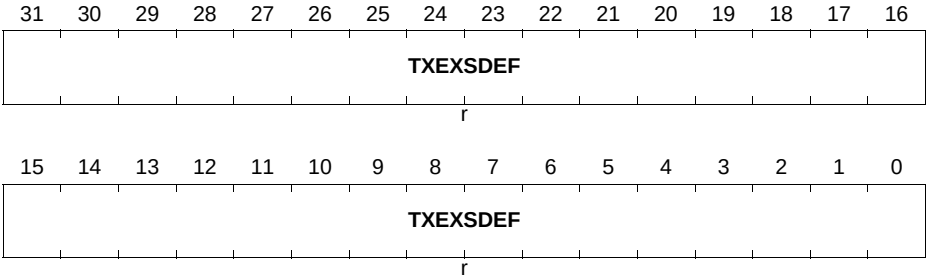


Field	Bits	Type	Description
TXFRMG	[31:0]	r	**TXFRMG** This field indicates the number of transmitted good frames, exclusive of preamble.

32-bit Register - Tx_Excessive_Deferral_Error

This register maintains the number of frames aborted because of excessive deferral error, that is, frames deferred for more than two max-sized frame times.

ETH_TX_EXCESSIVE_DEFERRAL_ERROR
Register 91 - Transmit Frame Count for Excessive Deferral Error Frames ($116C_H$)
Reset Value: $0000\ 0000_H$

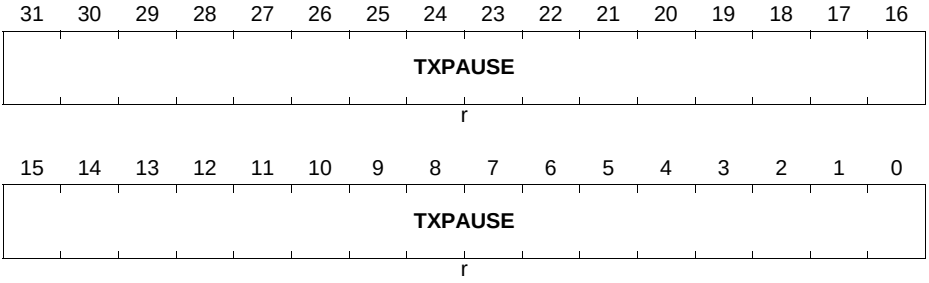


Field	Bits	Type	Description
TXEXSDEF	[31:0]	r	**TXEXSDEF** This field indicates the number of frames aborted because of excessive deferral error, that is, frames deferred for more than two max-sized frame times.

32-bit Register - Tx_Pause_Frames

This register maintains the number of transmitted good PAUSE frames.

ETH_TX_PAUSE_FRAMES
Register 92 - Transmit Frame Count for Good PAUSE Frames (1170_H) Reset Value: $0000\ 0000_H$

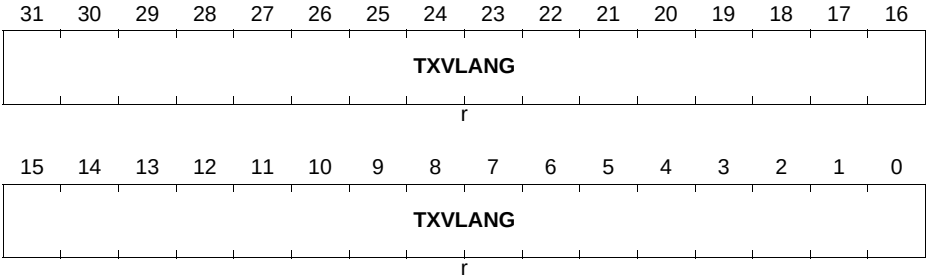


Field	Bits	Type	Description
TXPAUSE	[31:0]	r	**TXPAUSE** This field indicates the number of transmitted good PAUSE frames.

32-bit Register - Tx_VLAN_Frames_Good

This register maintains the number of transmitted good VLAN frames, exclusive of retried frames.

ETH_TX_VLAN_FRAMES_GOOD
Register 93 - Transmit Frame Count for Good VLAN Frames (1174_H) Reset Value: $0000\ 0000_H$

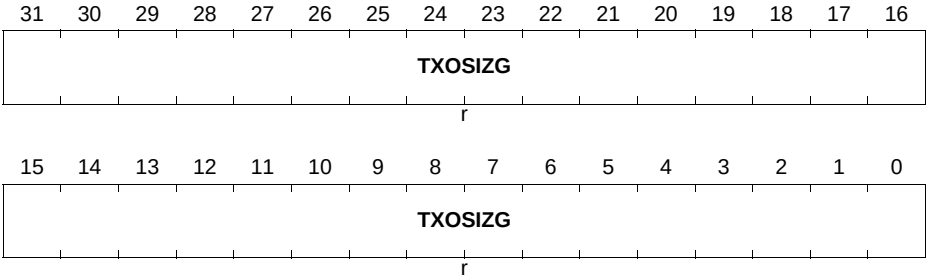


Field	Bits	Type	Description
TXVLANG	[31:0]	r	**TXVLANG** This register maintains the number of transmitted good VLAN frames, exclusive of retried frames.

32-bit Register - Tx_OSize_Frames_Good

This register maintains the number of transmitted good Oversize frames, exclusive of retried frames.

ETH_TX_OSIZE_FRAMES_GOOD
Register 94 - Transmit Frame Count for Good Oversize Frames (1178_H) Reset Value: $0000\ 0000_H$

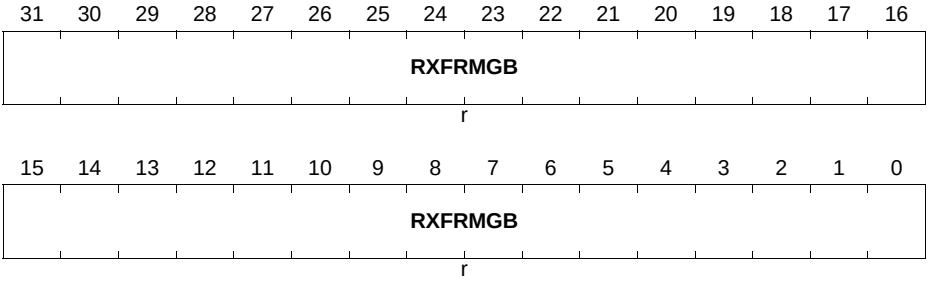


Field	Bits	Type	Description
TXOSIZG	[31:0]	r	**TXOSIZG** This field indicates the number of frames transmitted without errors and with length greater than the maxsize (1,518 or 1,522 bytes for VLAN tagged frames; 2000 bytes if enabled in bit 27 of Register 0 (MAC Configuration Register)).

32-bit Register - Rx_Frames_Count_Good_Bad

This register maintains the number of received good and bad frames.

ETH_RX_FRAMES_COUNT_GOOD_BAD
Register 96 - Receive Frame Count for Good and Bad Frames (1180_H) Reset Value: $0000\ 0000_H$

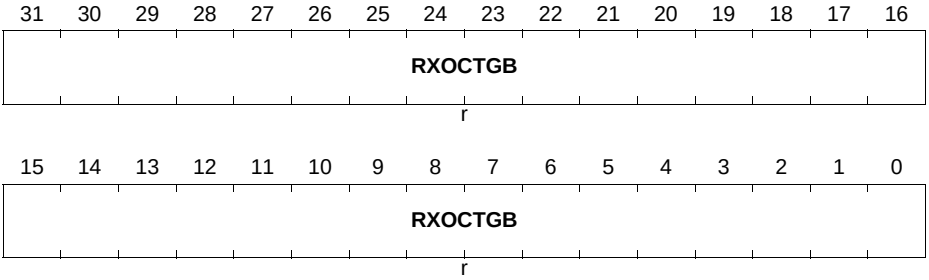


Field	Bits	Type	Description
RXFRMGB	[31:0]	r	**RXFRMGB** This field indicates the number of received good and bad frames.

32-bit Register - Rx_Octet_Count_Good_Bad

This register maintains the number of bytes received, exclusive of preamble, in good and bad frames.

ETH_RX_OCTET_COUNT_GOOD_BAD
Register 97 - Receive Octet Count for Good and Bad Frames (1184_H) Reset Value: $0000\ 0000_H$



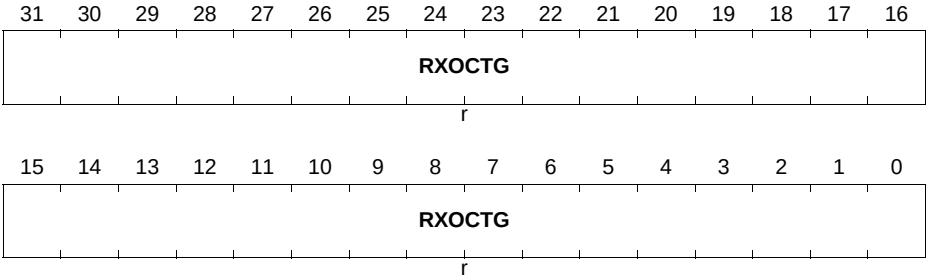
Field	Bits	Type	Description
RXOCTGB	[31:0]	r	**RXOCTGB** This field indicates the number of bytes received, exclusive of preamble, in good and bad frames.

32-bit Register - Rx_Octet_Count_Good

This register maintains the number of bytes received, exclusive of preamble, only in good frames.

ETH_RX_OCTET_COUNT_GOOD

Register 98 - Receive Octet Count for Good Frames (1188_H) Reset Value: $0000\ 0000_H$

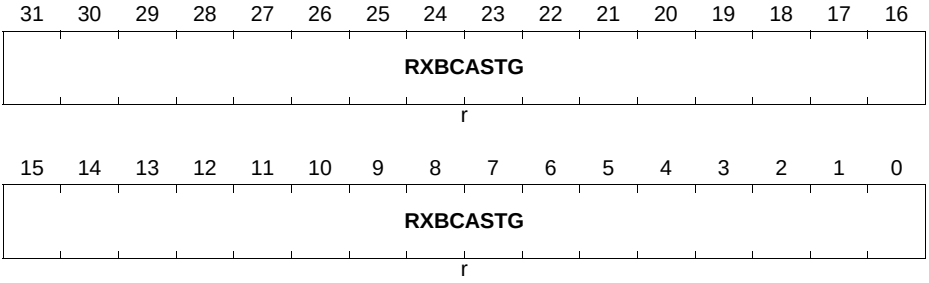


Field	Bits	Type	Description
RXOCTG	[31:0]	r	**RXOCTG** This field indicates the number of bytes received, exclusive of preamble, only in good frames.

32-bit Register - Rx_Broadcast_Frames_Good

This register maintains the number of received good broadcast frames.

ETH_RX_BROADCAST_FRAMES_GOOD
Register 99 - Receive Frame Count for Good Broadcast Frames ($118C_H$) Reset Value: $0000\ 0000_H$

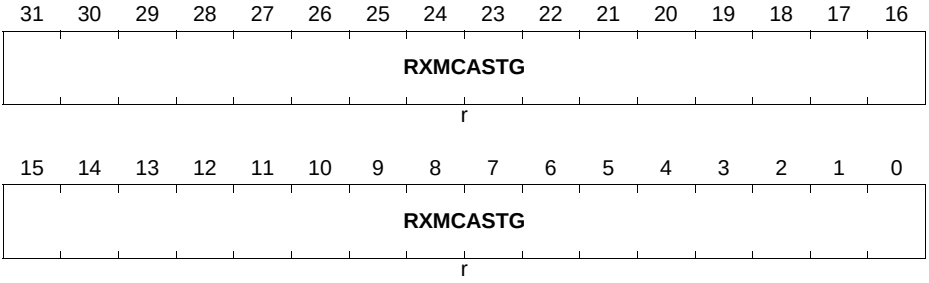


Field	Bits	Type	Description
RXBCASTG	[31:0]	r	**RXBCASTG** This field indicates the number of received good broadcast frames.

32-bit Register - Rx_Multicast_Frames_Good

This register maintains the number of received good multicast frames.

ETH_RX_MULTICAST_FRAMES_GOOD
Register 100 - Receive Frame Count for Good Multicast Frames (1190_H) Reset Value: $0000\ 0000_H$



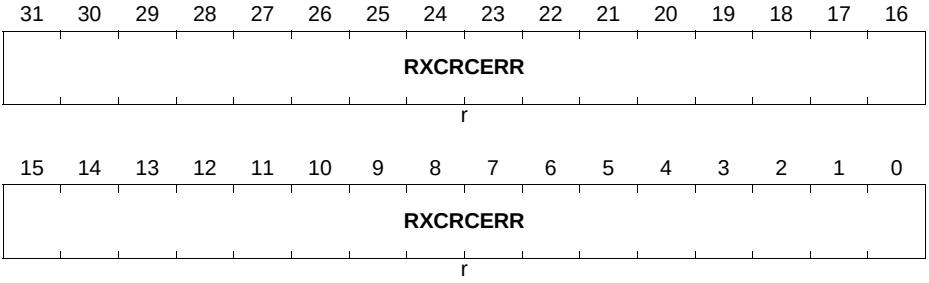
Field	Bits	Type	Description
RXMCASTG	[31:0]	r	**RXMCASTG** This field indicates the number of received good multicast frames.

32-bit Register - Rx_CRC_Error_Frames

This register maintains the number of frames received with CRC error.

ETH_RX_CRC_ERROR_FRAMES

Register 101 - Receive Frame Count for CRC Error Frames (1194_H) Reset Value: $0000\ 0000_H$

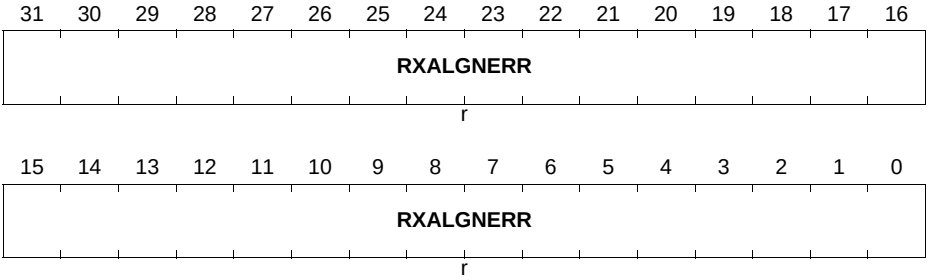


Field	Bits	Type	Description
RXCRCERR	[31:0]	r	**RXCRCERR** This field indicates the number of frames received with CRC error.

32-bit Register - Rx_Alignment_Error_Frames

This register maintains the number of frames received with alignment (dribble) error. This field is valid only in the 10 or 100 Mbps mode.

ETH_RX_ALIGNMENT_ERROR_FRAMES
Register 102 - Receive Frame Count for Alignment Error Frames (1198_H) Reset Value: $0000\ 0000_H$

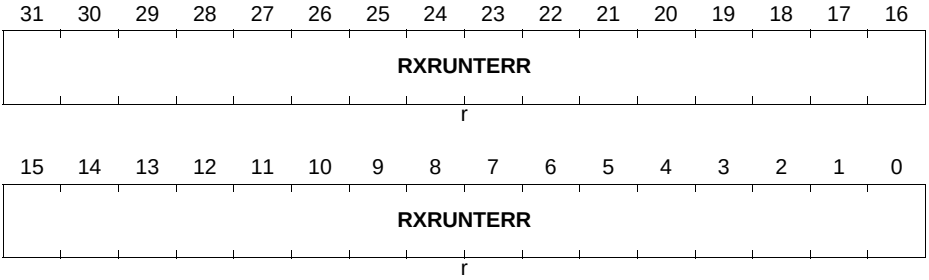


Field	Bits	Type	Description
RXALGNERR	[31:0]	r	**RXALGNERR** This field indicates the number of frames received with alignment (dribble) error. This field is valid only in the 10 or 100 Mbps mode.

32-bit Register - Rx_Runt_Error_Frames

This register maintains the number of frames received with runt error(<64 bytes and CRC error).

ETH_RX_RUNT_ERROR_FRAMES
Register 103 - Receive Frame Count for Runt Error Frames ($119C_H$) Reset Value: $0000\ 0000_H$



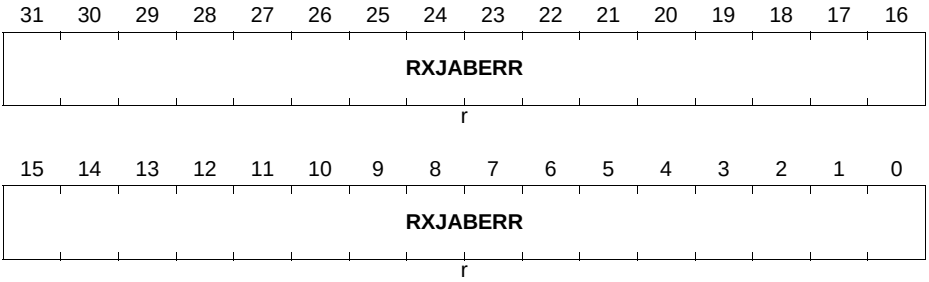
Field	Bits	Type	Description
RXRUNTERR	[31:0]	r	**RXRUNTERR** This field indicates the number of frames received with runt error(<64 bytes and CRC error).

32-bit Register - Rx_Jabber_Error_Frames

This register maintains the number of giant frames received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames.

ETH_RX_JABBER_ERROR_FRAMES

Register 104 - Receive Frame Count for Jabber Error Frames ($11A0_H$) Reset Value: $0000\ 0000_H$

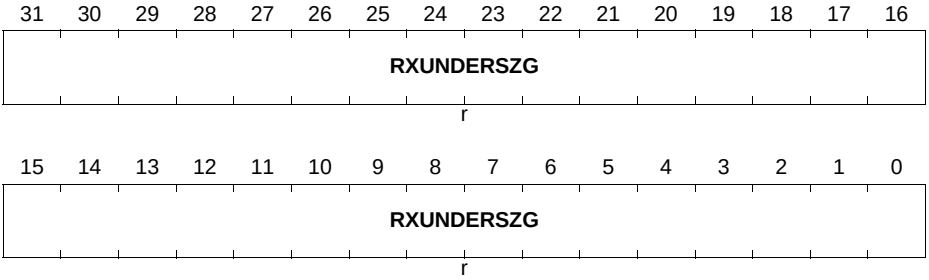


Field	Bits	Type	Description
RXJABERR	[31:0]	r	**RXJABERR** This field indicates the number of giant frames received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames.

32-bit Register - Rx_Undersize_Frames_Good

This register maintains the number of frames received with length less than 64 bytes and without errors.

ETH_RX_UNDERSIZE_FRAMES_GOOD
Register 105 - Receive Frame Count for Undersize Frames ($11A4_H$) Reset Value: $0000\ 0000_H$

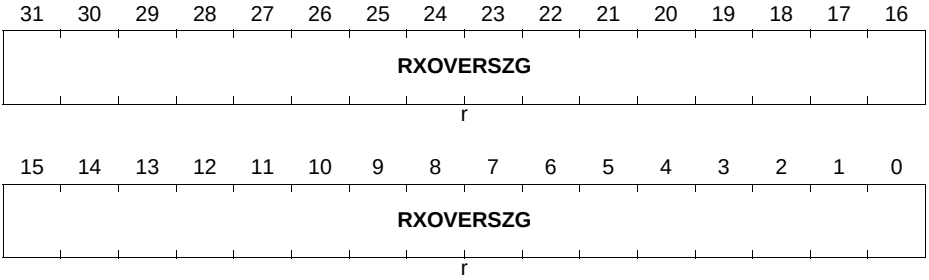


Field	Bits	Type	Description
RXUNDERSZG	[31:0]	r	**RXUNDERSZG** This field indicates the number of frames received with length less than 64 bytes and without errors.

32-bit Register - Rx_Oversize_Frames_Good

This register maintains the number of frames received with length greater than the maxsize (1,518 or 1,522 for VLAN tagged frames) and without errors.

ETH_RX_OVERSIZE_FRAMES_GOOD
Register 106 - Receive Frame Count for Oversize Frames ($11A8_H$) Reset Value: $0000\ 0000_H$

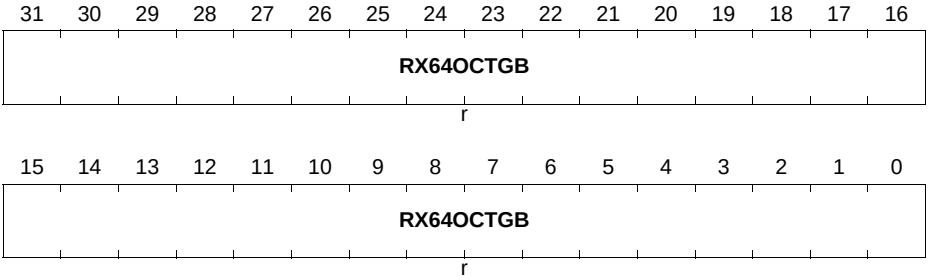


Field	Bits	Type	Description
RXOVERSZG	[31:0]	r	**RXOVERSZG** This field indicates the number of frames received without errors, with length greater than the maxsize (1,518 or 1,522 for VLAN tagged frames; 2,000 bytes if enabled in bit 27 of Register 0 (MAC Configuration Register)).

32-bit Register - Rx_64Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length 64 bytes, exclusive of preamble.

ETH_RX_64OCTETS_FRAMES_GOOD_BAD
Register 107 - Receive Frame Count for Good and Bad 64 Byte Frames ($11AC_H$)
Reset Value: $0000\ 0000_H$

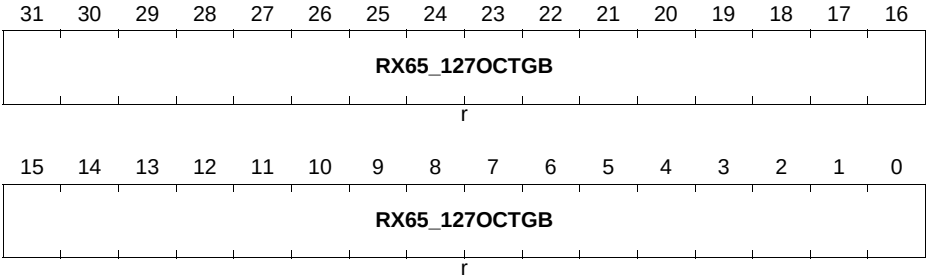


Field	Bits	Type	Description
RX64OCTGB	[31:0]	r	**RX64OCTGB** This field indicates the number of received good and bad frames with length 64 bytes, exclusive of preamble.

32-bit Register - Rx_65To127Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble.

ETH_RX_65TO127OCTETS_FRAMES_GOOD_BAD
Register 108 - Receive Frame Count for Good and Bad 65 to 127 Bytes Frames ($11B0_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RX65_127 OCTGB	[31:0]	r	**RX65_127OCTGB** This field indicates the number of received good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble.

32-bit Register - Rx_128To255Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble.

ETH_RX_128TO255OCTETS_FRAMES_GOOD_BAD
Register 109 - Receive Frame Count for Good and Bad 128 to 255 Bytes Frames ($11B4_H$) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
RX128_255OCTGB	[31:0]	r	**RX128_255OCTGB** This field indicates the number of received good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble.

32-bit Register - Rx_256To511Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble.

ETH_RX_256TO511OCTETS_FRAMES_GOOD_BAD
Register 110 - Receive Frame Count for Good and Bad 256 to 511 Bytes Frames ($11B8_H$) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
RX256_511OCTGB	[31:0]	r	**RX256_511OCTGB** This field indicates the number of received good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble.

32-bit Register - Rx_512To1023Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble.

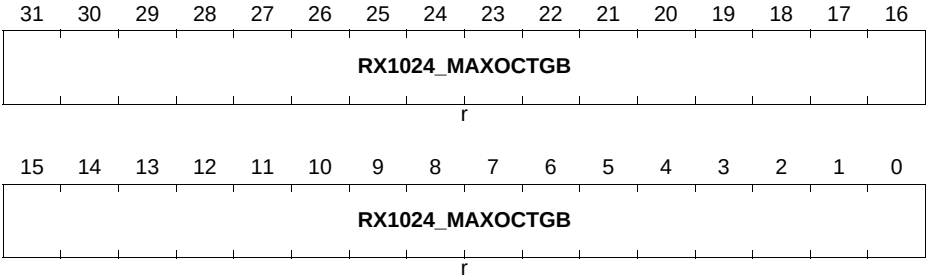
ETH_RX_512TO1023OCTETS_FRAMES_GOOD_BAD
Register 111 - Receive Frame Count for Good and Bad 512 to 1,023 Bytes Frames ($11BC_H$) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
RX512_1023OCTGB	[31:0]	r	**RX512_1023OCTGB** This field indicates the number of received good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble.

32-bit Register - Rx_1024ToMaxOctets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble.

ETH_RX_1024TOMAXOCTETS_FRAMES_GOOD_BAD
Register 112 - Receive Frame Count for Good and Bad 1,024 to Maxsize Bytes Frames **($11C0_H$)** **Reset Value: $0000\ 0000_H$**

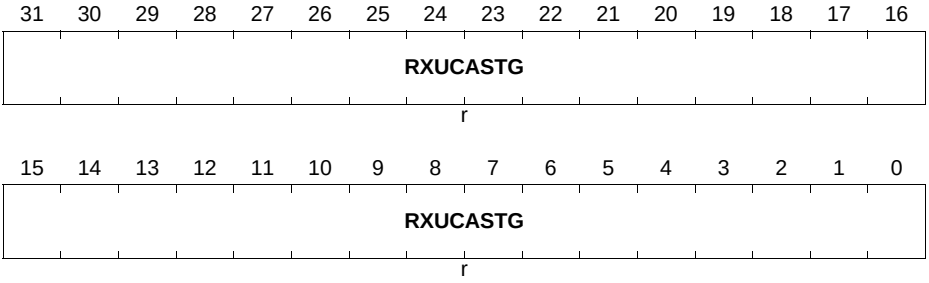


Field	Bits	Type	Description
RX1024_MAXOCTGB	[31:0]	r	**RX1024_MAXOCTGB** This field indicates the number of received good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Rx_Unicast_Frames_Good

This register maintains the number of received good unicast frames.

ETH_RX_UNICAST_FRAMES_GOOD
Register 113 - Receive Frame Count for Good Unicast Frames ($11C4_H$) Reset Value: $0000\ 0000_H$

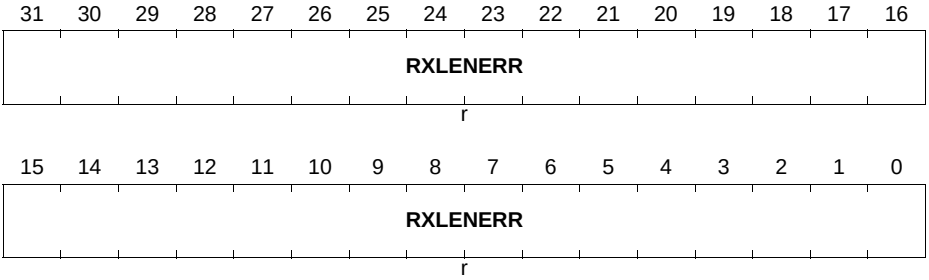


Field	Bits	Type	Description
RXUCASTG	[31:0]	r	**RXUCASTG** This field indicates the number of received good unicast frames.

32-bit Register - Rx_Length_Error_Frames

This register maintains the number of frames received with length error (Length type field not equal to frame size) for all frames with valid length field.

ETH_RX_LENGTH_ERROR_FRAMES
Register 114 - Receive Frame Count for Length Error Frames ($11C8_H$) Reset Value: $0000\ 0000_H$

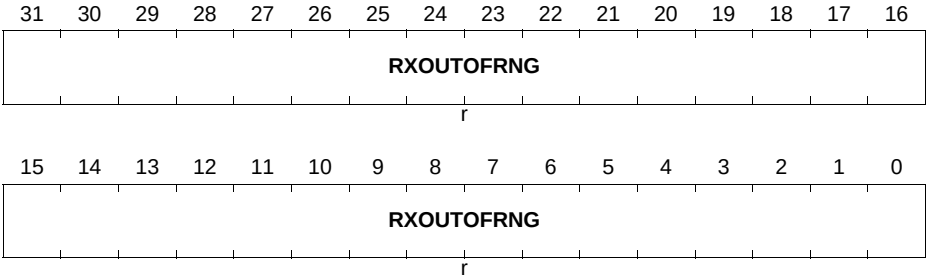


Field	Bits	Type	Description
RXLENERR	[31:0]	r	**RXLENERR** This field indicates the number of frames received with length error (Length type field not equal to frame size) for all frames with valid length field.

32-bit Register - Rx_Out_Of_Range_Type_Frames

This register maintains the number of received frames with length field not equal to the valid frame size (greater than 1,500 but less than 1,536).

ETH_RX_OUT_OF_RANGE_TYPE_FRAMES
Register 115 - Receive Frame Count for Out of Range Frames ($11CC_H$) Reset Value: $0000\ 0000_H$

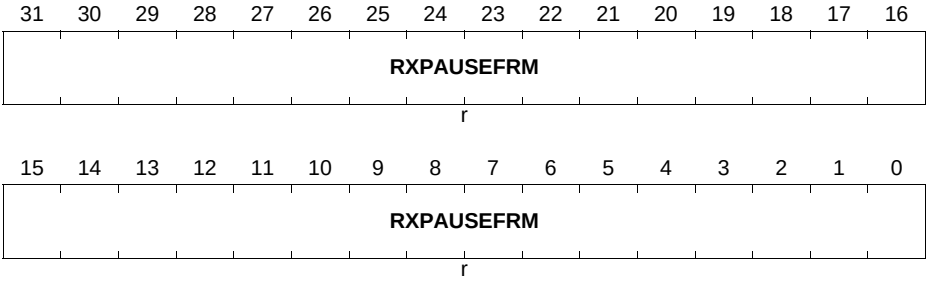


Field	Bits	Type	Description
RXOUTOFRNG	[31:0]	r	**RXOUTOFRNG** This field indicates the number of received frames with length field not equal to the valid frame size (greater than 1,500 but less than 1,536).

32-bit Register - Rx_Pause_Frames

This register maintains the number of received good and valid PAUSE frames.

ETH_RX_PAUSE_FRAMES
Register 116 - Receive Frame Count for PAUSE Frames ($11D0_H$)Reset Value: $0000\ 0000_H$

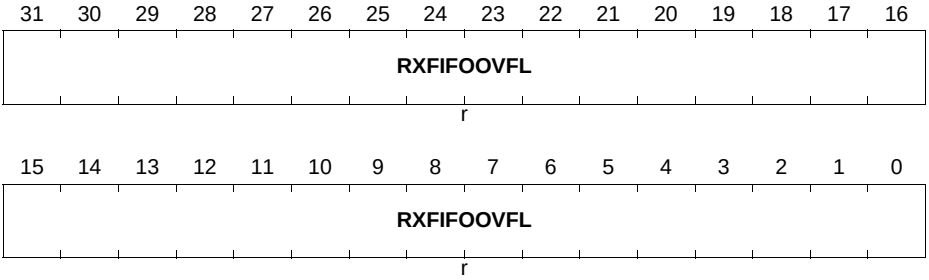


Field	Bits	Type	Description
RXPAUSEFRM	[31:0]	r	**RXPAUSEFRM** This field indicates the number of received good and valid PAUSE frames.

32-bit Register - Rx_FIFO_Overflow_Frames

This register maintains the number of received frames missed because of FIFO overflow.

ETH_RX_FIFO_OVERFLOW_FRAMES
Register 117 - Receive Frame Count for FIFO Overflow Frames ($11D4_H$) Reset Value: $0000\ 0000_H$

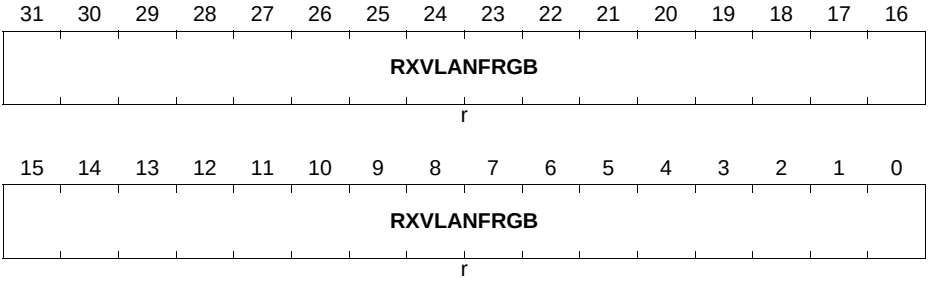


Field	Bits	Type	Description
RXFIFOOVFL	[31:0]	r	**RXFIFOOVFL** This field indicates the number of received frames missed because of FIFO overflow.

32-bit Register - Rx_VLAN_Frames_Good_Bad

This register maintains the number of received good and bad VLAN frames.

ETH_RX_VLAN_FRAMES_GOOD_BAD
Register 118 - Receive Frame Count for Good and Bad VLAN Frames ($11D8_H$)
Reset Value: $0000\ 0000_H$

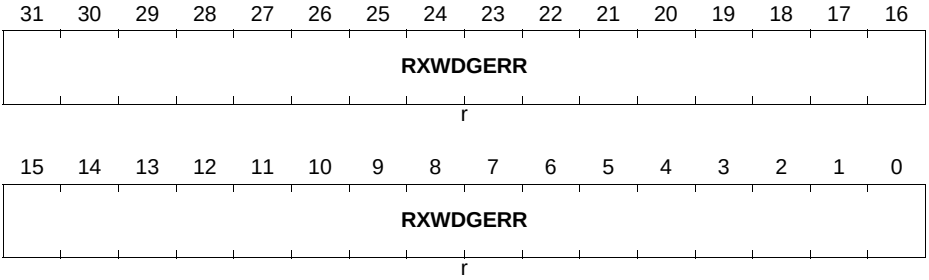


Field	Bits	Type	Description
RXVLANFRGB	[31:0]	r	**RXVLANFRGB** This field indicates the number of received good and bad VLAN frames.

32-bit Register - Rx_Watchdog_Error_Frames

This register maintains the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load).

ETH_RX_WATCHDOG_ERROR_FRAMES
Register 119 - Receive Frame Count for Watchdog Error Frames ($11DC_H$) Reset Value: $0000\ 0000_H$

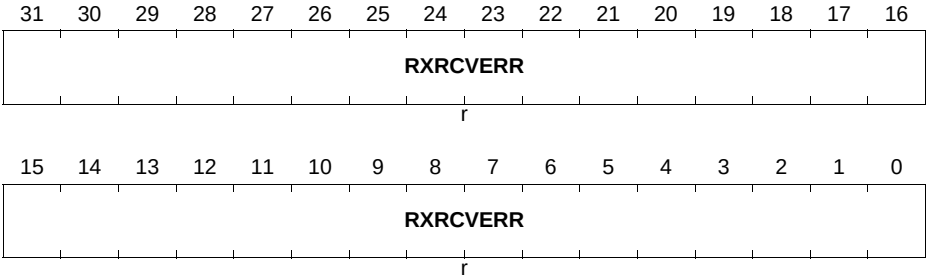


Field	Bits	Type	Description
RXWDGERR	[31:0]	r	**RXWDGERR** This field indicates the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load).

32-bit Register - Rx_Receive_Error_Frames

This register maintains the number of frames received with error because of the GMII/MII RXER error.

ETH_RX_RECEIVE_ERROR_FRAMES
Register 120 - Receive Frame Count for Receive Error Frames ($11E0_H$) Reset Value: $0000\ 0000_H$

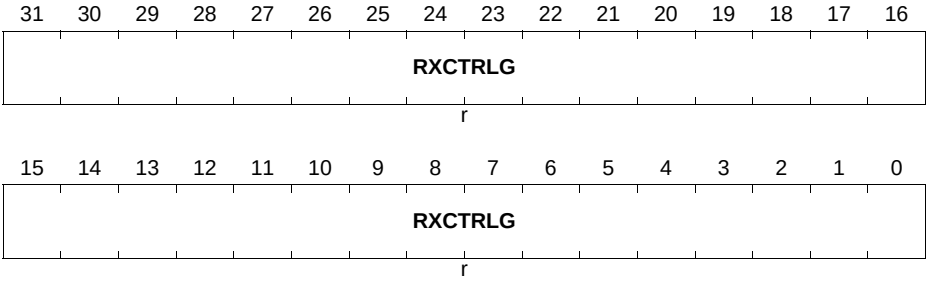


Field	Bits	Type	Description
RXRCVERR	[31:0]	r	**RXRCVERR** This field indicates the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load).

32-bit Register - Rx_Control_Frames_Good

This register maintains the number of godd control frames received.

ETH_RX_CONTROL_FRAMES_GOOD
Register 121 - Receive Frame Count for Good Control Frames Frames ($11E4_H$)
Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
RXCTRLG	[31:0]	r	**RXCTRLG** This field indicates the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load).

32-bit Register - MMC_IPC_Receive_Interrupt_Mask

This register maintains the mask for the interrupt generated from the receive IPC statistic counters. This register is 32-bits wide. This register is present only when any one of the MMC Receive IPC Counters is selected during core configuration.

ETH_MMC_IPC_RECEIVE_INTERRUPT_MASK
Register 128 - MMC Receive Checksum Offload Interrupt Mask Register (1200_H)
Reset Value: $0000\ 0000_H$

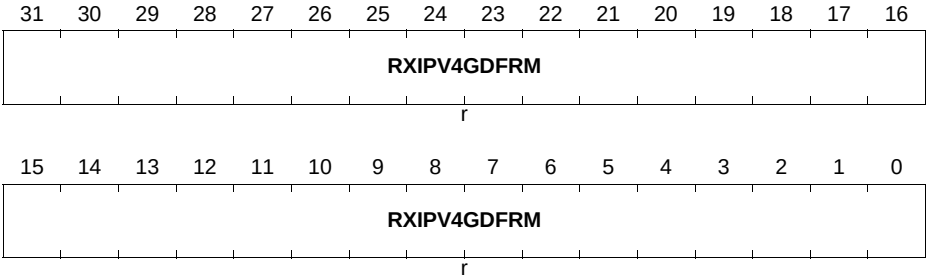
32-bit Register - RxIPv4_Good_Frames

This register maintains the number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload.

ETH_RXIPV4_GOOD_FRAMES
Register 132 - Receive IPV4 Good Frame Counter Register (1210_H) Reset Value: $0000\ 0000_H$

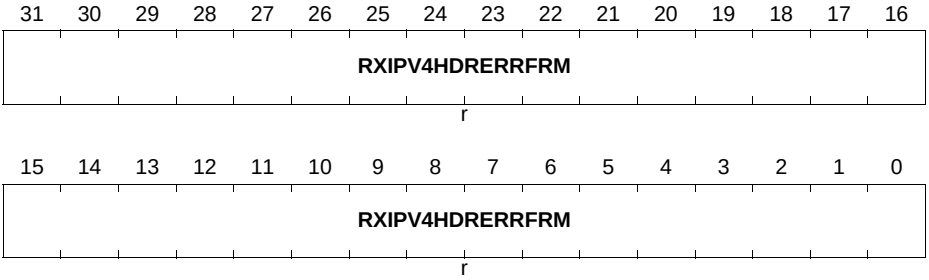


Field	Bits	Type	Description
RXIPV4GDFRM	[31:0]	r	**RXIPV4GDFRM** This field indicates the number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload.

32-bit Register - RxIPv4_Header_Error_Frames

This register maintains the number of IPv4 datagrams received with header errors (checksum, length, or version mismatch).

ETH_RXIPV4_HEADER_ERROR_FRAMES
Register 133 - Receive IPV4 Header Error Frame Counter Register (1214_H) Reset Value: $0000\ 0000_H$

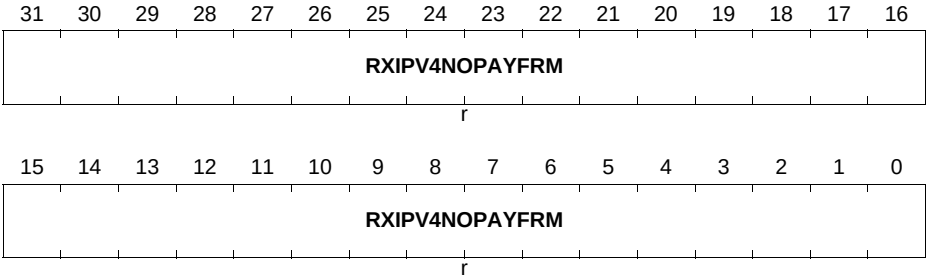


Field	Bits	Type	Description
RXIPV4HDRERRFRM	[31:0]	r	**RXIPV4HDRERRFRM** This field indicates the number of IPv4 datagrams received with header errors (checksum, length, or version mismatch).

32-bit Register - RxIPv4_No_Payload_Frames

This register maintains the number of received IPv4 datagram frames without a TCP, UDP, or ICMP payload processed by the Checksum engine.

ETH_RXIPV4_NO_PAYLOAD_FRAMES
Register 134 - Receive IPV4 No Payload Frame Counter Register (1218_H) Reset Value: $0000\ 0000_H$

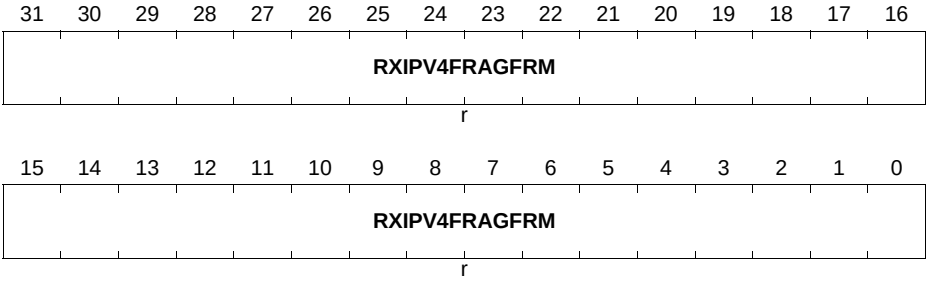


Field	Bits	Type	Description
RXIPV4NOPAYFRM	[31:0]	r	**RXIPV4NOPAYFRM** This field indicates the number of IPv4 datagram frames received that did not have a TCP, UDP, or ICMP payload processed by the Checksum engine.

32-bit Register - RxIPv4_Fragmented_Frames

This register maintains the number of good IPv4 datagrams received with fragmentation.

ETH_RXIPV4_FRAGMENTED_FRAMES
Register 135 - Receive IPV4 Fragmented Frame Counter Register ($121C_H$) Reset Value: $0000\ 0000_H$

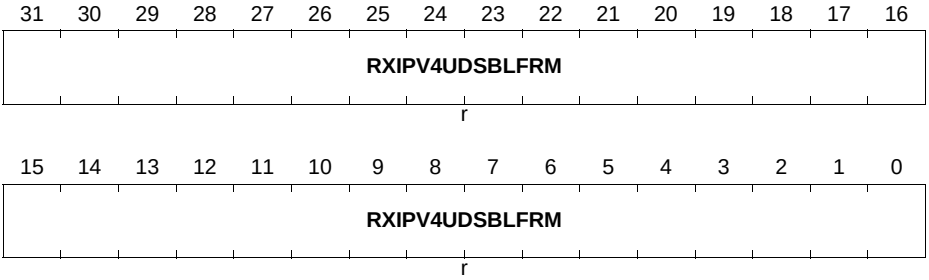


Field	Bits	Type	Description
RXIPV4FRAGFRM	[31:0]	r	**RXIPV4FRAGFRM** This field indicates the number of good IPv4 datagrams received with fragmentation.

32-bit Register - RxIPv4_UDP_Checksum_Disabled_Frames

This register maintains the number of received good IPv4 datagrams which have the UDP payload with checksum disabled.

ETH_RXIPV4_UDP_CHECKSUM_DISABLED_FRAMES
Register 136 - Receive IPV4 UDP Checksum Disabled Frame Counter Register (1220_H) **Reset Value: $0000\ 0000_H$**

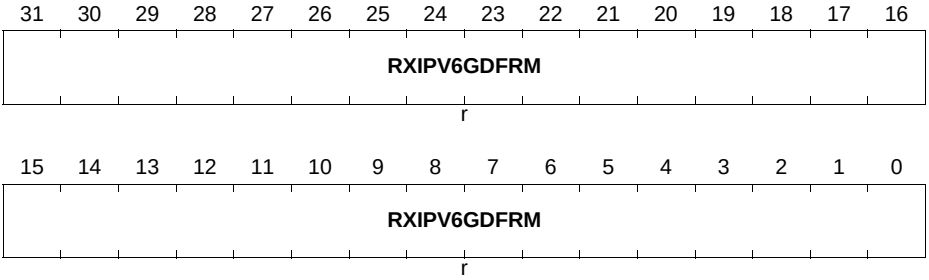


Field	Bits	Type	Description
RXIPV4UDSBLFRM	[31:0]	r	**RXIPV4UDSBLFRM** This field indicates the number of received good IPv4 datagrams which have the UDP payload with checksum disabled.

32-bit Register - RxIPv6_Good_Frames

This register maintains the number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads.

ETH_RXIPV6_GOOD_FRAMES
Register 137 - Receive IPV6 Good Frame Counter Register (1224_H) Reset Value: $0000\ 0000_H$

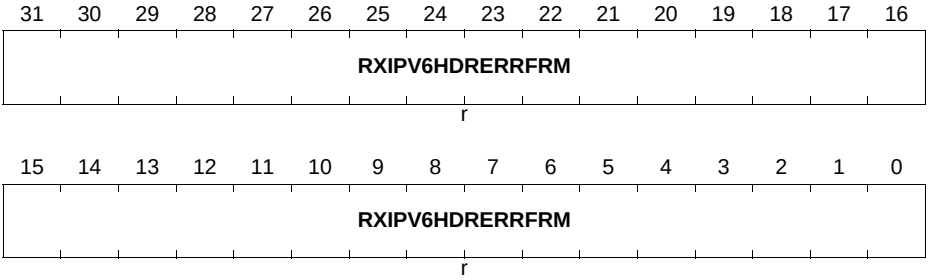


Field	Bits	Type	Description
RXIPV6GDFRM	[31:0]	r	**RXIPV6GDFRM** This field indicates the number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads.

32-bit Register - RxIPv6_Header_Error_Frames

This register maintains the number of IPv6 datagrams received with header errors (length or version mismatch).

ETH_RXIPV6_HEADER_ERROR_FRAMES
Register 138 - Receive IPV6 Header Error Frame Counter Register (1228_H) Reset Value: 0000 0000_H

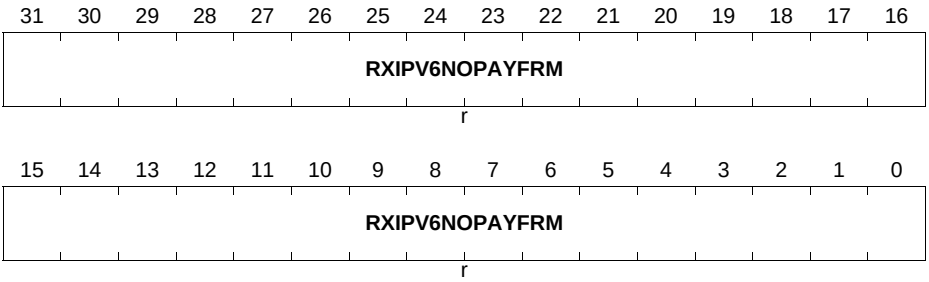


Field	Bits	Type	Description
RXIPV6HDRERRFRM	[31:0]	r	**RXIPV6HDRERRFRM** This field indicates the number of IPv6 datagrams received with header errors (length or version mismatch).

32-bit Register - RxIPv6_No_Payload_Frames

This register maintains the number of received IPv6 datagram frames without a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

ETH_RXIPV6_NO_PAYLOAD_FRAMES
Register 139 - Receive IPV6 No Payload Frame Counter Register ($122C_H$) Reset Value: $0000\ 0000_H$

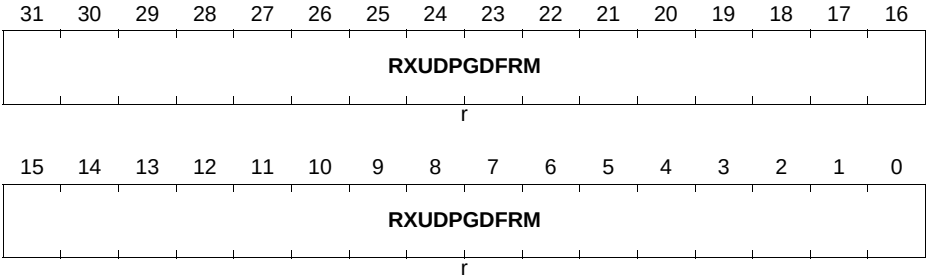


Field	Bits	Type	Description
RXIPV6NOPAYFRM	[31:0]	r	**RXIPV6NOPAYFRM** This field indicates the number of IPv6 datagram frames received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

32-bit Register - RxUDP_Good_Frames

This register maintains the number of good IP datagrams with a good UDP payload. This counter is not updated when the counter is incremented.

ETH_RXUDP_GOOD_FRAMES
Register 140 - Receive UDP Good Frame Counter Register (1230_H) Reset Value: $0000\ 0000_H$

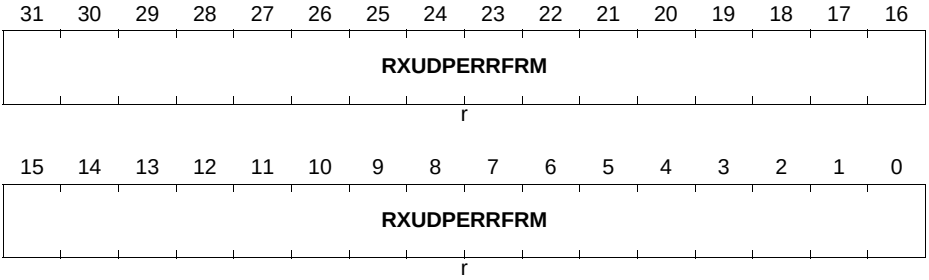


Field	Bits	Type	Description
RXUDPGDFRM	[31:0]	r	**RXUDPGDFRM** This field indicates the number of good IP datagrams with a good UDP payload. This counter is not updated when the counter is incremented.

32-bit Register - RxUDP_Error_Frames

This register maintains the number of good IP datagrams whose UDP payload has a checksum error.

ETH_RXUDP_ERROR_FRAMES
Register 141 - Receive UDP Error Frame Counter Register (1234_H) Reset Value: $0000\ 0000_H$

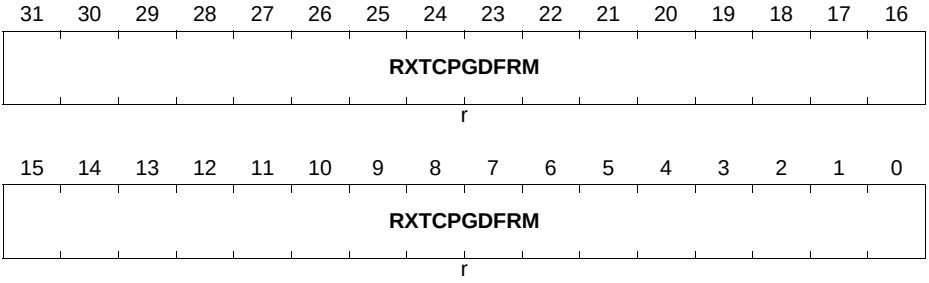


Field	Bits	Type	Description
RXUDPERRFRM	[31:0]	r	**RXUDPERRFRM** This field indicates the number of good IP datagrams whose UDP payload has a checksum error.

32-bit Register - RxTCP_Good_Frames

This register maintains the number of good IP datagrams with a good TCP payload.

ETH_RXTCP_GOOD_FRAMES
Register 142 - Receive TCP Good Frame Counter Register (1238_H) Reset Value: $0000\ 0000_H$

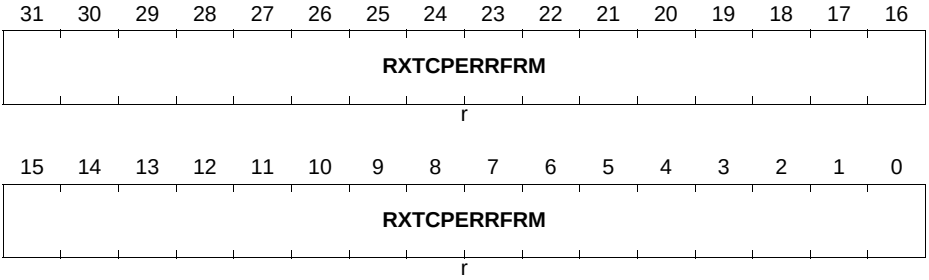


Field	Bits	Type	Description
RXTCPGDFRM	[31:0]	r	**RXTCPGDFRM** This field indicates the number of good IP datagrams with a good TCP payload.

32-bit Register - RxTCP_Error_Frames

This register maintains the number of good IP datagrams whose TCP payload has a checksum error.

ETH_RXTCP_ERROR_FRAMES
Register 143 - Receive TCP Error Frame Counter Register ($123C_H$) Reset Value: $0000\ 0000_H$

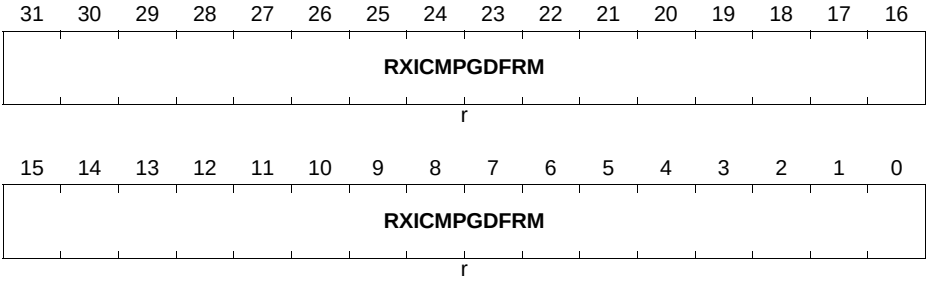


Field	Bits	Type	Description
RXTCPERRFRM	[31:0]	r	**RXTCPERRFRM** This field indicates the number of good IP datagrams whose TCP payload has a checksum error.

32-bit Register - RxICMP_Good_Frames

This register maintains the number of good IP datagrams with a good ICMP payload.

ETH_RXICMP_GOOD_FRAMES
Register 144 - Receive ICMP Good Frame Counter Register (1240_H) Reset Value: $0000\ 0000_H$

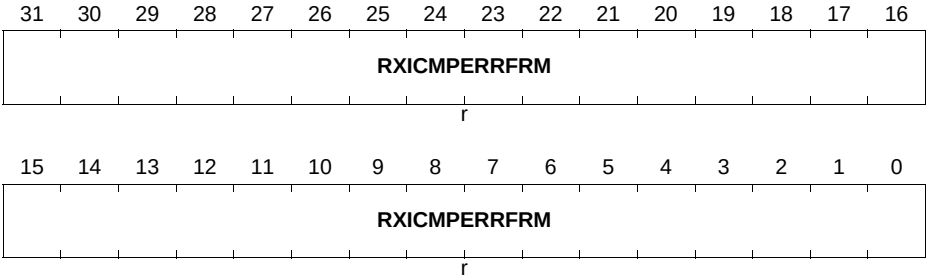


Field	Bits	Type	Description
RXICMPGDFRM	[31:0]	r	**RXICMPGDFRM** This field indicates the number of good IP datagrams with a good ICMP payload.

32-bit Register - RxICMP_Error_Frames

This register maintains the number of good IP datagrams whose ICMP payload has a checksum error.

ETH_RXICMP_ERROR_FRAMES
Register 145 - Receive ICMP Error Frame Counter Register (1244_H) Reset Value: $0000\ 0000_H$

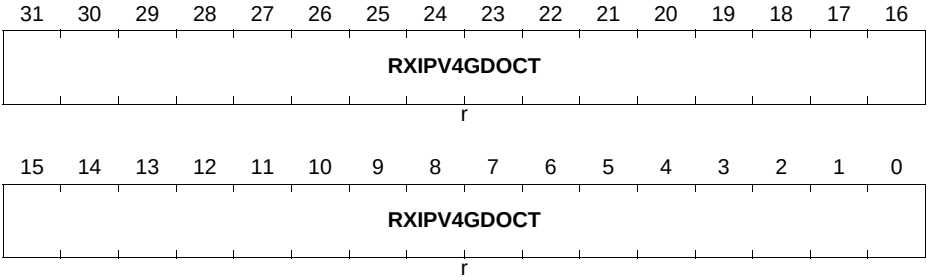


Field	Bits	Type	Description
RXICMPERRFRM	[31:0]	r	**RXICMPERRFRM** This field indicates the number of good IP datagrams whose ICMP payload has a checksum error.

32-bit Register - RxIPv4_Good_Octets

This register maintains the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data.

ETH_RXIPV4_GOOD_OCTETS
Register 148 - Receive IPV4 Good Octet Counter Register (1250_H) Reset Value: $0000\ 0000_H$

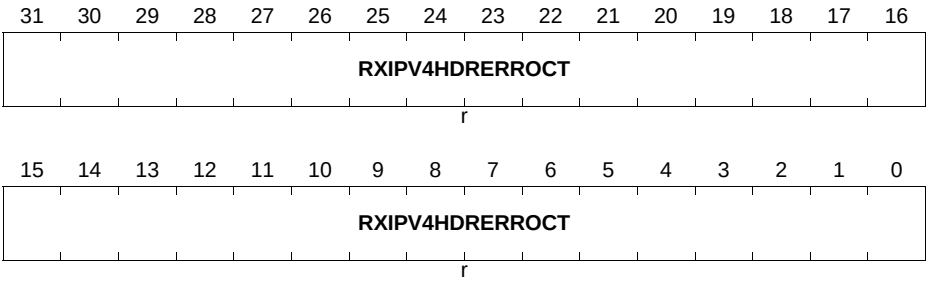


Field	Bits	Type	Description
RXIPV4GDOCT	[31:0]	r	**This field indicates the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. The Ethernet header, FCS, pad, or IP pad** bytes are not included in this counter.

32-bit Register - RxIPv4_Header_Error_Octets

This register maintains the number of bytes received in IPv4 datagrams with header errors (checksum, length, or version mismatch). The value in the Length field of the IPv4 header is used to update this counter.

ETH_RXIPV4_HEADER_ERROR_OCTETS
Register 149 - Receive IPV4 Header Error Octet Counter Register (1254_H) Reset Value: $0000\ 0000_H$

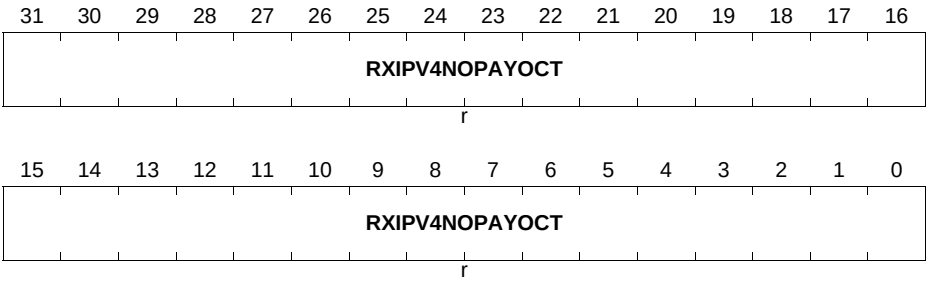


Field	Bits	Type	Description
RXIPV4HDRERROCT	[31:0]	r	**This field indicates the number of bytes received in the IPv4 datagrams with header errors (checksum, length, or version mismatch). The value in the Length field of IPv4 header is used to update this counter.** The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv4_No_Payload_Octets

This register maintains the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter.

ETH_RXIPV4_NO_PAYLOAD_OCTETS
Register 150 - Receive IPV4 No Payload Octet Counter Register (1258_H) Reset Value: $0000\ 0000_H$

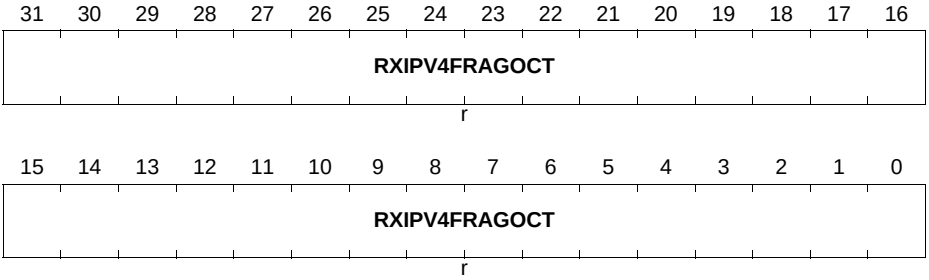


Field	Bits	Type	Description
RXIPV4NOPAYOCT	[31:0]	r	**This field indicates the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter.** The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv4_Fragmented_Octets

This register maintains the number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 headers Length field is used to update this counter.

ETH_RXIPV4_FRAGMENTED_OCTETS
Register 151 - Receive IPV4 Fragmented Octet Counter Register ($125C_H$) Reset Value: $0000\ 0000_H$

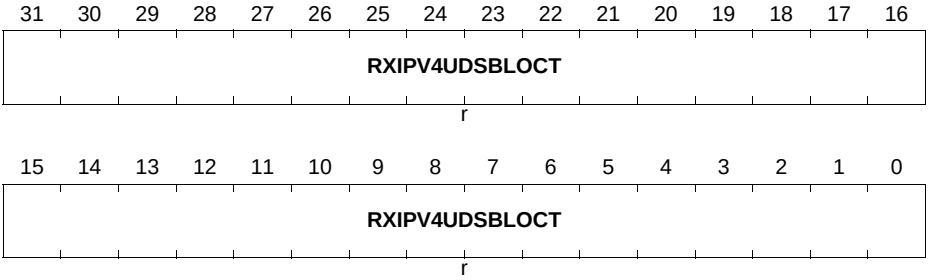


Field	Bits	Type	Description
RXIPV4FRAGOCT	[31:0]	r	**This field indicates the number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 headers Length field is used to update this counter.** The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv4_UDP_Checksum_Disable_Octets

This register maintains the number of bytes received in a UDP segment that had the UDP checksum disabled.

ETH_RXIPV4_UDP_CHECKSUM_DISABLE_OCTETS
Register 152 - Receive IPV4 Fragmented Octet Counter Register (1260_H) Reset Value: $0000\ 0000_H$

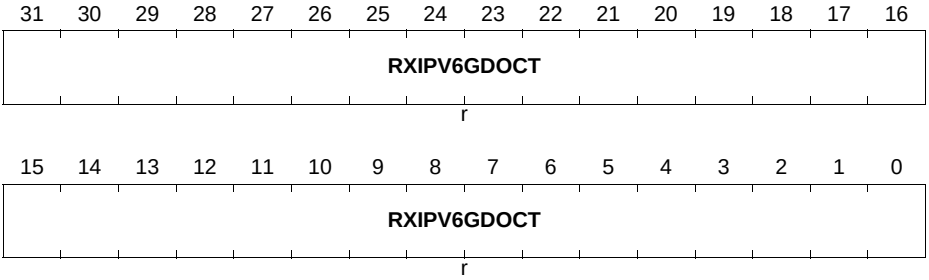


Field	Bits	Type	Description
RXIPV4UDSBLOCT	[31:0]	r	**RXIPV4UDSBLOCT** This field indicates the number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv6_Good_Octets

This register maintains the number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data.

ETH_RXIPV6_GOOD_OCTETS
Register 153 - Receive IPV6 Good Octet Counter Register (1264_H) Reset Value: $0000\ 0000_H$

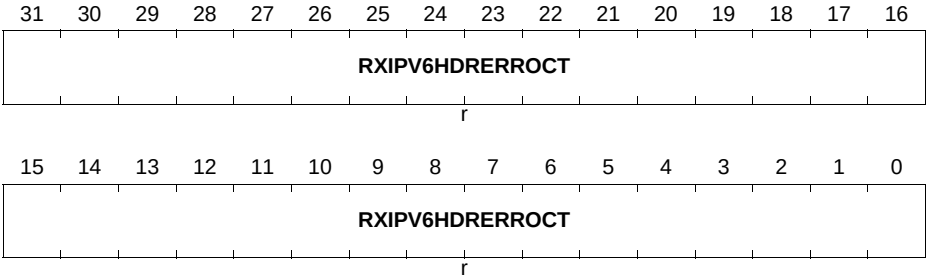


Field	Bits	Type	Description
RXIPV6GDOCT	[31:0]	r	**Thsi field indicates the number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data.** This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv6_Header_Error_Octets

This register maintains the number of bytes received in IPv6 datagrams with header errors (length or version mismatch).

ETH_RXIPV6_HEADER_ERROR_OCTETS
Register 154 - Receive IPV6 Header Error Octet Counter Register (1268_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
RXIPV6HDRERROCT	[31:0]	r	**This field indicates the number of bytes received in IPv6 datagrams with header errors (length or version mismatch). The value in the IPv6 headers Length field is used to update this counter.** This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv6_No_Payload_Octets

This register maintains the number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload.

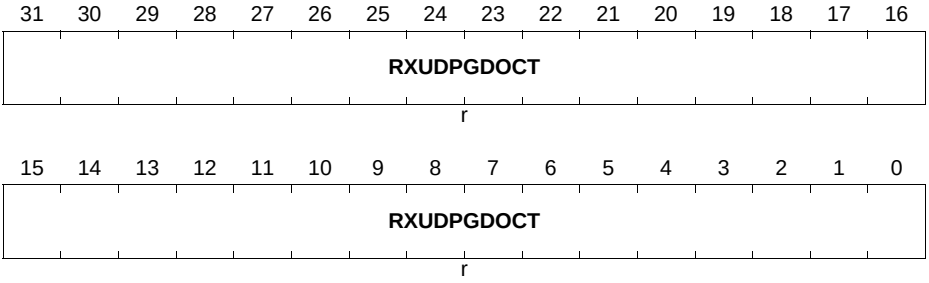
ETH_RXIPV6_NO_PAYLOAD_OCTETS
Register 155 - Receive IPV6 No Payload Octet Counter Register ($126C_H$) Reset Value: $0000\ 0000_H$

Field	Bits	Type	Description
RXIPV6NOPAYOCT	[31:0]	r	**This field indicates the number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv6 headers Length field is used to update this counter.** This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxUDP_Good_Octets

This register maintains the number of bytes received in a good UDP segment.

ETH_RXUDP_GOOD_OCTETS
Register 156 - Receive UDP Good Octet Counter Register (1270_H) Reset Value: $0000\ 0000_H$

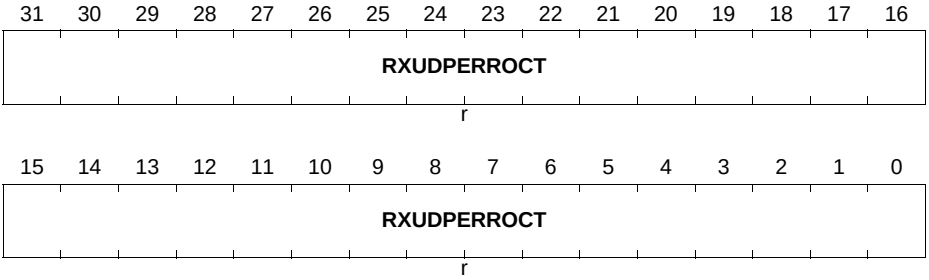


Field	Bits	Type	Description
RXUDPGDOCT	[31:0]	r	**RXUDPGDOCT** This field indicates the number of bytes received in a good UDP segment. This counter does not count IP header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxUDP_Error_Octets

This register maintains the number of bytes received in a UDP segment with checksum errors.

ETH_RXUDP_ERROR_OCTETS
Register 157 - Receive UDP Error Octet Counter Register (1274_H) Reset Value: $0000\ 0000_H$

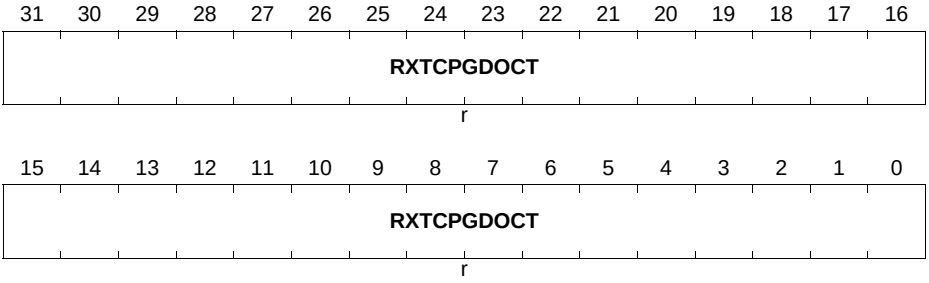


Field	Bits	Type	Description
RXUDPERROCT	[31:0]	r	**RXUDPERROCT** This field indicates the number of bytes received in a UDP segment with checksum errors. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxTCP_Good_Octets

This register maintains the number of bytes received in a good TCP segment.

ETH_RXTCP_GOOD_OCTETS
Register 158 - Receive TCP Good Octet Counter Register (1278_H) Reset Value: $0000\ 0000_H$

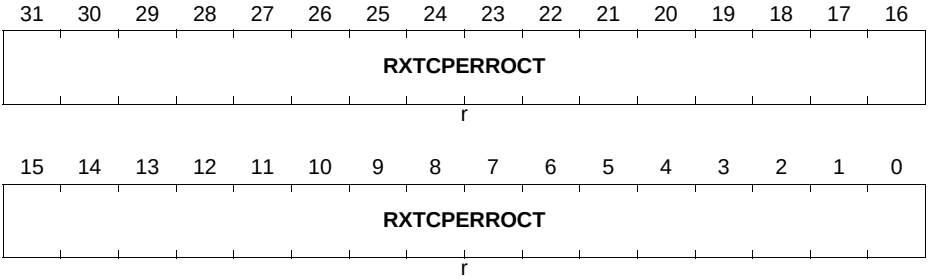


Field	Bits	Type	Description
RXTCPGDOCT	[31:0]	r	**RXTCPGDOCT** This field indicates the number of bytes received in a good TCP segment. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxTCP_Error_Octets

This register maintains the number of bytes received in a TCP segment with checksum errors.

ETH_RXTCP_ERROR_OCTETS
Register 159 - Receive TCP Error Octet Counter Register ($127C_H$) Reset Value: $0000\ 0000_H$

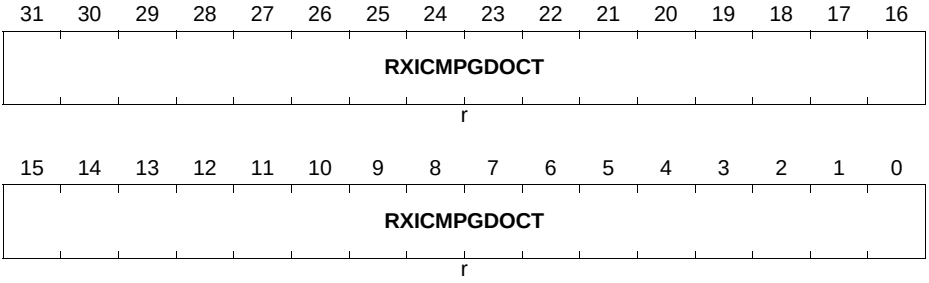


Field	Bits	Type	Description
RXTCPERROCT	[31:0]	r	**RXTCPERROCT** Thsi field indicates the number of bytes received in a TCP segment with checksum errors. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxICMP_Good_Octets

This register maintains the number of bytes received in a good ICMP segment.

ETH_RXICMP_GOOD_OCTETS
Register 160 - Receive ICMP Good Octet Counter Register (1280_H) Reset Value: $0000\ 0000_H$

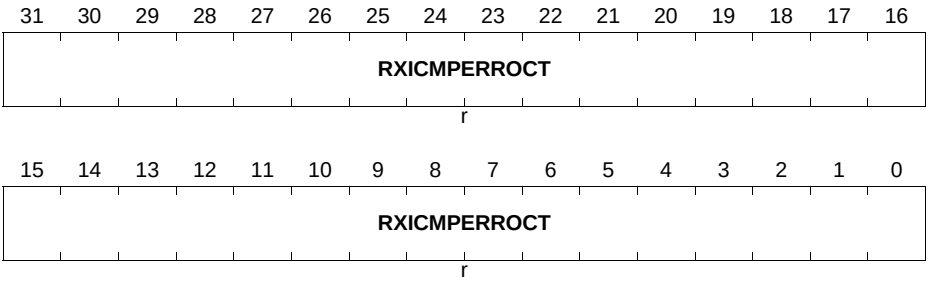


Field	Bits	Type	Description
RXICMPGDOCT	[31:0]	r	**RXICMPGDOCT** This field indicates the number of bytes received in a good ICMP segment. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxICMP_Error_Octets

This register maintains the number of bytes received in a ICMP segment with checksum errors. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

ETH_RXICMP_ERROR_OCTETS
Register 161 - Receive ICMP Error Octet Counter Register (1284_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
RXICMPERROCT	[31:0]	r	**RXICMPERROCT** Number of bytes received in an ICMP segment with checksum errors

32-bit Register - Timestamp_Control

This register controls the operation of the System Time generator and the processing of PTP packets for timestamping in the Receiver. Note: * Bits[5:1] are reserved when External Timestamp Input feature is enabled. * Bits[19:8] are reserved and read-only when Advanced Timestamp feature is not enabled. * Bits[28:24] are reserved and read-only when Auxiliary Snapshot feature is not enabled. * Release 3.60a onwards, the functions of Bits 17 and 16 (SNAPTYPSEL) have changed. These functions are not backward compatible with the functions described in release 3.50a.

ETH_TIMESTAMP_CONTROL

Register 448 - Timestamp Control Register (1700_H) **Reset Value: $0000\ 2000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RESERVED_31_29			ATSEN3	ATSEN2	ATSEN1	ATSEN0	ATSFC	RESERVED_23_19					TSENMACADDR	SNAPTYPSEL	
r			r	r	r	r	r	r					rw	rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TSMSTRENA	TSEVNTENA	TSIPV4ENA	TSIPV6ENA	TSIPENA	TSVER2ENA	TSCTRLSSR	TSENALL	RESERVED_7_6		TSADDREG	TSTRIG	TSUPDT	TSINIT	TSCFUPDT	TSENA
rw	rw	rw	rw	rw	rw	rw	rw	r		rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
TSENA	0	rw	**Timestamp Enable** When set, the timestamp is added for the transmit and receive frames. When disabled, timestamp is not added for the transmit and receive frames and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the receive side, the MAC processes the 1588 frames only if this bit is set.
TSCFUPDT	1	rw	**Timestamp Fine or Coarse Update** When set, this bit indicates that the system times update should be done using the fine update method. When reset, it indicates the system timestamp update should be done using the Coarse method.

Field	Bits	Type	Description
TSINIT	2	rw	**Timestamp Initialize** When set, the system time is initialized (overwritten) with the value specified in the Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during core configuration) can only be initialized.
TSUPDT	3	rw	**Timestamp Update** When set, the system time is updated (added or subtracted) with the value specified in Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the update is completed in hardware. The Timestamp Higher Word register (if enabled during core configuration) is not updated.
TSTRIG	4	rw	**Timestamp Interrupt Trigger Enable** When set, the timestamp interrupt is generated when the System Time becomes greater than the value written in the Target Time register. This bit is reset after the generation of the Timestamp Trigger Interrupt.
TSADDREG	5	rw	**Addend Reg Update** When set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This is cleared when the update is completed. This register bit should be zero before setting it.
RESERVED_7_6	[7:6]	r	**RESERVED_7_6**
TSENALL	8	rw	**Enable Timestamp for All Frames** When set, the timestamp snapshot is enabled for all frames received by the MAC.

Field	Bits	Type	Description
TSCTRLSSR	9	rw	**Timestamp Digital or Binary Rollover Control** When set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment has to be programmed correctly depending on the PTP reference clock frequency and the value of this bit.
TSVER2ENA	10	rw	**Enable PTP packet Processing for Version 2 Format** When set, the PTP packets are processed using the 1588 version 2 format. Otherwise, the PTP packets are processed using the version 1 format.
TSIPENA	11	rw	**Enable Processing of PTP over Ethernet Frames** When set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet frames. When this bit is clear, the MAC ignores the PTP over Ethernet packets.
TSIPV6ENA	12	rw	**Enable Processing of PTP Frames Sent Over IPv6-UDP** When set, the MAC receiver processes PTP packets encapsulated in UDP over IPv6 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv6 packets.
TSIPV4ENA	13	rw	**Enable Processing of PTP Frames Sent over IPv4-UDP** When set, the MAC receiver processes the PTP packets encapsulated in UDP over IPv4 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv4 packets. This bit is set by default.
TSEVNTENA	14	rw	**Enable Timestamp Snapshot for Event Messages** When set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When reset, the snapshot is taken for all messages except Announce, Management, and Signaling.
TSMSTRENA	15	rw	**Enable Snapshot for Messages Relevant to Master** When set, the snapshot is taken only for the messages relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.

Field	Bits	Type	Description
SNAPTYPSEL	[17:16]	rw	**Select PTP packets for Taking Snapshots** These bits along with Bits 15 and 14 decide the set of PTP packet types for which snapshot needs to be taken.
TSENMACADDR	18	rw	**Enable MAC address for PTP Frame Filtering** When set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP frames when PTP is directly sent over Ethernet.
RESERVED_23_19	[23:19]	r	**RESERVED_23_19**
ATSFC	24	r	**Auxiliary Snapshot FIFO Clear** When set, it resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, auxiliary snapshots get stored in the FIFO. This bit is reserved when the Add IEEE 1588 Auxiliary Snapshot option is not selected during core configuration.
ATSEN0	25	r	**Auxiliary Snapshot 0 Enable** This field controls capturing the Auxiliary Snapshot Trigger 0. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored. This bit is reserved when the IEEE 1588 Auxiliary Snapshot option is not selected during core configuration.
ATSEN1	26	r	**Auxiliary Snapshot 1 Enable** This field controls capturing the Auxiliary Snapshot Trigger 1. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[1] input is enabled. When this bit is reset, the events on this input are ignored. This bit is reserved when the IEEE 1588 Auxiliary Snapshot option is not selected during core configuration or the selected number in the Number of IEEE 1588 Auxiliary Snapshot Inputs option is less than two.

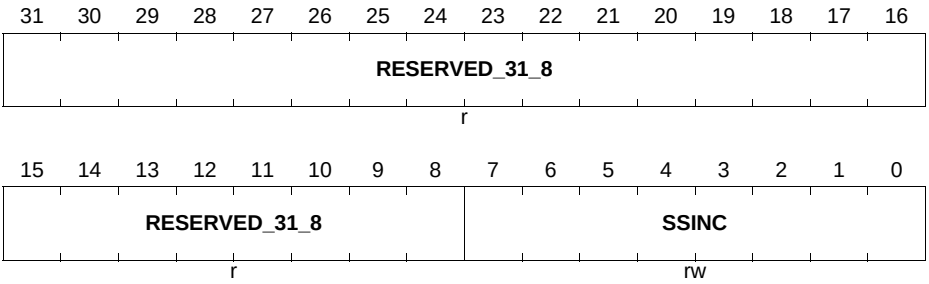
Field	Bits	Type	Description
ATSEN2	27	r	**Auxiliary Snapshot 2 Enable** This field controls capturing the Auxiliary Snapshot Trigger 2. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[2] input is enabled. When this bit is reset, the events on this input are ignored. This bit is reserved when the IEEE 1588 Auxiliary Snapshot option is not selected during core configuration or the selected number in the Number of IEEE 1588 Auxiliary Snapshot Inputs option is less than three.
ATSEN3	28	r	**Auxiliary Snapshot 3 Enable** This field controls capturing the Auxiliary Snapshot Trigger 3. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[3] input is enabled. When this bit is reset, the events on this input are ignored. This bit is reserved when the IEEE 1588 Auxiliary Snapshot option is not selected during core configuration or the selected number in the Number of IEEE 1588 Auxiliary Snapshot Inputs option is less than four.
RESERVED_31_29	[31:29]	r	**RESERVED_31_29**

32-bit Register - Sub_Second_Increment

This register is present only when the IEEE 1588 timestamp feature is selected without an external timestamp input. In the Coarse Update mode (TSCFUPDT bit in Register 448), the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

ETH_SUB_SECOND_INCREMENT

Register 449 - Sub-Second Increment Register (1704_H) Reset Value: $0000\ 0000_H$

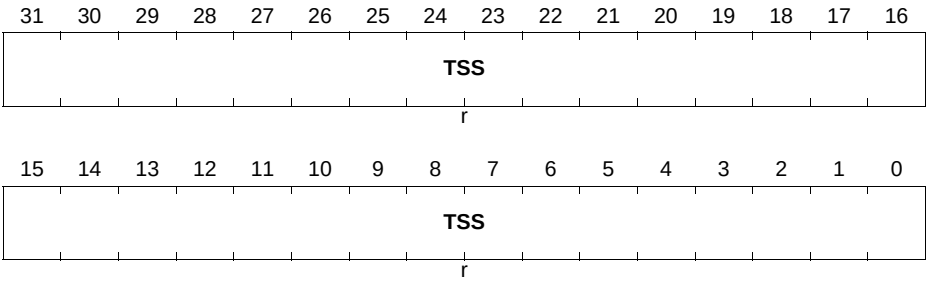


Field	Bits	Type	Description
SSINC	[7:0]	rw	**Sub-second Increment Value** The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time-Nanoseconds register has an accuracy of 1 ns (TSCTRLSSR bit is set). When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465ns. In this case, you should program a value of 43 (0x2B) that is derived by 20ns/0.465.
RESERVED_31_8	[31:8]	r	**RESERVED_31_8**

32-bit Register - System_Time_Seconds

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to clk_csr_i). These registers (450 and 451) are present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

ETH_SYSTEM_TIME_SECONDS
Register 450 - System Time - Seconds Register (1708_H) Reset Value: $0000\ 0000_H$

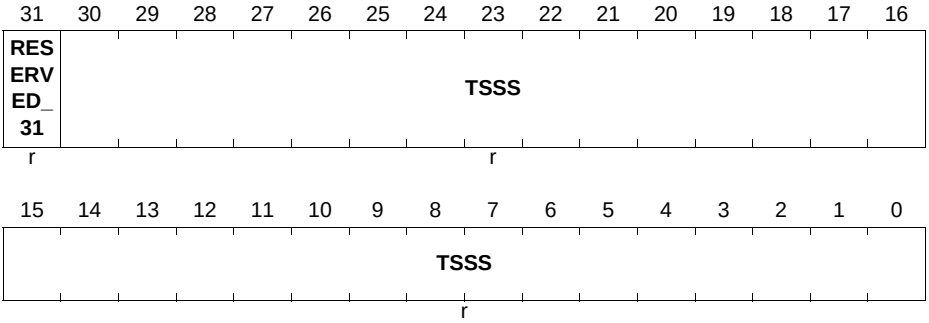


Field	Bits	Type	Description
TSS	[31:0]	r	**Timestamp Second** The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

32-bit Register - System_Time_Nanoseconds

The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When TSCTRLSSR is set, each bit represents 1 ns and the maximum value is 0x3B9A_C9FF, after which it rolls-over to zero.

ETH_SYSTEM_TIME_NANOSECONDS
Register 451 - System Time - Nanoseconds Register ($170C_H$) Reset Value: 0000 0000_H

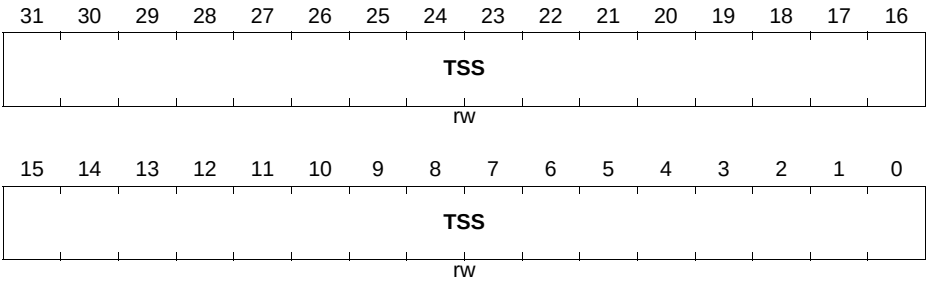


Field	Bits	Type	Description
TSSS	[30:0]	r	**Timestamp Sub Seconds** The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When bit 9 (TSCTRLSSR) is set in Register 448 (Timestamp Control Register), each bit represents 1 ns and the maximum value is 0x3B9A_C9FF, after which it rolls-over to zero.
RESERVED_31	31	r	**RESERVED_31**

32-bit Register - System_Time_Seconds_Update

The System Time - Seconds Update register, along with the System Time - Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both of these registers before setting the TSINIT or TSUPDT bits in the Timestamp Control register. This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

ETH_SYSTEM_TIME_SECONDS_UPDATE
Register 452 - System Time - Seconds Update Register (1710_H) Reset Value: 0000 0000_H

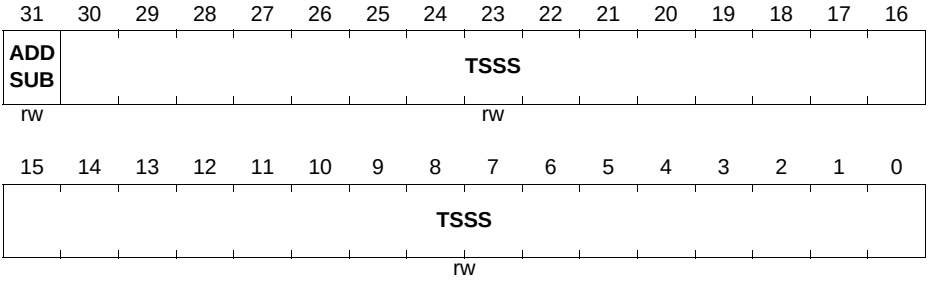


Field	Bits	Type	Description
TSS	[31:0]	rw	**Timestamp Second** The value in this field indicates the time in seconds to be initialized or added to the system time.

32-bit Register - System_Time_Nanoseconds_Update

This register is present only when IEEE 1588 timestamp feature is selected without external timestamp input.

ETH_SYSTEM_TIME_NANOSECONDS_UPDATE
Register 453 - System Time - Nanoseconds Update Register (1714_H) Reset Value: $0000\ 0000_H$

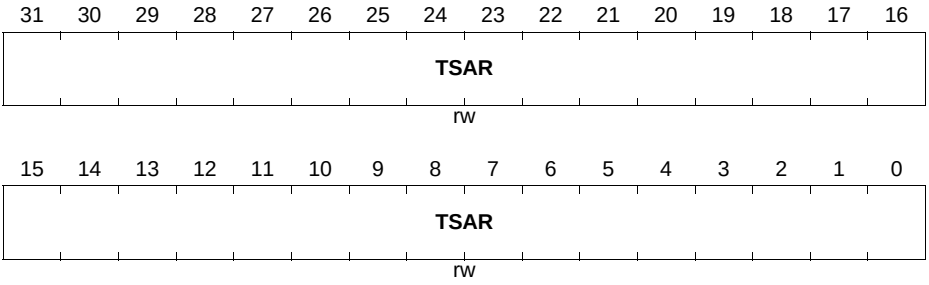


Field	Bits	Type	Description
TSSS	[30:0]	rw	**Timestamp Sub Second** The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When bit 9 (TSCTRLSSR) is set in Register 448 (Timestamp Control Register), each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF.
ADDSUB	31	rw	**Add or subtract time** When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register.

32-bit Register - Timestamp_Addend

This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input. This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in Register 448). This register content is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated whenever the accumulator overflows.

ETH_TIMESTAMP_ADDEND
Register 454 - Timestamp Addend Register (1718_H) **Reset Value: $0000\ 0000_H$**

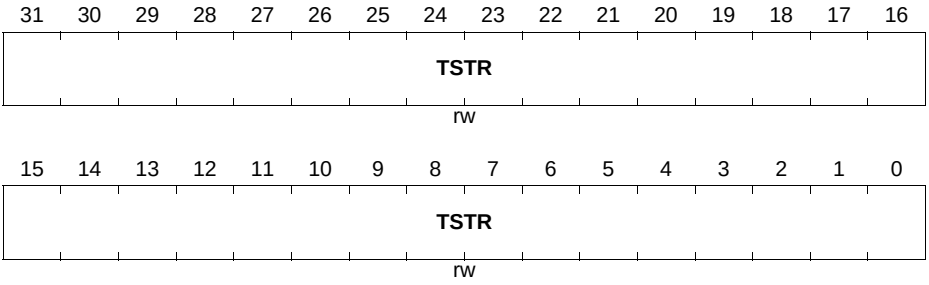


Field	Bits	Type	Description
TSAR	[31:0]	rw	**Timestamp Addend Register** This field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

32-bit Register - Target_Time_Seconds

The Target Time Seconds register, along with Target Time Nanoseconds register, is used to schedule an interrupt event (Register 458[1] when Advanced Timestamping is enabled; otherwise, TS interrupt bit in Register14[9]) when the system time exceeds the value programmed in these registers. This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

ETH_TARGET_TIME_SECONDS
Register 455 - Target Time Seconds Register ($171C_H$) **Reset Value: $0000\ 0000_H$**

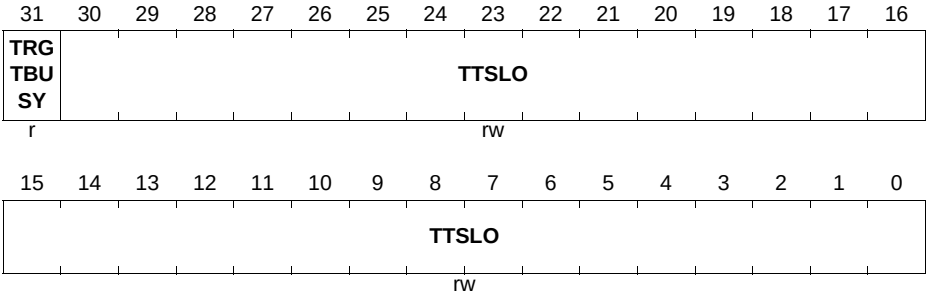


Field	Bits	Type	Description
TSTR	[31:0]	rw	**Target Time Seconds Register** This register stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, then based on Bits [6:5] of Register 459 (PPS Control Register), the MAC starts or stops the PPS signal output and generates an interrupt (if enabled).

32-bit Register - Target_Time_Nanoseconds

This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

ETH_TARGET_TIME_NANOSECONDS
Register 456 - Target Time Nanoseconds Register (1720_H) Reset Value: $0000\ 0000_H$



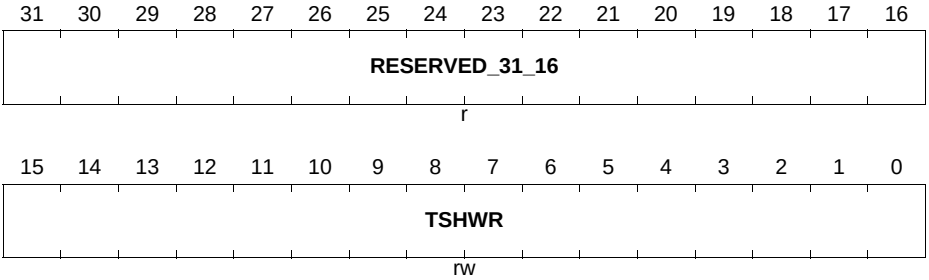
Field	Bits	Type	Description
TTSLO	[30:0]	rw	**Target Timestamp Low Register** This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the both Target Timestamp registers, then based on the TRGTMODSEL0 field (Bits [6:5]) in Register 459 (PPS Control Register), the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). This value should not exceed 0x3B9A_C9FF when TSCTRLSSR is set in the Timestamp control register. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.

Field	Bits	Type	Description
TRGTBUSY	31	r	**Target Time Register Busy** The MAC sets this bit when the PPSCMD field (Bits[3:0]) in Register 459 (PPS Control Register) is programmed to 010 or 011. Programming the PPSCMD field to 010 or 011, instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. This bit is reserved when the Enable Flexible Pulse-Per-Second Output feature is not selected.

32-bit Register - System_Time_Higher_Word_Seconds

This register is present only when the IEEE 1588 Advanced Timestamp feature is selected without an external timestamp input.

ETH_SYSTEM_TIME_HIGHER_WORD_SECONDS
Register 457 - System Time - Higher Word Seconds Register (1724_H) Reset Value: $0000\ 0000_H$



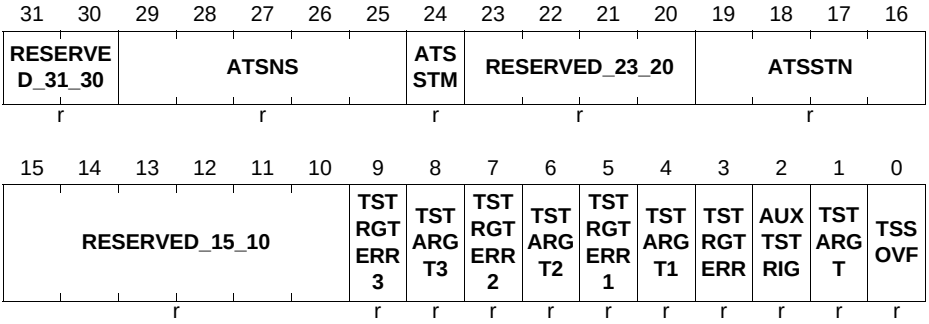
Field	Bits	Type	Description
TSHWR	[15:0]	rw	**Timestamp Higher Word Register** This field contains the most significant 16-bits of the timestamp seconds value. This register is optional and can be selected using the Enable IEEE 1588 Higher Word Register option during core configuration. The register is directly written to initialize the value. This register is incremented when there is an overflow from the 32-bits of the System Time - Seconds register.
RESERVED_31_16	[31:16]	r	**RESERVED_31_16**

32-bit Register - Timestamp_Status

This register is present only when Advanced IEEE 1588 Timestamp feature is selected. All bits except Bits[27:25] gets cleared when the host reads this register.

ETH_TIMESTAMP_STATUS

Register 458 - Timestamp Status Register (1728_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TSSOVF	0	r	**Timestamp Seconds Overflow** When set, this bit indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF.
TSTARGT	1	r	**Timestamp Target Time Reached** When set, this bit indicates that the value of system time is greater or equal to the value specified in the Register 455 (Target Time Seconds Register) and Register 456 (Target Time Nanoseconds Register).
AUXTSTRIG	2	r	**Auxiliary Timestamp Trigger Snapshot** This bit is set high when the auxiliary snapshot is written to the FIFO. This bit is valid only if the Enable IEEE 1588 Auxiliary Snapshot feature is selected.
TSTRGTERR	3	r	**Timestamp Target Time Error** This bit is set when the target time, being programmed in Target Time Registers, is already elapsed. This bit is cleared when read by the application.

Field	Bits	Type	Description
TSTARGT1	4	r	**Timestamp Target Time Reached for Target Time PPS1** When set, this bit indicates that the value of system time is greater than or equal to the value specified in Register 480 (PPS1 Target Time High Register) and Register 481 (PPS1 Target Time Low Register).
TSTRGTERR1	5	r	**Timestamp Target Time Error** This bit is set when the target time, being programmed in Register 480 and Register 481, is already elapsed. This bit is cleared when read by the application.
TSTARGT2	6	r	**Timestamp Target Time Reached for Target Time PPS2** When set, this bit indicates that the value of system time is greater than or equal to the value specified in Register 488 (PPS2 Target Time High Register) and Register 489 (PPS2 Target Time Low Register).
TSTRGTERR2	7	r	**Timestamp Target Time Error** This bit is set when the target time, being programmed in Register 488 and Register 489, is already elapsed. This bit is cleared when read by the application.
TSTARGT3	8	r	**Timestamp Target Time Reached for Target Time PPS3** When set, this bit indicates that the value of system time is greater than or equal to the value specified in Register 496 (PPS3 Target Time High Register) and Register 497 (PPS3 Target Time Low Register).
TSTRGTERR3	9	r	**Timestamp Target Time Error** This bit is set when the target time, being programmed in Register 496 and Register 497, is already elapsed. This bit is cleared when read by the application.
RESERVED_15_10	[15:10]	r	**RESERVED_15_10**

Field	Bits	Type	Description
ATSSTN	[19:16]	r	**Auxiliary Timestamp Snapshot Trigger Identifier** These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. These bits are applicable only if the number of Auxiliary snapshots is more than one. One bit is assigned for each trigger as shown in the following list: * Bit 16: Auxiliary trigger 0 * Bit 17: Auxiliary trigger 1 * Bit 18: Auxiliary trigger 2 * Bit 19: Auxiliary trigger 3 The software can read this register to find the triggers that are set when the timestamp is taken.
RESERVED_23_20	[23:20]	r	**RESERVED_23_20**
ATSSTM	24	r	**Auxiliary Timestamp Snapshot Trigger Missed** This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected during core configuration.
ATSNS	[29:25]	r	**Number of Auxiliary Timestamp Snapshots** This field indicates the number of Snapshots available in the FIFO. A value equal to the selected depth of FIFO (4, 8, or 16) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected during core configuration.
RESERVED_31_30	[31:30]	r	**RESERVED_31_30**

32-bit Register - PPS_Control

This register is present only when the Advanced Timestamp feature is selected and External Timestamp is not enabled. Note: * Bits[30:24] are valid only when four Flexible PPS outputs are selected. * Bits[22:16] are valid only when three or more Flexible PPS outputs are selected. * Bits[14:8] are valid only when two or more Flexible PPS outputs are selected. * Bits[6:4] are valid only when Flexible PPS feature is selected.

ETH_PPS_CONTROL

Register 459 - PPS Control Register ($172C_H$) **Reset Value: $0000\ 0000_H$**

r	r		r		r			r	r		r	rw			

Field	Bits	Type	Description
PPSCTRL _PPSCMD	[3:0]	rw	**PPSCTRL0 or PPSCMD0** PPSCTRL0: PPS0 Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: -0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. -0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. -0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. -0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. -... -1111: The binary rollover is 32.768 KHz, and the digital rollover is 16.384 KHz. Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: * When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms * When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of: - One clock of 50 percent duty cycle and 537 ms period - Second clock of 463 ms period (268 ms low and 195 ms high) * When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of: - Three clocks of 50 percent duty cycle and 268 ms period - Fourth clock of 195 ms period (134 ms low and 61 ms high) This behavior is because of the non-linear toggling of bits in the digital rollover mode in Register 451 (System Time - Nanoseconds Register). Flexible PPS0 Output (ptp_pps_o[0]) Control Programming these bits with a non-zero value instructs

Field	Bits	Type	Description
PPSEN0	4	r	**Flexible PPS Output Mode Enable** When set low, Bits[3:0] function as PPSCTRL (backward compatible). When set high, Bits[3:0] function as PPSCMD.
TRGTMODSEL0	[6:5]	r	**Target Time Register Mode for PPS0 Output** This field indicates the Target Time registers (register 455 and 456) mode for PPS0 output signal: * 00: Indicates that the Target Time registers are programmed only for generating the interrupt event. * 01: Reserved * 10: Indicates that the Target Time registers are programmed for generating the interrupt event and starting or stopping the generation of the PPS0 output signal. * 11: Indicates that the Target Time registers are programmed only for starting or stopping the generation of the PPS0 output signal. No interrupt is asserted.
RESERVED_7	7	r	**RESERVED_7**

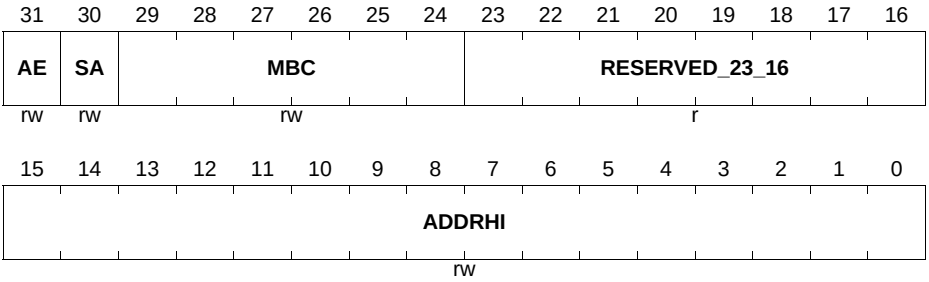
32-bit Register - MAC_Address16_High

The MAC Address16 High register holds the upper 16 bits of the 17th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address16 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address16 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS16_HIGH

Register 512 - MAC Address16 High Register (1800_H) **Reset Value: $0000\ FFFF_H$**



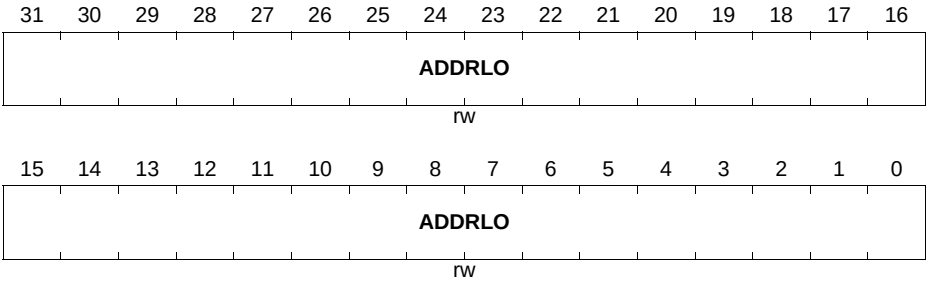
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address16 [47:32]** This field contains the upper 16 bits (47:32) of the 17th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address16 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address16[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address16[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 17th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address16_Low

The MAC Address16 Low register holds the lower 32 bits of the 17th 6-byte MAC address of the station.

ETH_MAC_ADDRESS16_LOW
Register 513 - MAC Address16 Low Register (1804_H) **Reset Value: $FFFF\ FFFF_H$**



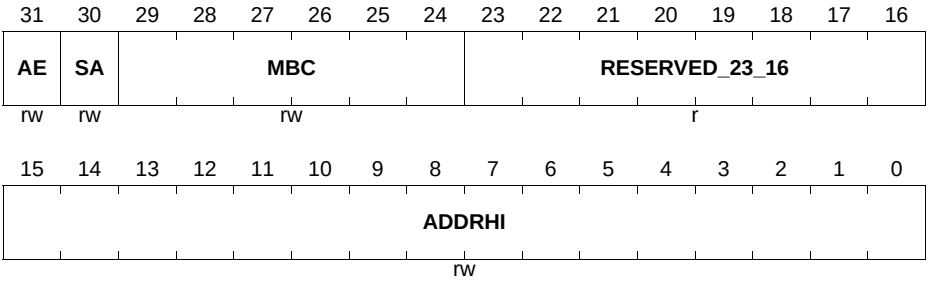
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address16 [31:0]** This field contains the lower 32 bits of the 17th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address17_High

The MAC Address17 High register holds the upper 16 bits of the 18th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address17 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address17 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS17_HIGH

Register 514 - MAC Address17 High Register (1808_H) **Reset Value: $0000\ FFFF_H$**



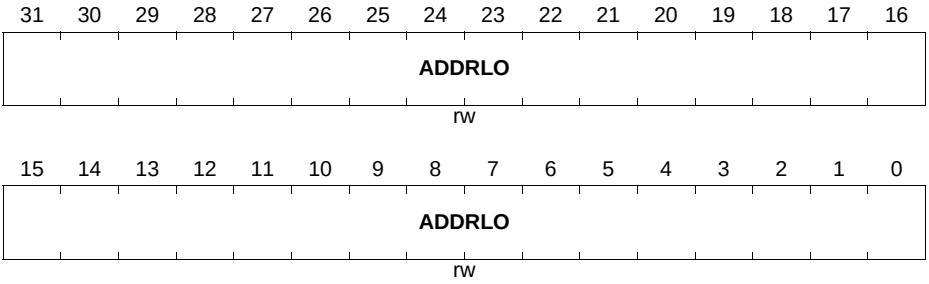
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address18 [47:32]** This field contains the upper 16 bits (47:32) of the 19th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address17 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address17[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address17[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 18th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address17_Low

The MAC Address17 Low register holds the lower 32 bits of the 18th 6-byte MAC address of the station.

ETH_MAC_ADDRESS17_LOW
Register 515 - MAC Address17 Low Register (180C$_H$) Reset Value: FFFF FFFF$_H$



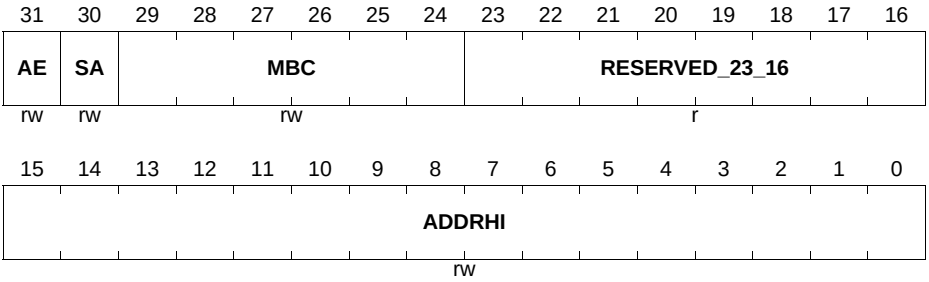
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address17 [31:0]** This field contains the lower 32 bits of the 18th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address18_High

The MAC Address18 High register holds the upper 16 bits of the 19th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address18 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address18 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS18_HIGH

Register 516 - MAC Address18 High Register (1810_H) **Reset Value: $0000\ FFFF_H$**



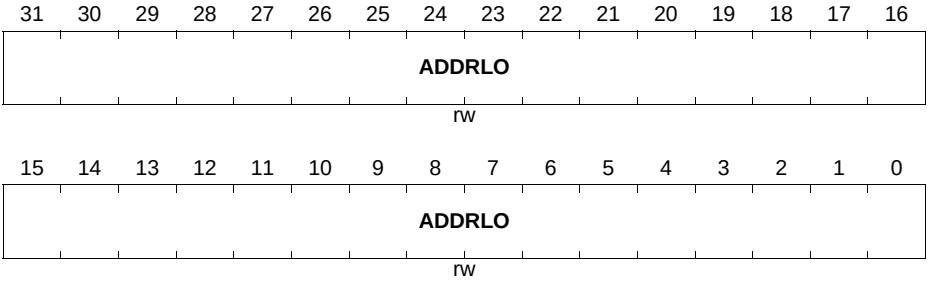
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address18 [47:32]** This field contains the upper 16 bits (47:32) of the 19th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address18 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address18[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address18[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 19th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address18_Low

The MAC Address18 Low register holds the lower 32 bits of the 19th 6-byte MAC address of the station.

ETH_MAC_ADDRESS18_LOW
Register 517 - MAC Address18 Low Register (1814_H) **Reset Value: $FFFF\ FFFF_H$**



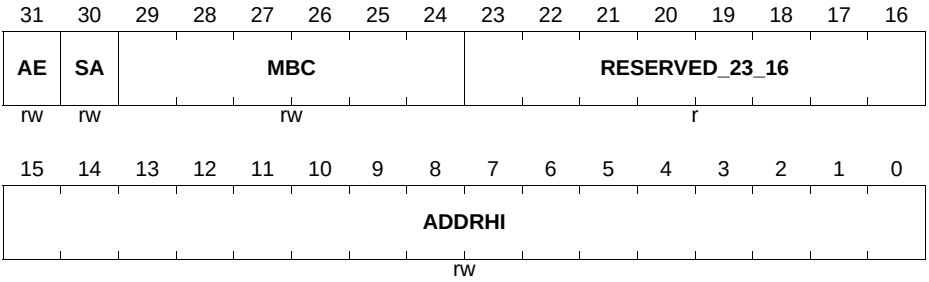
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address18 [31:0]** This field contains the lower 32 bits of the 19th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address19_High

The MAC Address19 High register holds the upper 16 bits of the 20th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address19 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address19 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS19_HIGH

Register 518 - MAC Address19 High Register (1818_H) **Reset Value: $0000\ FFFF_H$**



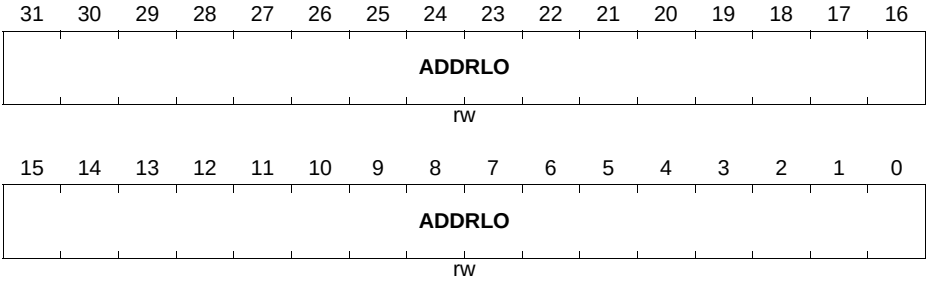
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address19 [47:32]** This field contains the upper 16 bits (47:32) of the 20th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address19 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address19[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address19[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 20th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address19_Low

The MAC Address19 Low register holds the lower 32 bits of the 20th 6-byte MAC address of the station.

ETH_MAC_ADDRESS19_LOW
Register 519 - MAC Address19 Low Register ($181C_H$) **Reset Value: $FFFF\ FFFF_H$**



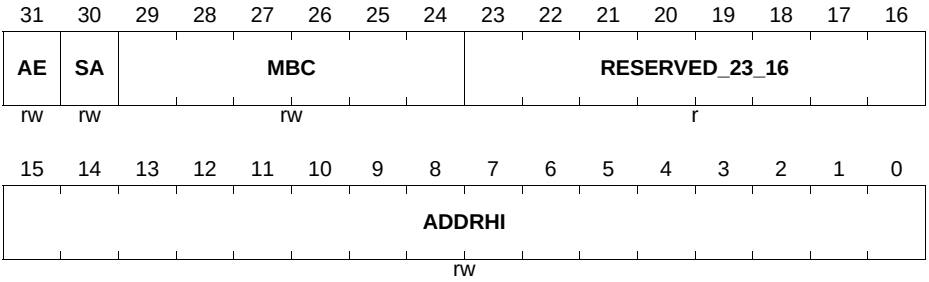
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address19 [31:0]** This field contains the lower 32 bits of the 20th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address20_High

The MAC Address20 High register holds the upper 16 bits of the 21st 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address20 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address20 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS20_HIGH

Register 520 - MAC Address20 High Register (1820_H) **Reset Value: $0000\ FFFF_H$**



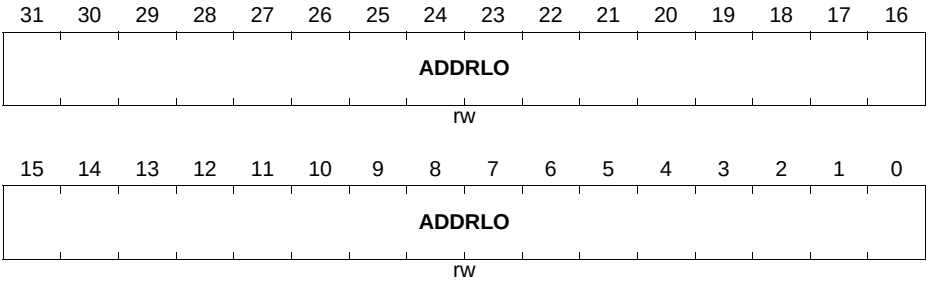
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address20 [47:32]** This field contains the upper 16 bits (47:32) of the 20th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address20 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address20[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address20[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 21st MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address20_Low

The MAC Address20 Low register holds the lower 32 bits of the 21st 6-byte MAC address of the station.

ETH_MAC_ADDRESS20_LOW
Register 521 - MAC Address20 Low Register (1824_H) **Reset Value: FFFF FFFF$_H$**



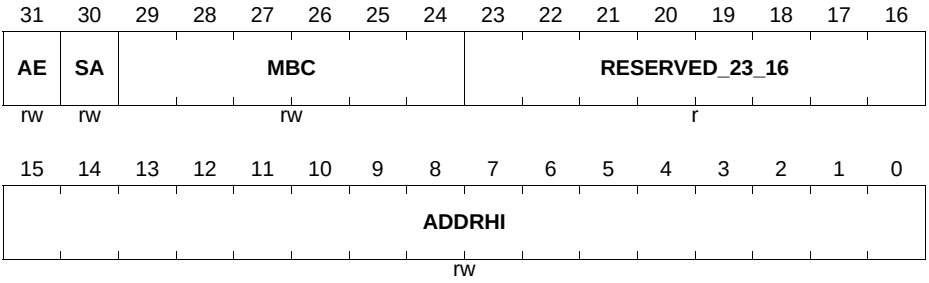
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address20 [31:0]** This field contains the lower 32 bits of the 21st 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address21_High

The MAC Address21 High register holds the upper 16 bits of the 22nd 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address21 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address21 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS21_HIGH

Register 522 - MAC Address21 High Register (1828_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address21 [47:32]** This field contains the upper 16 bits (47:32) of the 6-byte 22nd MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address21 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

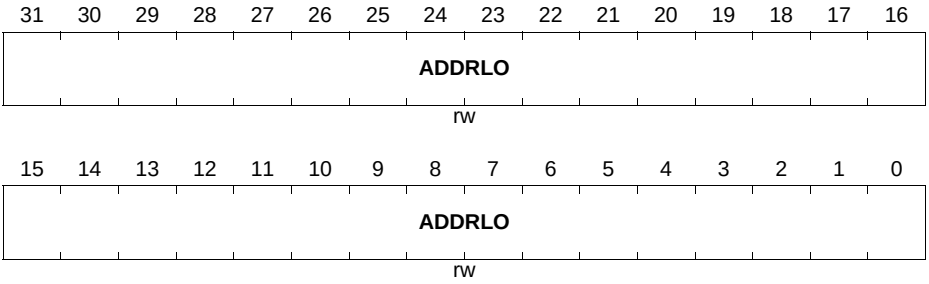
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address21[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address21[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 22nd MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address21_Low

The MAC Address21 Low register holds the lower 32 bits of the 22nd 6-byte MAC address of the station.

ETH_MAC_ADDRESS21_LOW

Register 523 - MAC Address21 Low Register (182C$_H$) Reset Value: FFFF FFFF$_H$



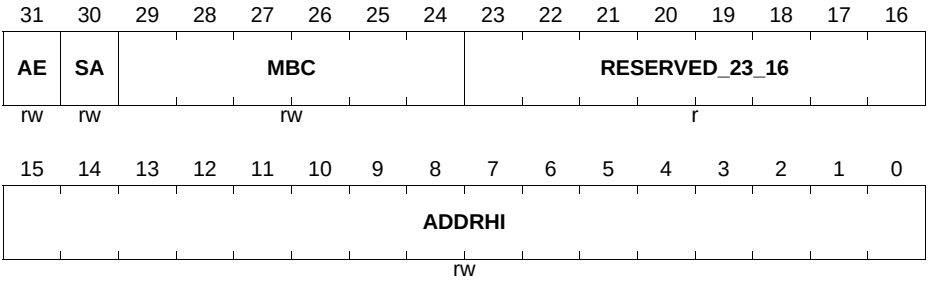
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address21 [31:0]** This field contains the lower 32 bits of the 22nd 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address22_High

The MAC Address22 High register holds the upper 16 bits of the 23rd 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address22 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address22 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS22_HIGH

Register 524 - MAC Address22 High Register (1830_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description

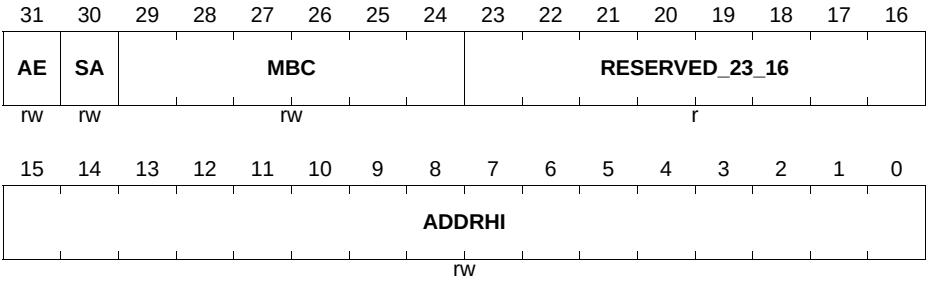
ADDRLO	[31:0]	rw	**MAC Address25 [31:0]** This field contains the lower 32 bits of the 26th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address26_High

The MAC Address26 High register holds the upper 16 bits of the 27th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address26 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address26 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS26_HIGH

Register 532 - MAC Address26 High Register (1850_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address26 [47:32]** This field contains the upper 16 bits (47:32) of the 27th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address26 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

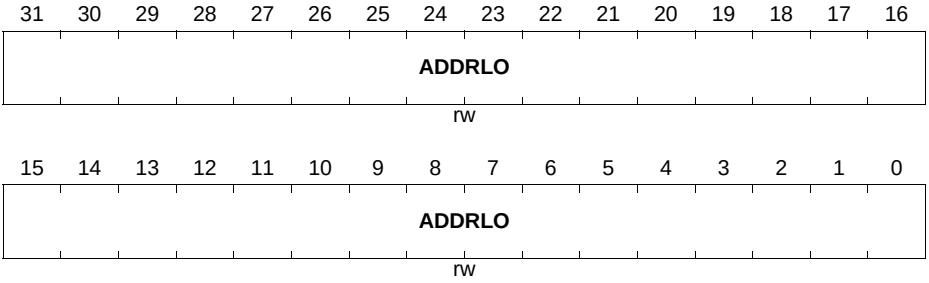
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address26[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address26[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 27th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address26_Low

The MAC Address26 Low register holds the lower 32 bits of the 27th 6-byte MAC address of the station.

ETH_MAC_ADDRESS26_LOW

Register 533 - MAC Address26 Low Register (1854_H) **Reset Value: $FFFF\ FFFF_H$**



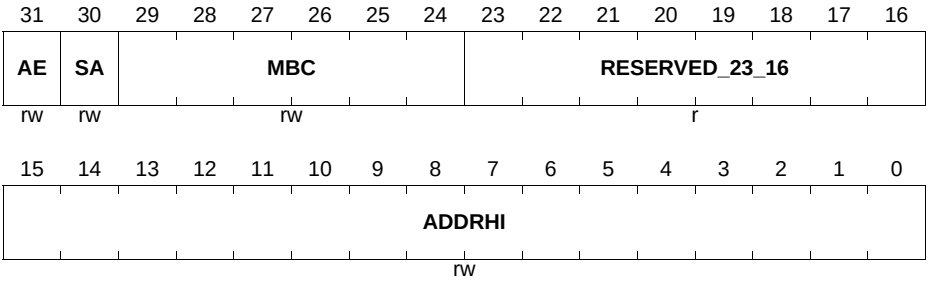
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address26 [31:0]** This field contains the lower 32 bits of the 27th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address27_High

The MAC Address27 High register holds the upper 16 bits of the 28th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address27 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address27 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS27_HIGH

Register 534 - MAC Address27 High Register (1858_H) **Reset Value: $0000\ FFFF_H$**



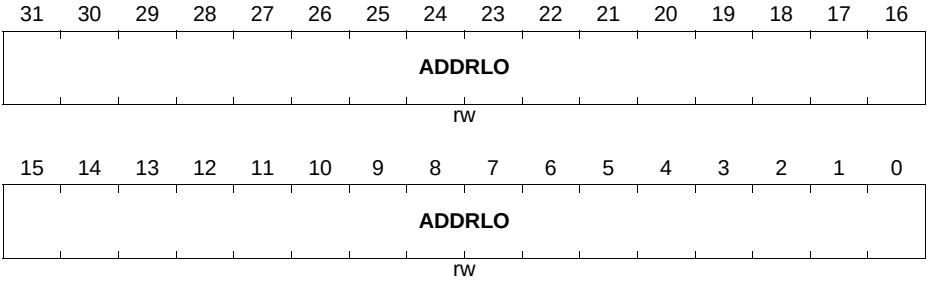
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address27 [47:32]** This field contains the upper 16 bits (47:32) of the 28th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address27 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address27[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address27[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 28th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address27_Low

The MAC Address27 Low register holds the lower 32 bits of the 28th 6-byte MAC address of the station.

ETH_MAC_ADDRESS27_LOW
Register 535 - MAC Address27 Low Register (185C$_H$) Reset Value: FFFF FFFF$_H$



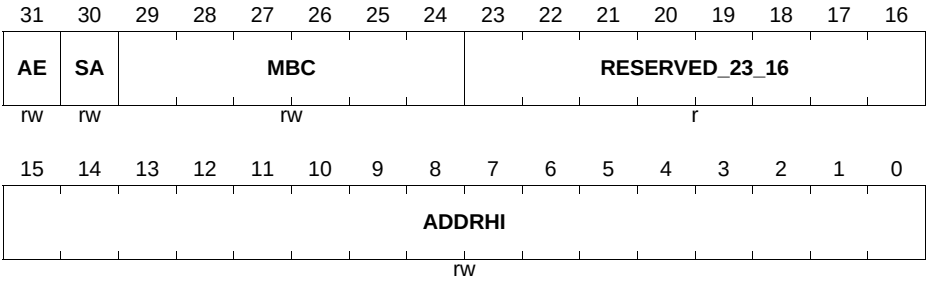
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address27 [31:0]** This field contains the lower 32 bits of the 28th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address28_High

The MAC Address28 High register holds the upper 16 bits of the 29th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address28 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address28 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS28_HIGH

Register 536 - MAC Address28 High Register (1860_H) **Reset Value: $0000\ FFFF_H$**



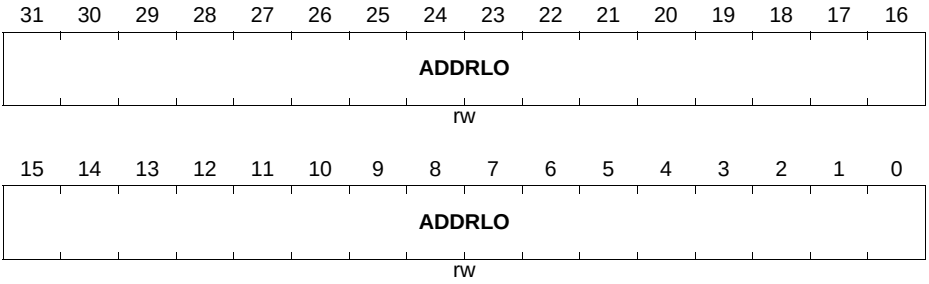
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address28 [47:32]** This field contains the upper 16 bits (47:32) of the 29th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address28 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address28[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address28[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 29th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address28_Low

The MAC Address28 Low register holds the lower 32 bits of the 29th 6-byte MAC address of the station.

ETH_MAC_ADDRESS28_LOW
Register 537 - MAC Address28 Low Register (1864_H) **Reset Value: $FFFF\ FFFF_H$**



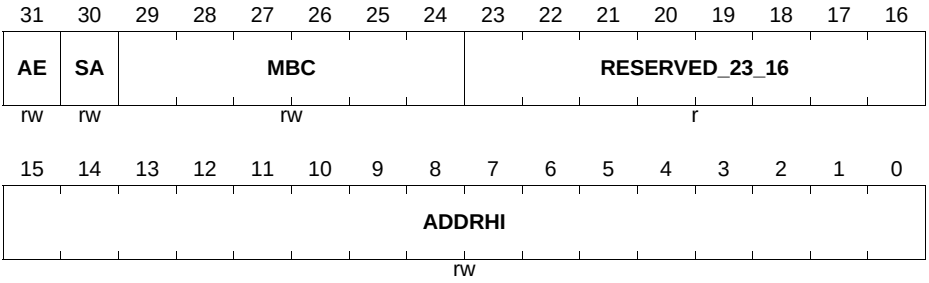
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address28 [31:0]** This field contains the lower 32 bits of the 29th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address29_High

The MAC Address29 High register holds the upper 16 bits of the 6-byte 30th MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address29 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address29 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS29_HIGH

Register 538 - MAC Address29 High Register (1868_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address29 [47:32]** This field contains the upper 16 bits (47:32) of the 30th 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address29 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

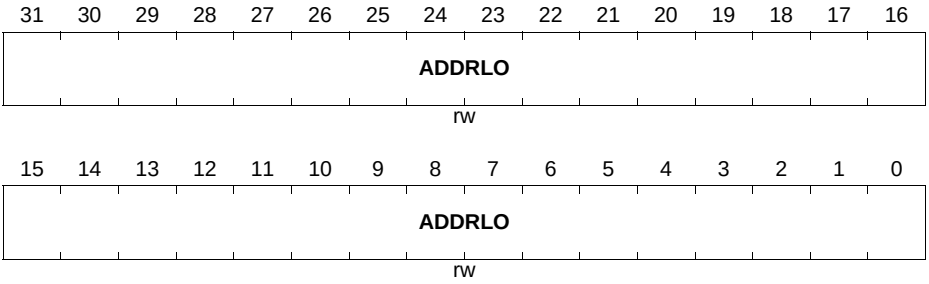
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address29[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address29[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 30th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address29_Low

The MAC Address29 Low register holds the lower 32 bits of the 30th 6-byte MAC address of the station.

ETH_MAC_ADDRESS29_LOW

Register 539 - MAC Address29 Low Register (186C$_H$) Reset Value: FFFF FFFF$_H$



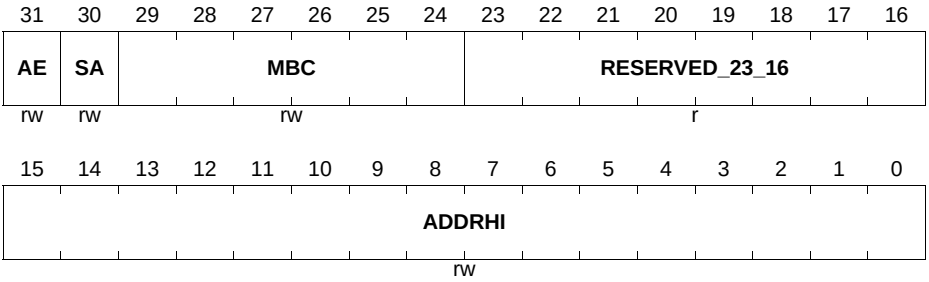
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address29 [31:0]** This field contains the lower 32 bits of the 30th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address30_High

The MAC Address30 High register holds the upper 16 bits of the 31st 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address30 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address30 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS30_HIGH

Register 540 - MAC Address30 High Register (1870_H) **Reset Value: $0000\ FFFF_H$**



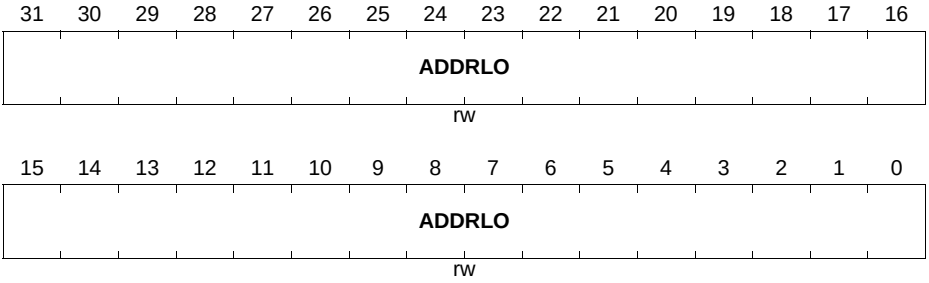
Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address30 [47:32]** This field contains the upper 16 bits (47:32) of the 31st 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address30 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address30[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address30[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 31st MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address30_Low

The MAC Address30 Low register holds the lower 32 bits of the 31st 6-byte MAC address of the station.

ETH_MAC_ADDRESS30_LOW
Register 541 - MAC Address30 Low Register (1874_H) **Reset Value: $FFFF\ FFFF_H$**



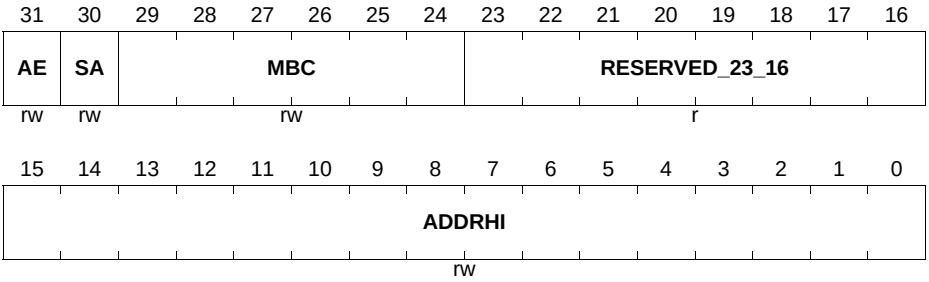
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address30 [31:0]** This field contains the lower 32 bits of the 31st 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address31_High

The MAC Address31 High register holds the upper 16 bits of the 32nd 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address31 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address31 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS31_HIGH

Register 542 - MAC Address31 High Register (1878_H) **Reset Value: $0000\ FFFF_H$**



Field	Bits	Type	Description
ADDRHI	[15:0]	rw	**MAC Address31 [47:32]** This field contains the upper 16 bits (47:32) of the 32nd 6-byte MAC address.
RESERVED_23_16	[23:16]	r	**RESERVED_23_16**
MBC	[29:24]	rw	**Mask Byte Control** These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address31 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

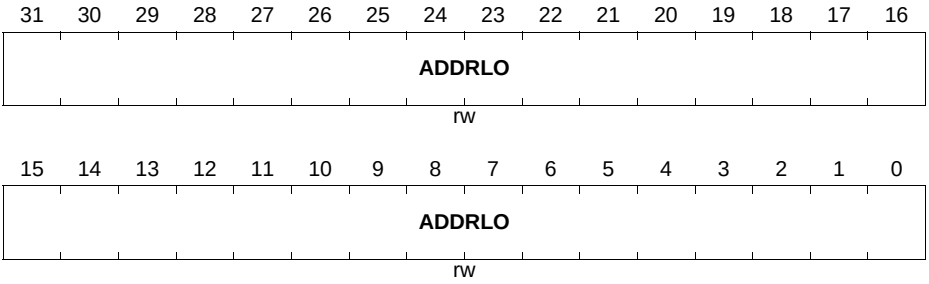
Field	Bits	Type	Description
SA	30	rw	**Source Address** When this bit is set, the MAC Address31[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address31[47:0] is used to compare with the DA fields of the received frame.
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the 32nd MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

32-bit Register - MAC_Address31_Low

The MAC Address31 Low register holds the lower 32 bits of the 32nd 6-byte MAC address of the station.

ETH_MAC_ADDRESS31_LOW

Register 543 - MAC Address31 Low Register (187C$_H$) Reset Value: FFFF FFFF$_H$



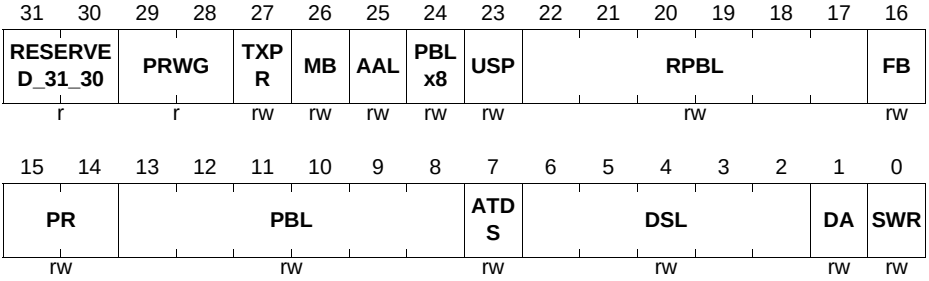
Field	Bits	Type	Description
ADDRLO	[31:0]	rw	**MAC Address31 [31:0]** This field contains the lower 32 bits of the 32nd 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - Bus_Mode

The Bus Mode register establishes the bus operating modes for the DMA.

ETH_BUS_MODE

Register 0 - Bus Mode Register (2000_H) Reset Value: $0002\ 0101_H$



Field	Bits	Type	Description
SWR	0	rw	**Software Reset** When this bit is set, the MAC DMA Controller resets the logic and all internal registers of the MAC. It is cleared automatically after the reset operation has completed in all of the DWC_gmac clock domains. Before reprogramming any register of the DWC_gmac, you should read a zero (0) value in this bit . Note: * The Software reset function is driven only by this bit. Bit 0 of Register 64 (Channel 1 Bus Mode Register) or Register 128 (Channel 2 Bus Mode Register) has no impact on the Software reset function. * The reset operation is completed only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for the software reset completion.

Field	Bits	Type	Description
DA	1	rw	**DMA Arbitration Scheme** This bit specifies the arbitration scheme between the transmit and receive paths of Channel 0. * 0: Weighted round-robin with Rx:Tx or Tx:Rx. The priority between the paths is according to the priority specified in bits 15:14 (PR) and priority weights specified in Bit 27 (TXPR). * 1: Fixed priority. The transmit path has priority over receive path when Bit 27 (TXPR) is set. Otherwise, receive path has priority over the transmit path. In the GMAC-AXI configuration, these bits are reserved and read-only (RO).
DSL	[6:2]	rw	**Descriptor Skip Length** This bit specifies the number of Word, Dword, or Lword (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When the DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA in Ring mode.

Field	Bits	Type	Description
ATDS	7	rw	**Alternate Descriptor Size** When set, the size of the alternate descriptor increases to 32 bytes (8 DWORDS). This is required when the Advanced Timestamp feature or the IPC Full Offload Engine (Type 2) is enabled in the receiver. The enhanced descriptor is not required if the Advanced Timestamp and IPC Full Checksum Offload (Type 2) features are not enabled. In such cases, you can use the 16 bytes descriptor to save 4 bytes of memory. This bit is present only when you select the Alternate Descriptor feature and any one of the following features during core configuration: * Advanced Timestamp feature * IPC Full Checksum Offload Engine (Type 2) feature Otherwise, this bit is reserved and read-only. When reset, the descriptor size reverts back to 4 DWORDs (16 bytes). This bit preserves the backward compatibility for the descriptor size. In versions prior to 3.50a, the descriptor size is 16 bytes for both normal and enhanced descriptor. In version 3.50a, descriptor size is increased to 32 bytes because of the Advanced Timestamp and IPC Full Checksum Offload Engine (Type 2) features.

Field	Bits	Type	Description
PBL	[13:8]	rw	**Programmable Burst Length** These bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. PBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable only for Tx DMA transactions. If the number of beats to be transferred is more than 32, then perform the following steps: 1. Set the PBLx8 mode. 2. Set the PBL. For example, if the maximum number of beats to be transferred is 64, then first set PBLx8 to 1 and then set PBL to 8. The PBL values have the following limitation: The maximum number of possible beats (PBL) is limited by the size of the Tx FIFO and Rx FIFO in the MTL layer and the data bus width on the DMA. The FIFO has a constraint that the maximum beat supported is half the depth of the FIFO, except when specified. For different data bus widths and FIFO sizes, the valid PBL range (including x8 mode) is provided in the following list. If the PBL is common for both transmit and receive DMA, the minimum Rx FIFO and Tx FIFO depths must be considered. Note: In the half-duplex mode, the valid PBL range specified in the following list is applicable only for Tx FIFO. * 32-Bit Data Bus Width - 2 KB and Higher FIFO Depth: All PBL values are supported in the full-duplex mode and half-duplex modes.

Field	Bits	Type	Description
PR	[15:14]	rw	**Priority Ratio** These bits control the priority ratio in the weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when Bit 1 (DA) is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether Bit 27 (TXPR) is reset or set. * 00: The Priority Ratio is 1:1. * 01: The Priority Ratio is 2:1. * 10: The Priority Ratio is 3:1. * 11: The Priority Ratio is 4:1. In the GMAC-AXI configuration, these bits are reserved and read-only (RO).
FB	16	rw	**Fixed Burst** This bit controls whether the AHB or AXI Master interface performs fixed burst transfers or not. When set, the AHB interface uses only SINGLE, INCR4, INCR8, or INCR16 during start of the normal burst transfers. When reset, the AHB or AXI interface uses SINGLE and INCR burst transfer operations. For more information, see Bit 0 (UNDEF) of the AXI Bus Mode register in the GMAC-AXI configuration.
RPBL	[22:17]	rw	**Rx DMA PBL** This field indicates the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read or Write. The Rx DMA always attempts to burst as specified in the RPBL bit each time it starts a Burst transfer on the host bus. You can program RPBL with values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. This field is valid and applicable only when USP is set high.
USP	23	rw	**Use Seperate PBL** When set high, this bit configures the Rx DMA to use the value configured in Bits[22:17] as PBL. The PBL value in Bits[13:8] is applicable only to the Tx DMA operations. When reset to low, the PBL value in Bits[13:8] is applicable for both DMA engines.

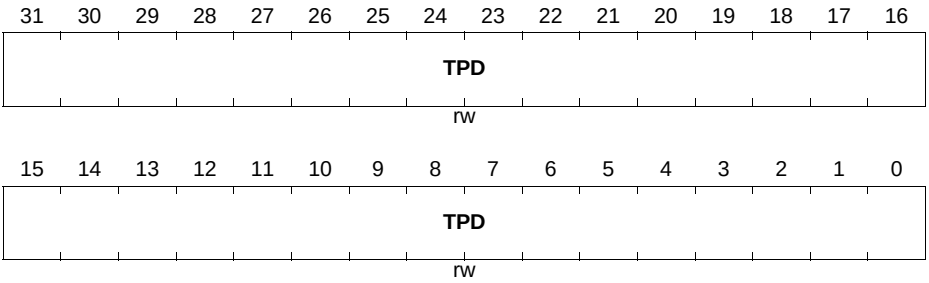
Field	Bits	Type	Description
PBLx8	24	rw	**PBLx8 Mode** When set high, this bit multiplies the programmed PBL value (Bits[22:17] and Bits[13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. Note: This bit function is not backward compatible. Before release 3.50a, this bit was 4xPBL.
AAL	25	rw	**Address Aligned Beats** When this bit is set high and the FB bit is equal to 1, the AHB or AXI interface generates all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffer's start address) is not aligned, but subsequent bursts are aligned to the address. This bit is valid only in the GMAC-AHB and GMAC-AXI configuration and is reserved (RO with default value 0) in all other configurations.
MB	26	rw	**Mixed Burst** When this bit is set high and the FB bit is low, the AHB Master interface starts all bursts of length more than 16 with INCR (undefined burst) whereas it reverts to fixed burst transfers (INCRx and SINGLE) for burst length of 16 and less. This bit is valid only in the GMAC-AHB configuration and reserved in all other configuration.
TXPR	27	rw	**Transmit Priority** When set, this bit indicates that the transmit DMA has higher priority than the receive DMA during arbitration for the system-side bus. In the GMAC-AXI configuration, this bit is reserved and read-only (RO).

Field	Bits	Type	Description
PRWG	[29:28]	r	**Channel Priority Weights** This field sets the priority weights for Channel 0 during the round-robin arbitration between the DMA channels for the system bus. * 00: The priority weight is 1. * 01: The priority weight is 2. * 10: The priority weight is 3. * 11: The priority weight is 4. This field is present in all DWC_gmac configurations except GMAC-AXI when you select the AV feature. Otherwise, this field is reserved and read-only (RO).
RESERVED_31_30	[31:30]	r	**RESERVED_31_30**

32-bit Register - Transmit_Poll_Demand

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

ETH_TRANSMIT_POLL_DEMAND
Register 1 - Transmit Poll Demand Register (2004_H) **Reset Value: $0000\ 0000_H$**



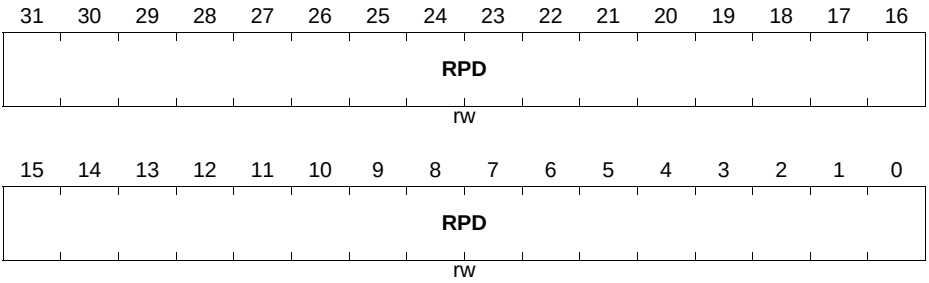
Field	Bits	Type	Description
TPD	[31:0]	rw	**Transmit Poll Demand** When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 18 (Current Host Transmit Descriptor Register). If that descriptor is not available (owned by the Host), the transmission returns to the Suspend state and the Bit 2 (TU) of Register 5 (Status Register) is asserted. If the descriptor is available, the transmission resumes.

32-bit Register - Receive_Poll_Demand

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

ETH_RECEIVE_POLL_DEMAND

Register 2 - Receive Poll Demand Register (2008_H) **Reset Value: $0000\ 0000_H$**

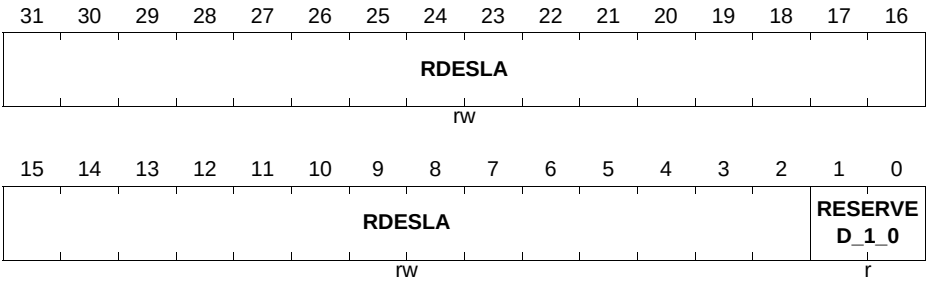


Field	Bits	Type	Description
RPD	[31:0]	rw	**Receive Poll Demand** When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 19 (Current Host Receive Descriptor Register). If that descriptor is not available (owned by the Host), the reception returns to the Suspended state and the Bit 7 (RU) of Register 5 (Status Register) is not asserted. If the descriptor is available, the Rx DMA returns to the active state.

32-bit Register - Receive_Descriptor_List_Address

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

ETH_RECEIVE_DESCRIPTOR_LIST_ADDRESS
Register 3 - Receive Descriptor List Address Register ($200C_H$) Reset Value: $0000\ 0000_H$

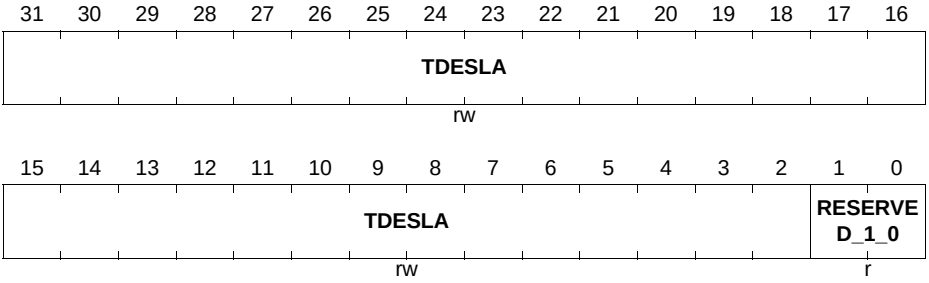


Field	Bits	Type	Description
RESERVED_1_0	[1:0]	r	**RESERVED_1_0**
RDESLA	[31:2]	rw	**Start of Receive List** This field contains the base address of the first descriptor in the Receive Descriptor list. The LSB bits (1:0) for 32-bit bus width are ignored and internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).

32-bit Register - Transmit_Descriptor_List_Address

The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

ETH_TRANSMIT_DESCRIPTOR_LIST_ADDRESS
Register 4 - Transmit Descriptor List Address Register (2010_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
RESERVED_1_0	[1:0]	r	**RESERVED_1_0**
TDESLA	[31:2]	rw	**Start of Transmit List** This field contains the base address of the first descriptor in the Transmit Descriptor list. The LSB bits (1:0) for 32-bit bus width are ignored and are internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).

32-bit Register - Status

The Status register contains all status bits that the DMA reports to the host. The Software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

ETH_STATUS
Register 5 - Status Register **(2014_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RESERVED_31	GLPII	TTI	GPI	GMI	GLI	EB			TS			RS			NIS
r	r	r	r	r	r	r			r			r			rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
AIS	ERI	FBI	RESERVED_12_11		ETI	RWT	RPS	RU	RI	UNF	OVF	TJT	TU	TPS	TI
rw	rw	rw	r		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
TI	0	rw	**Transmit Interrupt** This bit indicates that the frame transmission is complete. When transmission is complete, the Bit 31 (Interrupt on Completion) of TDES1 is reset in the first descriptor, and the specific frame status information is updated in the descriptor.
TPS	1	rw	**Transmit Process Stopped** This bit is set when the transmission is stopped.
TU	2	rw	**Transmit Buffer Unavailable** This bit indicates that the host owns the Next Descriptor in the Transmit List and the DMA cannot acquire it. Transmission is suspended. Bits[22:20] explain the Transmit Process state transitions. To resume processing Transmit descriptors, the host should change the ownership of the descriptor by setting TDES0[31] and then issue a Transmit Poll Demand command.

Field	Bits	Type	Description
TJT	3	rw	**Transmit Jabber Timeout** This bit indicates that the Transmit Jabber Timer expired, which happens when the frame size exceeds 2,048 (10,240 bytes when the Jumbo frame is enabled). When the Jabber Timeout occurs, the transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.
OVF	4	rw	**Receive Overflow** This bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to the application, the overflow status is set in RDES0[11].
UNF	5	rw	**Transmit Underflow** This bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.
RI	6	rw	**Receive Interrupt** This bit indicates that the frame reception is complete. When reception is complete, the Bit 31 of RDES1 (Disable Interrupt on Completion) is reset in the last Descriptor, and the specific frame status information is updated in the descriptor. The reception remains in the Running state.
RU	7	rw	**Receive Buffer Unavailable** This bit indicates that the host owns the Next Descriptor in the Receive List and the DMA cannot acquire it. The Receive Process is suspended. To resume processing Receive descriptors, the host should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, the Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor is owned by the DMA.
RPS	8	rw	**Receive Process Stopped** This bit is asserted when the Receive Process enters the Stopped state.

Field	Bits	Type	Description
RWT	9	rw	**Receive Watchdog Timeout** This bit is asserted when a frame with length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled).
ETI	10	rw	**Early Transmit Interrupt** This bit indicates that the frame to be transmitted is fully transferred to the MTL Transmit FIFO.
RESERVED_12_11	[12:11]	r	**RESERVED_12_11**
FBI	13	rw	**Fatal Bus Error Interrupt** This bit indicates that a bus error occurred, as described in Bits[25:23]. When this bit is set, the corresponding DMA engine disables all of its bus accesses.
ERI	14	rw	**Early Receive Interrupt** This bit indicates that the DMA had filled the first data buffer of the packet. Bit 6 (RI) of this register automatically clears this bit.
AIS	15	rw	**Abnormal Interrupt Summary** Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[1]: Transmit Process Stopped * Register 5[3]: Transmit Jabber Timeout * Register 5[4]: Receive FIFO Overflow * Register 5[5]: Transmit Underflow * Register 5[7]: Receive Buffer Unavailable * Register 5[8]: Receive Process Stopped * Register 5[9]: Receive Watchdog Timeout * Register 5[10]: Early Transmit Interrupt * Register 5[13]: Fatal Bus Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit, which causes AIS to be set, is cleared.

Field	Bits	Type	Description
NIS	16	rw	**Normal Interrupt Summary** Normal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[0]: Transmit Interrupt * Register 5[2]: Transmit Buffer Unavailable * Register 5[6]: Receive Interrupt * Register 5[14]: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in Register 7) affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing 1 to this bit) each time a corresponding bit, which causes NIS to be set, is cleared.
RS	[19:17]	r	**Received Process State** This field indicates the Receive DMA FSM state. This field does not generate an interrupt. * 3'b000: Stopped: Reset or Stop Receive Command issued * 3'b001: Running: Fetching Receive Transfer Descriptor * 3'b010: Reserved for future use * 3'b011: Running: Waiting for receive packet * 3'b100: Suspended: Receive Descriptor Unavailable * 3'b101: Running: Closing Receive Descriptor * 3'b110: TIME_STAMP write state * 3'b111: Running: Transferring the receive packet data from receive buffer to host memory

Field	Bits	Type	Description
TS	[22:20]	r	**Transmit Process State** This field indicates the Transmit DMA FSM state. This field does not generate an interrupt. * 3'b000: Stopped; Reset or Stop Transmit Command issued * 3'b001: Running; Fetching Transmit Transfer Descriptor * 3'b010: Running; Waiting for status * 3'b011: Running; Reading Data from host memory buffer and queuing it to transmit buffer (Tx FIFO) * 3'b100: TIME_STAMP write state * 3'b101: Reserved for future use * 3'b110: Suspended; Transmit Descriptor Unavailable or Transmit Buffer Underflow * 3'b111: Running; Closing Transmit Descriptor
EB	[25:23]	r	**Error Bits** This field indicates the type of error that caused a Bus Error, for example, error response on the AHB or AXI interface. This field is valid only when Bit 13 (FBI) is set. This field does not generate an interrupt. * Bit 23 - 1'b1: Error during data transfer by the Tx DMA - 1'b0: Error during data transfer by the Rx DMA * Bit 24 - 1'b1: Error during read transfer - 1'b0: Error during write transfer * Bit 25 - 1'b1: Error during descriptor access - 1'b0: Error during data buffer access
GLI	26	r	**GMAC Line interface Interrupt** This bit reflects an interrupt event in the PCS (link change and AN complete), SMII (link change), or RGMII (link change) interface block of the DWC_gmac. The software must read the corresponding registers (Register 49 for PCS or Register 54 for SMII or RGMII) in the DWC_gmac to get the exact cause of the interrupt and clear the source of interrupt to make this bit as 1'b0. The interrupt signal from the DWC_gmac subsystem (sbd_intr_o) is high when this bit is high.

Field	Bits	Type	Description
GMI	27	r	**GMAC MMC Interrupt** This bit reflects an interrupt event in the MMC module of the DWC_gmac. The software must read the corresponding registers in the DWC_gmac to get the exact cause of interrupt and clear the source of interrupt to make this bit as 1'b0. The interrupt signal from the DWC_gmac subsystem (sbd_intr_o) is high when this bit is high. This bit is applicable only when the MAC Management Counters (MMC) are enabled. Otherwise, this bit is reserved.
GPI	28	r	**GMAC PMT Interrupt** This bit indicates an interrupt event in the PMT module of the DWC_gmac. The software must read the PMT Control and Status Register in the MAC to get the exact cause of interrupt and clear its source to reset this bit to 1'b0. The interrupt signal from the DWC_gmac subsystem (sbd_intr_o) is high when this bit is high. This bit is applicable only when the Power Management feature is enabled. Otherwise, this bit is reserved. Note: This interrupt is different from the pmt_intr_o interrupt.
TTI	29	r	**Timestamp Trigger Interrupt** This bit indicates an interrupt event in the Timestamp Generator block of DWC_gmac. The software must read the corresponding registers in the DWC_gmac to get the exact cause of interrupt and clear its source to reset this bit to 1'b0. When this bit is high, the interrupt signal from the DWC_gmac subsystem (sbd_intr_o) is high. This bit is applicable only when the IEEE 1588 Timestamp feature is enabled. Otherwise, this bit is reserved.

Field	Bits	Type	Description
GLPII	30	r	**GMAC LPI Interrupt (for Channel 0)** This bit indicates an interrupt event in the LPI logic of the DWC_gmac. To reset this bit to 1'b0, the software must read the corresponding registers in the DWC_gmac to get the exact cause of the interrupt and clear its source. Note: GLPII status is given only in Channel 0 DMA register and is applicable only when the Energy Efficient Ethernet feature is enabled. Otherwise, this bit is reserved.When this bit is high, the interrupt signal from the MAC (sbd_intr_o) is high.
RESERVED_31	31	r	**RESERVED_31**

32-bit Register - Operation_Mode

The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization. This register is also present in the GMAC-MTL configuration with unused and reserved bits 24, 13, 2, and 1.

ETH_OPERATION_MODE

Register 6 - Operation Mode Register (2018_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw		rw	rw		rw		rw	rw	rw	r	rw		rw	rw	r

Field	Bits	Type	Description
RESERVED_0	0	r	**RESERVED_0**

Field	Bits	Type	Description
SR	1	rw	**Start or Stop Receive** When this bit is set, the Receive process is placed in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes the incoming frames. The descriptor acquisition is attempted from the current position in the list, which is the address set by Register 3 (Receive Descriptor List Address Register) or the position retained when the Receive process was previously stopped. If the DMA does not own the descriptor, reception is suspended and Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set. The Start Receive command is effective only when the reception has stopped. If the command is issued before setting Register 3 (Receive Descriptor List Address Register), the DMA behavior is unpredictable. When this bit is cleared, the Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state.
OSF	2	rw	**Operate on Second Frame** When this bit is set, it instructs the DMA to process the second frame of the Transmit data even before the status for the first frame is obtained.
RTC	[4:3]	rw	**Receive Threshold Control** These two bits control the threshold level of the MTL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MTL Receive FIFO is larger than the threshold. In addition, full frames with length less than the threshold are transferred automatically. The value of 11 is not applicable if the configured Receive FIFO size is 128 bytes. These bits are valid only when the RSF bit is zero, and are ignored when the RSF bit is set to 1. * 00: 64 * 01: 32 * 10 : 96 * 11: 128

Field	Bits	Type	Description
RESERVED_5	5	r	**RESERVED_5**
FUF	6	rw	**Forward Undersized Good Frames** When set, the Rx FIFO forwards Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC. When reset, the Rx FIFO drops all frames of less than 64 bytes, unless a frame is already transferred because of the lower value of Receive Threshold, for example, RTC = 01.
FEF	7	rw	**Forward Error Frames** When this bit is reset, the Rx FIFO drops frames with error status (CRC error, collision error, GMII_ER, giant frame, watchdog timeout, or overflow). However, if the start byte (write) pointer of a frame is already transferred to the read controller side (in Threshold mode), then the frame is not dropped. In the GMAC-MTL configuration in which the Frame Length FIFO is also enabled during core configuration, the Rx FIFO drops the error frames if that frame's start byte is not transferred (output) on the ARI bus. When the FEF bit is set, all frames except runt error frames are forwarded to the DMA. If the Bit 25 (RSF) is set and the Rx FIFO overflows when a partial frame is written, then the frame is dropped irrespective of the FEF bit setting. However, if the Bit 25 (RSF) is reset and the Rx FIFO overflows when a partial frame is written, then a partial frame may be forwarded to the DMA.
EFC	8	rw	**Enable HW Flow Control** When this bit is set, the flow control signal operation based on the fill-level of Rx FIFO is enabled. When reset, the flow control operation is disabled. This bit is not used (reserved and always reset) when the Rx FIFO is less than 4 KB.

Field	Bits	Type	Description
RFA	[10:9]	rw	**Threshold for Activating Flow Control (in half-duplex and full-duplex)** These bits control the threshold (Fill level of Rx FIFO) at which the flow control is activated. - 00: Full minus 1 KB, that is, FULL - 1KB - 01: Full minus 2 KB, that is, FULL - 2KB - 10: Full minus 3 KB, that is, FULL - 3KB - 11: Full minus 4 KB, that is, FULL - 4KB These values only apply to Rx FIFOs of 4 KB or more when the EFC bit is set high. If the Rx FIFO is 8 KB or more, an additional bit (RFA_2) is used for more threshold levels as described in Bit 23. These bits are reserved and read-only when the depth of Rx FIFO is less than 4 KB.
RFD	[12:11]	rw	**Threshold for Deactivating Flow Control (in half-duplex and full-duplex)** These bits control the threshold (Fill-level of Rx FIFO) at which the flow control is de-asserted after activation. - 00: Full minus 1 KB, that is, FULL - 1KB - 01: Full minus 2 KB, that is, FULL - 2KB - 10: Full minus 3 KB, that is, FULL - 3KB - 11: Full minus 4 KB, that is, FULL - 4KB The de-assertion is effective only after flow control is asserted. If the Rx FIFO is 8 KB or more, an additional bit (RFD_2) is used for more threshold levels as described in Bit 22. These bits are reserved and read-only when the Rx FIFO depth is less than 4 KB.

Field	Bits	Type	Description
ST	13	rw	**Start or Stop Transmission Command** When this bit is set, transmission is placed in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Register 4 (Transmit Descriptor List Address Register), or from the position retained when transmission was stopped previously. If the DMA does not own the current descriptor, transmission enters the Suspended state and Bit 2 (Transmit Buffer Unavailable) of Register 5 (Status Register) is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting Register 4 (Transmit Descriptor List Address Register), then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and it becomes the current position when transmission is restarted. To change the list address, you need to program Register 4 (Transmit Descriptor List Address Register) with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.

Field	Bits	Type	Description
TTC	[16:14]	rw	**Transmit Threshold Control** These bits control the threshold level of the MTL Transmit FIFO. Transmission starts when the frame size within the MTL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when Bit 21 (TSF) is reset. * 000: 64 * 001: 128 * 010: 192 * 011: 256 * 100: 40 * 101: 32 * 110: 24 * 111: 16
RESERVED_19_17	[19:17]	r	**RESERVED_19_17**
FTF	20	rw	**Flush Transmit FIFO** When this bit is set, the transmit FIFO controller logic is reset to its default values and thus all data in the Tx FIFO is lost or flushed. This bit is cleared internally when the flushing operation is completed. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation is complete only when the Tx FIFO is emptied of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. To complete this flush operation, the PHY transmit clock (clk_tx_i) is required to be active.
TSF	21	rw	**Transmit Store and Forward** When this bit is set, transmission starts when a full frame resides in the MTL Transmit FIFO. When this bit is set, the TTC values specified in Bits[16:14] are ignored. This bit should be changed only when the transmission is stopped.

Field	Bits	Type	Description
RFD_2	22	r	**MSB of Threshold for Deactivating Flow Control** If the DWC_gmac is configured for Rx FIFO size of 8 KB or more, this bit (when set) provides additional threshold levels for deactivating the flow control in both half-duplex and full-duplex modes. This bit (as Most Significant Bit) along with the RFD (Bits[12:11]) gives the following thresholds for deactivating flow control: * 100: Full minus 5 KB, that is, FULL - 5KB * 101: Full minus 6 KB, that is, FULL - 6KB * 110: Full minus 7 KB, that is, FULL - 7KB * 111: Reserved This bit is reserved (and RO) if the Rx FIFO is 4 KB or less deep.
RFA_2	23	r	**MSB of Threshold for Activating Flow Control** If the DWC_gmac is configured for an Rx FIFO depth of 8 KB or more, this bit (when set) provides additional threshold levels for activating the flow control in both half-duplex and full-duplex modes. This bit (as Most Significant Bit) along with the RFA (Bits[10:9]) gives the following thresholds for activating flow control: * 100: Full minus 5 KB, that is, FULL - 5KB * 101: Full minus 6 KB, that is, FULL - 6KB * 110: Full minus 7 KB, that is, FULL - 7KB * 111: Reserved This bit is reserved (and RO) if the Rx FIFO is 4 KB or less deep.
DFF	24	rw	**Disable Flushing of Received Frames** When this bit is set, the Rx DMA does not flush any frames because of the unavailability of receive descriptors or buffers as it does normally when this bit is reset. This bit is reserved (and RO) in the GMAC-MTL configuration.

Field	Bits	Type	Description
RSF	25	rw	**Receive Store and Forward** When this bit is set, the MTL reads a frame from the Rx FIFO only after the complete frame has been written to it, ignoring the RTC bits. When this bit is reset, the Rx FIFO operates in the cut-through mode, subject to the threshold specified by the RTC bits.
DT	26	rw	**Disable Dropping of TCP/IP Checksum Error Frames** When this bit is set, the MAC does not drop the frames which only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors only in the encapsulated payload. When this bit is reset, all error frames are dropped if the FEF bit is reset. If the IPC Full Checksum Offload Engine (Type 2) is disabled, this bit is reserved (RO with value 1'b0).
RESERVED_31_27	[31:27]	r	**RESERVED_31_27**

32-bit Register - Interrupt_Enable

The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

ETH_INTERRUPT_ENABLE

Register 7 - Interrupt Enable Register (201C$_H$) **Reset Value: 0000 0000$_H$**

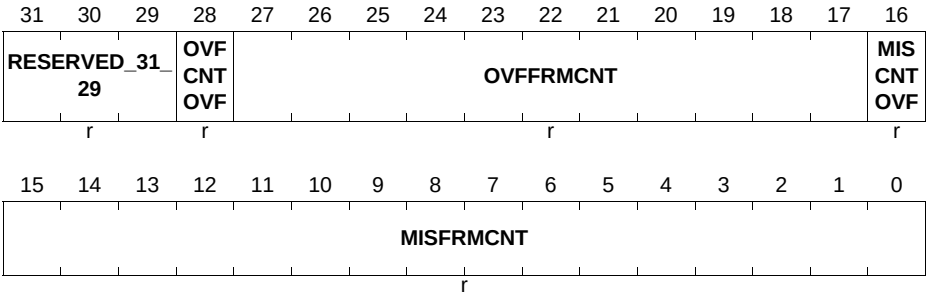
RESERVED_31_17	[31:17]	r	**RESERVED_31_17**

32-bit Register - Missed_Frame_And_Buffer_Overflow_Counter

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

ETH_MISSED_FRAME_AND_BUFFER_OVERFLOW_COUNTER
Register 8 - Missed Frame and Buffer Overflow Counter Register (2020_H) Reset Value: 0000 0000_H



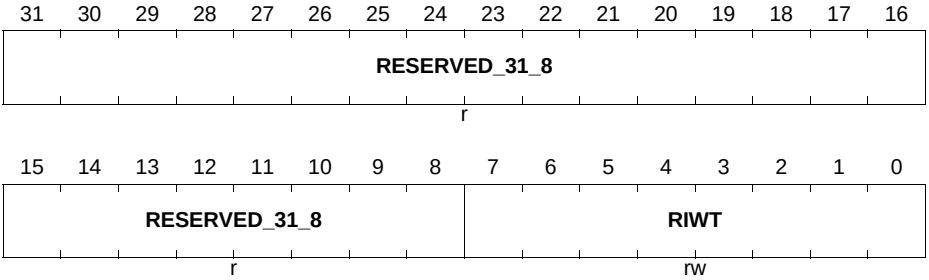
Field	Bits	Type	Description
MISFRMCNT	[15:0]	r	**MISFRMCNT** This field indicates the number of frames missed by the controller because of the Host Receive Buffer being unavailable. This counter is incremented each time the DMA discards an incoming frame. The counter is cleared when this register is read with mci_be_i[0] at 1'b1.
MISCNTOVF	16	r	**MISCNTOVF** Overflow bit for Missed Frame Counter
OVFFRMCNT	[27:17]	r	**OVFFRMCNT** This field indicates the number of frames missed by the application. This counter is incremented each time the MTL asserts the sideband signal mtl_rxoverflow_o. The counter is cleared when this register is read with mci_be_i[2] at 1'b1.

Field	Bits	Type	Description
OVFCNTOVF	28	r	**OVFCNTOVF** Overflow bit for FIFO Overflow Counter
RESERVED_31_29	[31:29]	r	**RESERVED_31_29**

32-bit Register - Receive_Interrupt_Watchdog_Timer

This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt (Bit 6) of Register 5 (Status Register)

ETH_RECEIVE_INTERRUPT_WATCHDOG_TIMER
Register 9 - Receive Interrupt Watchdog Timer Register (2024_H)Reset Value: 0000 0000_H

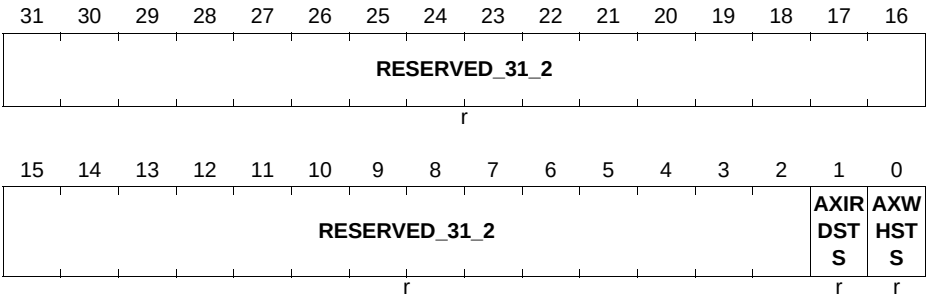


Field	Bits	Type	Description
RIWT	[7:0]	rw	**RI Watchdog Timer Count** This bit indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per RDES1[31] of any received frame.
RESERVED_31_8	[31:8]	r	**RESERVED_31_8**

32-bit Register - AHB_or_AXI_Status

This register provides the active status of the AHB master interface or AXI interface's read and write channels. This register is present and valid only in the GMAC-AHB and GMAC-AXI configurations. This register is useful for debugging purposes. In addition, this register is valid only in the Channel 0 DMA when multiple channels are present in the AV mode.

ETH_AHB_OR_AXI_STATUS
Register 11 - AHB or AXI Status Register ($202C_H$) **Reset Value: $0000\ 0000_H$**

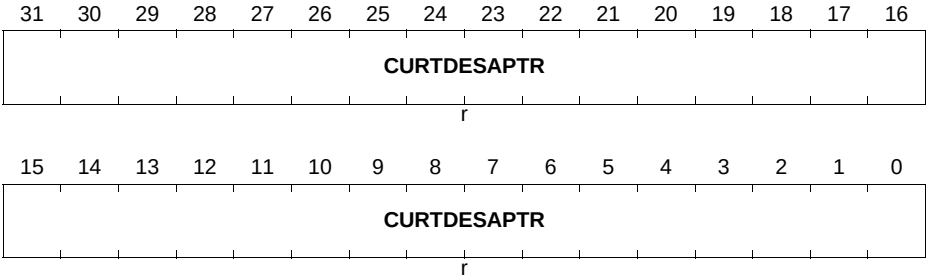


Field	Bits	Type	Description
AXWHSTS	0	r	**AXI Master Write Channel or AHB Master Status** When high, it indicates that AXI Master's write channel is active and transferring data in the GMAC-AXI configuration. In the GMAC-AHB configuration, it indicates that the AHB master interface FSMs are in the non-idle state.
AXIRDSTS	1	r	**AXI Master Read Channel Status** When high, it indicates that AXI Master's read channel is active and transferring data.
RESERVED_31_2	[31:2]	r	**RESERVED_31_2**

32-bit Register - Current_Host_Transmit_Descriptor

The Current Host Transmit Descriptor register points to the start address of the current Transmit Descriptor read by the DMA.

ETH_CURRENT_HOST_TRANSMIT_DESCRIPTOR
Register 18 - Current Host Transmit Descriptor Register (2048_H)Reset Value: 0000 0000_H

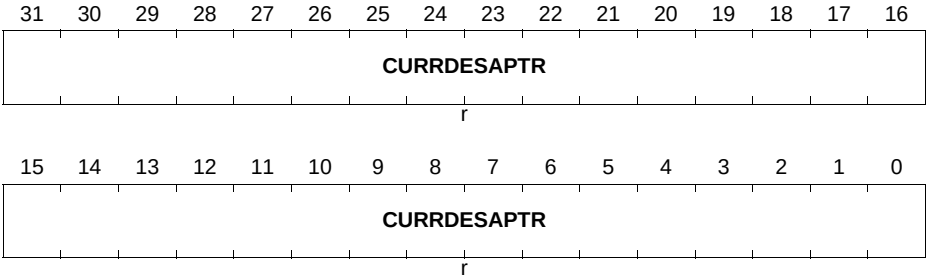


Field	Bits	Type	Description
CURTDESAPTR	[31:0]	r	**Host Transmit Descriptor Address Pointer** Cleared on Reset. Pointer updated by the DMA during operation.

32-bit Register - Current_Host_Receive_Descriptor

The Current Host Receive Descriptor register points to the start address of the current Receive Descriptor read by the DMA.

ETH_CURRENT_HOST_RECEIVE_DESCRIPTOR
Register 19 - Current Host Receive Descriptor Register ($204C_H$) Reset Value: $0000\ 0000_H$

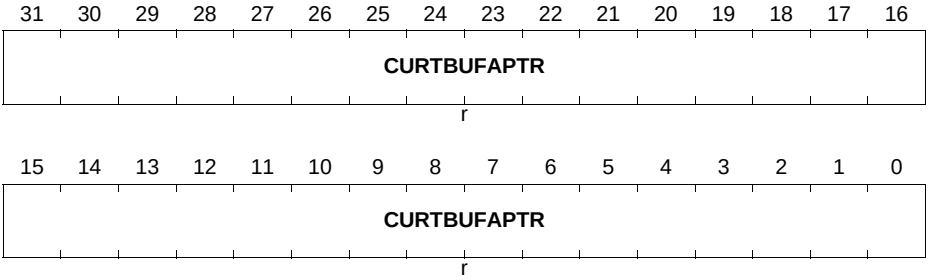


Field	Bits	Type	Description
CURRDESAPTR	[31:0]	r	**Host Receive Descriptor Address Pointer** Cleared on Reset. Pointer updated by the DMA during operation.

32-bit Register - Current_Host_Transmit_Buffer_Address

The Current Host Transmit Buffer Address register points to the current Transmit Buffer Address being read by the DMA.

ETH_CURRENT_HOST_TRANSMIT_BUFFER_ADDRESS
Register 20 - Current Host Transmit Buffer Address Register (2050_H) Reset Value: $0000\ 0000_H$

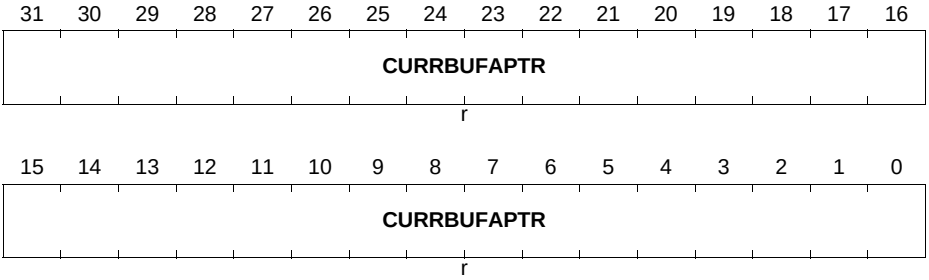


Field	Bits	Type	Description
CURTBUFAPTR	[31:0]	r	**Host Transmit Buffer Address Pointer** Cleared on Reset. Pointer updated by the DMA during operation.

32-bit Register - Current_Host_Receive_Buffer_Address

The Current Host Receive Buffer Address register points to the current Receive Buffer address being read by the DMA.

ETH_CURRENT_HOST_RECEIVE_BUFFER_ADDRESS
Register 21 - Current Host Receive Buffer Address Register (2054_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
CURRBUFAPTR	[31:0]	r	**Host Receive Buffer Address Pointer** Cleared on Reset. Pointer updated by the DMA during operation.

32-bit Register - HW_Feature

This register indicates the presence of the optional features or functions of the DWC_gmac. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks. Note: All bits are set or reset as per the selection of features during the DWC_gmac configuration.

34.4 Descriptors

This chapter comprises the following subsections:

- **Normal Descriptor Formats**
- **Alternate or Enhanced Descriptors**

Note: The Ethernet MAC *in* TC27x *does not support Normal Descriptor Format as it is configured to support IEEE1588 PTP time stamping! Nevertheless parts of the explanations in the chapter* **Chapter 1.7.1** *are required for complete understanding.*

34.4.1 Normal Descriptor Formats

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors, as explained in **DMA Controller**. The default descriptor formats (common for both Receive and Transmit Descriptors) are shown in **Figure 34-24**, and field descriptions are provided in **Chapter 1.7.1.1** to **Chapter 1.7.1.2**.

Note:

3. *All descriptions in* ***Chapter 1.7.1.1*** *and* ***Chapter 1.7.1.2*** *correspond to the default descriptor format. The alternate enhanced descriptor format is discussed in* ***Chapter 1.7.2*** *"Alternate or Enhanced Descriptors" on* ***Page 1-680****.*
4. *Changes to the default descriptor format when IEEE1588 time stamping is enabled are described in* ***Chapter 1.7.1.3 "Descriptor Format With IEEE 1588 Time Stamping Enabled" on Page 1-676****".*

Each descriptor contains two buffers, two byte-count buffers, and two address pointers, which enable the adapter port to be compatible with various types of memory management schemes.

The descriptor addresses must be aligned to the bus width used (Word/Dword/Lword for 32-bit buses).

Figure 34-24 shows the descriptor format in a 32-bit data bus.

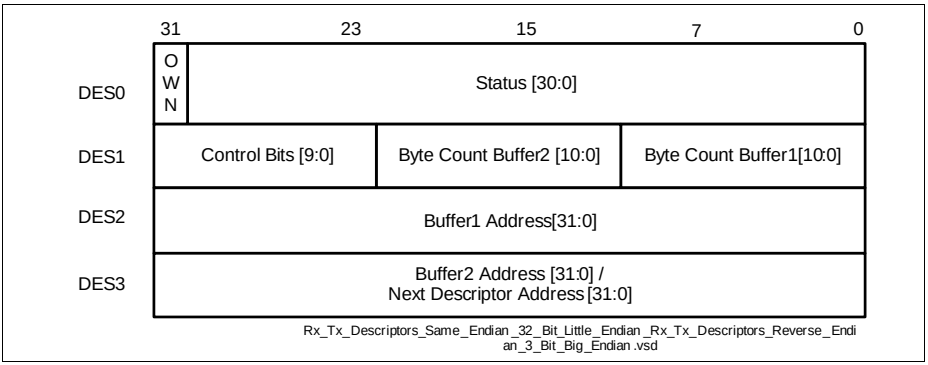

Figure 34-24 Rx/Tx Descriptors for 32-Bit Data Bus

34.4.1.1 Receive Descriptor

The GMAC Subsystem requires at least two descriptors when receiving a frame. The Receive state machine of the DMA (in the GMAC Subsystem) always attempts to acquire an extra descriptor in anticipation of an incoming frame. (The size of the incoming frame is unknown). Before the RxDMA closes a descriptor, it will attempt to acquire the next descriptor even if no frames are received.

In a single descriptor (receive) system, the subsystem will generate a descriptor error if the receive buffer is unable to accommodate the incoming frame and the next descriptor is not owned by the DMA. Thus, the Host is forced to increase either its descriptor pool or the buffer size. Otherwise, the subsystem starts dropping all incoming frames.

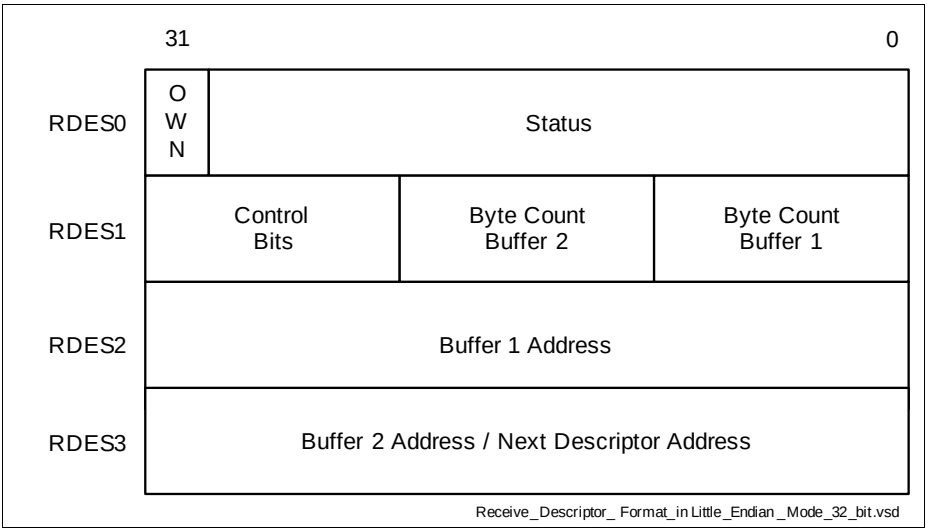

Figure 34-25 Receive Descriptor Format in Little-Endian Mode With a 32-bit Data Bus

Receive Descriptor 0 (RDES0)

RDES0 contains the received frame status, the frame length, and the descriptor ownership information. The descriptions in the following tables (**Table 1-83** through **Table 1-91**) are for the default mode of a Little-Endian 32-bit data bus with Same Endian descriptors, or Big-Endian data bus with Reverse-Endian descriptors. If the DUT is configured for Big-Endian mode, 32-bit data bus with Same Endian descriptors or Little-Endian data bus with Reverse Endian descriptors, then byte lanes 3 and 0 are swapped while byte lanes 1 and 2 are swapped, that is, bits [31:24] will be available on data bus [7:0], and vice-versa.

Table 34-23 Receive Descriptor 0

Bit	Description
31	**OWN: Own Bit** When set, this bit indicates that the descriptor is owned by the DMA of the GMAC Subsystem. When this bit is reset, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.
30	**AFM: Destination Address Filter Fail** When set, this bit indicates a frame that failed in the DA Filter in the GMAC Core.

Table 34-23 Receive Descriptor 0 (cont'd)

Bit	Description
29:16	**FL: Frame Length** These bits indicate the byte length of the received frame that was transferred to host memory (including CRC). This field is valid when Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or Overflow Error bits are are reset. The frame length also includes the two bytes appended to the Ethernet frame when IP checksum calculation (Type 1) is enabled and the received frame is not a MAC control frame. This field is valid when Last Descriptor (RDES0[8]) is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame.
15	**ES: Error Summary** Indicates the logical OR of the following bits: • RDES0[0]: Payload Checksum Error • RDES0[1]: CRC Error • RDES0[3]: Receive Error • RDES0[4]: Watchdog Timeout • RDES0[6]: Late Collision • RDES0[7]: IPC Checksum (Type 2) / Giant Frame • RDES0[11]: Overflow Error • RDES0[14]: Descriptor Error This field is valid only when the Last Descriptor (RDES0[8]) is set.
14	**DE: Descriptor Error** When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next Descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]) is set.
13	**SAF: Source Address Filter Fail** When set, this bit indicates that the SA field of frame failed the SA Filter in the GMAC Core.
12	**LE: Length Error** When set, this bit indicates that the actual length of the frame received and that the Length/ Type field does not match. This bit is valid only when the Frame Type (RDES0[5]) bit is reset. Length error status is not valid when CRC error is present.
11	**OE: Overflow Error** When set, this bit indicates that the received frame was damaged due to buffer overflow in MTL.

Table 34-23 Receive Descriptor 0 (cont'd)

Bit	Description
10	**VLAN: VLAN Tag** When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the GMAC Core.
9	**FS: First Descriptor** When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame.
8	**LS: Last Descriptor** When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame
7	**IPC Checksum Error/Giant Frame** When IP Checksum Engine (Type 1) is enabled, this bit, when set, indicates that the 16-bit IPv4 Header checksum calculated by the core did not match the received checksum bytes. The Error Summary bit[15] is NOT set when this bit is set in this mode. If this bit is set when Full Checksum Offload Engine (Type 2) is enabled, it indicates an error in the IPv4 or IPv6 header. This error can be due to inconsistent Ethernet Type field and IP header Version field values, a header checksum mismatch in IPv4, or an Ethernet frame lacking the expected number of IP header bytes. Refer to **Table 1-84** for more details. If you do not select IP Checksum Module during core configuration, this bit, when set, indicates that the received frame was a Giant Frame. Giant frames are larger-than-1.518-byte (or 1.522-byte for VLAN) normal frames and larger-than-9,018-byte (9.022-byte for VLAN) frame when Jumbo Frame processing is enabled.
6	**LC: Late Collision** When set, this bit indicates that a late collision has occurred while receiving the frame in Half-Duplex mode.
5	**FT: Frame Type** When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 16'h0600). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes. Refer to **Table 1-84** for more details.
4	**RWT: Receive Watchdog Timeout** When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout.

Table 34-23 Receive Descriptor 0 (cont'd)

Bit	Description
3	**RE: Receive Error** When set, this bit indicates that the gmii_rxer_i signal is asserted while gmii_rxdv_i is asserted during frame reception. This error also includes carrier extension error in GMII and Half-duplex mode. Error can be of less/no extension, or error (rxd ≠ 0f) during extension.
2	**DE: Dribble Bit Error** When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII Mode.
1	**CE: CRC Error** When set, this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor (RDES0[8]) is set.
0	**Rx MAC Address/Payload Checksum Error** When set, this bit indicates that the Rx MAC Address registers value (1 to 15) matched the frame's DA field. When reset, this bit indicates that the Rx MAC Address Register 0 value matched the DA field. If Full Checksum Offload Engine is enabled, this bit, when set, indicates the TCP, UDP, or ICMP checksum the core calculated does not match the received encapsulated TCP, UDP, or ICMP segment's Checksum field. This bit is also set when the received number of payload bytes does not match the value indicated in the Length field of the encapsulated IPv4 or IPv6 datagram in the received Ethernet frame. Refer to **Table 1-84** for more details.

When the Full Checksum Offload Engine (Type 2) is enabled, the permutations of bits 5, 7, and 0 reflect the conditions discussed in **Table 1-84**.

Table 34-24 Receive Descriptor 0 When COE (Type 2) Is Enabled

Bit 5: Frame Type	Bit 7: IPC Checksum Error	Bit 0: Payload Checksum Error	Frame Status
0	0	0	IEEE 802.3 Type frame (Length field value is less than 0600_H)
1	0	0	IPv4/IPv6 Type frame, no checksum error detected
1	0	1	IPv4/IPv6 Type frame with a payload checksum error (as described for PCE) detected

Table 34-24 Receive Descriptor 0 When COE (Type 2) Is Enabled (cont'd)

Bit 5: Frame Type	Bit 7: IPC Checksum Error	Bit 0: Payload Checksum Error	Frame Status
1	1	0	IPv4/IPv6 Type frame with an IP header checksum error (as described for IPC CE) detected
1	1	1	IPv4/IPv6 Type frame with both IP header and payload checksum errors detected
0	0	1	IPv4/IPv6 Type frame with no IP header checksum error and the payload check bypassed, due to an unsupported payload
0	1	1	A Type frame that is neither IPv4 or IPv6 (the Checksum Offload engine bypasses checksum completely.)
0	1	0	Reserved

Note: The first five conditions are backward-compatible to versions 3.30a and previous. The last two conditions (001, 011), which had been reserved, are not backward-compatible, because the Frame Type (FT) bit is reset during bypasses, even for valid Type frames.

Receive Descriptor 1 (RDES1)

RDES1 contains the buffer sizes and other bits that control the descriptor chain/ring.

*Note: See **Buffer Size Calculations** for further detail on calculating buffer sizes.*

Table 34-25 Receive Descriptor 1

Bit	Description
31	**Disable Interrupt on Completion** When set, this bit will prevent the setting of the RI (CSR5[6]) bit of the Status Register for the received frame that ends in the buffer pointed to by this descriptor. This, in turn, will disable the assertion of the interrupt to Host due to RI for that frame.
30:26	**Reserved**
25	**RER: Receive End of Ring** When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a Descriptor Ring.

Table 34-25 Receive Descriptor 1 (cont'd)

Bit	Description
24	**RCH: Second Address Chained** When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When RDES1[24] is set, RBS2 (RDES1[21-11]) is a "don't care" value. RDES1[25] takes precedence over RDES1[24].
23:22	**Reserved**
21:11	**RBS2: Receive Buffer 2 Size** These bits indicate the second data buffer size in bytes. The buffer size must be a multiple of 4/8/16 depending upon the bus widths (32/64/128), even if the value of RDES3 (buffer2 address pointer) is not aligned to bus width. In the case where the buffer size is not a multiple of 4/8/16, the resulting behavior is undefined. This field is not valid if RDES1[24] is set.
10:0	**RBS1: Receive Buffer 1 Size** Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4/8/16 depending upon the bus widths (32/64/128), even if the value of RDES2 (buffer1 address pointer) is not aligned. In the case where the buffer size is not a multiple of 4/8/16, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of RCH (Bit 24).

Receive Descriptor 2 (RDES2)

RDES2 contains the address pointer to the first data buffer in the descriptor.

*Note: See **Host Data Buffer Alignment** for further detail on buffer address alignment.*

Table 34-26 Receive Descriptor 2 (Default Operation)

Bit	Description
31:0	**Buffer 1 Address Pointer** These bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. Note that the DMA performs a write operation with the RDES2[3/2/1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[3/2/1:0] (corresponding to bus width of 128/64/32) if the address pointer is to a buffer where the middle or last part of the frame is stored.

Receive Descriptor 3 (RDES3)

RDES3 contains the address pointer either to the second data buffer in the descriptor or to the next descriptor.

Table 34-27 Receive Descriptor 3

Bit	Description
31:0	**Buffer 2 Address Pointer (Next Descriptor Address)** These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. If RDES1[24] is set, the buffer (Next Descriptor) address pointer must be bus width-aligned (RDES3[3, 2, or 1:0] = 0, corresponding to a bus width of 128, 64, or 32. LSBs are ignored internally.) However, when RDES1[24] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3[3, 2, or 1:0] (corresponding to a bus width of 128, 64, or 32) if the address pointer is to a buffer where the middle or last part of the frame is stored.

34.4.1.2 Transmit Descriptor

The descriptor addresses must be aligned to the bus width used (32). **Figure 34-26** shows the transmit descriptor format in Little-Endian mode with a 32-bit data bus.

Each descriptor is provided with two buffers, two byte-count buffers, and two address pointers, which enable the adapter port to be compatible with various types of memory-management schemes.

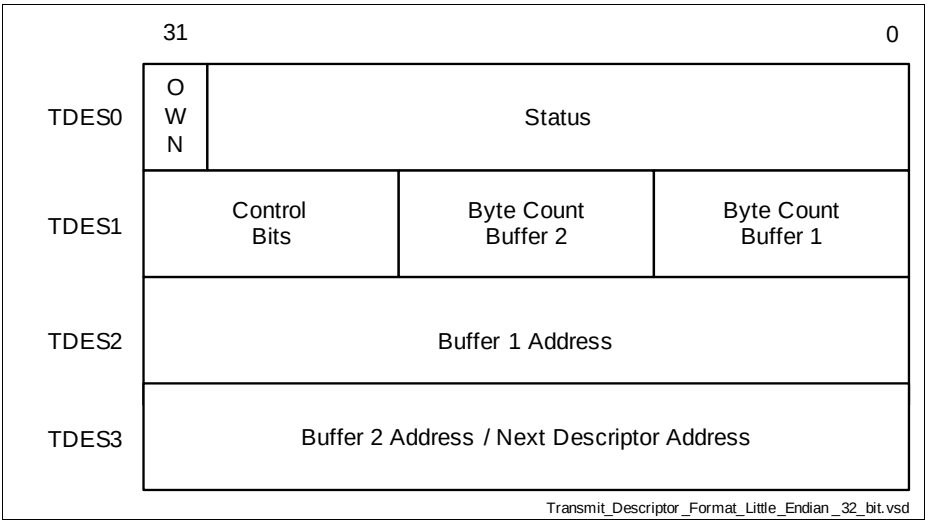

Figure 34-26 Transmit Descriptor Format in Little-Endian Mode With a 32-bit Data Bus

Transmit Descriptor 0 (TDES0)

TDES0 contains the transmitted frame status and the descriptor ownership information.

Table 34-28 Transmit Descriptor 0

Bit	Description
31	**OWN: Own Bit** When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are empty. The ownership bit of the First Descriptor of the frame should be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit.
30:18	**Reserved**

Table 34-28 Transmit Descriptor 0 (cont'd)

Bit	Description
17	**TTSS: Tx Time Stamp Status** This status bit indicates that a time stamp has been captured for the corresponding transmit frame. When this bit is set, TDES2 and TDES3 have time stamp values that were captured for the transmit frame. This field is valid only when the Last Segment control bit (TDES1[30]) in a descriptor is set. This bit is valid only when IEEE1588 time stamping feature is enabled; otherwise, it is reserved.
16	**IHE: IP Header Error** When set, this bit indicates that the Checksum Offload engine detected an IP header error and consequently did not modify the transmitted frame for any checksum insertion. This bit is valid only when Full Checksum Offload is enabled; otherwise, it is reserved.
15	**ES: Error Summary** Indicates the logical OR of the following bits: • TDES0[14]: Jabber Timeout • TDES0[13]: Frame Flush • TDES0[11]: Loss of Carrier • TDES0[10]: No Carrier • TDES0[9]: Late Collision • TDES0[8]: Excessive Collision • TDES0[2]: Excessive Deferral • TDES0[1]: Underflow Error
14	**JT: Jabber Timeout** When set, this bit indicates the GMAC transmitter has experienced a jabber time-out. This bit is only set when the GMAC configuration register's JD bit is not set.
13	**FF: Frame Flushed** When set, this bit indicates that the DMA/MTL flushed the frame due to a SW flush command given by the CPU.

Table 34-28 Transmit Descriptor 0 (cont'd)

Bit	Description
12	**PCE: Payload Checksum Error** This bit, when set, indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either due to insufficient bytes, as indicated by the IP Header's Payload Length field, or the MTL starting to forward the frame to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet frame being transmitted: to avoid deadlock, the MTL starts forwarding the frame when the FIFO is full, even in Store-and-Forward mode. When the Full Checksum Offload engine is not enabled during configuration, this bit is reserved.
11	**LC: Loss of Carrier** When set, this bit indicates that Loss of Carrier occurred during frame transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during frame transmission). This is valid only for the frames transmitted without collision and when the GMAC operates in Half-Duplex Mode.
10	**NC: No Carrier** When set, this bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
9	**LC: Late Collision** When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte times including Preamble in MII Mode and 512 byte times including Preamble and Carrier Extension in GMII Mode). Not valid if Underflow Error is set.
8	**EC: Excessive Collision** When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the DR (Disable Retry) bit in the GMAC Configuration Register is set, this bit is set after the first collision and the transmission of the frame is aborted.
7	**VF: VLAN Frame** When set, this bit indicates that the transmitted frame was a VLAN-type frame.
6:3	**CC: Collision Count** This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collisions bit (TDES0[8]) is set.

Table 34-28 Transmit Descriptor 0 (cont'd)

Bit	Description
2	**ED: Excessive Deferral** When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbit/s mode, or in Jumbo Frame enabled mode) if the Deferral Check (DC) bit is set high in the GMAC Control Register.
1	**UF: Underflow Error** When set, this bit indicates that the GMAC aborted the frame because data arrived late from the Host memory. Underflow Error indicates that the DMA encountered an empty Transmit Buffer while transmitting the frame. The transmission process enters the suspended state and sets both Transmit Underflow (Register 5[5]) and Transmit Interrupt (Register 5[0]).
0	**DB: Deferred Bit** When set, this bit indicates that the GMAC defers before transmission because of the presence of carrier. This bit is valid only in Half-Duplex mode.

Transmit Descriptor 1 (TDES1)

TDES1 contains the buffer sizes and other bits which control the descriptor chain/ring and the frame being transferred.

*Note: See **Buffer Size Calculations** for further detail on calculating buffer sizes.*

Table 34-29 Transmit Descriptor 1

Bit	Description
31	**IC: Interrupt on Completion** When set, this bit sets Transmit Interrupt (Register 5[0]) after the present frame has been transmitted.
30	**LS: Last Segment** When set, this bit indicates that the buffer contains the last segment of the frame.
29	**FS: First Segment** When set, this bit indicates that the buffer contains the first segment of a frame.

Table 34-29 Transmit Descriptor 1 (cont'd)

Bit	Description
28:27	**CIC: Checksum Insertion Control** These bits control the insertion of checksums in Ethernet frames that encapsulate TCP, UDP, or ICMP over IPv4 or IPv6 as described below. • 2'b00: Do nothing. Checksum Engine is bypassed • 2'b01: Insert IPv4 header checksum. Use this value to insert IPv4 header checksum when the frame encapsulates an IPv4 datagram. • 2'b10: Insert TCP/UDP/ICMP checksum. The checksum is calculated over the TCP, UDP, or ICMP segment only and the TCP, UDP, or ICMP pseudo-header checksum is assumed to be present in the corresponding input frame's Checksum field. An IPv4 header checksum is also inserted if the encapsulated datagram conforms to IPv4. • 2'b11: Insert a TCP/UDP/ICMP checksum that is fully calculated in this engine. In other words, the TCP, UDP, or ICMP pseudo-header is included in the checksum calculation, and the input frame's corresponding Checksum field has an all-zero value. An IPv4 Header checksum is also inserted if the encapsulated datagram conforms to IPv4. The Checksum engine detects whether the TCP, UDP, or ICMP segment is encapsulated in IPv4 or IPv6 and processes its data accordingly.
26	**DC: Disable CRC** When set, the GMAC does not append the Cyclic Redundancy Check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES1[29]).
25	**TER: Transmit End of Ring** When set, this bit indicates that the descriptor list reached its final descriptor. The returns to the base address of the list, creating a descriptor ring.
24	**TCH: Second Address Chained** When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When TDES1[24] is set, TBS2 (TDES1[21–11]) are "don't care" values. TDES1[25] takes precedence over TDES1[24].
23	**DP: Disable Padding** When set, the GMAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes and the CRC field is added despite the state of the DC (TDES1[26]) bit. This is valid only when the first segment (TDES1[29]) is set.

Table 34-29 Transmit Descriptor 1 (cont'd)

Bit	Description
22	**TTSE: Transmit Time Stamp Enable** When set, this bit enables IEEE1588 hardware time stamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit (TDES1[29]) is set.
21:11	**TBS2: Transmit Buffer 2 Size** These bits indicate the Second Data Buffer in bytes. This field is not valid if TDES1[24] is set.
10:0	**TBS1: Transmit Buffer 1 Size** These bits indicate the First Data Buffer byte size. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of TCH (Bit 24).

Transmit Descriptor 2 (TDES2)

TDES2 contains the address pointer to the first buffer of the descriptor.

Table 34-30 Transmit Descriptor 2

Bit	Description
31:0	**Buffer 1 Address Pointer** These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. See **Host Data Buffer Alignment** for further detail on buffer address alignment.

Transmit Descriptor 3 (TDES3)

TDES3 contains the address pointer either to the second buffer of the descriptor or the next descriptor.

Table 34-31 Transmit Descriptor 3

Bit	Description
31:0	**Buffer 2 Address Pointer (Next Descriptor Address)** Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES1[24] is set. (LSBs are ignored internally.)

34.4.1.3 Descriptor Format With IEEE 1588 Time Stamping Enabled

The default descriptor format (as described in **"Receive Descriptor" on Page 1-677** and **"Transmit Descriptor" on Page 1-669**), and field descriptions remain unchanged when created by software (Own bit is set in DES0). However, if the software has enabled IEEE 1588 functionality, the DES2 and DES3 descriptor fields (see **Figure 34-27**) take on a different meaning when the DMA closes the descriptor (own bit in DES0 is cleared).

The DMA updates the DES2 and DES3 with the time stamp value before clearing the Own bit in DES0.

When the core is operating in 32-bit mode (**Figure 34-24**), DES2 is updated with the lower 32 time stamp bits (the Sub-Second field, called TSL in subsequent sections) and DES3 is updated with the upper 32 time stamp bits (the Seconds field, called TSH in subsequent sections).

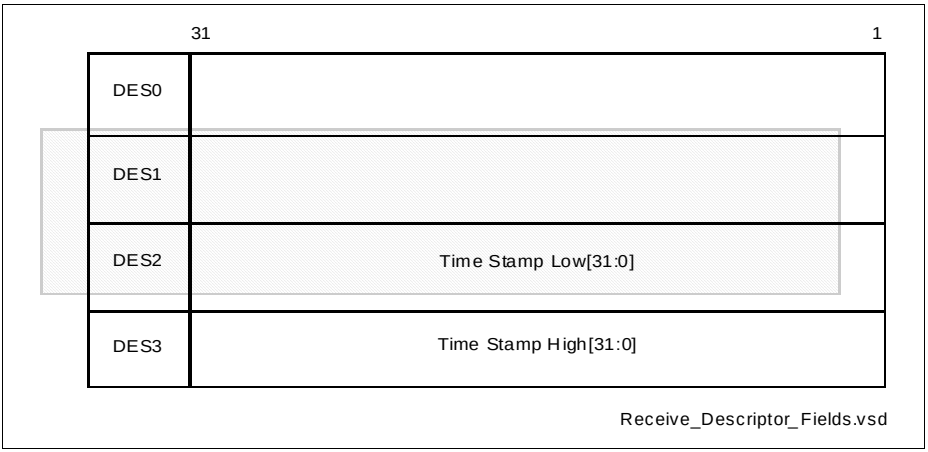

Figure 34-27 Receive Descriptor Fields When DMA Clears the Own Bit

The following sections describe the details specific to receive and transmit descriptors in this mode.

Receive Descriptor

Receive Time Stamp

The tables below describe the fields that have different meaning for RDES2 and RDES3 when the receive descriptor is closed and time stamping is enabled.

Note: When software disables the time stamping feature (the TSENA bit in Register 448 is low), the DMA does not update the descriptor's RDES2/RDES3 fields before closing the RDES0.

Table 34-32 Receive Descriptor Fields (RDES2)

Bit	Description
31:0	**RTSL: Receive Frame Time Stamp Low** The DMA updates this field with the least significant 32 bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by Last Descriptor status bit (RDES0[8]). When this field and the RTSH field in RDES3 show an all-ones value, the time stamp must be treated as corrupt.

Table 34-33 Receive Descriptor Fields (RDES3)

Bit	Description
31:0	**RTSH: Receive Frame Time Stamp High** The DMA updates this field with the most significant 32 bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by Last Descriptor status bit (RDES0[8]). When this field and RDES2's RTSL field show all-ones values, the time stamp must be treated as corrupt.

Transmit Descriptor

In addition to the changes described in **"Descriptor Format With IEEE 1588 Time Stamping Enabled" on Page 1-676**, the Transmit descriptor has additional control and status bits (TTSE and TTSS, respectively) for time stamping, as shown in **Figure 34-28**. Software sets the TTSE bit (when the Own bit is set), instructing the core to generate a time stamp for the corresponding Ethernet frame being transmitted. The DMA sets the TTSS bit if the time stamp has been updated in the TDES2 and TDES3 fields when the descriptor is closed (Own bit is cleared).

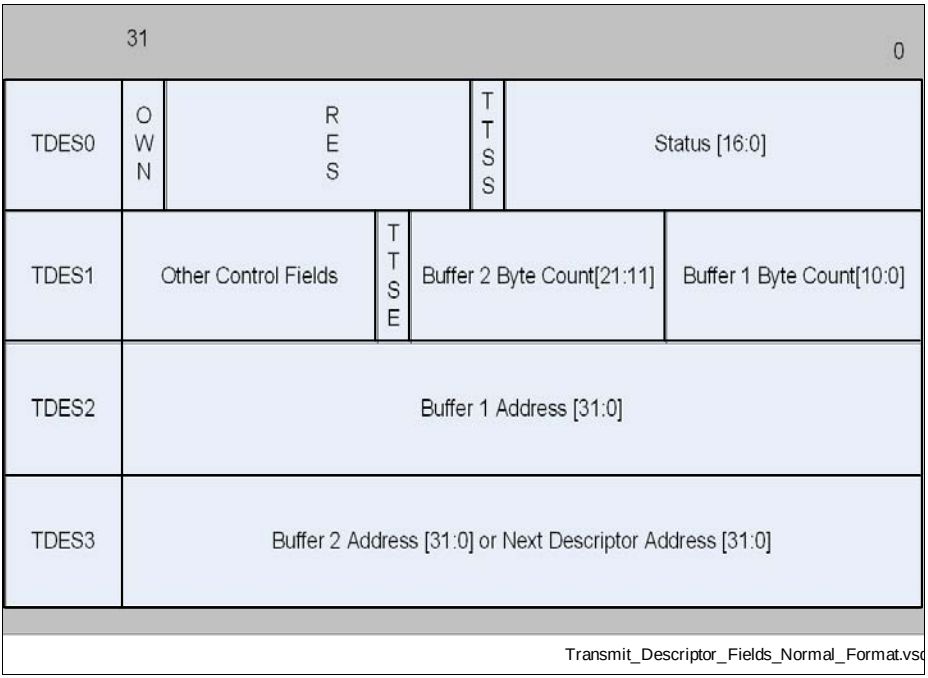

Figure 34-28 Transmit Descriptor Fields– Normal Format

Transmit Time Stamp Control and Status Fields

The position of these fields is different for normal transmit descriptor and enhanced format transmit descriptor. The value of this field in both the cases shall be preserved by the DMA at the time of closing the descriptor.

Updates to **Table 1-87** and **Table 1-88** for the default (normal) descriptor format are described below.

Table 34-34 Transmit Time Stamp Status – Normal Descriptor Format Case (TDES0)

Bit	Description
17	**TTSS: Transmit Time Stamp Status** This field is a status bit indicating that a time stamp was captured for the corresponding transmit frame. When this bit is set, both TDES2 and TDES3 have a time stamp value that was captured for the transmit frame. This field is valid only when the Last Segment control bit (TDES1[30] in the descriptor) is set.

Table 34-35 Transmit Time Stamp Control – Normal Descriptor Format Case (TDES1)

Bit	Description
22	**TTSE: Transmit Time Stamp Enable** When set, this field enables IEEE1588 hardware time stamping for the transmit frame described by the descriptor. This field is valid only when the First Segment control bit (TDES1[29] in the descriptor) is set.

Transmit Time Stamp Field

The transmit descriptor format and field descriptions remain unchanged when they are created by software (when the Own bit is set). However, when the DMA closes the last descriptor (marked, in the alternative descriptor format, by the LS bit in TDES1 or TDES0) and IEEE 1588 functionality is enabled (the Own bit is cleared), the TDES2 and TDES3 descriptor fields are updated with the time stamp, if taken, for that frame.

The fields in TDES2 and TDES3 are swapped when the core operates in 64- or 128-bit and with the descriptor in Reverse-Endian mode

Table 1-96 and **Table 1-97** describe the fields that have different meaning when the descriptor is closed.

Table 34-36 Transmit Descriptor Fields (TDES2)

Bit	Description
31:0	**TTSL: Transmit Frame Time Stamp Low** This field is updated by DMA with the least significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last Segment control bit (LS) in the descriptor is set.

Table 34-37 Transmit Descriptor Fields (TDES3)

Bit	Description
31:0	**TTSH: Transmit Frame Time Stamp High** This field is updated by DMA with the most significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last Segment control bit (LS) in the descriptor is set.

34.4.2 Alternate or Enhanced Descriptors

The alternate (or enhanced) descriptor structure can have 8 DWORDS (32-bytes) instead of the 4 DWORDS as in the case of normal descriptor format. The features of the alternate descriptor structure are

- The normal descriptor structure allows data buffers of up to 2.048 bytes. The alternative descriptor structure has been implemented to support buffers of up to 8 KB (useful for Jumbo frames).
- There is a re-assignment of control and status bits in TDES0, TDES1, RDES0 (Advanced time stamp or IPC full offload configuration), RDES1.
- The transmit descriptor stores the time stamp in TDES6 and TDES7 when advanced time stamp feature is selected.
- This receive descriptor structure is also used for storing the extended status (RDES4) and time stamp (RDES6 and RDES7) when advanced time stamp feature or IPC full offload is selected.
- When alternate descriptor mode is selected, and Time-stamping feature is enabled, the software needs to allocate 32-bytes (8 DWORDS) of memory for every descriptor. When Time-stamping or Receive IPC FullOffload engine are not enabled, the extended descriptors are not required and the SW can use alternate descriptors with the default size of 16 bytes. The core also needs to be configured for this change using the DMA Bus Mode Register[7].
- When alternate descriptor is chosen without Time Stamp or Full IPC Offload feature, the descriptor size is always 4 DWORDs (DES0-DES3).

The description or bit-mapping alternate descriptor structure (in Little Endian mode) is given below.

*Note: The effect of Big Endian mode (byte-swap) explained in **"Normal Descriptor Formats" on Page 1-658** apply to this descriptor structure as well.*
When alternate descriptor with only Full IPC Offload (Type 2) is selected, it is not backward compatible to the previous release 3.4x with respect to status bits[7,5,0] in RDES0. In this mode, you should enable the extended descriptor mode (8 DWORDS) to get the IPC checksum engine status in RDES4.

34.4.2.1 Transmit Descriptor

The transmit descriptor structure is shown in **Figure 34-29**. The application software must program the control bits TDES0[31:20] during descriptor initialization. When the DMA updates the descriptor, it write backs all the control bits except the OWN bit (which it clears) and updates the status bits[19:0]. The contents of the transmitter descriptor word 0 (TDES0) through word 3 (TDES3) are given in **Table 1-98** through **Table 1-101**, respectively.

With the advance time stamp support, the snapshot of the time stamp to be taken can be enabled for a given frame by setting the "TTSE: Transmit Time Stamp Enable" (bit-25 of TDES0). When the descriptor is closed (i.e. when the OWN bit is cleared), the time-

stamp is written into TDES6 and TDES7. This is indicated by the status bit “TTSS: Transmit Time Stamp Status” (bit-17 of TDES0). This is shown in **Figure 34-29**. The contents of TDES6 and TDES7 are mentioned in **Table 1-102** and **Table 1-103**.

Note: When either of Advanced Time Stamp or IPC Offload (Type 2) features is enabled, the SW should set the DMA Bus Mode register[7], so that the DMA operates with extended descriptor size. When this control bit is reset, the TDES4-TDES7 descriptor space are not valid.

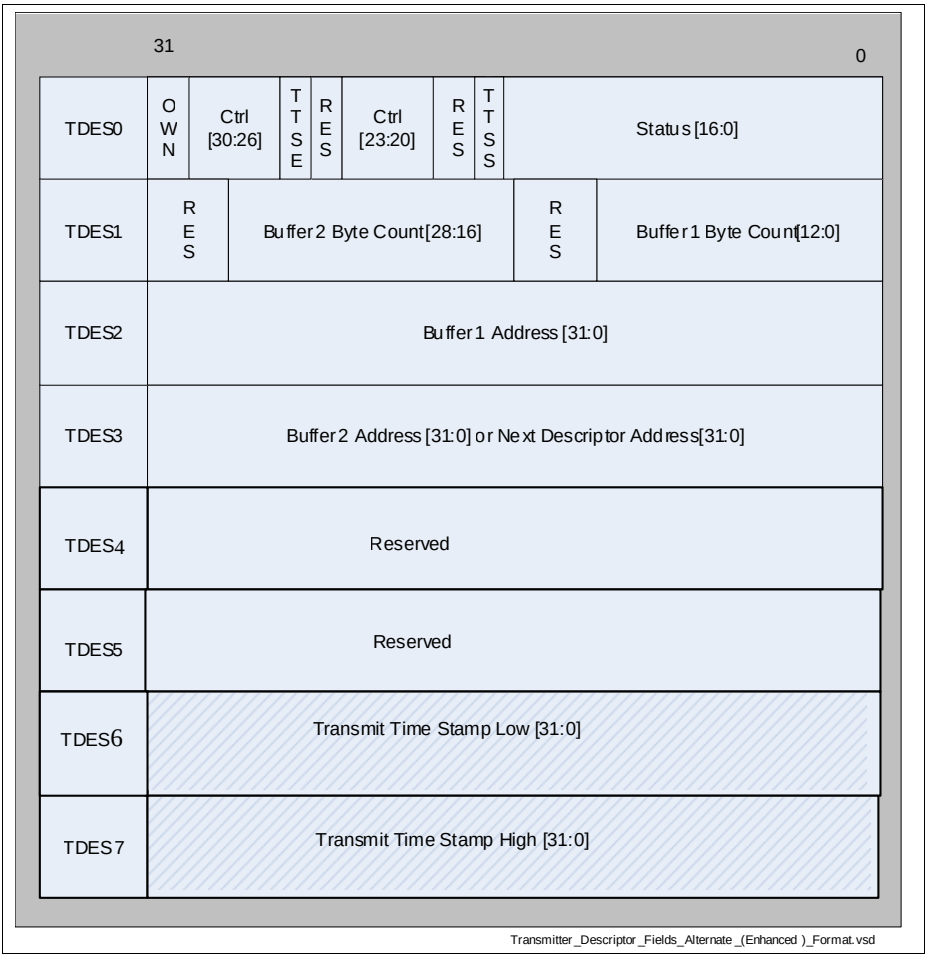

Figure 34-29 Transmitter Descriptor Fields - Alternate (Enhanced) Format

.

Table 34-38 Transmit Descriptor Word 0 (TDES0)

Bit	Description
31	**OWN: Own Bit** When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are read completely. The ownership bit of the frame's first descriptor must be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit.
30	**IC: Interrupt on Completion** When set, this bit sets the Transmit Interrupt (Register 5[0]) after the present frame has been transmitted.
29	**LS: Last Segment** When set, this bit indicates that the buffer contains the last segment of the frame.
28	**FS: First Segment** When set, this bit indicates that the buffer contains the first segment of a frame.
27	**DC: Disable CRC** When this bit is set, the GMAC does not append a cyclic redundancy check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES0[28]) is set.
26	**DP: Disable Pad** When set, the GMAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This is valid only when the first segment (TDES0[28]) is set.
25	**TTSE: Transmit Time Stamp Enable** When set, this bit enables IEEE1588 hardware time stamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit (TDES0[28]) is set.
24	**Reserved**

Table 34-38 Transmit Descriptor Word 0 (TDES0) (cont'd)

Bit	Description
23:22	**CIC: Checksum Insertion Control** These bits control the checksum calculation and insertion. Bit encodings are as shown below. • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled. • 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is reserved when the IPC_FULL_OFFLOAD configuration parameter is not selected.
21	**TER: Transmit End of Ring** When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.
20	**TCH: Second Address Chained** When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a "don't care" value. TDES0[21] takes precedence over TDES0[20].
19:18	**Reserved**
17	**TTSS: Transmit Time Stamp Status** This field is used as a status bit to indicate that a time stamp was captured for the described transmit frame. When this bit is set, TDES2 and TDES3 have a time stamp value captured for the transmit frame. This field is only valid when the descriptor's Last Segment control bit (TDES0[29]) is set.
16	**IHE: IP Header Error** When set, this bit indicates that the GMAC transmitter detected an error in the IP datagram header. The transmitter checks the header length in the IPv4 packet against the number of header bytes received from the application and indicates an error status if there is a mismatch. For IPv6 frames, a header error is reported if the main header length is not 40 bytes. Furthermore, the Ethernet Length/Type field value for an IPv4 or IPv6 frame must match the IP header version received with the packet. For IPv4 frames, an error status is also indicated if the Header Length field has a value less than 0x5.

Table 34-38 Transmit Descriptor Word 0 (TDES0) (cont'd)

Bit	Description
15	**ES: Error Summary** Indicates the logical OR of the following bits: • TDES0[14]: Jabber Timeout • TDES0[13]: Frame Flush • TDES0[11]: Loss of Carrier • TDES0[10]: No Carrier • TDES0[9]: Late Collision • TDES0[8]: Excessive Collision • TDES0[2]: Excessive Deferral • TDES0[1]: Underflow Error • TDES0[16]: IP Header Error • TDES0[12]: IP Payload Error
14	**JT: Jabber Timeout** When set, this bit indicates the GMAC transmitter has experienced a jabber time-out. This bit is only set when the GMAC configuration register's JD bit is not set.
13	**FF: Frame Flushed** When set, this bit indicates that the DMA/MTL flushed the frame due to a software Flush command given by the CPU.
12	**IPE: IP Payload Error** When set, this bit indicates that GMAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application and issues an error status in case of a mismatch.
11	**LC: Loss of Carrier** When set, this bit indicates that a loss of carrier occurred during frame transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during frame transmission). This is valid only for the frames transmitted without collision when the GMAC operates in Half-Duplex mode.
10	**NC: No Carrier** When set, this bit indicates that the Carrier Sense signal form the PHY was not asserted during transmission.
9	**LC: Late Collision** When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte-times, including preamble, in MII mode and 512 byte-times, including preamble and carrier extension, in GMII mode). This bit is not valid if the Underflow Error bit is set.

Table 34-38 Transmit Descriptor Word 0 (TDES0) (cont'd)

Bit	Description
8	**EC: Excessive Collision** When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the DR (Disable Retry) bit in the GMAC Configuration register is set, this bit is set after the first collision, and the transmission of the frame is aborted.
7	**VF: VLAN Frame** When set, this bit indicates that the transmitted frame was a VLAN-type frame.
6:3	**CC: Collision Count** This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collisions bit (TDES0[8]) is set.
2	**ED: Excessive Deferral** When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1,000-Mbit/s mode or if Jumbo Frame is enabled) if the Deferral Check (DC) bit in the GMAC Control register is set high.
1	**UF: Underflow Error** When set, this bit indicates that the GMAC aborted the frame because data arrived late from the Host memory. Underflow Error indicates that the DMA encountered an empty transmit buffer while transmitting the frame. The transmission process enters the Suspended state and sets both Transmit Underflow (Register 5[5]) and Transmit Interrupt (Register 5[0]).
0	**DB: Deferred Bit** When set, this bit indicates that the GMAC defers before transmission because of the presence of carrier. This bit is valid only in Half-Duplex mode.

Table 34-39 Transmit Descriptor Word 1 (TDES1)

Bit	Description
31:29	Reserved
28:16	**TBS2: Transmit Buffer 2 Size** These bits indicate the second data buffer size in bytes. This field is not valid if TDES0[20] is set. See **Buffer Size Calculations** for further detail on calculating buffer sizes.

Table 34-39 Transmit Descriptor Word 1 (TDES1) (cont'd)

Bit	Description
15:13	**Reserved**
12:0	**TBS1: Transmit Buffer 1 Size** These bits indicate the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]).

Table 34-40 Transmit Descriptor 2 (TDES2)

Bit	Description
31:0	**Buffer 1 Address Pointer** These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. See **Host Data Buffer Alignment** for further detail on buffer address alignment.

Table 34-41 Transmit Descriptor 3 (TDES3)

Bit	Description
31:0	**Buffer 2 Address Pointer (Next Descriptor Address)** Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES1[24] is set. (LSBs are ignored internally.)

Table 34-42 Transmit Descriptor 6 (TDES6)

Bit	Description
31:0	**TTSL: Transmit Frame Time Stamp Low** This field is updated by DMA with the least significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last Segment bit (LS) in the descriptor is set and Time stamp status (TTSS) bit is set.

Table 34-43 Transmit Descriptor 7 (TDES7)

Bit	Description
31:0	**TTSH: Transmit Frame Time Stamp High** This field is updated by DMA with the most significant 32 bits of the time stamp captured for the corresponding receive frame. This field has the time stamp only if the Last Segment bit (LS) in the descriptor is set and Time stamp status (TTSS) bit is set.

34.4.2.2 Receive Descriptor

The structure of the received descriptor is shown in **Figure 34-30**. This can have 32 bytes of descriptor data (8 DWORDs) when Advanced Time Stamping or IPC Full Offload feature is selected.

Note: When either of these features is enabled, the SW should set the DMA Bus Mode register[7] so that the DMA operates with extended descriptor size. When this control bit is reset, RDES0[7] and RDES0[0] will be always cleared and the RDES4-RDES7 descriptor space are not valid

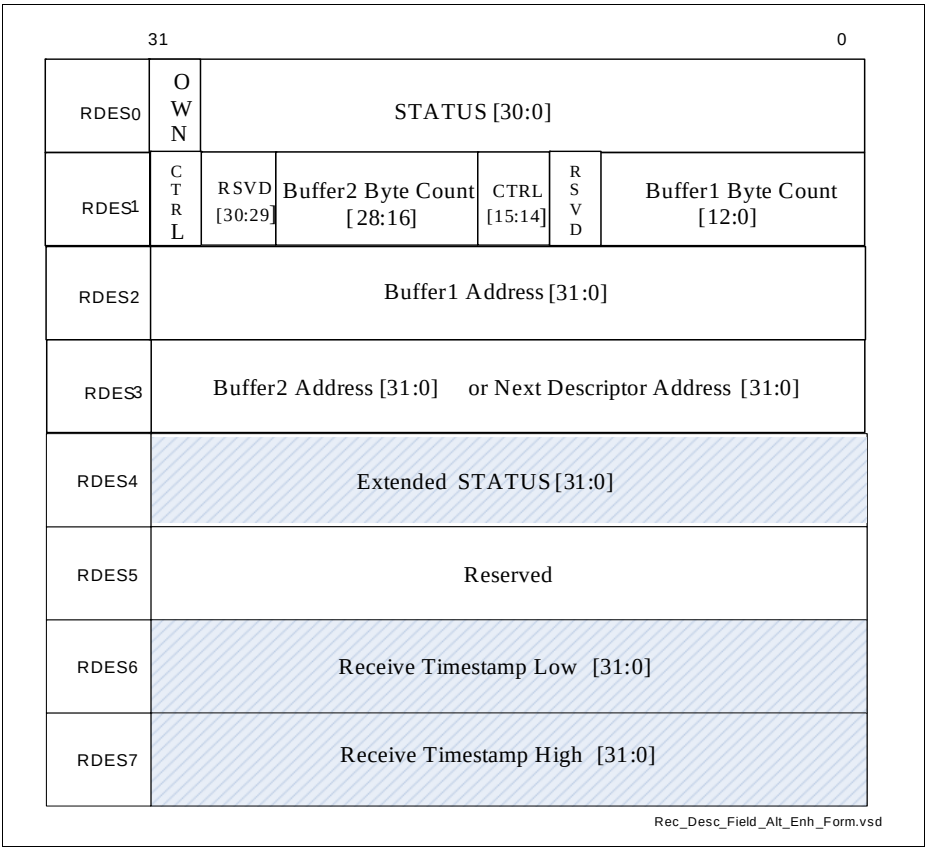

Figure 34-30 Receive Descriptor Fields - Alternate (Enhanced) Format

The contents of RDES0 are identified in **Table 1-104**. The contents of RDES1 through RDES3 are identified in **Table 1-105** through **Table 1-107**, respectively.

Note: Some of the bit functions of RDES0 are not backward compatible to Release 3.41a and previous versions. These bits are Bit[7], Bit[0] and Bit[5]. The function of Bit[5] is backward compatible to Release 3.30a and previous versions.

Table 34-44 Receive Descriptor Fields (RDES0)

Bit	Description
31	**OWN: Own Bit** When set, this bit indicates that the descriptor is owned by the DMA of the GMAC Subsystem. When this bit is reset, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.
30	**AFM: Destination Address Filter Fail** When set, this bit indicates a frame that failed in the DA Filter in the GMAC Core.
29:16	**FL: Frame Length** These bits indicate the byte length of the received frame that was transferred to host memory (including CRC). This field is valid when Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or Overflow Error bits are are reset. The frame length also includes the two bytes appended to the Ethernet frame when IP checksum calculation (Type 1) is enabled and the received frame is not a MAC control frame. This field is valid when Last Descriptor (RDES0[8]) is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame.
15	**ES: Error Summary** Indicates the logical OR of the following bits: • RDES0[1]: CRC Error • RDES0[3]: Receive Error • RDES0[4]: Watchdog Timeout • RDES0[6]: Late Collision • RDES0[7]: Giant Frame • RDES4[4:3]: IP Header/Payload Error • RDES0[11]: Overflow Error • RDES0[14]: Descriptor Error This field is valid only when the Last Descriptor (RDES0[8]) is set.
14	**DE: Descriptor Error** When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next Descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]) is set.
13	**SAF: Source Address Filter Fail** When set, this bit indicates that the SA field of frame failed the SA Filter in the GMAC Core.

Table 34-44 Receive Descriptor Fields (RDES0) (cont'd)

Bit	Description
12	**LE: Length Error** When set, this bit indicates that the actual length of the frame received and that the Length/ Type field does not match. This bit is valid only when the Frame Type (RDES0[5]) bit is reset.
11	**OE: Overflow Error** When set, this bit indicates that the received frame was damaged due to buffer overflow in MTL.
10	**VLAN: VLAN Tag** When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the GMAC Core.
9	**FS: First Descriptor** When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame.
8	**LS: Last Descriptor** When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame
7	**Time Stamp Available/IP Checksum Error (Type1) /Giant Frame** When Advanced Time Stamp feature is present, this bit, when set, indicates that a snapshot of the timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This is valid only when the Last Descriptor bit (RDES0[8]) is set. When IP Checksum Engine (Type 1) is selected, this bit, when set, indicates that the 16-bit IPv4 Header checksum calculated by the core did not match the received checksum bytes. Otherwise, this bit, when set, indicates the Giant Frame Status. Giant frames are larger-than-1,518-byte (or 1,522-byte for VLAN) normal frames and larger-than-9,018-byte (9,022-byte for VLAN) frame when Jumbo Frame processing is enabled.
6	**LC: Late Collision** When set, this bit indicates that a late collision has occurred while receiving the frame in Half-Duplex mode.
5	FT: Frame Type When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 16'h0600). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes.

Table 34-44 Receive Descriptor Fields (RDES0) (cont'd)

Bit	Description
4	**RWT: Receive Watchdog Timeout** When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout.
3	**RE: Receive Error** When set, this bit indicates that the gmii_rxer_i signal is asserted while gmii_rxdv_i is asserted during frame reception. This error also includes carrier extension error in GMII and Half-duplex mode. Error can be of less/no extension, or error (rxd ≠ 0f) during extension.
2	**DE: Dribble Bit Error** When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII Mode.
1	**CE: CRC Error** When set, this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor (RDES0[8]) is set.
0	**Extended Status Available/Rx MAC Address** When either Advanced Time Stamp or IP Checksum Offload (Type 2) is present, this bit, when set, indicates that the extended status is available in descriptor word 4 (RDES4). This is valid only when the Last Descriptor bit (RDES0[8]) is set. When Advance Time Stamp Feature or IPC Full Offload is not selected, this bit indicates Rx MAC Address status. When set, this bit indicates that the Rx MAC Address registers value (1 to 31) matched the frame's DA field. When reset, this bit indicates that the Rx MAC Address Register 0 value matched the DA field.

Table 34-45 Receive Descriptor Fields 1 (RDES1)

Bit	Description
31	**DIC: Disable Interrupt on Completion** When set, this bit prevents setting the Status Register's RI bit (CSR5[6]) for the received frame ending in the buffer indicated by this descriptor. This, in turn, disables the assertion of the interrupt to Host due to RI for that frame.
30:29	**Reserved**

Table 34-45 Receive Descriptor Fields 1 (RDES1) (cont'd)

Bit	Description
28:16	**RBS2: Receive Buffer 2 Size** These bits indicate the second data buffer size, in bytes. The buffer size must be a multiple of 4, 8, or 16, depending on the bus widths (32, 64, or 128, respectively), even if the value of RDES3 (buffer2 address pointer) is not aligned to bus width. If the buffer size is not an appropriate multiple of 4, 8, or 16, the resulting behavior is undefined. This field is not valid if RDES1[14] is set. See **Buffer Size Calculations** for further details on calculating buffer sizes.
15	**RER: Receive End of Ring** When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.
14	**RCH: Second Address Chained** When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When this bit is cleared, RBS2 (RDES1[28:16]) is a "don't care" value. RDES1[15] takes precedence over RDES1[14].
13	**Reserved**
12:0	**RBS1: Receive Buffer 1 Size** Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4, 8, or 16, depending upon the bus widths (32, 64, or 128), even if the value of RDES2 (buffer1 address pointer) is not aligned. When the buffer size is not a multiple of 4, 8, or 16, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of RCH (Bit 14). See **Buffer Size Calculations** for further details on calculating buffer sizes.

Table 34-46 Receive Descriptor Fields 2 (RDES2)

Bit	Description
31:0	**Buffer 1 Address Pointer** These bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. Note that the DMA performs a write operation with the RDES2[3/2/1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[3/2/1:0] (corresponding to bus width of 128/64/32) if the address pointer is to a buffer where the middle or last part of the frame is stored. See **Host Data Buffer Alignment** for further details on buffer address alignment.

Table 34-47 Receive Descriptor Fields 3 (RDES3)

Bit	Description
31:0	**Buffer 2 Address Pointer (Next Descriptor Address)** These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. If RDES1[24] is set, the buffer (Next Descriptor) address pointer must be bus width-aligned (RDES3[3, 2, or 1:0] = 0, corresponding to a bus width of 128, 64, or 32. LSBs are ignored internally.) However, when RDES1[24] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3[3, 2, or 1:0] (corresponding to a bus width of 128, 64, or 32) if the address pointer is to a buffer where the middle or last part of the frame is stored.

The extended status written is as shown in **Table 1-108**. The extended status is written only when there is status related to IPC or Time Stamp available. The availability of extended status is indicated by bit-0 of RDES0. This status is available only when Advance Time Stamp or IPC Full Offload feature is selected.

Table 34-48 Receive Descriptor Fields 4 (RDES4)

Bit	Description
31:14	**Reserved**
13	**PTP Version** When set, indicates that the received PTP message is having the IEEE 1588 version 2 format. When reset, it has the version 1 format. This is valid only if the message type is non-zero. This bit is available only if Advance Time Stamp feature is selected else it is reserved
12	**PTP Frame Type** When set, this bit that the PTP message is sent directly over Ethernet. When this bit is not set and the message type is non-zero, it indicates that the PTP message is sent over UDP-IPv4 or UDP-IPv6. The information on IPv4 or IPv6 can be obtained from bits 6 and 7. This bit is available only if Advanced Time Stamp feature is selected

Table 34-48 Receive Descriptor Fields 4 (RDES4) (cont'd)

Bit	Description
11:8	**Message Type** These bits are encoded to give the type of the message received. • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011-1111: Reserved These bits are valid only when you select the Advance Time Stamp feature.
7	**IPv6 Packet Received** When set, this bit indicates that the received packet is an IPv6 packet.
6	**IPv4 Packet Received** When set, this bit indicates that the received packet is an IPv4 packet.
5	**IP Checksum Bypassed** When set, this bit indicates that the checksum offload engine is bypassed.
4	**IP Payload Error** When set, this bit indicates that the 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) that the core calculated does not match the corresponding checksum field in the received segment. It is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field.

Table 34-48 Receive Descriptor Fields 4 (RDES4) (cont'd)

Bit	Description
3	**IP Header Error** When set, this bit indicates either that the 16-bit IPv4 header checksum calculated by the core does not match the received checksum bytes, or that the IP datagram version is not consistent with the Ethernet Type value.
2:0	**IP Payload Type** These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE). The COE also sets these bits to 2'b00 if it does not process the IP datagram's payload due to an IP header error or fragmented IP. • 3'b000: Unknown or did not process IP payload • 3'b001: UDP • 3'b010: TCP • 3'b011: ICMP • 3'b1xx: Reserved

RDES6 and RDES7 contain the snapshot of the time-stamp. The availability of the snapshot of the time-stamp in RDES6 and RDES7 is indicated by bit-7 in the RDES0 descriptor. The contents of RDES6 and RDES7 are identified in **Table 1-109** and **Table 1-110**, respectively.

Table 34-49 Receive Descriptor Fields 6 (RDES6)

Bit	Description
31:0	**RTSL: Receive Frame Time Stamp Low** This field is updated by DMA with the least significant 32 bits of the time stamp captured for the corresponding receive frame. This field is updated by DMA only for the last descriptor of the receive frame which is indicated by Last Descriptor status bit (RDES0[8]).

Table 34-50 Receive Descriptor Fields 7 (RDES7)

Bit	Description
31:0	**RTSH: Receive Frame Time Stamp High** This field is updated by DMA with the most significant 32 bits of the time stamp captured for the corresponding receive frame. This field is updated by DMA only for the last descriptor of the receive frame which is indicated by Last Descriptor status bit (RDES0[8]).

34.5 Ethernet MAC Module Implementation

This section describes the Ethernet MAC module interface as it is implemented in the TC27x. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

34.5.1 Interface Connections of the Ethernet MAC Module

The Ethernet MAC module is supplied with a separate clock control, address decoding, and interrupt control logic. The modules' service request outputs are connected with one interrupt node.

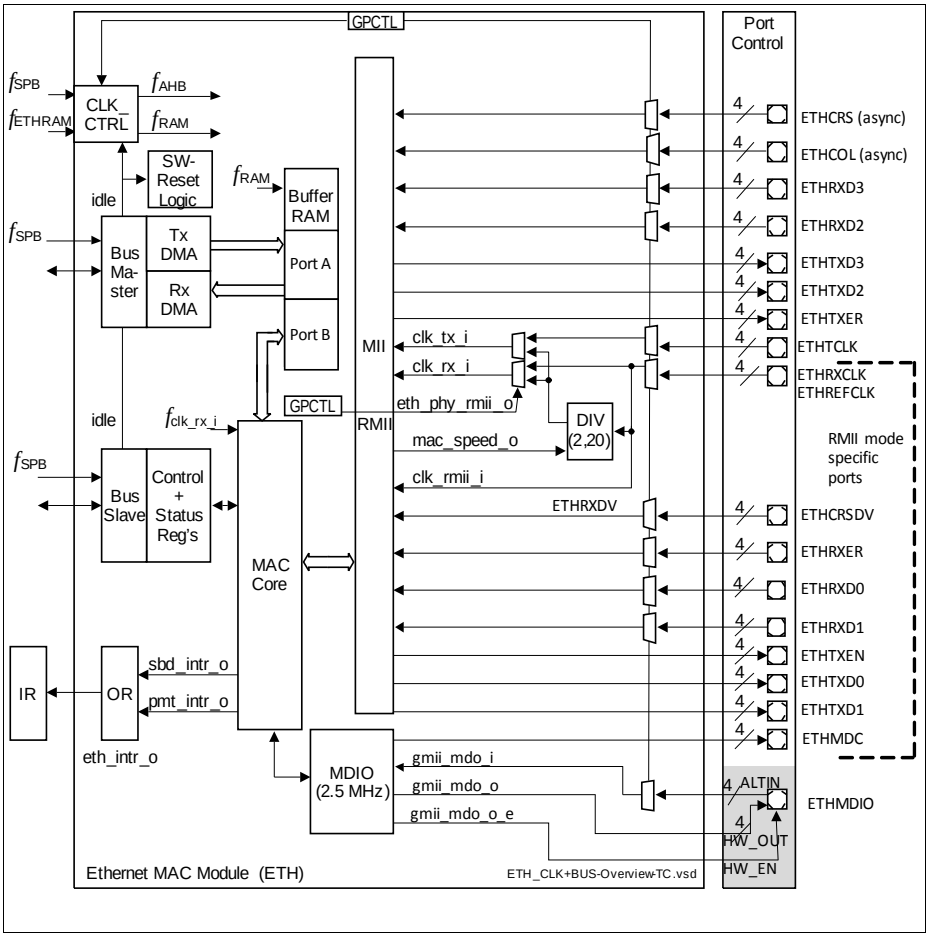

Figure 34-31 Ethernet MAC Module Implementation and Interconnections

34.5.1.1 On-Chip Connections

This section describes the on-chip connections of the Ethernet MAC module.

Interrupt Service Requests

The module has one Service Request Node connecting it to the interrupt system. The interrupt request line is connected to the interrupt controller as shown in **Table 1-112**.

Table 34-51 Service Request Lines of Ethernet MAC

Request Line	Connected to	Description
ETH_SRC0	eth_intr_o	DMA functions (sbd_intr_o), this internal line is connected via OR gate to ETH.SR0
ETH_SRC0	eth_intr_o	wake up on LAN (pmt_intr_o), this internal line is connected via OR gate to ETH.SR0

34.5.1.2 Clocks

The module has multiple clock inputs connecting it to the system. They are connected to the system as shown in **Table 1-113**.

Table 34-52 Clock Lines of Ethernet MAC

Clock Line	Connected to	Description
hclk_i / f_{AHB}	f_{SPB}	AHB Master Interface Clock, divided by 2 if GPCTL.DIV is set
clk_ram_i / f_{RAM}	f_{ETHRAM}	RAM Clock (separate clock from SCU.CGU) • it is by default 2 x f_{SPB} • must always be 2, 3, 4 ... (natural number) times higher than f_{SPB} • it must be ≥ 4 x clk_tx_i / clk_rx_i (Both are 25 MHz for 100 MBit/s and 2.5 MHz for 10 MBit/s) • divided by 2 if GPCTL.DIV is set
clk_csr_i	f_{SPB}	AHB Slave Interface Clock
clk_tx_i	ETHTXCLK (port pin)	Transmission Clock from Phy needs a clock input during SW reset (ETH_BUS_MODE.SWR)
clk_rx_i	ETHRXCLK (port pin)	Reception Clock from Phy needs a clock input during SW reset (ETH_BUS_MODE.SWR)

Table 34-52 Clock Lines of Ethernet MAC (cont'd)

Clock Line	Connected to	Description
clk_rmii_i	ETHREFCLK (port pin)	50-MHz clock used by the RMII from Phy needs a clock input during SW reset (ETH_BUS_MODE.SWR)
clk_ptp_ref_i	f_{SPB}	Reference Clock for the Time Stamp Update Logic

34.5.2 Ethernet MAC Module-Implementation Related Registers

The registers listed in **Figure 34-32** Ethernet MAC must be programmed for proper operation of the Ethernet MAC module.

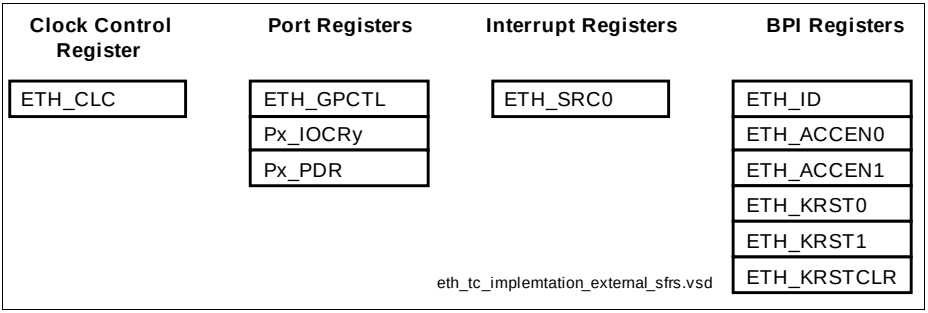

Figure 34-32 Ethernet MAC Implementation-specific Special Function Registers

34.5.2.1 Port Control

The Ethernet MAC is connected to general purpose I/O lines. Each line is connected to up to four different general purpose I/O lines that can be chosen alternatively. The selection from one of these alternatives is done by application SW by programming ETH_GPCTL.ALTIx respectively.

For MDIO, ALTIx selects the direction control signal (“HW_OUT control”) gmii_mdo_o_e_[x] as well. The signals gmii_mdo_o_e_[n] that are not selected are forced passive.

The following port control operations and selections must be executed for these I/O lines:

- Input/output function selection (Port IOCR registers)
- Pad driver characteristics selection for the outputs (Port PDR registers)

Table 34-53 shows an overview how bits and bit fields must be programmed for the required I/O functionality of the Ethernet MAC I/O lines.

Note: Some PHYs provide an interrupt output, signalling e.g. line activity. It might be useful to connect this to an interrupt input on system level. This signal is not connected to the Ethernet MAC*!*

Table 34-53 Ethernet MAC **I/O Control Selection and Setup**

Port	MAC signals	R/ Mii	Input Select Register	Input/Output Control Register Bits	I/ O
P02.8	ETHMDC		na	P02_IOCR8.PC8 = $1X110_B$	O

Table 34-53 Ethernet MAC **I/O Control Selection and Setup** (cont'd)

Port	MAC signals	R/ Mii	Input Select Register	Input/Output Control Register Bits	I/ O
P12.0	ETHMDC		na	P12_IOCR0.PC0 = $1X110_B$	O
P21.0	ETHMDC		na	P21_IOCR0.PC0 = $1X110_B$	O
P21.2	ETHMDC		na	P21_IOCR0.PC2 = $1X101_B$	O
P00.0	ETHMDIOA		ETH_GPCTL.ALTI0 = 00_B	P00_IOCR0.PC0 = $0XXX_B$	I/ O
	gmii_mdo_o_e_0 (I/O direction control of MDIO) connected to HW_DIR and HW_EN input of this port; choose Single EN - the pin is controlled by its own, dedicated, single HW_EN signal; gmii_mdo_o is connected to HW_OUT of the port, gmii_mdo_i is connected to ALTIN of the port (via input demultiplexer controlled by ALTI).				
P21.1	ETHMDIOB		ETH_GPCTL.ALTI0 = 01_B	P21_IOCR0.PC1 = $1X110_B$	I/ O
	No support of I/O direction control by HW. Unidirectional input or output only as configured in P21_IOCR0.PC1 by SW.				
P21.3	ETHMDIOD		ETH_GPCTL.ALTI0 = 11_B	P21_IOCR0.PC3 = $0XXX_B$	I/ O
	gmii_mdo_o_e_3 (I/O direction control of MDIO) connected to HW_DIR and HW_EN input of this port; choose Single EN - the pin is controlled by its own, dedicated, single HW_EN signal; gmii_mdo_o is connected to HW_OUT of the port, gmii_mdo_i is connected to ALTIN of the port (via input demultiplexer controlled by ALTI).				
P12.1	ETHMDIOC		ETH_GPCTL.ALTI0 = 10_B	P12_IOCR0.PC1 = $0XXX_B$	I/ O
	gmii_mdo_o_e_2 (I/O direction control of MDIO) connected to HW_EN input of this port; choose Single EN - the pin is controlled by its own, dedicated, single HW_EN signal; gmii_mdo_o is connected to HW_OUT of the port, gmii_mdo_i is connected to ALTIN of the port (via input demultiplexer controlled by ALTI).				

Table 34-53 Ethernet MAC **I/O Control Selection and Setup** (cont'd)

Port	MAC signals	R/ Mii	Input Select Register	Input/Output Control Register Bits	I/ O
P11.12	ETHRXCLKA / ETHREFCLKA	M / R	ETH_GPCTL.ALTI1 = 00_B	P11_IOCR12.PC12 = $0XXX_B$	I
	RMII: EXTCLK1 can be selected as output (P11_IOCR12.PC12 = $1X110_B$) while ETH_GPCTL.ALTI1 selects this pin as input. This setting supplies both: external PHY and this module with ETHREFCLK. Note that the jitter requirement of IEEE802.3 can not be met with this internal clock. If used as REFCLK, use fast input mode (P11_PDR1.PD12 = $X00_B$ and P11_IOCR12.PC12 = $0XXXX_B$) MII: This pin can supply the external PHY as said above but ETHRXCLK is selected from an alternate port (P11.4 or P12.0)				
P11.12	ETHTXCLKB	R	ETH_GPCTL.ALTI10 =01_B	P11_IOCR12.PC12 = $0XXX_B$	I
	Not for application but for SW development and test. This allows to use MII loop back without external circuit if TXCLK and RXCLK are clocked with EXTCLK1.				
P11.4	ETHRXCLKB	M	ETH_GPCTL.ALTI1 = 01_B	P11_IOCR4.PC4 = $0XXX_B$	I
P12.0	ETHRXCLKC	M	ETH_GPCTL.ALTI1 = 10_B	P12_IOCR0.PC0 = $0XXX_B$	I
P11.14	ETHCRSA	M	ETH_GPCTL.ALTI2 = 00_B	P11_IOCR12.PC14 = $0XXX_B$	I

34.5.2.2 Clock Control

The master interface (DMAs) of the Ethernet MAC is connected to f_{SPB}via a clock control in register GPCTL.

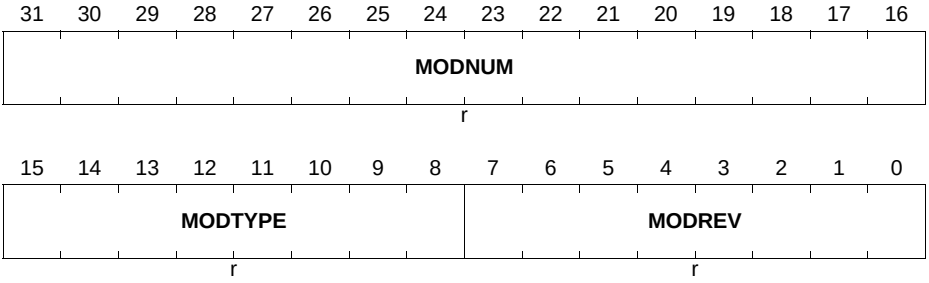
Note: The RAM frequency needs to run at double the application clock!

34.5.2.3 Additional Register

Module Identification Register

The Ethernet MAC Module Identification Register ID contains read-only information about the module version.

ETH_ID
Module Identification Register (0004$_H$) Reset Value: 00BF C0XX$_H$

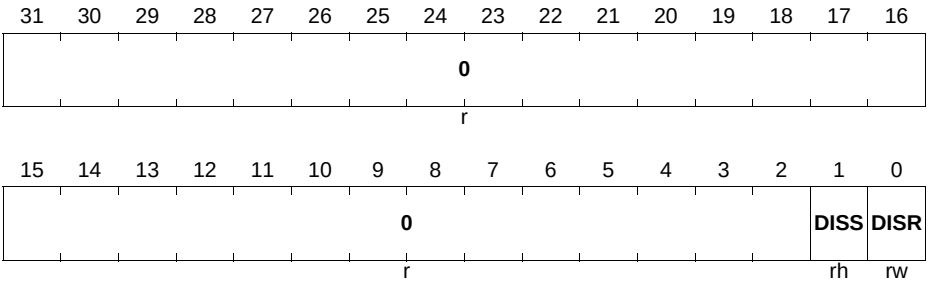


Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field defines the module as a 32-bit module: C0$_H$
MODNUM	[31:16]	r	**Module Number Value** This bit field defines the module identification number for the Ethernet MAC: 00BF$_H$

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock for the module.

ETH_CLC
Clock Control Register **(0000_H)** **Reset Value: 0000 0003_H**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. The disable request is delayed internally until all pending transactions on the master and slave interface to the SPB are completed.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset operation, the $f_{Ethernet\ MAC}$ clock is switched off and the Ethernet MAC module is disabled (DISS set).

Input and Output Control Register Functions

The Input and Output Control Register GPCTLx determines for the Ethernet MAC which alternate input is to be used and selects the phy interface.

This register is reset by power on reset and hardware reset.

Note: This register is not affected by the local module reset!

ETH_GPCTL
Input and Output Control Register (0008_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0						DIV	EPR	0		ALTI10		ALTI9		ALTI8	
r						rw	rw	r		rw		rw		rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALTI7		ALTI6		ALTI5		ALTI4		ALTI3		ALTI2		ALTI1		ALTI0	
rw		rw		rw		rw		rw		rw		rw		rw	

Field	Bits	Type	Description
ALTIy (y = 0-10)	[2*y+1: 2*y]	rw	**Alternate Input Select** Selects the alternate input for channel y. If no signal is connected to an alternate input, it is connected to GND. 0000_B Alternate Input 0 selected 0001_B Alternate Input 1 selected $\ldots_B$ … 0011_B Alternate Input 3 selected

Field	Bits	Type	Description
EPR	24	rw	**External Phy Interface RMMI Mode Bit** Used to select the phy interface during module reset of MAC triggered by setting SWR bit of DMA Register 0. If set during this reset, RMII is selected and an internal predivider divides the clock clk_rmii_i from pin ETHRXC by 2 or 20 and provides it to the internal signals clk_tx_i and clk_rx_i. The division factor depends from the signal mac_speed_o, controlled by bit FES in Register 0 (MAC Configuration Register). If cleared during the module reset said above, MII is selected and the divider is not active but the clock signals clk_tx_i and clk_rx_i are connected directly to the referring port pins. Note that the status of this bit is latched in during module reset only.
DIV	25	rw	**Module Clock Divider Request Bit** If set, f_{AHB} and f_{RAM} will be divided by 2.
0	[31:26], [23:22]	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset, all clocks are switched off and the Ethernet module is disabled (DISS set). In this case, only register CLC is accessible for configuration.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

ETH_ACCEN0

Access Enable Register 0 ($000C_H$) Reset Value: FFFF FFFF$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

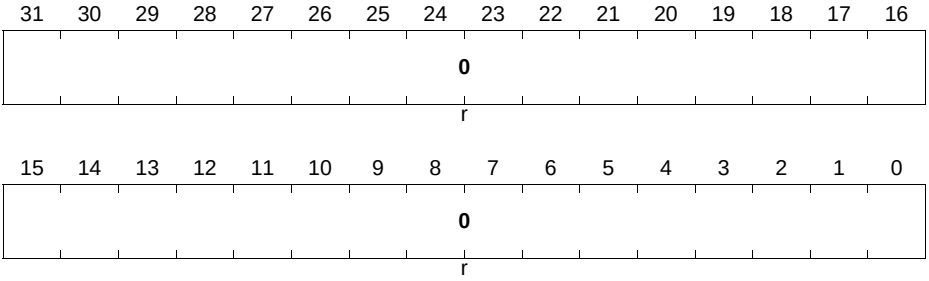
Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ETH_ACCEN1

Access Enable Register 1 **(0010_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
0	[31:0]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

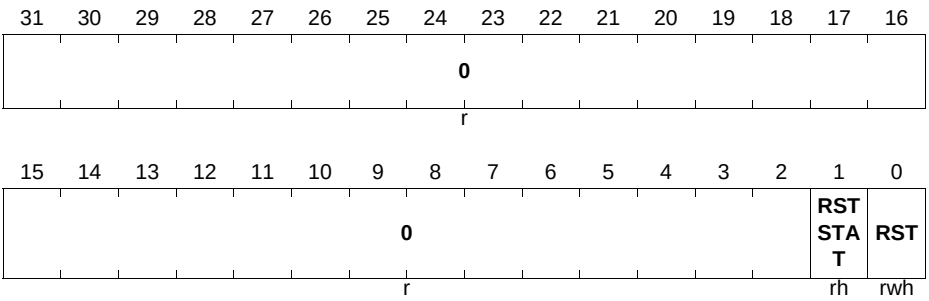
The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

ETH_KRST0

Kernel Reset Register 0 **(0014_H)** **Reset Value: 0000 0000$_H$**



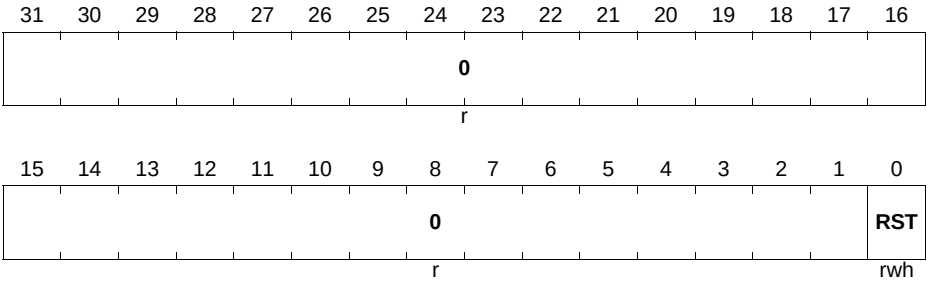
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set and both: master and slave interface are idle. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is

necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

ETH_KRST1
Kernel Reset Register 1 **(0018_H)** **Reset Value: $0000\ 0000_H$**



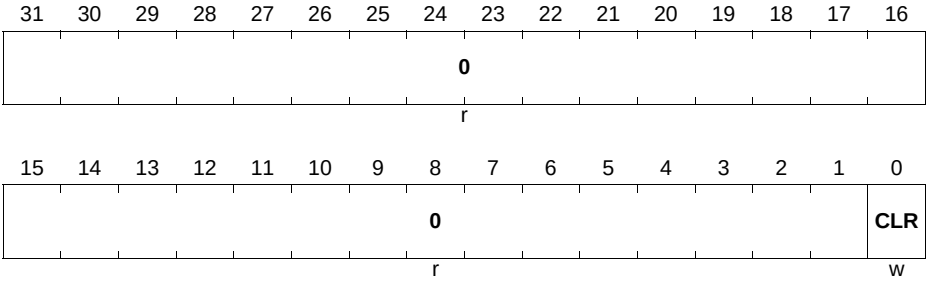
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set and both: master and slave interface are idle. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

ETH_KRSTCLR

Kernel Reset Status Clear Register ($001C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

34.6 Revision History

This User's Manual is based on: **Revision DWC Ether MAC 10/100/1000 Universal, V3.7a**".

Table 34-54 Revision History

Version Number	Changes to Previous Version
Rev_0.1	First Draft in IFX template
Rev_0.2	First configured version
Rev_0.3	First TS version
Rev_0.4	First ITS version
Rev_0.5	TS version
Rev_0.6	Module Implementation chapter updated: - removed the fractional dividers - added V1.11 containing ALTI bit fields for multiple input selection - pin list contains reference to relevant ALTI bit field - added correct address space - corrected clock signal connections
Rev_0.8	Removed unresolved cross references, Removed signal sbd_pwr_down_ack_o Added signals eth_phy_rmii_i and eth_rmii_speed_10_i
Rev_0.9	Updated Module Implementation Chapter
Rev_1.0	Changed Number of MAC Address Filters to 32 (from 128)
Rev_1.1	Updated Module Implementation Chapter wrt. port mapping Expanded GMACREG19 headers for extraction
Rev_1.2	Updated Module Implementation Chapter wrt. IOCR.DIV Added ACCEN0 and ACCEN1
Rev_1.3	Added CLC, MODID, KRST0, KRST1, KRSTCLR Renamed IOCR -> GPCTL Changed Base Address of ACCEN0, ACCEN1, GPCTL (was IOCR) Removed IOCR.DISR and DISS (now in CLC) Defined Module ID Changed single interrupt output name to eth_intr_o
Rev_1.5	Removed non configured registers: GMACREG48 .. 54, DMAREG10 ..11 Updated reset values of registers GMACREG0, 8, 9, DMAREG22 Added clarification that normal descriptor format can not be supported
Rev_1.6	Updated Registers Chapter

Table 34-54 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.7	Changed bit names to comply with compiler requirements - MAC_CONFIGURATION.2KPE -> TWOKPE - BUS_MODE.8xPBL -> PBLx8
Rev_1.8	P21.1 ETHMDIO: No more support of I/O direction control by HW. P21.3: ETHMDIO mapping added Outputs remapped from O5 to O6 on all output ports P11.11 ETHCRSDV renamed to ETHCRSDVA P11.11 ETHCRSDVA: added ETHRXDVA and ETHCRSB P11.14 ETHCRS renamed to ETHCRSA P11.14 ETHCRSA: added ETHRXDVB and ETHCRSDVB P11.12: ETHTXCLKB mapping added P11.5 ETHTXCLK renamed ETHTXCLKA Fixed Synopsys issue: 9000522312 ("MAC inserts incorrect IP Payload Checksum at incorrect location for IPv6 packets with Authentication extension header") Fixed Synopsys issue: 9000522313 ("MAC provides incorrect IP Payload Checksum Error status when IPv6 packet with Authentication extension header is received") P21.2: ETHMDC added
Rev_1.9	Added port configuration hints for TXD0, TXD1, TXEN and REFCLK P11.13: ETHRXER renamed to ETHRXERA P21.7: ETHRXERB added
Rev_1.10	Port configuration changed for products with RMII only
Rev_1.11	Port configuration changed for TXD2 and TXD3 Added Port configuration for TC23x
